- ▶ Laboratory work-up: CBC with platelets, blood group and cross-match, PT/INR/aPTT, fibrinogen, FDP or D-dimer, renal and hepatic function, electrolytes, glucose, creatine kinase, urinalysis for blood/myoglobin; ECG/chest radiograph in severe envenomation or major comorbidity; ABG if respiratory compromise.

- ▶ **20-min whole-blood clotting test (20WBCT):** place 1-2 mL venous blood in a clean dry glass tube, leave undisturbed for **20 min**, then invert. Persistent liquid blood/no clot indicates coagulopathy when laboratory coagulation tests are unavailable.
- ▶ If initial labs are normal, repeat CBC and coagulation tests every **4 h** until systemic envenomation is excluded; after antivenom, recheck about every **6 h** until clinical stability.

Treatment: antivenom and supportive care

- ▶ **Specific antivenom is the mainstay** for significant envenomation. Use the geographically appropriate monovalent or polyvalent antivenom; in India this means locally available polyvalent anti-snake venom as per institutional protocol and manufacturer instructions.
- ▶ Indications for antivenom:
 - progressive local injury: rapidly spreading swelling, swelling involving more than half the limb, extensive bruising/blistering, or severe pain;
 - any systemic feature: hypotension, shock, vomiting not controlled, bleeding, neurotoxicity, rhabdomyolysis, AKI, cardiac collapse;
 - any significant laboratory abnormality: thrombocytopenia, prolonged clotting times, low fibrinogen, positive 20WBCT, rising CK, renal injury.
- ▶ Give antivenom **IV only**; do not inject IM or into a digit. Start slowly with the clinician at bedside, then increase if no reaction. Skin testing is not sensitive or specific and is not useful.
- ▶ Treat acute antivenom reaction by stopping the infusion temporarily and giving **IM epinephrine 0.01 mg/kg up to 0.5 mg**, IV antihistamine such as **diphenhydramine 1 mg/kg up to 50 mg**, and glucocorticoid such as **hydrocortisone 2 mg/kg up to 100 mg**; restart slowly at **5-10 mL/h** if antivenom remains necessary.
- ▶ Resuscitate shock with isotonic crystalloid **20-40 mL/kg IV**; if shock persists after fluids and antivenom, use vasopressors such as norepinephrine or epinephrine.
- ▶ Neurotoxic paralysis: secure airway early; ventilatory support may be needed for days to weeks. In objective postsynaptic neurotoxicity, a trial of acetylcholinesterase inhibitor may be used: atropine **0.6 mg IV**, then neostigmine **0.02 mg/kg IV/IM**; if objective improvement occurs, neostigmine **0.5 mg** every 1 h as needed with atropine cover. This never replaces intubation or antivenom.
- ▶ Blood products are rarely needed and, if essential for life-threatening bleeding or dangerously low platelets, should be given **after adequate antivenom** to avoid fueling consumptive coagulopathy.
- ▶ Wound care: soap-water cleansing, sterile dressing, splintage with padding between digits, tetanus prophylaxis, acetaminophen/opioids for pain, avoid salicylates/NSAIDs, and avoid routine prophylactic antibiotics unless infection, incision, or mouth suction occurred.

Complications, disposition and follow-up

- ▶ Important complications: shock, airway edema, aspiration, respiratory paralysis, DIC-like coagulopathy, recurrent coagulopathy, AKI, rhabdomyolysis, hyperkalemia, tissue necrosis, compartment syndrome, secondary infection, serum sickness, and chronic disability.
- ▶ Suspect compartment syndrome with severe compartment-localized pain resistant to opioids, weakness, sensory change, cyanosis, or apparent pulselessness. Measure pressure; **>30-40 mmHg** indicates additional antivenom and elevation. Fasciotomy is a last resort after antivenom, because fasciotomy is needed in **<1%** of cases in modern series and may increase morbidity.
- ▶ Observe any envenomated patient in hospital for at least **24 h**. An apparently dry viperid bite needs **8-12 h** observation; coral snake/other elapid/sea snake bites need at least **24 h** because systemic toxicity may be delayed.
- ▶ ICU admission: head/neck bite, progressive findings despite initial antivenom, respiratory or cardiovascular instability, severe neurotoxicity, severe coagulopathy/bleeding, renal failure, or acute hypersensitivity to antivenom.
- ▶ Discharge only when swelling is improving, coagulopathy is corrected, pain is controlled, and the patient is ambulatory. Warn about recurrence of bleeding/coagulopathy over **2-3 weeks**, serum sickness at **1-2 weeks**, wound infection, and need for repeat CBC/PT/fibrinogen if coagulopathy occurred.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Flowchart: snakebite management** — Bite -> ABC and immobilization -> classify dry/mild/moderate/severe -> labs including 20WBCT -> antivenom indications -> IV antivenom -> monitor swelling/coagulation/respiration -> complications and follow-up.
- ▶ **Limb monitoring diagram** — fang marks, leading edge of swelling, ecchymosis, bullae, three circumference measurement levels, distal pulse/capillary refill, sensory-motor status, compartment-pressure site.

Clinical / Diagnostic significance

- ▶ Ptosis after snakebite is respiratory failure until proved otherwise; do not wait for cyanosis before intubating or ventilating.
- ▶ 20WBCT is a bedside triage test, not a substitute for PT/INR/aPTT/fibrinogen where available; persistent liquid blood after 20 min is clinically significant.
- ▶ Antivenom reverses circulating venom, not established necrosis, renal failure, or fixed presynaptic paralysis; delay is the main preventable cause of poor outcome.
- ▶ Recurrent coagulopathy occurs because venom antigens may outlast antivenom; repeat labs and counsel against trauma/elective surgery for 2-3 weeks after acute coagulopathy.
- ▶ Routine antibiotics, routine fasciotomy, incision/suction, and tight tourniquets are common harmful errors in exam and practice.

High-yield exam pointers

- ▶ Write the two syndromes first: **hemotoxic/cytotoxic viper bite** and **neuromuscular elapid bite**.
- ▶ First aid mantra: **reassure, immobilize, remove constrictors, rapid transport; no incision, suction, ice, alcohol, or tourniquet**.
- ▶ Must mention **ABC**, early intubation for bulbar/respiratory signs, and mechanical ventilation when needed.
- ▶ Must write investigations: CBC/platelet, PT/INR/aPTT, fibrinogen, FDP/D-dimer, renal function, CK, urine myoglobin, and **20WBCT**.
- ▶ Antivenom indications: progressive swelling, systemic toxicity, neurotoxicity, coagulopathy, rhabdomyolysis, renal failure, shock.
- ▶ Antivenom is **IV only**; manage anaphylaxis with epinephrine and restart slowly if benefit outweighs risk.
- ▶ Blood products only after adequate antivenom; NSAIDs and salicylates are avoided.
- ▶ Compartment syndrome is diagnosed by pressure and treated first with antivenom; fasciotomy is last resort.
- ▶ Observe dry bite 8-12 h, envenomation at least 24 h, and warn about serum sickness and recurrent coagulopathy.

What are the risk factors, clinical features and treatment of lead toxicity?

Asked in: Paper IV May 2025 — RGUHS MD General Medicine

Definition / Introduction — Lead (Pb) is a *xenobiotic* heavy metal with **no physiological role and no safe threshold of exposure** — it is theoretically toxic at any level. Toxicity (*plumbism / saturnism*) usually results from **chronic, repeated low-level exposure** rather than a single ingestion, and predominantly injures the **nervous system, haematopoietic system, gastrointestinal tract and kidneys**. Because absorbed lead is ~95–99% sequestered in red cells and bone (bone half-life >20 years), it accumulates silently and causes both acute encephalopathic crises and insidious chronic organ damage.

Risk factors and sources of exposure

- ▶ **Occupational (the dominant adult risk)**: manufacture and recycling of automobile/storage batteries, smelting, soldering, plumbing, demolition or sanding of lead-painted houses and

bridges, stained-glass making, ceramic/pottery glazing, radiator repair, and firing ranges (inhalation of bullet dust).

- ▶ **Environmental / domestic:** ingestion of **paint chips and house dust in homes built before ~1975**, lead-contaminated soil, drinking water from **lead pipes and plumbing/solder**, food or drink from **improperly glazed ceramics or lead-contaminated cookware**, and historic combustion of **leaded gasoline** (now globally phased out) plus electronic-waste recycling.
- ▶ **Ingested / cultural sources:** **contaminated spices, traditional herbal and folk remedies (Ayurvedic medicines, Latino azarcon/greta), contaminated candies, and retained lead bullet fragments lodged in or near a joint** (synovial fluid corrodes the metal → chronic toxicity).
- ▶ **Organic lead** (e.g., *tetraethyl lead* in older fuels) is additionally **absorbed dermally** and is highly neurotoxic.
- ▶ **Host susceptibility factors:** **young children** (hand-to-mouth/pica behaviour, higher fractional GI absorption, immature blood–brain barrier, developing CNS); **nutritional deficiency of iron, calcium and zinc** (enhances GI lead absorption); **pregnancy and lactation** (bone lead is mobilised into blood and crosses the placenta and into breast milk); and genetic polymorphisms (e.g., *ALAD* variants) modifying handling and effect.

Toxicokinetics and mechanism of toxicity

- ▶ **Absorption** via ingestion or inhalation (organic lead also dermally); in blood **95–99% is bound to red cells**, so lead must be measured in **whole blood, not serum**.
- ▶ **Distribution:** soft-tissue half-life ~30 days; ~15% of a dose is deposited in **bone (half-life >20 years)**, the major cumulative reservoir reflected by *KXRF bone-lead* measurement. Excreted mainly in **urine**, also in breast milk.
- ▶ **Molecular toxicity:** interferes with **mitochondrial oxidative phosphorylation**, ATPases and **calcium-dependent second messengers**; binds **sulphydryl groups**; enhances oxidative stress and apoptosis; and substitutes for calcium/zinc in metalloproteins.
- ▶ **Haem-synthesis block (key for exam):** lead **inhibits δ -aminolevulinic acid dehydratase (ALA-dehydratase, ALAD)** and **ferrochelatase** → accumulation of **ALA and coproporphyrin III** in urine and a rise in **free erythrocyte / zinc protoporphyrin (FEP/ZPP)**, with impaired haem formation causing anaemia. Lead intoxication is a recognised differential of *ALA-dehydratase-deficient porphyria*. Inhibition of **pyrimidine-5'-nucleotidase** leaves ribosomal RNA aggregates producing **basophilic stippling** of red cells.

Clinical features

System	Acute / high-level exposure	Chronic / subclinical exposure
CNS (children)	Lead encephalopathy — convulsions, coma, death	Impaired IQ, developmental & neurobehavioural delays,

System	Acute / high-level exposure	Chronic / subclinical exposure
	(BPb >80–120 µg/dL); raised ICP	language/motor/balance/hearing/behaviour & school-performance deficits (BPb 25–60 µg/dL; <i>no safe threshold</i>)
CNS / PNS (adults)	Headache, irritability, lethargy; severe → encephalopathy	* <i>Demyelinating peripheral neuropathy, mainly motor</i> → wrist drop (<i>radial nerve</i>)*, foot drop; slowed reaction time, impaired short-term memory, declining cognition, depression, loss of libido
GI	Lead colic — colicky abdominal pain, anorexia, constipation , nausea	<i>Burton's line</i> — bluish-grey lead line at the gingiva–tooth border
Haematological	Anaemia, impaired haematopoiesis	Anaemia with basophilic stippling ; microcytic in children, normocytic–normochromic in adults; elevated FEP/ZPP
Renal	Proximal tubular dysfunction → Fanconi syndrome , pyuria, azotaemia	Chronic interstitial nephritis and chronic renal failure; hyperuricaemia → saturnine gout
Other	—	Hypertension, ECG conduction delays, ↑cardiovascular morbidity/mortality, reduced sperm counts , spontaneous abortion

- ▶ **Blood-lead severity bands (CMDT/Harrison):** *subclinical* neurodevelopmental effects even at 1–25 µg/dL; 25–60 µg/dL — headache, irritability, subclinical neuropathy, anaemia (children); 60–80 µg/dL — moderate toxicity, impaired neurotransmission; >80–100 µg/dL — severe poisoning/encephalopathy.

Diagnosis / Investigations

- ▶ **Venous whole-blood lead level (BPb)** is the *diagnostic gold standard*. The **CDC blood-lead reference value** is 3.5 µg/dL — exceeding it triggers source investigation; OSHA mandates worker removal at BPb >40 µg/dL (newer proposals: keep <10 µg/dL, remove >20 µg/dL).
- ▶ **Peripheral smear:** normocytic/normochromic (adults) or microcytic (children) anaemia with basophilic stippling.
- ▶ **Biochemical markers of haem-pathway block:** elevated **free erythrocyte / zinc protoporphyrin (FEP/ZPP)**, raised **urinary ALA and coproporphyrin III**.
- ▶ **Imaging:** long-bone x-rays show dense **metaphyseal “lead lines”** in children; abdominal radiograph may reveal radiopaque ingested lead (paint chips, fishing weight, retained bullet).
- ▶ **Bone-lead by KXRF** estimates cumulative body burden (research/specialist).

- ▶ **Screening:** CDC recommends screening US children when they begin to crawl (~6 months).

Treatment

- ▶ **First and most important step — identify and remove the source of exposure (occupational hygiene, abatement of lead paint/water, report to public-health authority); chelation is reserved for symptomatic and/or high-level toxicity*.*
- ▶ **Decontamination:** for recent ingestion of a retained lead object (e.g., fishing weight) visible on x-ray, use **whole-bowel irrigation, endoscopy or surgical removal** (activated charcoal does **not** bind lead).
- ▶ **Supportive care:** secure airway, treat seizures and coma; manage raised ICP in encephalopathy.
- ▶ **Chelation agents** (consult a toxicologist / poison centre, 1-800-222-1222):

Severity	First-line chelation (per CMDT 2026)
Severe — encephalopathy or BPb >70–100 µg/dL	Edetate calcium disodium (CaEDTA) ~50 mg/kg/day (1500 mg/m ² /day) in 4–6 divided doses or continuous IV infusion, + dimercaprol (BAL) 4–5 mg/kg IM every 4 h × 5 days for encephalopathy
Moderate — symptomatic / BPb 45–69 µg/dL	CaEDTA (as above) or oral succimer (DMSA) 10 mg/kg every 8 h × 5 days, then every 12 h × 2 weeks
Mild–moderate, ambulatory	Oral succimer (DMSA) is preferred

- ▶ **Sequencing pearl:** in encephalopathy give **dimercaprol (BAL)** first/with CaEDTA — CaEDTA alone can redistribute lead into the CNS and *worsen encephalopathy*.
- ▶ **Adjuncts:** correct **iron, calcium, magnesium and zinc deficiency** to reduce further lead absorption; **calcium supplementation (1200 mg)** lowers blood lead and limits bone-lead mobilisation in pregnancy; vitamin C is only a weak natural chelator.
- ▶ **Evidence caveats:** a large RCT of chelation in **asymptomatic children (BPb 20–40 µg/dL)** showed **no improvement in IQ**; benefit of chelation for chronic adult cardiovascular outcomes remains unproven (TACT-2 negative).

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Haem-synthesis pathway showing the two lead-blocked enzymes.** Labels: *Glycine + Succinyl-CoA* → ALA synthase → δ -ALA → ALA-dehydratase (**BLOCKED by lead**) → Porphobilinogen → ... → Protoporphyrin IX → Ferrochelatase (**BLOCKED by lead**) + Fe^{2+} → Haem; annotate “↑urinary ALA & coproporphyrin III”, “↑FEP/ZPP”, “anaemia”.
- ▶ **Clinical signs schematic of plumbism.** Labels: *Burton’s (gingival) lead line, basophilic stippling on smear, wrist drop (motor neuropathy), lead colic / constipation, metaphyseal lead lines on x-ray, encephalopathy*.

Clinical / Diagnostic significance

- ▶ Suspect lead in any patient with **unexplained abdominal colic + anaemia + peripheral motor neuropathy**, or a child with developmental regression/encephalopathy and a relevant exposure history (old housing, occupation, folk remedies).
- ▶ **Basophilic stippling + microcytic anaemia + raised ZPP** strongly suggests plumbism and helps separate it from iron-deficiency and sideroblastic anaemia.
- ▶ Lead is a **reportable / notifiable** exposure in many jurisdictions; OSHA-style biological monitoring and medical removal protect occupational cohorts.
- ▶ Chronic low-level lead is now an established risk factor for **hypertension, resistant hypertension, chronic kidney disease and cardiovascular mortality** — relevant to the internist beyond overt poisoning.

High-yield exam pointers

- ▶ **No safe blood-lead level**; CDC reference value = 3.5 µg/dL. Measure lead in **whole blood, not serum**.
- ▶ Lead **inhibits ALA-dehydratase and ferrochelatase** → ↑urinary ALA/coproporphyrin, ↑FEP/ZPP, anaemia.
- ▶ **Basophilic stippling** (pyrimidine-5'-nucleotidase inhibition) is the classic smear clue.
- ▶ **Burton's line** = gingival lead line; **wrist drop** = motor (radial) neuropathy; **lead colic** = abdominal pain with constipation.
- ▶ **Children get metaphyseal “lead lines”** on x-ray and are most vulnerable (pica, ↑absorption, developing brain).
- ▶ Encephalopathy appears at BPb >80–120 µg/dL.
- ▶ **Treatment hierarchy**: remove source → supportive care → chelation. **Severe/encephalopathy** → CaEDTA + dimercaprol (BAL given first); **moderate/oral** → succimer (DMSA).
- ▶ Iron/calcium/zinc repletion reduces lead absorption; **calcium 1200 mg** curbs bone-lead mobilisation in pregnancy.
- ▶ **Saturnine gout** = lead nephropathy with hyperuricaemia/gout.

SOURCE & COVERAGE

- ▶ **Harrison's Principles of Internal Medicine, 22e** — “Heavy Metal Poisoning” (lead sources, toxicokinetics, blood-lead toxicity bands, diagnosis, chelation) and “The Porphyrrias” (lead inhibition of ALA-dehydratase; raised urinary ALA/coproporphyrin III); smear chapter on basophilic stippling in lead poisoning.
- ▶ **CMDT 2026** — “Poisoning” chapter, *Lead* section (clinical findings, blood-lead severity ranges, CaEDTA / dimercaprol / succimer regimens and doses, decontamination, source removal).

Coverage note: The spec lists no dedicated toxicology subspecialty textbook; grounding is from Harrison 22e + CMDT 2026, which cover this topic comprehensively. *Burton's line*, *saturnine gout*, ferrochelatase inhibition and the BAL-before-EDTA sequencing pearl are universally accepted standard internal medicine added for exam completeness; the corpus explicitly supports the gingival “lead line”, ALA-dehydratase inhibition, raised protoporphyrin, and the chelation regimens.

Hematology & oncology

Apoptosis pathways and role in cancer

Asked in: Paper I Nov 2021 — RGUHS MD General Medicine

Definition / Introduction — *Apoptosis* is the genetically programmed, energy-dependent, **non-inflammatory** form of regulated cell death that culls aged, terminally differentiated, or irreparably damaged cells and so maintains tissue homeostasis. It is executed by a conserved family of cysteine-aspartate proteases (**caspases**) triggered through two principal routes — the **extrinsic (death-receptor)** pathway and the **intrinsic (mitochondrial)** pathway — that converge on common executioner caspases. Because the net cell number in a tissue reflects the balance between proliferation and death, *evasion of apoptosis* is a core enabling hallmark of malignancy: it lets cells carrying oncogenic mutations and genetic instability survive, expand clonally, and resist chemotherapy and radiation.

Regulated cell death — apoptosis and its alternatives

- ▶ The cell can respond to lethal stress by several distinct programmes: **apoptosis**, **autophagy** (lysosomal degradation of proteins/organelles), and irreversible growth arrest (**senescence**), plus newer caspase-variant deaths.
- ▶ Other regulated death modes (roles in cancer still being defined): **pyroptosis** — caspase-1-dependent, cleaves *gasdermins* to form plasma-membrane pores; **ferroptosis** — iron- and reactive-oxygen-species-dependent lipid peroxidation; **necroptosis** — caspase-independent, with cell rupture causing inflammation and tissue damage.
- ▶ Apoptosis is morphologically defined: cell shrinkage, chromatin condensation and nuclear fragmentation (pathologists' *karyorrhexis*, “nucleus bursting”), lamin and cytoskeletal cleavage, internucleosomal DNA degradation, and membrane blebbing into apoptotic bodies that are phagocytosed **without an inflammatory response** — contrasting with necrosis.

Feature	Apoptosis	Necrosis
Trigger	Physiologic or pathologic, programmed	Severe injury/ischaemia
Energy (ATP)	Required (active)	Not required (passive)
Cell volume	Shrinkage	Swelling
DNA	Internucleosomal cleavage ("ladder")	Random smear
Membrane	Intact; apoptotic bodies	Early rupture
Inflammation	Absent	Present

The extrinsic (death-receptor) pathway

- ▶ Activated by cross-linking of **TNF-receptor-superfamily** death receptors by their ligands: **CD95 (Fas)** by Fas ligand, and **DR4/DR5** by **TRAIL** (TNF-related apoptosis-inducing ligand).
- ▶ Ligation recruits the adaptor **FADD** (Fas-associated death domain) and **procaspase-8** to the receptor's cytoplasmic death domains, forming the death-inducing signalling complex (DISC).
- ▶ **Caspase-8** is autoactivated and directly cleaves the executioner **caspases-3 and -7**, producing the morphologic features of apoptosis.
- ▶ Physiologic brake: **FLIP**, which competes with caspase-8 for FADD; *decoy receptors* also blunt TRAIL signalling. Normal cells often express these inhibitors while tumour cells may not — the basis for therapeutic TRAIL/agonist-antibody selectivity.

The intrinsic (mitochondrial) pathway and the Bcl-2 family

- ▶ Initiated by **mitochondrial outer-membrane permeabilisation (MOMP)** in response to *DNA damage, oncogene-induced proliferation, loss of attachment to extracellular matrix, growth-factor deprivation, hypoxia, chemotherapy and radiation*.
- ▶ MOMP releases **cytochrome c** and **SMAC/DIABLO** from the mitochondrial intermembrane space. Cytochrome c associates with **dATP**, **procaspase-9** and the adaptor **APAF-1** to assemble the **apoptosome**, which activates **caspase-9** and then the effector caspases.
- ▶ **SMAC** binds and neutralises **inhibitor-of-apoptosis proteins (IAPs)** — e.g. **XIAP** — which otherwise restrain caspase activation.
- ▶ MOMP is governed by the **Bcl-2 family**, whose relative levels at the mitochondrial membrane set the apoptotic threshold:

Class	Members	Action
Anti-apoptotic (guardians)	Bcl-2, Bcl-XL, Mcl-1	Anchor to outer membrane; sequester pro-apoptotic proteins via a hydrophobic BH (Bcl-2-homology) pocket

Class	Members	Action
Pro-apoptotic effectors	Bax, Bak	Oligomerise to form outer-membrane pores → cytochrome c release
BH3-only activators/sensitisers	Bad, Bim, Bid, Puma, Noxa	Neutralise anti-apoptotic members and/or activate Bax/Bak

- ▶ If BH3-only proteins are mopped up by Bcl-2/Bcl-XL/Mcl-1, pores do not form and apoptosis is averted; when they predominate, Bax/Bak oligomerise and the cell dies. The **mitochondrion** is thus the central regulatory organelle of intrinsic apoptosis.

Convergence, executioner caspases and survival signalling

- ▶ **Initiator caspases** (-8, -9, -10) sit atop each pathway; **executioner/effector caspases** (-3, -6, -7) are the common downstream blades that cleave structural and regulatory substrates (caspase-activated DNase, lamins, cytoskeletal proteins).
- ▶ **Cross-talk:** caspase-8 cleaves the BH3-only protein **Bid** to truncated tBid, amplifying the death signal through the mitochondrial pathway — linking extrinsic and intrinsic routes.
- ▶ **p53 — “guardian of the genome”:** on DNA damage, ATM/ATR and Chk1/Chk2 phosphorylate p53 and MDM2, freeing p53 from MDM2-mediated degradation; oncogene stress induces **p14ARF**, which binds MDM2 and likewise stabilises p53. p53 then transactivates cell-cycle arrest (p21) or, if damage is severe, apoptosis via the pro-apoptotic BH3-only members **Puma and Noxa**.
- ▶ **Pro-survival pathways subverted in cancer:** the **PI3K/Akt** axis (Akt phosphorylates and inactivates BAD and FOXO/FKHR), **NF-κB** (held inactive by IκB; IKK phosphorylation → proteasomal IκB degradation → NF-κB-driven survival genes), and epigenetic silencing of **APAF-1** and caspase-8.

Apoptosis evasion as a hallmark of cancer

- ▶ **Bcl-2 overexpression** from the t(14;18) translocation underlies *follicular lymphoma*; Bcl-2 is also high in chronic lymphocytic leukaemia (CLL) and in prostate, breast, lung cancers and melanoma.
- ▶ **p53 inactivation** (the most frequent mutation in human cancer, chromosome 17p; germline loss = **Li-Fraumeni syndrome**; aflatoxin gives the codon-249 arginine→serine signature mutation in hepatocellular carcinoma) removes the damage-triggered death programme. **HPV E6** degrades p53 (and E7 inactivates Rb).
- ▶ Up-regulation of **IAPs/XIAP**, expression of **decoy death receptors** and **FLIP**, loss of **APAF-1/caspase-8**, and constitutive **PI3K-Akt / NF-κB** signalling all raise the apoptotic threshold.

- ▶ **Anoikis** — apoptosis normally triggered by loss of ECM contact — is suppressed in cells that invade and metastasise. **Cancer stem cells** further resist therapy through high anti-apoptotic Bcl-2 levels combined with ABC/P-glycoprotein (MDR) drug-efflux pumps.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Two-pathway apoptosis schematic.** Left **extrinsic limb**: FasL/TRAIL → *Fas* / *DR4* / *DR5* → *FADD* → *procaspase-8* → *caspase-8*. Right **intrinsic limb**: death stimuli (DNA damage, growth-factor withdrawal, chemo/radiation) → *BH3-only proteins* → *Bax/Bak* pore in mitochondrial outer membrane → release of *cytochrome c* + *SMAC*; *cytochrome c* + *APAF-1* + *dATP* + *procaspase-9* → *apoptosome* → *caspase-9*; *Bcl-2/Bcl-XL/Mcl-1* shown blocking *Bax/Bak*; *SMAC* inhibiting *IAP/XIAP*. Both converge on *executioner caspases-3/-7* → substrate cleavage → DNA degradation, chromatin condensation, lamin cleavage (apoptosis). Show *caspase-8* → *tBid* arrow linking the two limbs. Label drug targets: **venetoclax/BH3-mimetic** → *Bcl-2*, **SMAC-mimetic** → *IAP*, **bortezomib** → **proteasome/NF-κB**.
- ▶ **Bcl-2 rheostat bar**: anti-apoptotic (*Bcl-2*, *Bcl-XL*, *Mcl-1*) on one side versus pro-apoptotic (*Bax*, *Bak*, *BH3-only*) on the other, balance point = apoptotic threshold.

Clinical / Diagnostic significance

- ▶ **BH3 mimetics**: **venetoclax (ABT-199)**, an oral BCL-2 inhibitor, is approved for relapsed/refractory CLL with 17p deletion and is active in AML (e.g. with azacitidine/hypomethylating agents); the tool compound **ABT-737** is synergistic with docetaxel preclinically — proof of “targeting the dependence.”
- ▶ **Restoring the death signal**: recombinant TRAIL and agonist DR4/DR5 antibodies kill tumour (not normal) cells in preclinical work; **SMAC mimetics** lower the apoptotic threshold by neutralising IAPs; **HDAC inhibitors** up-regulate death receptors (DR4/5, FAS) and down-regulate XIAP.
- ▶ **Indirect pro-apoptotic agents**: **proteasome inhibitors** (bortezomib) prevent IκB destruction and block NF-κB survival signalling; **PI3K/Akt** and **BTK inhibitors** sensitise cells to apoptosis; **PARP inhibitors** exploit defective DNA-damage repair (BRCA-mutant tumours) to drive lethal DNA damage; **taxanes** stabilise microtubules and phosphorylate Bcl-2.
- ▶ **Diagnostic readouts**: apoptosis is detected by **annexin-V** (phosphatidylserine externalisation), TUNEL assay, caspase-3 activation, and the DNA “ladder” — used in tissue prognostication and as pharmacodynamic markers of drug response.
- ▶ **Therapeutic principle**: tumours “addicted” to anti-apoptotic proteins may be *more* vulnerable than normal cells to agents that re-engage apoptosis — the rationale for the whole BH3-mimetic class.

High-yield exam pointers

- ▶ Two pathways: **extrinsic** (Fas/DR4/DR5 → FADD → caspase-8) and **intrinsic** (mitochondrial: cytochrome c + APAF-1 + procaspase-9 → **apoptosome** → caspase-9); both converge on **executioner caspases-3/-7**.
- ▶ **Bcl-2 family rheostat**: anti-apoptotic **Bcl-2/Bcl-XL/Mcl-1** vs effectors **Bax/Bak** vs **BH3-only** (**Bad, Bim, Bid, Puma, Noxa**) sets MOMP.
- ▶ **SMAC/DIABLO** neutralises **IAP/XIAP**; **FLIP** blocks caspase-8 at the DISC; **caspase-8** → **tBid** cross-links the pathways.
- ▶ **p53** (“guardian of the genome”) drives apoptosis via **Puma/Noxa**; most-mutated cancer gene; germline loss = **Li-Fraumeni**.
- ▶ Apoptosis evasion = **hallmark of cancer**: Bcl-2 overexpression via **t(14;18)** in follicular lymphoma; loss of anoikis aids metastasis.
- ▶ **Venetoclax** (**BH3 mimetic, anti-BCL-2**) — CLL with 17p deletion, AML — is the flagship clinical translation.
- ▶ Apoptosis is **ATP-dependent, non-inflammatory**; necrosis is passive and inflammatory.

SOURCE & COVERAGE

- ▶ **Harrison’s Principles of Internal Medicine, 22e** — “Cancer Cell Biology” (apoptosis pathways, Bcl-2 family, extrinsic/intrinsic mechanisms, p53/MDM2/p14ARF checkpoint, evasion of apoptosis, cancer stem cells, *Figs. 77-1 and 77-5*) and “Cancer Genetics.”
- ▶ **DeVita, Hellman & Rosenberg’s Cancer: Principles & Practice of Oncology, 12e** — apoptosis-directed therapeutics: BH3 mimetics (**ABT-737, ABT-199/venetoclax**), taxane-induced Bcl-2 phosphorylation and caspase-8 scaffolding, venetoclax–azacitidine in AML.
- ▶ Coverage note: Harrison provides the full mechanistic and clinical content; DeVita’s full text in this corpus is treatment-weighted, so it was used chiefly for the apoptosis-targeting drug detail. Apoptosis-versus-necrosis morphology, initiator/executioner caspase numbering, annexin-V/TUNEL detection, and the Bid→tBid cross-talk are standard, universally accepted internal-medicine content included for completeness.

Causes and management of Aplastic anemia

Asked in: Paper IV May 2019 — RGUHS MD General Medicine

Definition / Introduction — Aplastic anemia is **pancytopenia accompanied by a hypocellular (“empty,” fat-replaced) bone marrow**, with no abnormal infiltrate and no marrow fibrosis. It results from quantitative and qualitative failure of the pluripotent **haematopoietic stem cell (HSC)**, most often through immune-mediated (T-cell) destruction, less often from direct chemical/physical injury or an

inherited stem-cell defect. It is distinguished from peripheral cytopenias (haemolysis, ITP, hypersplenism) by the *deficient production* of cells. Incidence is **2 per million/year in Europe and Israel** and **5–7 per million in Thailand and China**, with a **biphasic age distribution** (major peak in the teens–twenties, second peak in older adults) and equal sex incidence.

Classification & Causes (Aetiology)

Aplastic anemia is broadly **acquired** (~80%, usually immune/idiopathic) or **inherited/constitutional** (inherited bone marrow failure syndromes, IBMFS). The major recognised associations:

Category	Specific causes
Idiopathic (immune)	Most common; T-cell–mediated autoimmune HSC destruction
Radiation	Marrow aplasia is a major acute sequela; accidental/occupational/therapeutic
Chemicals	Benzene (best-substantiated), toluene, insecticides
Drugs — regular (dose-dependent)	Cytotoxic chemotherapy: alkylators, antimetabolites, antimetotics
Drugs — idiosyncratic	Chloramphenicol , gold salts, sulfonamides, phenylbutazone/NSAIDs, anticonvulsants (phenytoin, carbamazepine, felbamate), antithyroid drugs (methimazole, PTU, carbimazole), penicillamine, allopurinol, quinacrine, tolbutamide
Viruses / infection	Seronegative (non-A, non-B, non-C) hepatitis (~5%, young men, very severe), EBV (infectious mononucleosis), parvovirus B19, CMV, HIV-1
Immune disorders	Eosinophilic fasciitis, SLE, thymoma/thymic carcinoma, hypogammaglobulinaemia, transfusion-associated GVHD, large granular lymphocytosis (LGL)
Clonal / other	Paroxysmal nocturnal haemoglobinuria (PNH); pregnancy (resolves with delivery)
Inherited (constitutional)	Fanconi anemia (AR; <i>FANCA</i> commonest; short stature, café-au-lait spots, thumb/radius & GU anomalies); Dyskeratosis congenita / telomere biology disorders (<i>DKC1</i> X-linked; <i>TERC/TERT</i> AD; <i>TINF2</i> shelterin); Shwachman-Diamond (<i>SBDS</i> ; neutropenia + pancreatic insufficiency); GATA2 deficiency , RUNX1 familial platelet disorder

- *Pearl*: “Association is not causation” — an incriminated drug may have merely been given to treat the *first* symptom of marrow failure (e.g., NSAIDs for petechiae, antibiotics for fever).

Pathophysiology

- ▶ **Immune destruction (the dominant mechanism in acquired disease):** activated, oligoclonal cytotoxic CD8 T cells and Type-1 cytokines (chiefly interferon- γ and TNF) suppress and kill CD34⁺ progenitors. IFN- γ induces Fas on CD34 cells $\rightarrow$ Fas/FasL-mediated apoptosis. The stem-cell pool falls to $\leq 1\%$ of normal in severe disease; CD34⁺ cells and committed progenitors are virtually absent. Response to anti-thymocyte globulin proves the immune basis.
- ▶ **Constitutional defect:** intrinsic stem-cell flaw — defective DNA inter-strand cross-link repair (Fanconi, FANCD2 mono-ubiquitination pathway), defective telomere maintenance/shelterin (telomere disorders), or impaired transcriptional regulation (GATA2, RUNX1) $\rightarrow$ limited proliferative capacity and genomic instability.
- ▶ **Chemical/drug injury:** generation of reactive electrophilic intermediates (e.g., benzene hydroquinones/quinolones) that bind cellular macromolecules; genetically determined detoxification differences explain idiosyncratic susceptibility.
- ▶ **Clonal escape:** PNH clones (PIG-A mutation) and somatic myeloid mutations may emerge, reflecting immune selection and explaining later clonal evolution.

Clinical features & Laboratory diagnosis

- ▶ **History/exam:** insidious or abrupt onset. **Bleeding is the commonest early symptom** (bruising, gum oozing, epistaxis, menorrhagia, petechiae); anaemic symptoms (fatigue, dyspnoea); infection is an *unusual* presenting feature (unlike agranulocytosis). Patients often “look well.” **Lymphadenopathy and splenomegaly are atypical** and should prompt another diagnosis. Look for IBMFS clues: short stature/café-au-lait (Fanconi), nail dystrophy/leukoplakia (dyskeratosis congenita), premature greying/pulmonary or hepatic fibrosis (telomere disorder), warts/unusual infections (GATA2).
- ▶ **Blood:** pancytopenia; normochromic, often macrocytic (raised MCV) RBCs; reticulocytopenia; no immature/abnormal forms (their presence suggests leukaemia/MDS).
- ▶ **Bone marrow:** aspirate dilute; trephine biopsy (>1 cm) hypocellular with haematopoietic cells <25%, mostly fat; megakaryocytes greatly reduced/absent; residual cells morphologically normal. MRI spine shows fatty marrow.
- ▶ **Ancillary / aetiological work-up:** chromosome breakage test (diepoxybutane / mitomycin C) in children & young adults for Fanconi; leucocyte telomere length for telomere disorders; flow cytometry for a PNH clone (CD55/CD59, FLAER); marrow cytogenetics (abnormal favours MDS); serology (EBV, HIV, hepatitis); next-generation sequencing germline + myeloid panels to separate inherited and clonal disease.

Severity grading (Camitta criteria) — guides treatment

Grade	Criteria
Severe aplastic anemia (SAA)	Marrow cellularity <25% plus any two of three: ANC <500/ μ L, platelets <20,000/ μ L, corrected reticulocyte count <1% (absolute reticulocytes <60,000/ μ L)
Very severe (VSAA)	As SAA but ANC <200/ μ L
Non-severe / moderate	Cytopenias not meeting SAA thresholds

- ▶ Better modern predictors of treatment response: **absolute reticulocytes >25,000/ μ L** and **lymphocytes >1000/ μ L**; presence of a PNH clone or small somatic mutations also informs prognosis.

Management

General principles: stop any suspected drug/chemical; glucocorticoids are **not effective as primary therapy**; spontaneous recovery is rare, so treat early in SAA. Choice between transplant and immunosuppression hinges on **age, donor availability and depth of neutropenia**. HLA-type early and **avoid family-member transfusions** in transplant candidates (sensitisation). Use **leucodepleted, irradiated** blood products.

1. Haematopoietic stem cell (bone marrow) transplantation — definitive/curative

- ▶ **First choice for the younger patient (<40 yr) with an HLA-matched sibling donor.** Long-term survival in children $\approx$ 90%; CMTD quotes **>80% under age 20** and **$\sim$ 65–70% in those 20–50**, dropping 10–15% with matched-unrelated donors.
- ▶ Matched-unrelated-donor transplant: initial option in children, salvage in adults failing immunosuppression. **Haploidentical** transplant with **post-transplant cyclophosphamide (PT-Cy)** is increasingly used as a donor is almost always available; cord blood for children.
- ▶ Radiation is generally omitted from conditioning (except some alternative-donor protocols) to reduce late malignancy.

2. Immunosuppressive “triple therapy” — for those without a donor or aged >40 yr

- ▶ **Standard of care (FDA-approved 2018): horse ATG + ciclosporin + eltrombopag**, achieving haematologic response in **70–80%** (CMTD cites up to $\sim$ 90%; complete responses $\sim$ 50%).
- ▶ **Equine (horse) ATG 40 mg/kg/day IV for 4 days** — *superior to rabbit ATG* (better response/survival); give with **methylprednisolone/prednisone 1–2 mg/kg/day for $\sim$ 1 week then taper over 2 weeks** to prevent infusion reactions and **serum sickness** (occurs $\sim$ day 10).
- ▶ **Ciclosporin 6 mg/kg PO twice daily**, level-adjusted, generally continued **$\sim$ 2 years**; toxicities — **nephrotoxicity, hypertension, seizures** (tacrolimus is an alternative).
- ▶ **Eltrombopag (TPO-receptor mimetic) 150 mg PO once daily for 6 months** then stop in responders; stimulates the HSC; main toxicity **hepatotoxicity**. Romiplostim is an alternative.

- ▶ Response usually within **1–3 months** (assessed at ~4 months); responses are often partial. **Relapse** occurs in up to one-third (often on tapering ciclosporin/eltrombopag) and usually responds to re-treatment. Patients failing immunosuppression can be salvaged by later transplant.

3. **Androgens** — fluoxymesterone 10–20 mg/day or **danazol 200 mg PO twice daily**; modest, unproven benefit; useful in **moderate disease and telomere disorders** (up-regulate telomerase).

4. Supportive care (essential to survive to definitive therapy)

- ▶ **Infection:** neutropenic fever is an emergency — **prompt empirical broad-spectrum parenteral antibiotics**; suspect **fungal** disease (*Candida*, *Aspergillus*) with persistent fever and add antifungals; granulocyte transfusions for refractory infection.
- ▶ **Platelets:** prophylactic transfusion to keep count **>10,000/μL**; HLA-matched/single-donor units if alloimmunised; suppress menstruation; avoid aspirin/NSAIDs.
- ▶ **Red cells:** transfuse to Hb ~70 g/L (**90 g/L if cardiac/pulmonary disease**); add iron chelation (**deferoxamine/deferasirox**) around the **50th transfusion** to prevent secondary haemochromatosis.
- ▶ **Not useful:** EPO and G-CSF are **ineffective** in aplastic anemia; reverse isolation and gut decontamination do not reduce mortality.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Pathophysiology schematic of aplastic anemia (after Harrison Fig 107-1):** three aetiologic arrows — *Physical/chemical damage*, *Immune (T-cell) destruction*, *Constitutional genetic defect* — converging on “**empty bone marrow replaced by fat**”, with treatment boxes beneath each: *HGF/Support + BMT*; *IST + BMT + Eltrombopag*; *Sex hormones + BMT*. Labels: HSC, CD34⁺ cell, cytotoxic T cell, IFN-γ, Fas/FasL, apoptosis, fatty marrow.
- ▶ **Treatment algorithm:** Confirm SAA → assess age & HLA-matched sibling → *Young + matched sibling* → **Allogeneic HSCT**; *No donor / >40 yr* → **Horse ATG + Ciclosporin + Eltrombopag (triple therapy)** → response → taper; no response → **MUD/haploidentical transplant** or second IST. Side panel: **supportive care** (antibiotics, platelets >10k, RBC to Hb 70, chelation).

Clinical / Diagnostic significance

- ▶ **Differentiate from hypoplastic MDS** (favoured by dysplasia, increased blasts, clonal cytogenetics, spliceosome/cohesin mutations) and from **hypocellular hairy cell leukaemia** (splenomegaly, hairy cells) — both are pancytopenia mimics.
- ▶ A **PNH clone** at diagnosis supports an immune mechanism and predicts immunosuppression-responsiveness; it may later expand to clinical haemolytic PNH.

- ▶ Clonal evolution to MDS/AML or PNH occurs in ~10–15% (up to one-quarter at 10 years) after immunosuppression — long-term marrow surveillance is mandatory.
- ▶ Recognising IBMFS (Fanconi, telomere disorders, GATA2) changes management: avoid standard high-dose conditioning, screen relatives, and counsel on malignancy risk.

High-yield exam pointers

- ▶ Triad = pancytopenia + reticulocytopenia + hypocellular (fatty) marrow with no organomegaly.
- ▶ Commonest acquired cause = idiopathic (immune, T-cell mediated); classic toxins = benzene and chloramphenicol; ~5% follow seronegative hepatitis in young men.
- ▶ Camitta SAA: marrow <25% + 2 of (ANC <500, platelets <20,000, retic <1%); VSAA = ANC <200.
- ▶ Cure = HLA-matched sibling allogeneic transplant (first choice in young patients).
- ▶ No donor / older → triple therapy = horse ATG + ciclosporin + eltrombopag (~70–90% response); horse ATG > rabbit ATG.
- ▶ Eltrombopag = TPO mimetic, 150 mg/day × 6 months, hepatotoxicity; ciclosporin continued ~2 years.
- ▶ Glucocorticoids, EPO and G-CSF are NOT primary therapy.
- ▶ Platelets transfused to keep >10,000/μL; RBC to Hb 70 g/L; iron chelation from ~50th unit.
- ▶ Always exclude Fanconi anemia (DEB/mitomycin C chromosome breakage) and telomere disorders in young patients.

SOURCE & COVERAGE

- ▶ **Harrison's Principles of Internal Medicine, 22e** — “Bone Marrow Failure Syndromes Including Aplastic Anemia and Myelodysplasia” (Neal S. Young & Emma M. Groarke) — primary source for definition, classification/aetiology, pathophysiology, Camitta severity, transplant and triple-therapy (ATG/ciclosporin/eltrombopag), androgens and supportive care.
- ▶ **CMDT 2026** — “Blood Disorders” (Aplastic Anemia) — current severity definition, drug regimens/doses (equine ATG 40 mg/kg × 4 days, ciclosporin 6 mg/kg BID, eltrombopag 150 mg/day, danazol/fluoxymesterone) and survival figures.
- ▶ **Coverage note:** The dedicated specialty text for this spec, *DeVita's Cancer (Principles & Practice of Oncology)*, is an oncology/haematologic-malignancy reference and addresses aplastic anemia only peripherally (as a differential of hypoplastic MDS and via the eltrombopag-immunosuppression trial); the substantive grounding here is therefore Harrison 22e (authored by the world authority on the disease) and CMDT 2026. The

VSAA threshold (ANC <200) is universally accepted Camitta-criteria internal medicine and is included as standard.

Cell cycle and regulation

Asked in: Paper I Nov 2019 — RGUHS MD General Medicine

Definition / Introduction — The **cell division cycle** is the ordered, tightly regulated sequence of events by which a cell duplicates its genome and divides into two daughter cells. It comprises four active phases — **G1** (growth/preparation for DNA synthesis), **S** (DNA synthesis), **G2** (preparation to divide) and **M** (mitosis) — together with a quiescent out-of-cycle state, **G0**. Orderly progression is driven by **cyclin–cyclin-dependent kinase (CDK) complexes** and policed at a series of **checkpoints** that verify genomic integrity before allowing the cell to advance. Loss of this control — through activation of positive regulators (oncogenes such as *Ras*, *Myc*, cyclin D) or inactivation of negative regulators (tumour-suppressors *Rb* and *p53*) — produces the deregulated proliferation that is the defining feature of cancer.

Phases of the cell cycle

- ▶ **G1 (gap 1)**: the cell grows, senses growth-factor and nutrient signals, and takes “inventory” — Is the DNA-repair machinery in place? Are nucleotides, replicating enzymes and energy adequate? A late-G1 point of no return, the **restriction (R) point**, commits the cell irreversibly to division; beyond it the cell no longer needs external mitogens.
- ▶ **S (synthesis)**: semiconservative replication; each segment of DNA must be copied **once and only once**.
- ▶ **G2 (gap 2)**: the cell confirms faithful, complete duplication and synthesises the mitotic spindle and proteins needed to produce two daughter cells.
- ▶ **M (mitosis)**: prophase → metaphase → anaphase → telophase + cytokinesis; chromosomes segregate to opposite poles.
- ▶ **G0 (quiescence)**: a reversible resting state outside the cycle, maintained by signals including **Notch** and **STING** pathways; cells can be recalled into G1 by appropriate mitogenic/tissue-repair signals (e.g., hepatocytes after partial hepatectomy).

The molecular engine — cyclins, CDKs and CDK inhibitors

- ▶ **CDKs** are serine/threonine kinases that are catalytically inert until bound by their regulatory **cyclin** partner; the cyclin level oscillates (“cyclic”) through the cycle while CDK protein is constant. Sequential cyclin–CDK activation phosphorylates downstream substrates to push the cell forward.
- ▶ Activity is opposed by two families of **CDK inhibitors (CKIs)**:

- **INK4 family** — $p16^{INK4a}$ and $p15^{INK4b}$ — specifically inhibit CDK4/6.
- **CIP/KIP family** — $p21^{Cip1/Waf1}$, $p27^{Kip1}$, $p57^{Kip2}$ — broadly inhibit cyclin-CDK complexes; $p21$ is the principal transcriptional effector of p53.

Phase / transition	Cyclin	CDK partner	Key action
Mid-late G1	Cyclin D	CDK4 / CDK6	Initial phosphorylation (inactivation) of Rb
G1 → S	Cyclin E	CDK2	Completes Rb inactivation; fires the R point
S	Cyclin A	CDK2	Drives/limits DNA replication
G2 → M	Cyclin A / B	CDK1 (Cdc2)	Triggers mitotic entry

Cell-cycle checkpoints — the quality-control machinery

Checkpoints are surveillance circuits that arrest the cycle until prerequisites are met; the critical proteins controlling them are frequently the **tumour-suppressor genes** mutated in cancer.

- ▶ **G1/S (restriction) checkpoint:** decides whether the cell is fit to replicate. When ready, cyclin D-CDK4/6 then cyclin E-CDK2 **phosphorylate Rb**, releasing the transcription factor **E2F/DP1**, which switches on S-phase genes. If not ready, CKIs ($p21$, $p16$, $p27$) block the CDKs. *Nearly every cancer has a defect in the G1 checkpoint.*
- ▶ **Intra-S checkpoint:** slows replication when DNA damage is sensed, allowing repair.
- ▶ **G2/M checkpoint:** verifies that DNA is fully and accurately replicated before mitosis. DNA damage activates the **ATM/ATR → Chk1/Chk2 → p53** axis (and WEE1 kinase, which restrains CDK1); damaged cells are held in G2.
- ▶ **M-phase spindle (spindle-assembly) checkpoint:** ensures every chromosome is correctly attached to the mitotic spindle before anaphase. Failure permits **aneuploidy** (abnormal chromosome number), a frequent feature of cancers.

The two master tumour-suppressors — Rb and p53

- ▶ **Retinoblastoma protein (Rb)** is the molecular “brake” at G1/S. In its hypophosphorylated state it sequesters E2F/DP1; CDK-mediated hyperphosphorylation releases E2F and licenses S-phase entry. Rb is inactivated in cancer by mutation/deletion (RB1 on **13q14**), by CDK4/6 hyperactivity, by loss of $p16^{INK4a}$, or by viral oncoproteins. Per **Knudson’s two-hit hypothesis** (derived from inherited vs sporadic retinoblastoma), **both alleles** of a tumour-suppressor must be inactivated; germline carriers inherit one “hit” and need only one somatic event, explaining earlier and multiple tumours.

- ▶ **p53** — “guardian of the genome” — a transcription factor normally kept at very low levels by MDM2 (an E3 ubiquitin ligase that both blocks p53 transactivation and targets it for proteasomal degradation). Two activating circuits:
 - **DNA-damage checkpoint:** ATM/ATR and Chk1/Chk2 **phosphorylate p53 and MDM2**, dissociating them; stabilised p53 then drives **cell-cycle arrest** (via *p21*), **DNA repair**, or, if damage is irreparable, **apoptosis** (via pro-apoptotic Bcl-2 members *Noxa* and *Puma*). Inducers include hypoxia, ionising/UV radiation, chemotherapy, ribonucleotide depletion and telomere shortening.
 - **Oncogene checkpoint:** hyperproliferative oncogenes (*Myc*, *E2F*) induce **p14^{ARF}**, which binds MDM2 and rescues p53 — eliminating “renegade” cells by senescence or apoptosis.
- ▶ **Clinical correlates of p53:** *TP53* on 17p is among the most commonly mutated genes in human cancer; germline mutation causes **Li–Fraumeni syndrome**; aflatoxin produces a signature **codon 249 Arg→Ser** mutation in hepatocellular carcinoma; HPV E6 degrades p53 and HPV E7 inactivates Rb — together required for epithelial transformation.

Replicative senescence, telomeres and loss of apoptosis

- ▶ Normal somatic cells divide only ~25–50 population doublings, then enter **replicative senescence** (irreversible growth arrest, cells remaining viable) — a tumour-protective mechanism mediated by the **Rb, p16^{INK4a} and p53** pathways.
- ▶ Each S phase fails to copy chromosome tips, so **telomeres** (tandem TTAGGG repeats; ~15–20 kb at birth, forming a protective T-loop) shorten progressively; critically short telomeres trigger a p53-dependent damage response. **>90% of human cancers re-express telomerase** (catalytic subunit **hTERT** + RNA template) to maintain telomeres and achieve replicative immortality. *Germline telomerase defects cause dyskeratosis congenita.*
- ▶ Cancer cells also subvert **programmed cell death**: the **intrinsic (mitochondrial)** pathway — cytochrome c/SMAC release, APAF-1/caspase-9 activation, governed by the **Bcl-2 family** balance — and the **extrinsic (death-receptor)** pathway — Fas/DR4/DR5 → FADD → caspase-8. Overexpression of antiapoptotic **Bcl-2** or loss of p53 lets genetically damaged cells survive and accumulate further mutations.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Circular cell-cycle map:** draw the ring G1 → S → G2 → M with **G0** branching off G1. Label the **restriction point** in late G1; mark the **G1/S, intra-S, G2/M and M (spindle)** checkpoints; annotate each segment with its cyclin–CDK pair (**Cyclin D–CDK4/6**, **Cyclin E–CDK2**, **Cyclin A–CDK2**, **Cyclin B–CDK1**) and the CKIs (**INK4**, **CIP/KIP**).
- ▶ **Rb/p53 control circuit:** boxes for **Cyclin D–CDK4/6 → P-Rb → release of E2F/DP1 → S-phase genes**, with *p16* inhibiting CDK4/6; and a parallel limb **DNA damage → ATM/ATR**

→ Chk1/Chk2 → p53 ⊣ MDM2 → p21 (arrest) / Noxa-Puma (apoptosis), with *p14ARF* linking oncogenes to MDM2.

Clinical / Diagnostic significance

- ▶ **Therapeutic exploitation:** CDK4/6 inhibitors — *palbociclib*, *ribociclib*, *abemaciclib* — combined with endocrine therapy markedly improve progression-free survival in **ER-positive/HER2-negative metastatic breast cancer** (e.g., palbociclib + letrozole in PALOMA-2); intact **RB1** is required for response, and *RB1* loss confers resistance.
- ▶ **Disease associations:** Cyclin D1 (*CCND1*) overexpression from t(11;14) defines **mantle cell lymphoma**; *CDKN2A* (*p16*) deletion/methylation is common across many tumours; **CDK4 amplification** characterises well-/de-differentiated liposarcoma.
- ▶ **Checkpoint as a drug target:** **WEE1 inhibitors** (e.g., adavosertib) are synthetically lethal in *TP53*-deficient tumours (which rely on the G2/M checkpoint); **PARP inhibitors** exploit DNA-repair defects (*BRCA1/2*); proteasome inhibitors (bortezomib) raise p21/p27 and induce arrest/apoptosis in myeloma.
- ▶ **Proliferation markers:** **Ki-67** indexes the growth fraction; tumours grow by **Gompertzian kinetics** (growth fraction falls from 100% to <5% by presentation), explaining chemoresponsiveness and dose-limiting marrow/gut toxicity.

High-yield exam pointers

- ▶ Four active phases **G1–S–G2–M** + quiescent **G0**; commitment occurs at the **restriction point** in late G1.
- ▶ **Cyclins** (oscillating) activate **CDKs** (constant); pairs: D–CDK4/6, E–CDK2, A–CDK2, B–CDK1.
- ▶ **CKIs:** **INK4** (p16, p15) inhibit CDK4/6; **CIP/KIP** (p21, p27, p57) inhibit broadly; **p21** is the p53 effector.
- ▶ Checkpoints: G1/S (**Rb–E2F**), intra-S, G2/M (p53, ATM/ATR–Chk, WEE1), M **spindle-assembly** (prevents aneuploidy).
- ▶ **Rb** = G1/S brake; phosphorylation releases **E2F/DP1**. **Knudson two-hit** for tumour-suppressors (*RB1* 13q14).
- ▶ **p53** = “guardian of the genome” (17p); MDM2-regulated; ATM/ATR–Chk activate it → *p21* arrest, repair, or *Noxa/Puma* apoptosis; **p14^{ARF}** = oncogene checkpoint.
- ▶ **HPV E6** → **p53 degradation**; **HPV E7** → **Rb inactivation**; **Li–Fraumeni** = germline *TP53*; aflatoxin **codon 249**.
- ▶ **Telomere shortening** (TTAGGG) limits division; **telomerase/hTERT** reactivated in >90% of cancers → immortality.

- ▶ Therapeutics: CDK4/6 inhibitors (palbo/ribo/abemaciclib) in ER+ breast cancer; WEE1 and PARP inhibitors exploit checkpoint/repair defects.

SOURCE & COVERAGE

- ▶ **Harrison's Principles of Internal Medicine, 22e** — “Cancer Cell Biology” (cell-cycle phases and checkpoints, Rb–E2F, p53/MDM2/p14ARF, ATM/ATR–Chk, spindle checkpoint, senescence/telomerase, apoptosis) and “Cancer Genetics” (Knudson two-hit hypothesis, tumour-suppressor biallelic inactivation).
- ▶ **DeVita, Hellman & Rosenberg's Cancer: Principles & Practice of Oncology, 12e** — CDK4/6–cyclin D–RB1–E2F axis, *CDKN2A/CCND1/CCNE1*, Cyclin E–CDK2/Cyclin B–CDK1, CDK4/6 inhibitors (palbociclib/ribociclib/abemaciclib, PALOMA-2), WEE1 inhibition and synthetic lethality, mantle-cell t(11;14).
- ▶ **Coverage note:** The corpus is rich on checkpoint and Rb/p53 biology. The full per-phase cyclin–CDK pairing table (Cyclin A–CDK2, Cyclin B–CDK1) is standard, universally-accepted cell biology; the corpus explicitly names cyclins A, B, D, E and CDK1/2/4/6 and the Cyclin D–CDK4/6, Cyclin E–CDK2 pairings, but does not tabulate every pairing. *p57^Kip2* is included as a standard CIP/KIP member though the corpus names principally p21 and p27.

Coagulation Cascade

Asked in: Paper I Jul 2020 · Paper I Nov 2019 (2×) — RGUHS MD General Medicine

Definition / Introduction — The **coagulation cascade** is the sequence of reactions in which inactive plasma clotting factors (zymogens) are converted, in an amplifying, enzyme-driven chain, into active serine proteases that culminate in **thrombin** generation and the conversion of soluble **fibrinogen** to an insoluble **fibrin** clot. Originally described as a *waterfall* or *cascade* (Macfarlane; Davie & Ratnoff, 1964) with separate **extrinsic** and **intrinsic** limbs converging on a **common pathway**, it is now understood that *in vivo* coagulation is initiated by **tissue factor** (TF) exposure with critical amplification through intrinsic-pathway elements. It operates on activated, phospholipid (anionic) cell membranes, requires **calcium** (**factor IV**), and is one arm of secondary hemostasis (fibrin formation), distinct from primary hemostasis (platelet plug).

Classification of clotting factors

- ▶ **Nomenclature:** Factors are numbered I–XIII (Roman numerals); the activated form carries the suffix “a” (e.g., factor Xa). There is no factor VI.
- ▶ **Functional groups:**

Group	Factors	Key feature
Fibrinogen / thrombin-sensitive group	I (fibrinogen), V (<i>proaccelerin</i> , labile), VIII (<i>antihemophilic factor</i>), XIII (<i>fibrin-stabilising factor</i>)	Consumed in clotting; V & VIII are cofactors activated by thrombin
Prothrombin / vitamin K-dependent group	II (prothrombin), VII (<i>proconvertin</i>), IX (<i>Christmas factor</i>), X (<i>Stuart-Prower factor</i>)	Need vitamin K for γ -carboxylation; also anticoagulant proteins C, S, Z
Contact group	XII (<i>Hageman</i>), XI, prekallikrein (PK), high-molecular-weight kininogen (HMWK)	Initiate intrinsic limb <i>in vitro</i>
Cofactors	Tissue factor (III), Ca^{2+} (IV), V, VIII	Accelerate but are not enzymes

- ▶ **Vitamin K dependence:** Factors II, VII, IX, X and the natural anticoagulants **protein C**, **protein S**, **protein Z** require vitamin K-dependent γ -glutamyl carboxylation of glutamic acid residues ($\rightarrow$ Gla residues), a step essential for Ca^{2+} -mediated binding to phospholipid surfaces. Warfarin inhibits **vitamin K epoxide reductase (VKORC1)**, depleting reduced vitamin K (Fig. 121-3).
- ▶ All coagulation factors are **synthesised in the liver** (TF and VWF are extrahepatic); hepatic failure $\rightarrow$ combined factor deficiencies.

The cascade: extrinsic, intrinsic & common pathways

- ▶ **Extrinsic (TF) pathway — physiologic initiator:** Vascular injury exposes blood to **tissue factor**, constitutively expressed on subendothelial smooth-muscle cells/fibroblasts (also on circulating microparticles). TF binds **factor VIIa**; the TF/VIIa complex activates **factor X $\rightarrow$ Xa** directly, and also activates **factor IX $\rightarrow$ IXa** (indirect route). Tested by the PT.
- ▶ **Intrinsic (contact) pathway:** *In vitro* begins with **factor XII, prekallikrein, HMWK** on a negatively charged surface $\rightarrow$ XIIa $\rightarrow$ activates XI $\rightarrow$ XIa $\rightarrow$ IXa (with VIIIa cofactor) $\rightarrow$ Xa. Tested by the aPTT. *In vivo* the contact factors are dispensable — **factor XII deficiency causes a long aPTT but NO bleeding**; physiologically **factor XI is activated chiefly by thrombin** (positive feedback), so XIa amplifies/propagates rather than initiates.
- ▶ **Common pathway:** **Factor Xa**, with cofactor **Va** on phospholipid (the *prothrombinase complex*), converts **prothrombin (II) $\rightarrow$ thrombin (IIa)**. Thrombin then cleaves **fibrinogen $\rightarrow$ fibrin monomer**, which polymerises; **factor XIIIa** (activated by thrombin) covalently **cross-links** fibrin to a stable clot. Tested by aPTT and PT; the fibrinogen $\rightarrow$ fibrin step by the **thrombin time (TT)**.
- ▶ **Thrombin — the pivotal protease (central amplifier):** Beyond cleaving fibrinogen, thrombin feeds back to activate **FV $\rightarrow$ Va**, **FVIII $\rightarrow$ VIIIa**, **FXI $\rightarrow$ XIa**, and **FXIII $\rightarrow$ XIIIa**, hugely amplifying its own generation; it also activates platelets and protein C.
- ▶ **Modern in vivo (cell-based) view** — three overlapping phases on cell surfaces:

- ▶ **Initiation:** TF/VIIa on TF-bearing cells generates small amounts of Xa and thrombin.
- ▶ **Amplification:** Trace thrombin activates platelets and cofactors V, VIII, XI on the platelet surface.
- ▶ **Propagation:** The “tenase” (IXa/VIIIa) and “prothrombinase” (Xa/Va) complexes assemble on activated platelet phospholipid → a **thrombin burst** → robust fibrin clot.
- ▶ **Key insight (Harrison):** Once TF/VIIa/Xa forms, **TFPI shuts off the TF/VIIa trigger**, making sustained coagulation dependent on the **amplification loop via factors XI, IX and VIII** — explaining why severe FVIII/FIX deficiency (haemophilia) bleeds despite an intact extrinsic start.

Natural anticoagulant (antithrombotic) mechanisms

Physiologic inhibitors localise clotting to the site of injury and preserve fluidity:

- ▶ **Antithrombin (AT):** Major plasma inhibitor of **thrombin and other serine proteases** (Xa, IXa, XIa, XIIa); forms a 1:1 covalent complex. Its rate is accelerated **several-thousand-fold** by **heparin / endothelial heparan sulfate** — the basis of heparin action. Deficiency → lifelong VTE risk.
- ▶ **Protein C – protein S system:** Thrombin bound to endothelial **thrombomodulin** (with **endothelial protein C receptor, EPCR**) activates **protein C** → **activated protein C (APC)**; APC, with cofactor **protein S**, proteolytically **inactivates FVa and FVIIIa** (Fig. 69-3). A point mutation at the APC cleavage site in FVa (**factor V Leiden**) confers **APC resistance** and a hypercoagulable state.
- ▶ **Tissue factor pathway inhibitor (TFPI):** Inhibits the TF/VIIa/Xa complex, switching off extrinsic initiation; partly released from endothelium by heparin.
- ▶ **Endothelial antithrombotic products:** prostacyclin (PGI₂), nitric oxide, ecto-ADPase/CD39 (inhibit platelets), plus heparan proteoglycans and thrombomodulin.

The fibrinolytic system

- ▶ **Plasmin** is the key fibrinolytic protease, generated from **plasminogen** by **tissue plasminogen activator (tPA)** and **urokinase (uPA)**, which cleave the **Arg560-Val561** bond.
- ▶ **Fibrin specificity:** Lysine-binding sites let plasminogen and tPA bind fibrin, forming a ternary (fibrin–plasminogen–tPA) complex that localises and accelerates plasmin generation on the clot.
- ▶ **Products:** Plasmin digests fibrin → **fibrin degradation products (FDPs)**; lysis of *cross-linked* fibrin releases **d-dimers** (specific marker of clot turnover; used to exclude DVT/PE; rises with age → age-adjusted cut-offs).
- ▶ **Regulation (three levels):** (1) **PAI-1 and PAI-2** inhibit tPA/uPA; (2) **TAFI** (thrombin-activatable fibrinolysis inhibitor) removes terminal lysines and limits lysis; (3) **α₂-antiplasmin** inactivates free plasmin.

Laboratory assessment of the cascade

Test	What it measures	Prolonged in
PT / INR	Extrinsic + common: I, II, V, VII, X	FVII deficiency, warfarin , early vitamin K deficiency, liver disease, direct Xa inhibitors (may be normal on apixaban)
aPTT	Intrinsic + common: XII, XI, IX, VIII, X, V, II, I, PK, HMWK	Haemophilia A/B, heparin , lupus anticoagulant, FXI/XII deficiency, vWD
Thrombin time (TT)	Fibrinogen → fibrin	Heparin, direct thrombin inhibitors (dabigatran, argatroban, bivalirudin) , dys-/afibrinogenaemia
Reptilase time	Fibrinogen → fibrin (heparin-insensitive)	Dysfibrinogenaemia (normal with heparin)
Clot solubility	Fibrin cross-linking	Factor XIII deficiency

- ▶ $INR = (PT_{\text{patient}} / PT_{\text{mean-normal}})^{ISI}$, where ISI = International Sensitivity Index; standardises warfarin monitoring across thromboplastins.
- ▶ **Mixing study:** Patient plasma + normal plasma 1:1. **Corrects** → factor deficiency; **fails to correct** → inhibitor (e.g., lupus anticoagulant, acquired FVIII inhibitor — the latter prolongs further on 37 °C incubation).
- ▶ Anti-Xa assay monitors LMWH/UFH and direct Xa inhibitors; **bleeding time is no longer recommended** for predicting bleeding risk.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Diagram 1 — The coagulation cascade (Y-shaped scheme).** Left limb labelled *Intrinsic (contact) pathway*: XII → XIIa (with PK, HMWK) → XI → XIa → IX → IXa; right limb *Extrinsic pathway*: Tissue factor + VIIa. Both converge on X → Xa (*common pathway*); show VIIIa (tenase cofactor) and Va (prothrombinase cofactor) on a **phospholipid + Ca²⁺** surface; then **Prothrombin (II) → Thrombin (IIa) → Fibrinogen (I) → Fibrin → (XIIIa) cross-linked fibrin clot**. Bracket the aPTT over the intrinsic+common limbs and the PT over the extrinsic+common limbs; mark TT at the fibrinogen→fibrin step.
- ▶ **Diagram 2 — Natural anticoagulant loops.** Label TFPI (on TF/VIIa/Xa), **antithrombin + heparin** (on thrombin & Xa), and the **thrombomodulin–EPCR → APC + protein S** loop inactivating FVa/FVIIIa.

Clinical / Diagnostic significance

- ▶ **Pattern recognition:** Isolated ↑PT → FVII deficiency/early warfarin; isolated ↑aPTT → haemophilia A/B or FXI deficiency (or heparin/lupus anticoagulant); **both** ↑ → deficiency of II, V, X or fibrinogen, late vitamin K deficiency, liver disease, **DIC**.
- ▶ **Haemophilia A (FVIII) & B (FIX):** X-linked; severity by factor level — **severe** <1%, **moderate** 1–5%, **mild** 6–30%; hallmark **haemarthrosis** and deep-muscle bleeds; treat with factor concentrates, **emicizumab** (bispecific FIXa/FX antibody mimicking FVIIIa), or gene therapy.
- ▶ **Acquired coagulopathies:** liver disease (combined deficiency + thrombocytopenia), **vitamin K deficiency/warfarin** (factors II, VII, IX, X), and **DIC** (consumption → ↑PT/aPTT, ↓fibrinogen, ↓platelets, ↑d-dimer).
- ▶ **Reversal/replacement:** **4-factor PCC** (II, VII, IX, X + proteins C & S) for warfarin reversal; **FFP**, **cryoprecipitate** (fibrinogen, VIII, XIII, VWF); **FXIII concentrate** for FXIII deficiency.
- ▶ **Thrombophilia:** Factor V Leiden, prothrombin **G20210A**, and deficiencies of **antithrombin**, **protein C**, **protein S** predispose to VTE; test only when results change management, in steady state off anticoagulants.

High-yield exam pointers

- ▶ **Thrombin (IIa)** is the central enzyme — converts fibrinogen→fibrin, activates V, VIII, XI, XIII, platelets and protein C.
- ▶ *In vivo* the cascade is **TF-initiated**; the intrinsic limb chiefly **amplifies** — hence **FXII deficiency = long aPTT but no bleeding**.
- ▶ **Vitamin K-dependent factors:** II, VII, IX, X + **proteins C, S, Z** (mnemonic “1972 → 2,7,9,10”).
- ▶ FVII has the **shortest half-life** → PT/INR is the earliest test to prolong with warfarin/vitamin K deficiency.
- ▶ **PT = extrinsic; aPTT = intrinsic; both = common pathway; TT = fibrinogen→fibrin.**
- ▶ **Factor XIII** is *not* detected by PT/aPTT — diagnose by **clot solubility (urea)**.
- ▶ **APC resistance = factor V Leiden** is the commonest inherited thrombophilia.
- ▶ **d-dimer** = lysis of cross-linked fibrin; sensitive for excluding VTE, not specific.
- ▶ **Mixing study corrects** = deficiency; **does not correct** = inhibitor.

The spec's DeVita reference (heme malignancies) is peripheral to cascade physiology and was not required.

Describe Erythropoiesis. Write briefly on Polycythaemia rubra vera

Asked in: Paper I Nov 2022 — RGUHS MD General Medicine

Definition / Introduction — Erythropoiesis is the regulated process of red cell production within the **erythron** — the dynamic “organ” comprising the rapidly proliferating pool of marrow erythroid precursors plus the large mass of circulating red cells. It begins with the pluripotent **haematopoietic stem cell** (HSC) and is driven principally by the hormone **erythropoietin** (EPO) so that tissue oxygen delivery is matched to demand. **Polycythaemia rubra vera** (PV) — polycythaemia *vera* — is a clonal HSC (myeloproliferative) neoplasm in which phenotypically normal red cells, granulocytes and platelets accumulate **in the absence of a recognisable physiologic stimulus**, almost always driven by a *JAK2* mutation.

Erythropoiesis — lineage, cell sequence and kinetics

- **Haematopoiesis** produces all formed elements from the HSC, which can generate red cells, all granulocytes, monocytes, platelets and immune cells. Erythroid cells arise from a **common erythroid/megakaryocytic progenitor** whose development requires the transcription factors **GATA-1** and **FOG-1** (friend of GATA-1).
- After lineage commitment, progenitors fall progressively under the control of growth factors/hormones; **EPO is the primary regulatory hormone**. EPO maintains committed erythroid progenitors, which **undergo apoptosis (programmed cell death) in its absence**.
- The first morphologically recognisable erythroid precursor is the **pronormoblast (proerythroblast)**; it undergoes **four to five cell divisions**, yielding **16–32 mature red cells** per pronormoblast.
- The mature red cell is **8 µm, anucleate, biconcave/discoid** and highly pliable; the biconcave disc maximises surface area for oxygen exchange and membrane integrity is sustained by **intracellular ATP**.

- ▶ **Kinetics:** normal production replaces 0.8–1% of circulating red cells daily, since the average red cell survives 100–120 days. Marrow cellularity is expressed as the **myeloid:erythroid (M:E) ratio**, normally ~2.5:1 (range 2:1–5:1).
- ▶ The **reticulocyte** (residual ribosomal RNA, seen as *polychromasia* on Wright–Giemsa) is the youngest red cell released; the **reticulocyte count is the clinical marker of effective erythropoiesis** — high with haemolysis/blood loss, low/inappropriate with hypoproliferative marrow.

Erythropoietin and oxygen-sensing regulation (HIF axis)

- ▶ EPO is a **glycoprotein hormone** produced and released by **peritubular capillary lining (interstitial) cells of the kidney**, with a small contribution from **hepatocytes**.
- ▶ The **fundamental stimulus is oxygen availability** for tissue metabolism. The master regulator is **hypoxia-inducible factor-1 α (HIF-1 α)**:
 - In **normoxia**, HIF-1 α is **hydroxylated at a key proline**, ubiquitinated and degraded by the **proteasome** → low EPO.
 - In **hypoxia**, hydroxylation fails → HIF-1 α partners with other proteins, **translocates to the nucleus and upregulates the EPO gene**.
- ▶ Impaired renal O₂ delivery (and hence ↑EPO) results from **decreased red cell mass (anaemia)**, **impaired O₂ loading of haemoglobin/hypoxaemia**, a **high-O₂-affinity haemoglobin**, or **reduced renal blood flow** (e.g., renal artery stenosis).
- ▶ Normal plasma EPO is **10–25 U/L**; when haemoglobin falls below **100–120 g/L (10–12 g/dL)**, EPO rises logarithmically in proportion to anaemia severity. EPO **half-life is 6–9 h**.
- ▶ EPO binds receptors on marrow erythroid precursors → proliferation and maturation; with stimulation, **red cell output can increase 4–5 fold over 1–2 weeks**, but only if substrate is adequate.
- ▶ An effective erythron therefore requires (1) normal renal EPO production, (2) a functioning erythroid marrow, and (3) adequate substrate — **iron, vitamin B12 and folate**.

Polycythaemia — definition and classification

- ▶ **Polycythaemia** = haemoglobin above normal; *erythrocytosis* strictly implies a **documented increase in red cell mass**. A rise may be **real (absolute)** or **apparent (relative/spurious)** from plasma volume contraction.
- ▶ Thresholds prompting concern: **Hb >17 g/dL (men) / >15 g/dL (women)**; **Hct >50% (men)/>45% (women)** may be abnormal; **Hct >60% (men)/>55% (women)** almost invariably reflects a raised red cell mass. Red cell mass **<36 mL/kg (men) / <32 mL/kg (women)** indicates spurious polycythaemia.

Category	Mechanism	Examples
Relative / spurious	↓ plasma volume, normal red cell mass	Dehydration, diuretics, alcohol/tobacco; Gaisböck's syndrome (stress erythrocytosis)
Primary	Intrinsic clonal marrow defect; EPO low/normal	Polycythaemia vera; EPO-receptor mutation; familial polycythaemia
Secondary — appropriate EPO	Tissue hypoxia → physiologic ↑EPO	High altitude, chronic lung disease, sleep apnoea, cyanotic heart disease, CO poisoning ("smoker's polycythaemia"), high-O ₂ -affinity haemoglobinopathy
Secondary — inappropriate EPO	Autonomous/ectopic EPO; HIF-pathway defects	Renal cysts/artery stenosis, post-transplant; tumours — hypernephroma, hepatoma, cerebellar haemangioblastoma, uterine myoma, pheochromocytoma; Chuvash polycythaemia (VHL), PHD2/EGLN1, HIF-2α/EPAS1 mutations; exogenous androgens, recombinant EPO, SGLT2 inhibitors

Polycythaemia rubra vera — pathogenesis and clinical features

- ▶ **Pathogenesis:** PV is the **commonest myeloproliferative neoplasm**, incidence ~2.5/100,000 (rising with age to >10/100,000). The central lesion is a mutation (V617F — valine→phenylalanine) in the **autoinhibitory pseudokinase domain of JAK2**, causing constitutive kinase activation**.
- ▶ JAK2 is the cognate non-receptor tyrosine kinase for the **EPO and thrombopoietin receptors**. Constitutive activation produces **EPO hypersensitivity, EPO-independent erythroid colony formation, ↑Bcl-XL and apoptosis resistance**.
- ▶ >95% of PV patients carry JAK2 V617F; most of the remainder carry **exon 12 mutations**. JAK2 lies on chromosome 9p; uniparental disomy causing **homozygosity for V617F** occurs in ~60% of PV. Non-random cytogenetic changes (del 20q, del 13q, trisomy 9) occur in up to 30%.
- ▶ **Clinical features** — PV is a *panmyelopathy*; presentation is often an **incidental high Hb/Hct/red cell count**:
 - **Hyperviscosity:** vertigo, tinnitus, headache, visual disturbance, TIAs; systolic hypertension; *ruddy* (plethoric) complexion.

- **Thrombosis (arterial & venous)** — the dominant complication; cerebral, cardiac and mesenteric vessels; **Budd–Chiari (hepatic vein) thrombosis**, classically in young women (the only thrombosis specifically linked to JAK2 V617F); **portal vein thrombosis** commoner in men.
- **Bleeding**: easy bruising, epistaxis, GI haemorrhage; extreme thrombocytosis ($>900,000/\mu\text{L}$) causes **acquired von Willebrand's disease**.
- **Erythromelalgia** (erythema, burning, pain of digits $\pm$ infarction), **aquagenic pruritus**, splenomegaly, peptic ulcer disease, and **hyperuricaemia** $\rightarrow$ **secondary gout / uric acid stones**.

PV — diagnosis

- ▶ Diagnosis is straightforward when **erythrocytosis coexists with leukocytosis, thrombocytosis or splenomegaly**. With isolated red cell elevation it is harder, because in PV the **plasma volume expands and can mask a raised red cell mass** (especially in women) — true erythrocytosis cannot be reliably separated from plasma contraction unless **Hb ≥ 20 g/dL (Hct $\geq 60\%$)**.
- ▶ **Serum EPO** is the pivotal screening test: **low/unmeasurable EPO favours PV**, whereas an **elevated EPO points to a secondary cause**.
- ▶ **Quantitative JAK2 V617F / exon 12 assay by next-generation sequencing is now the confirmatory test and has superseded surrogate tests. Supportive findings: leukocytosis, raised absolute basophil count, thrombocytosis*.*
- ▶ Only **three causes** produce a **microcytic erythrocytosis**: **β -thalassaemia trait, hypoxic erythrocytosis and PV** (the latter two via associated iron deficiency, with raised RDW). Bone marrow aspirate/biopsy is **non-specific** (may resemble ET/PMF).
- ▶ *Standard add (WHO 2016 criteria, not detailed in the provided text):* Hb >16.5 g/dL (men)/ >16.0 g/dL (women) or raised red cell mass + trilineage marrow panmyelosis + JAK2 mutation, with **subnormal serum EPO** as a minor criterion.

PV — management

- ▶ PV is **indolent** (course measured in decades); **thrombosis from erythrocytosis is the most significant complication**, so red cell mass control is mandatory.

Modality	Role / target
Phlebotomy	First-line; maintain Hct $<45\%$ (men)/ $<42\%$ (women) [Hb ≤ 14 / ≤ 12 g/dL]; induces iron deficiency limiting re-expansion — usually only every ~3 months once iron-deplete
Low-dose aspirin (salicylate)	Reduces thrombosis — only if red cell mass is controlled ; risk of bleeding (esp. age >60) if uncontrolled

Modality	Role / target
Anticoagulation	After a thrombotic event; newer oral anticoagulants preferred (no monitoring)
Hydroxyurea	Cytoreduction; does not target the malignant HSC and is mutagenic/leukemogenic — short-course
Pegylated interferon- α	Targets involved HSC, non-mutagenic; ~20% complete haematologic/molecular remission
Ruxolitinib (JAK1/2 inhibitor)	Refractory pruritus, symptomatic splenomegaly (replaces splenectomy)
Anagrelide	Lowers platelets (PDE inhibitor); marrow-sparing but cardiotoxic/nephrotoxic in elderly
Allopurinol	Hyperuricaemia when cytoreduction is used; tranexamic/ ϵ -aminocaproic acid for vWD-related bleeding

- ▶ Avoid alkylating agents and radioactive ^{32}P — strongly leukaemogenic.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Diagram 1 — Erythropoiesis pathway (vertical flow):** HSC $\rightarrow$ common myeloid progenitor $\rightarrow$ BFU-E $\rightarrow$ CFU-E $\rightarrow$ Pronormoblast $\rightarrow$ basophilic normoblast $\rightarrow$ polychromatophilic normoblast $\rightarrow$ orthochromatic normoblast $\rightarrow$ Reticulocyte $\rightarrow$ Mature RBC. **Side-label:** EPO acting at CFU-E/pronormoblast; GATA-1/FOG-1** at commitment; “16–32 RBC per pronormoblast”; “lifespan 100–120 days”.
- ▶ **Diagram 2 — Renal O_2 -sensing/EPO feedback loop:** labels Tissue hypoxia $\rightarrow$ Kidney (peritubular cells) $\rightarrow$ HIF-1 α stabilised $\rightarrow$ $\uparrow$ EPO $\rightarrow$ Erythroid marrow $\rightarrow$ $\uparrow$ Red cell mass $\rightarrow$ $\uparrow$ O_2 delivery $\rightarrow$ (negative feedback) $\rightarrow$ HIF-1 α hydroxylated/degraded.

Clinical / Diagnostic significance

- ▶ Serum EPO + JAK2 mutation together separate PV (low EPO, JAK2+) from secondary polycythaemia (high EPO) — order both simultaneously.
- ▶ A “normal” Hct in a PV patient with massive splenomegaly should be assumed to mask a raised red cell mass until proven otherwise.
- ▶ Suspect PV in any patient (esp. a young woman) with Budd–Chiari/splanchnic vein thrombosis, aquagenic pruritus or erythromelalgia.
- ▶ The reticulocyte count triages anaemia (high = haemolysis/blood loss; low = hypoproliferative) and reflects EPO-driven erythropoiesis — the mirror image of the polycythaemia work-up.

High-yield exam pointers

- ▶ EPO source = renal peritubular interstitial cells; master switch = HIF-1 α (degraded in normoxia via proline hydroxylation).
- ▶ Pronormoblast $\rightarrow$ 4–5 divisions $\rightarrow$ 16–32 RBCs; RBC lifespan 100–120 days; daily turnover 0.8–1%; normal M:E ratio 2.5:1.
- ▶ Normal EPO 10–25 U/L; rises once Hb <10–12 g/dL; half-life 6–9 h.
- ▶ PV = JAK2 V617F (>95%), exon 12 in most others; low/absent serum EPO is the hallmark.
- ▶ Hct targets: <45% men / <42% women; phlebotomy + low-dose aspirin are first-line.
- ▶ Budd–Chiari is the thrombosis specifically tied to JAK2 V617F.
- ▶ Only 3 causes of microcytic erythrocytosis: β -thalassaemia trait, hypoxic erythrocytosis, PV.
- ▶ Avoid ^{32}P / alkylators (leukaemogenic); hydroxyurea is short-course; pegIFN- α and ruxolitinib target the disease clone.

SOURCE & COVERAGE

Harrison's Principles of Internal Medicine, 22e — Ch 66 “Anemia and Polycythemia” (erythropoiesis, EPO/HIF regulation, definition and classification of polycythaemia) and Ch 108 “Polycythemia Vera and Other Myeloproliferative Neoplasms” (PV pathogenesis, clinical features, diagnosis, treatment). *Coverage note:* the intermediate erythroid maturation stages (BFU-E/CFU-E, basophilic $\rightarrow$ orthochromatic normoblast) and the explicit WHO 2016 diagnostic criteria are universally accepted standard haematology added for completeness — they are not spelled out verbatim in the provided chapters (which name only the *pronormoblast* and *reticulocyte*, and present a JAK2/EPO-based diagnostic algorithm).

Describe Vitamin B12 metabolism. Write briefly about the Neurological manifestations of Vitamin B12 deficiency

Asked in: Paper I Nov 2022 — RGUHS MD General Medicine

Definition / Introduction — Vitamin B12 (cobalamin) is a water-soluble cobalt-containing vitamin synthesised solely by micro-organisms; humans obtain it only from animal foods. It is the obligatory cofactor for just two human enzymatic reactions, yet its deficiency produces both a **megaloblastic anaemia** (defective DNA synthesis) and a distinctive **neurological syndrome** (demyelination), the latter often dominating the picture in the non-anaemic patient. Understanding its metabolism — structure, dietary source, intrinsic-factor-dependent absorption, plasma transport and intracellular function — explains why deficiency develops slowly, why pernicious anaemia is the commonest cause, and how the neuropathy arises.

Structure and biochemical forms

- ▶ All cobalamins have a **cobalt atom at the centre of a corrin ring**. They differ only in the upper axial ligand.
- ▶ **Adenosylcobalamin (2-deoxyadenosyl / ado-cobalamin)** — the main natural form, located in **mitochondria**; cofactor for **L-methylmalonyl-CoA mutase**.
- ▶ **Methylcobalamin** — the predominant form in **human plasma and cell cytoplasm**; cofactor for **methionine synthase**.
- ▶ Minor amounts of **hydroxocobalamin** are present; methyl- and ado-cobalamin are converted to it rapidly on exposure to light (relevant to the therapeutic forms used).

Dietary sources, requirement and body stores

Parameter	Value (Harrison 22e)
Source	Synthesised only by micro-organisms; for humans, animal origin only — meat, fish, dairy. Plant foods free of B12 unless bacterially contaminated
Dietary content (Western diet)	5–30 µg/day
Daily loss / requirement	1–3 µg/day (~0.1% of body stores); body cannot degrade cobalamin
Body stores	2–3 mg, sufficient for 3–4 years if intake stops

- ▶ Because stores are large and an enterohepatic circulation conserves cobalamin, dietary deficiency (strict vegans) develops only after years; in contrast, **malabsorption** depletes stores faster because biliary reabsorption is also lost.

Absorption (intrinsic-factor pathway)

- ▶ Two mechanisms exist: a **passive** route (through buccal, duodenal and ileal mucosa; rapid but very inefficient — <1% of an oral dose) and the physiological **active** route (ileal, **intrinsic-factor dependent**, efficient for small doses).
- ▶ Sequential steps of active absorption:

Step	Event
1	Dietary B12 released from protein in stomach/duodenum/jejunum by acid and enzymes
2	Binds salivary haptocorrin (HC) in the stomach
3	Pancreatic trypsin digests HC in the intestine; B12 transferred to intrinsic factor (IF)
4	IF (gene at chromosome 11q13) is secreted by gastric parietal cells (fundus/body); secretion parallels HCl

Step	Event
5	IF-B12 complex reaches the ileum and binds the receptor cubilin on enterocyte microvilli; cubilin traffics via amnionless (AMN)
6	Complex is endocytosed; IF is destroyed; after ~6 h B12 enters portal blood bound to transcobalamin II

- ▶ 0.5–5 µg of B12 enters bile daily, binds IF and is largely **reabsorbed (enterohepatic circulation)** together with B12 from sloughed cells.

Plasma transport and cellular uptake

- ▶ Two plasma transport proteins each bind B12 one-to-one:
 - **Transcobalamin I (TC I / haptocorrin)** — gene *TCN1* (chr 11); derived mainly from **neutrophil granules**; normally ~two-thirds saturated; does **not** deliver B12 to tissues but carries analogues to the **liver for biliary excretion**.
 - **Transcobalamin II (TC II)** — gene on **chromosome 22q11–q13.1**; synthesised by liver, macrophages, ileum and vascular endothelium; carries only 20–60 ng/L but is the **functional delivery protein**, readily giving up B12 to marrow, placenta and other tissues.
- ▶ Cellular uptake of TC II–B12 is by **receptor-mediated endocytosis** via the **TC II receptor** and **megalín (LRP-2 gene)** through clathrin-coated pits; the complex is degraded and free B12 exported via an ABC transporter.

Intracellular biochemical functions (the two B12-dependent reactions)

- ▶ **Reaction 1** — Methylmalonyl-CoA → succinyl-CoA (methylmalonyl-CoA mutase, needs **adocobalamin**). Block raises **methylmalonic acid (MMA)** — the basis of the MMA diagnostic test and a contributor to neuropathy.
- ▶ **Reaction 2** — Homocysteine → methionine (methionine synthase, needs **methylcobalamin** + 5-methyl-THF). This is the first step that regenerates intracellular **tetrahydrofolate (THF)** and produces **methionine** → **S-adenosylmethionine (SAM)**, the universal methyl donor for >100 methyltransferase reactions (including myelin lipids, myelin basic protein and DNA).
- ▶ **Methylfolate trap (“THF starvation”)**: in B12 deficiency, 5-MTHF cannot be demethylated, so it accumulates in plasma while intracellular folate falls — explaining the **megaloblastic anaemia** and why it partially responds to large doses of folic acid (which must not be given alone, as it masks anaemia while neuropathy progresses).

Neurological manifestations of B12 deficiency (brief)

- ▶ Cobalamin is required for **myelination of the CNS**; deficiency causes demyelination.

- ▶ **Subacute combined degeneration (SCD) of the spinal cord** is the hallmark: **demyelination of the posterior (dorsal) columns and lateral (pyramidal) tracts** of the cervical and thoracic cord; MRI may show “spongy” degeneration.
- ▶ **Bilateral peripheral neuropathy** — symmetrical glove-and-stocking **paraesthesiae**, often the earliest symptom.
- ▶ **Posterior-column signs**: loss of **vibration and proprioception (position) sense**, **positive Romberg sign**, **Lhermitte sign**, sensory ataxia.
- ▶ **Pyramidal (lateral-column) signs**: spastic, ataxic gait with **hyperreflexia** and extensor plantars (a combination of upgoing toes with absent ankle jerks is classic).
- ▶ **Autonomic involvement**: postural hypotension, **impotence**, urinary/faecal incontinence.
- ▶ **Cerebral / cranial**: **dementia**, depression, psychotic symptoms, cognitive impairment (“megaloblastic madness”), **optic atrophy**, and **anosmia / loss of taste**; cranial-nerve involvement is less frequent.
- ▶ **Infancy**: poor brain and intellectual development, feeding difficulty, lethargy, coma, convulsions and myoclonus.
- ▶ Patients are **more often male** and may present with neurological disease **before or without anaemia** — the non-anaemic patient with neuropsychiatric features and a low/borderline serum B12 is an important clinical trap.
- ▶ **Proposed mechanism**: the neuropathy correlates with the **defect in homocysteine→methionine conversion**; accumulation of **S-adenosylhomocysteine** in brain inhibits transmethylation, and failure of SAM-dependent methylation of biogenic amines (e.g., dopamine), proteins and phospholipids is implicated (the exact biochemical basis “remains obscure”). Importantly, neuropathy can occur **without** methylmalonic aciduria (as in TC II deficiency).

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Diagram 1 — B12 absorption & transport pathway (flow diagram)**: Label — *Dietary B12 (animal food) → Stomach: acid/enzymes + Haptocorrin (HC) → Duodenum: pancreatic trypsin → Intrinsic factor (IF) from gastric parietal cells → IF-B12 complex → Ileum: cubilin-amnionless receptor → enterocyte endocytosis → portal blood → Transcobalamin II (TC II) → tissues (marrow, CNS) via TC II receptor / megalin (LRP-2). Side branch: Bile → enterohepatic recirculation.*
- ▶ **Diagram 2 — Spinal cord cross-section in SCD**: Label — *Posterior (dorsal) columns — fasciculus gracilis & cuneatus (demyelinated), Lateral corticospinal (pyramidal) tracts (demyelinated), Anterior columns spared, grey matter butterfly; annotate “cervical & thoracic cord, bilateral, symmetrical.”*

Clinical / Diagnostic significance

- ▶ **Causes of deficiency: pernicious anaemia** (gastric atrophy, anti-IF / anti-parietal-cell antibodies) — commonest; total gastrectomy, ileal resection/Crohn's disease, **strict vegetarianism/veganism**, fish tapeworm (*Diphyllobothrium*), tropical sprue, stagnant-loop syndrome, and drugs — **metformin, proton-pump inhibitors / H2-blockers**.
- ▶ **Investigations: serum B12** by ELISA/CBLA (normal $\approx 160\text{--}1000$ ng/L; deficiency usually <100 ng/L; **false-normal in up to 50% of PA** when anti-IF antibodies interfere). **Serum MMA and homocysteine** are raised and are sensitive early markers (homocysteine alone rises in folate deficiency too; **MMA is specific to B12**). Peripheral film: **oval macrocytes**, **MCV >100 fL**, **hypersegmented neutrophils (>5 lobes)**. PA work-up: **anti-IF and anti-parietal-cell antibodies**, raised serum gastrin, low pepsinogen I, endoscopy.
- ▶ **Treatment: parenteral hydroxocobalamin (UK) or cyanocobalamin (US)**. Replenishment: **six 1000- μg IM hydroxocobalamin injections at 3–7 day intervals**; maintenance **1000 μg IM every 3 months** (hydroxocobalamin) or **1000 μg cyanocobalamin IM monthly**. High-dose oral cyanocobalamin (**1000–2000 $\mu\text{g}/\text{day}$**) exploits passive absorption. More frequent dosing is used if neuropathy is present.
- ▶ **Pearls: never treat suspected B12 deficiency with folate alone** (precipitates/worsens SCD). Neurological recovery depends on early treatment — long-standing cord signs may be irreversible. Watch for **hypokalaemia and thrombocytosis** during early response; give aspirin if platelets rise $>800 \times 10^9/\text{L}$. Screen for coexisting **iron deficiency** in pernicious anaemia (occurs in 15–20% of those >60 y).

High-yield exam pointers

- ▶ B12 = **cobalt in a corrin ring**; only two human reactions need it — **methylmalonyl-CoA mutase (ado-B12)** and **methionine synthase (methyl-B12)**.
- ▶ **Body stores 2–3 mg last 3–4 years** $\rightarrow$ deficiency is slow; faster in malabsorption than in vegans (loss of enterohepatic recycling).
- ▶ Absorption chain to memorise: HC $\rightarrow$ **trypsin** $\rightarrow$ **IF (parietal cell)** $\rightarrow$ **cubilin/amnionless (ileum)** $\rightarrow$ **TC II**.
- ▶ **TC II** is the functional delivery protein; **TC I (haptocorrin)** carries analogues for biliary excretion.
- ▶ **Methylfolate trap** links B12 deficiency to megaloblastic anaemia and the folate response.
- ▶ **SCD = demyelination of dorsal columns + lateral pyramidal tracts** of cervical/thoracic cord.
- ▶ Classic sign-set: **absent ankle jerks + extensor plantars**, positive Romberg and Lhermitte, loss of vibration/position sense.
- ▶ **MMA specific for B12; homocysteine raised in both B12 and folate deficiency**.
- ▶ **Never give folate alone** — masks anaemia, worsens neuropathy.

- ▶ Neuropathy can precede anaemia and may occur with **normal serum B12** (use MMA/homocysteine).

SOURCE & COVERAGE

Harrison 22e — Ch 104 “Megaloblastic Anemias” (cobalamin structure, dietary source, IF-dependent absorption, TC I/TC II transport, the two B12-dependent reactions, methylfolate trap, neurologic manifestations, diagnosis and treatment) + Ch 344 “Vitamin and Trace Mineral Deficiency and Excess” (B12 deficiency clinical features — loss of vibratory/position sense, abnormal gait, dementia, impotence, bladder/bowel involvement, ↑homocysteine/↑MMA — and causes). *Coverage note:* The eponymous physical signs (Romberg, Lhermitte) and the “absent ankle jerks with extensor plantars” combination, plus the explicit term *subacute combined degeneration* and the standard PA causes/drug list, are universally accepted textbook internal medicine used here to satisfy the exam ask; Harrison Ch 104 describes the underlying tract demyelination, positive Romberg/Lhermitte signs and hyperreflexia, and Ch 344 lists the deficiency features verbatim.

Diagnosis and management of chronic Myeloid Leukemia

Asked in: Paper IV May 2022 — RGUHS MD General Medicine

Definition / Introduction — Chronic myeloid leukemia (CML) is a clonal hematopoietic myeloproliferative *stem-cell* neoplasm driven by the **BCR::ABL1** chimeric gene, which encodes a constitutively active tyrosine kinase. It arises from a balanced reciprocal translocation between the long arms of chromosomes 9 and 22, *t(9;22)(q34.1;q11.2)*, cytogenetically recognised as the **Philadelphia (Ph) chromosome**. Untreated, the course is biphasic/triphasic — an indolent **chronic phase**, followed by an **accelerated phase** and a terminal **blastic phase**. The introduction of BCR::ABL1 **tyrosine kinase inhibitors (TKIs)** in 2000 transformed CML from a fatal disease (pre-TKI median survival 3–7 years; 10-year survival ≤30%) to one with a 10-year survival >85%, approaching that of an age-matched population.

Epidemiology and pathophysiology

- ▶ CML accounts for ~15% of all leukemias; male:female 1.6:1; median age at diagnosis 55–65 years; only ~3% are <20 years. Annual incidence ~2 per 100,000. No familial association; the only established risk factor is **ionizing radiation** exposure.
- ▶ The **t(9;22)** is present in >90% of classical CML and occurs in hematopoietic cells but not stromal cells. ABL1 (chr 9) is juxtaposed to the **major breakpoint cluster region (M-BCR)** of BCR (chr 22), generating the hybrid oncogene.

- ▶ Breakpoint determines transcript and oncoprotein: **M-BCR (e13/e14)** → e13a2 (b2a2)/e14a2 (b3a2) → **p210** (commonest in CML); **m-BCR (e1a2)** → **p190** (two-thirds of Ph-positive ALL; rare in CML; *worse outcome*); **μ-BCR (e19a2)** → **p230** (indolent course).
- ▶ p210 has **constitutive kinase activity** → increased proliferation, reduced apoptosis, and growth advantage, suppressing normal hematopoiesis. Signalling proceeds via **RAS, MAP kinases, STAT, PI3K and MYC** through adapter proteins (GRB-2, CRK, CRK-L, SHC). Most TKIs bind the **ATP-binding domain**; **asciminib** uniquely binds the **myristoyl pocket** (*STAMP* — Specifically Targeting the ABL1 Myristoyl Pocket).
- ▶ Transformation is associated with **additional chromosomal abnormalities** (double Ph, trisomy 8, isochromosome 17/17p loss of TP53, 3q26) and mutations (*TP53, RBL, RUNX1, ASXL1*). >100 **ABL1 kinase-domain mutations** drive TKI resistance; **T315I** is the “gatekeeper” mutation conferring resistance to imatinib and all second-generation TKIs.

Clinical features and phases

- ▶ ~90% present in **chronic phase**. In settings with screening, 50–60% are diagnosed incidentally on a routine blood count with minimal symptoms (fatigue).
- ▶ Symptomatic disease reflects **anemia and splenomegaly**: fatigue, malaise, weight loss, early satiety, left-upper-quadrant pain. **Splenomegaly is the commonest physical sign** (20–70%); hepatomegaly 5–10%, lymphadenopathy 5%.
- ▶ Less common: leukostasis/hyperviscosity from extreme leukocytosis or thrombocytosis (priapism, visual disturbance, MI, CVA, dyspnea); basophilia-related histamine excess (pruritus, flushing, diarrhea, GI ulcers).
- ▶ **Phase definitions (key marks):**

Phase	Defining features (Harrison 22e)
Chronic	Blasts ≤5%; controllable counts; >90% present here
Accelerated	≥15% peripheral blasts; ≥30% blasts + promyelocytes; ≥20% peripheral basophils; cytogenetic clonal evolution (ACAs other than Ph); platelets <100 × 10 ⁹ /L (therapy-unrelated)
Blastic	≥30% blasts in peripheral blood or marrow, or sheets of blasts in extramedullary disease

- ▶ Blastic phase is **myeloid in ~60%** and **lymphoid in ~25%** (lymphoblasts TdT-positive, peroxidase-negative; CD10/19/20/22, often co-express myeloid markers). The newest WHO classification proposes eliminating “accelerated phase,” reclassifying such patients as **high-risk CML**.

Diagnostic approach and investigations

- ▶ **Peripheral blood:** leukocytosis ($10\text{--}500 \times 10^9/\text{L}$), left-shifted granulocytosis with all maturation stages and blasts usually $\leq 5\%$; **basophilia/eosinophilia**; thrombocytosis common (thrombocytopenia suggests acceleration). **Low leukocyte alkaline phosphatase (LAP)** score; high vitamin B₁₂, uric acid, LDH and lysozyme.
- ▶ **Bone marrow:** hypercellular with myeloid hyperplasia, **myeloid:erythroid ratio 15–20:1**, blasts $\leq 5\%$; reticulin fibrosis (grade 3–4 in 30–40%).
- ▶ **Cytogenetics/molecular — confirm the diagnosis:** the diagnosis depends on documenting **t(9;22)** by **G-banding** (positive in $\sim 90\%$). **FISH** quantifies Ph-positive cells; **RT-PCR** detects/quantifies BCR::ABL1 transcripts (can be done on peripheral blood). Diagnosis should rest on a **marrow with routine cytogenetics** (detects ACAs that FISH misses); the **transcript type must be documented at diagnosis** to avoid spuriously “undetectable” follow-up PCR. $\sim 10\%$ have complex/variant or “masked” Ph; $\sim 5\text{--}10\%$ have additional chromosomal abnormalities.
- ▶ **Response milestones (standardised on the International Scale, IS) — the basis of monitoring:**

Response	Definition
Partial cytogenetic	$\leq 35\%$ Ph-positive metaphases ($\approx \text{IS } \leq 10\%$)
Complete cytogenetic (CCyR / MR2)	0% Ph-positive ($\approx \text{IS } \leq 1\%$)
Major molecular (MMR / MR3)	BCR::ABL1 (IS) $\leq 0.1\%$ ($\geq 3\text{-log}$ reduction)
Deep molecular (DMR / MR4)	BCR::ABL1 (IS) $\leq 0.01\%$
MR4.5	BCR::ABL1 (IS) $\leq 0.0032\%$ ($\geq 4.5\text{-log}$ reduction)

- ▶ **Resistance** = BCR::ABL1 (IS) $> 10\%$ at 6 months or $> 1\%$ at ≥ 12 months. Pre-TKI prognostic scores (Sokal, Hasford, EUTOS) have lost much impact; **achievement of CCyR/MR2** is now the key prognostic endpoint, while MMR/DMR reduces relapse and enables treatment-free remission.

Management — frontline TKI therapy

The goal of management is durable disease control with TKIs; **achievement of CCyR by 12 months** is the principal therapeutic endpoint. Six oral BCR::ABL1 TKIs are FDA-approved.

TKI (brand)	Generation / indication	Frontline dose	Notable toxicities
Imatinib (Gleevec/Glivec)	1st; all phases	400 mg once daily	Fluid retention, periorbital edema, myelosuppression, rashes, cramps
Dasatinib (Sprycel)	2nd; all phases	100 mg daily (50 mg as effective, less toxic)	Pleural/pericardial effusions, pulmonary hypertension, myelosuppression

TKI (brand)	Generation / indication	Frontline dose	Notable toxicities
Nilotinib (Tasigna)	2nd; all phases except blastic	300 mg twice daily (empty stomach)	Hyperglycemia, pancreatitis, arterio-occlusive events , hypertension, QT/hyperbilirubinemia
Bosutinib (Bosulif)	2nd; all phases	400 mg daily (with dose escalation)	Diarrhea/colitis, liver and renal toxicity
Ponatinib (Iclusig)	3rd; T315I, failure of ≥ 2 TKIs	45 mg daily (reduce to 15–30 mg on response)	Highest arterio-occlusive events , hypertension (50–60%), pancreatitis
Asciminib (Scemblix)	3rd (STAMP inhibitor); third-line, T315I	40 mg twice daily or 80 mg daily; T315I 200 mg twice daily	Generally well tolerated

- ▶ **All four of imatinib, dasatinib, bosutinib and nilotinib are acceptable frontline.** Second-generation TKIs give faster/deeper molecular responses (ENESTnd, DASISION, BFORE) and lower early transformation, but **no overall-survival advantage** over imatinib. Choice is individualised by: (1) **treatment aim** (survival vs treatment-free remission, linked to age); (2) **cost/affordability** (generic imatinib ~US\$500/year); (3) **comorbidities** — avoid dasatinib with lung disease, nilotinib with diabetes/pancreatitis/vascular disease, bosutinib with hepatic/renal/GI disease. If survival is the aim, **generic imatinib** is appropriate; if TFR is the aim, a **second-generation TKI** (e.g., dasatinib) is preferred, as in high-risk disease.
- ▶ **Omacetaxine mepesuccinate, hydroxyurea (0.5–10 g/day, cytoreductive bridge), low-dose cytarabine, decitabine and leukapheresis** (for leukostasis) are adjuncts; **interferon- α** is used in pregnancy.

Resistance, transformation, transplant and treatment-free remission

- ▶ **Resistance:** before switching, perform BCR::ABL1 kinase-domain mutation analysis (Sanger sequencing; ~50% of resistant patients have mutations). Mutation-guided salvage: Y253H, E255K/V, F359V/C/I → **dasatinib or bosutinib**; V299L, T315A, F317L → **nilotinib**; T315I → **ponatinib or asciminib** and consider allogeneic HSCT.
- ▶ **TKI toxicity management:** in patients already in good molecular response, **dose reduction** (rather than switching) is acceptable for reversible toxicity; switch for prohibitive toxicities (recurrent pleural effusion/dasatinib; vaso-occlusive events/ponatinib, nilotinib; pulmonary hypertension; pancreatitis; immune-mediated pneumonitis/myocarditis/hepatitis treated with steroids).

- ▶ **Allogeneic HSCT** — the only proven *curative* modality, now a **later-line** option: indicated for resistance to a second-generation TKI, **T315I** disease, or advanced phase. Chronic-phase long-term survival 50–70% (1-year mortality 5–30%); accelerated phase cure 30–50%; **blastic phase** ≤20%.
- ▶ **Accelerated/blastic phase**: TKIs (2nd/3rd generation) ± chemotherapy to reduce burden, **bridging to allogeneic HSCT**. **Lymphoid blast crisis** — anti-ALL chemotherapy (**hyper-CVAD**) + TKI (CR ~70%, median survival ~3 years); **myeloid blast crisis** — anti-AML chemotherapy + TKI (CR 30–50%).
- ▶ **Treatment-free remission (TFR)**: discontinuation after durable **DMR (MR4)** for >2–3 years yields TFR in 40–60% (≥5 years DMR → 80%+). Eligibility: low/intermediate Sokal risk, first chronic phase, quantifiable transcripts (e13a2/e14a2), ≥5 years of TKI, sustained DMR >2–5 years; restart the TKI only if BCR::ABL1 (IS) rises >0.1% (confirmed twice).
- ▶ **Pregnancy**: TKIs are teratogenic (malformations 2–10%); **discontinue immediately** on confirmed pregnancy and manage with leukapheresis/hydroxyurea (and interferon-α if needed).

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **The Philadelphia chromosome / BCR::ABL1 fusion**. Labels: *Chromosome 9 — ABL1 locus (q34.1); Chromosome 22 — BCR gene (q11.2); Reciprocal translocation t(9;22); Derivative 22q = Philadelphia chromosome; Fusion BCR::ABL1 gene → p210 oncoprotein (constitutive tyrosine kinase).*
- ▶ **Natural history / phase flow with response monitoring**. Labels: *Chronic phase (blasts ≤5%) → Accelerated phase (≥15% blasts / clonal evolution) → Blastic phase (≥30% blasts); alongside, the response ladder Hematologic → Cytogenetic (CCyR/MR2) → Molecular (MMR/MR3 → DMR/MR4 → MR4.5).*

Clinical / Diagnostic significance

- ▶ Sustained unexplained **leukocytosis with splenomegaly and a low LAP score** should prompt marrow examination and cytogenetics — the screen that uncovers CML.
- ▶ Demonstrating **BCR::ABL1** (G-banding/FISH/RT-PCR) is both diagnostic and the substrate for monitoring; **quantitative RT-PCR on the International Scale** drives every therapeutic decision (response, resistance, TFR).
- ▶ A “**masked Ph**” (morphologic CML, Ph not seen on karyotype) still responds to TKIs if FISH/PCR confirm BCR::ABL1 — do not exclude CML on G-banding alone.
- ▶ TKIs have made **CCyR achievement** the dominant prognostic factor, displacing the older Sokal/Hasford/EUTOS scores.

High-yield exam pointers

- ▶ **Hallmark**: Ph chromosome, t(9;22)(q34.1;q11.2), **BCR::ABL1** → p210 tyrosine kinase.

- ▶ **Diagnostic triad:** neutrophilic leukocytosis with full myeloid spectrum + basophilia, **low LAP**, splenomegaly; confirm with cytogenetics/FISH/PCR.
- ▶ **Three phases:** chronic ($\leq 5\%$ blasts) $\rightarrow$ accelerated ($\geq 15\%$ blasts / clonal evolution) $\rightarrow$ blastic ($\geq 30\%$ blasts).
- ▶ **Frontline:** imatinib 400 mg OD, dasatinib 100 mg OD, nilotinib 300 mg BD, bosutinib 400 mg OD — all acceptable; second-gen = deeper responses, no survival edge.
- ▶ **T315I** = gatekeeper mutation $\rightarrow$ only **ponatinib** / **asciminib** ($\pm$ allo-HSCT) work.
- ▶ **Asciminib** = **STAMP inhibitor** (myristoyl pocket); ponatinib inhibits VEGFR $\rightarrow$ hypertension.
- ▶ **Monitoring milestones:** CCyR/MR2 (IS $\leq 1\%$), MMR/MR3 (IS $\leq 0.1\%$), DMR/MR4 (IS $\leq 0.01\%$). Resistance: IS $> 10\%$ at 6 mo or $> 1\%$ at 12 mo.
- ▶ **Allo-HSCT** = only curative option, reserved for TKI failure / T315I / advanced phase.
- ▶ **TFR** possible after durable DMR ≥ 2 years; **stop TKIs in pregnancy** (teratogenic).

SOURCE & COVERAGE

Harrison 22e — Ch 110 “Chronic Myeloid Leukemia” (Kantarjian & Jabbour). Fully covered by the provided chapter; no coverage gap. Standard textbook adjuncts (LAP score, hyper-CVAD regimen composition) are corroborated by the chapter text.

Coagulation Cascade and Disseminated Intravascular Coagulation (DIC)

Asked in: Paper I Jul 2021 — RGUHS MD General Medicine

Definition / Introduction — The **coagulation cascade** is the sequence of reactions in which inactive plasma serine-protease zymogens are sequentially activated on phospholipid (activated platelet) surfaces, culminating in **thrombin** generation and conversion of soluble **fibrinogen to an insoluble cross-linked fibrin clot**. It functions as one limb of the hemostatic system, balanced against natural anticoagulants and fibrinolysis. **Disseminated intravascular coagulation (DIC)** is, per the ISTH (2001), “an acquired syndrome characterised by intravascular activation of coagulation with loss of localisation arising from different causes that can originate from and cause damage to the microvasculature, which, if sufficiently severe, can produce organ dysfunction” — i.e., uncontrolled thrombin generation causing simultaneous microvascular thrombosis and consumptive bleeding.

Steps of Normal Haemostasis

- ▶ **Primary haemostasis (platelet plug):** vascular injury exposes subendothelial collagen; **von Willebrand factor (VWF)** acts as molecular glue mediating platelet adhesion under high shear; adhesion via Gp Ib-IX-V and collagen receptors triggers activation, the release reaction (ADP,

serotonin, thromboxane A₂), and aggregation through the **Gp IIb/IIIa (αIIbβ₃)** receptor binding fibrinogen/VWF (≈50,000 sites/platelet).

- ▶ **Secondary haemostasis (fibrin formation):** the coagulation cascade stabilises the platelet plug with fibrin.
- ▶ **Fibrinolysis & remodelling:** plasmin degrades fibrin to restore vessel patency once bleeding is arrested.

The Coagulation Cascade — Cell-Based (“Waterfall”) Model

Originally described as **extrinsic (tissue factor)** and **intrinsic (contact)** pathways converging on a **common pathway**; the modern view is that coagulation is *initiated* by tissue factor with *amplification* through intrinsic elements. All reactions require **calcium (Ca²⁺)** and occur on activated phospholipid surfaces.

- ▶ **Initiation (extrinsic):** vascular damage exposes **tissue factor (TF)**, constitutively expressed on subendothelial smooth muscle/fibroblasts and on circulating microparticles. TF binds **factor VIIa**; the TF/VIIa complex activates **FX→FXa** (directly) and **FIX→FIXa** (indirectly).
- ▶ **Amplification (intrinsic loop):** **Tissue factor pathway inhibitor (TFPI)** rapidly switches off the TF/VIIa/FXa complex, making sustained coagulation dependent on the amplification loop — **thrombin** feeds back to activate **FXI, FVIII and FV**. **FXIa** is thus important in *propagation/amplification*, not initiation.
- ▶ **Common pathway:** **FXa**, with cofactor **FVa** on phospholipid, converts **prothrombin (FII)→thrombin (FIIa)** — the pivotal protease. Thrombin converts **fibrinogen→fibrin** and activates **FXIII→FXIIIa**, which covalently cross-links fibrin to stabilise the clot.
- ▶ **Note:** **FXII, prekallikrein and high-molecular-weight kininogen (HMWK)** (contact phase) prolong the aPTT but cause *no bleeding*, because thrombin can directly activate **FXI** — explaining why **FXII** deficiency is asymptomatic.

Pathway	Key factors	Screening test
Extrinsic	TF, FVII	PT
Intrinsic (contact)	FXII, FXI, FIX, FVIII, PK, HMWK	aPTT
Common	FX, FV, FII (prothrombin), fibrinogen (FI)	PT + aPTT
Fibrin formation	thrombin → fibrinogen; FXIII cross-link	Thrombin time (TT)

Natural Anticoagulants and the Fibrinolytic System

- ▶ **Antithrombin (AT):** major plasma inhibitor of thrombin and other proteases; activity accelerated several-thousand-fold by **heparin/heparan sulfate**. Deficiency → lifelong VTE risk.

- ▶ **Protein C / Protein S pathway:** thrombin bound to endothelial **thrombomodulin** (with the endothelial **protein C receptor, EPCR**) activates **protein C**; **activated protein C (APC)** with cofactor **protein S** cleaves and inactivates **FVa and FVIIIa**. Resistance to APC due to **Factor V Leiden** causes a hypercoagulable state.
- ▶ **TFPI:** inhibits the TF/FVIIa/FXa initiation complex.
- ▶ **Fibrinolysis:** **tPA** and **urokinase (uPA)** convert **plasminogen**→**plasmin**, which digests fibrin to fibrin degradation products (FDPs); complete lysis of cross-linked fibrin releases **D-dimer** (a specific marker of clot formation/breakdown). Regulated by **PAI-1/PAI-2** (inhibit tPA/uPA), **α2-antiplasmin** (inhibits plasmin), and **TAFI** (thrombin-activatable fibrinolysis inhibitor).

DIC — Aetiology and Pathophysiology

DIC is always **secondary** to an underlying trigger; common causes (ISTH/Harrison):

Category	Examples
Sepsis/infection	Gram-negative bacilli, staph/strep/pneumococci/meningococci; viral, fungal, parasitic, rickettsial
Trauma/tissue injury	Brain injury, extensive burns, fat embolism, rhabdomyolysis
Obstetric	Abruptio placentae, amniotic-fluid embolism, dead-fetus (retained), septic abortion, HELLP
Malignancy	Mucin-producing adenocarcinoma (prostate, pancreas), acute promyelocytic leukaemia (APL/M3)
Vascular	Giant haemangioma (Kasabach-Merritt), large-vessel/aortic aneurysm
Others	Snake/insect envenomation , acute haemolytic transfusion reaction, transplant rejection/GVHD, fulminant hepatic failure, shock, ARDS, massive transfusion

- ▶ **Central mechanism — uncontrolled thrombin generation.** Inflammatory activation (sepsis) → increased **TF expression**, neutrophil/monocyte activation, cytokine release, **neutrophil extracellular traps (NETs)** and polyphosphates → **thrombo-inflammation** and excess thrombin.
- ▶ Simultaneous **loss of endothelial antithrombotic properties** and disrupted natural anticoagulants + abnormal fibrinolysis.
- ▶ → **Systemic fibrin deposition** in small/midsize vessels → microvascular thrombosis → **ischaemic multi-organ damage** (lung→ARDS, kidney, liver, brain) and **microangiopathic haemolysis** (schistocytes).

- ▶ → Consumption of platelets and clotting factors + secondary hyperfibrinolysis (late) → diffuse bleeding.
- ▶ **Purpura fulminans**: severe DIC with extensive cutaneous thrombosis, in children after viral/bacterial infection and in **homozygous protein C deficiency** neonates.

DIC — Clinical Features and Diagnosis

- ▶ **Bleeding**: petechiae, ecchymoses, oozing from venepuncture/catheter/incision sites, GI/pulmonary/CNS haemorrhage; **purpura fulminans**.
- ▶ **Thrombosis**: microvascular occlusion → organ failure; large-vessel thrombosis, cerebral embolism; cancer-associated DIC may present chiefly as thrombosis (**Trousseau syndrome**).
- ▶ **Acute DIC**: haemodynamic instability/shock; mortality **30 to >80%**, largely determined by the underlying disease.
- ▶ **Laboratory hallmark**: ↓platelets, **prolonged PT and aPTT**, **low/falling fibrinogen**, **raised D-dimer/FDPs**, schistocytes on smear. Serial testing (every 6–8 h) is essential as values evolve.

ISTH scoring system for overt DIC (validated; uses platelet count, D-dimer, PT prolongation, fibrinogen):

Parameter	Value	Points
Platelets	>100 ×10 ⁹ /L / >50–<100 / <50	0 / 1 / 2
D-dimer	Normal / Moderate ↑ / Severe ↑	0 / 2 / 3
PT prolongation	<3 s / 3–<6 s / >6 s	0 / 1 / 2
Fibrinogen	>1 g/L / <1 g/L	0 / 1

- ▶ **Score ≥5** → **overt DIC** (repeat labs daily); **<5** → **non-overt/low-grade DIC** (repeat every 1–2 days). *Not to be used in pregnancy* (a separate obstetric tool exists).
- ▶ **Chronic (compensated) DIC**: giant haemangioma, metastatic carcinoma, late fetal demise; D-dimer/FDP elevated but PT/aPTT/fibrinogen often normal, mild/no thrombocytopenia.
- ▶ **Differential: severe liver disease** (similar abnormalities but change slowly, not rapidly) and **TTP** (acute thrombocytopenia + schistocytes + organ failure, but distinguished by **ADAMTS13 deficiency/inhibitor**).

DIC — Management

- ▶ **Treat the underlying cause** — this is the cornerstone (antimicrobials for sepsis, chemotherapy, surgery, evacuation of uterus/delivery for obstetric DIC).
- ▶ **Blood-product support for active bleeding / high bleeding risk** (not merely to correct numbers):
 - **Platelets** for count <10,000–20,000/μL (goal >20 ×10⁹/L; >50 ×10⁹/L for serious/intracranial bleeding).

- Cryoprecipitate or fibrinogen concentrate to keep fibrinogen >100–150 mg/dL (correct fibrinogen *before* giving FFP for prolonged PT/aPTT).
- FFP for prolonged PT/aPTT *with* bleeding (target PT/aPTT <1.5× normal).
- Vitamin K should be given.
- ▶ **Heparin** (low-dose continuous infusion, e.g., 5–10 U/kg/h, **no bolus**): for **low-grade/chronic** DIC with solid tumour or APL, for recognised thrombosis, and for **purpura fulminans**. *Aggravates bleeding in acute haemorrhagic DIC*; contraindicated if platelets cannot be kept >20,000–30,000/μL, in CNS/GI bleeding, placental abruption, or imminent surgery. No proven survival benefit in severe DIC.
- ▶ **Antifibrinolytics** (tranexamic acid/EACA): only in **primary hyperfibrinolytic** DIC with severe bleeding (e.g., APL, giant haemangioma) — use cautiously (thrombosis risk), often with heparin and only with haematology input.
- ▶ **Antithrombin / thrombomodulin concentrates**: post-hoc benefit suggested in sepsis-associated DIC; require further study. (Recombinant activated protein C was withdrawn.)
- ▶ **Special situations**: APL-associated DIC needs immediate treatment (start ATRA early) within ~24 h; **Trousseau syndrome** is treated with **heparin/LMWH** (warfarin less effective); **HELLP** requires delivery/evacuation of the uterus.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Cell-based coagulation cascade**: vessel injury → TF + FVIIa → activate FIX→FIXa and FX→FXa; cofactors FVIIIa and FVa; **prothrombin (FII)→thrombin (FIIa)**; **fibrinogen→fibrin**; **FXIIIa cross-linking**; thrombin feedback arrows to FXI, FVIII, FV; TFPI inhibiting TF/FVIIa/FXa. Bracket-label the PT (**extrinsic**), aPTT (**intrinsic**) and **common pathway**.
- ▶ **DIC pathophysiology flowchart**: *Trigger* → **Uncontrolled thrombin generation** → branch 1: **fibrin deposits in microcirculation** → ischaemic tissue damage + RBC damage/haemolysis + multi-organ failure; branch 2: **consumption of platelets & clotting factors** → **diffuse bleeding**; with **secondary fibrinolysis** → ↑FDP/D-dimer.

Clinical / Diagnostic significance

- ▶ **PT** screens the extrinsic/common pathway (FVII, X, V, II, fibrinogen) and underpins the **INR** for warfarin monitoring and liver-disease assessment; **aPTT** screens the intrinsic/common pathway and monitors unfractionated heparin.
- ▶ **Mixing studies** distinguish factor deficiency (corrects) from an inhibitor/lupus anticoagulant (fails to correct).
- ▶ **D-dimer** is a sensitive marker to *exclude* DVT/PE (age-adjusted thresholds) and is raised in DIC.

- ▶ A combined prolonged PT + aPTT with falling fibrinogen, thrombocytopenia, raised D-dimer and schistocytes in a sick patient is the classic DIC signature — always search for the underlying trigger.

High-yield exam pointers

- ▶ Coagulation is initiated by tissue factor, amplified by the intrinsic loop, occurs on phospholipid surfaces, and needs Ca^{2+} ; thrombin is the pivotal enzyme.
- ▶ FXII deficiency → long aPTT but no bleeding; FXIII deficiency → normal PT/aPTT but abnormal clot solubility and bleeding.
- ▶ Vitamin K-dependent factors = II, VII, IX, X + protein C and S.
- ▶ DIC is always secondary; commonest triggers = sepsis, trauma, obstetric complications, malignancy (APL, mucinous adenocarcinoma).
- ▶ ISTH overt-DIC score ≥ 5 (platelets, D-dimer, PT, fibrinogen).
- ▶ Schistocytes in 10–20%; D-dimer/FDP raised, fibrinogen low.
- ▶ HELLP = severe peripartum DIC variant; Trousseau = cancer DIC presenting as thrombosis; Kasabach-Merritt = haemangioma-associated.
- ▶ Treat the cause first; products only if bleeding; low-dose heparin for thrombotic/chronic DIC and purpura fulminans, *not* for acute haemorrhagic DIC.

SOURCE & COVERAGE

- ▶ Harrison's Principles of Internal Medicine, 22e — "Bleeding and Thrombosis" (coagulation cascade physiology, natural anticoagulants, fibrinolysis, PT/aPTT correlation) and "Coagulation Disorders" (DIC definition, causes, pathophysiology, ISTH scoring, management; differential vs liver disease and TTP).
- ▶ CMDT 2026 — "Disorders of Hemostasis, Thrombosis & Antithrombotic Therapy" (DIC essentials of diagnosis, management table, HELLP, Trousseau syndrome, APL-associated DIC, heparin thresholds).
- ▶ Coverage note: The DeVita oncology text was screened for the APL/malignancy-associated DIC angle; the substantive exam-grade DIC detail is fully covered by Harrison and CMDT, which were used as the primary sources.

Megaloblastic Anaemia

Asked in: Paper IV Jun 2024 — RGUHS MD General Medicine

Definition / Introduction — Megaloblastic anaemias are a group of disorders characterised by a distinctive morphological abnormality of the developing red cells in the bone marrow (megaloblasts), arising from defective DNA synthesis with relatively preserved RNA and cytoplasmic (haemoglobin)

maturation — i.e. **nuclear–cytoplasmic asynchrony**. The marrow is typically hypercellular, yet the anaemia results from **ineffective erythropoiesis** (intramedullary death of haemopoietic precursors by apoptosis). The overwhelming majority are due to deficiency of **cobalamin (vitamin B12)** or **folate (vitamin B9)**, or to drugs/genetic defects impairing their metabolism or DNA synthesis directly.

Etiology

Cobalamin (B12) deficiency	Folate deficiency	Independent of B12/folate
Nutritional: strict vegans (large at-risk Indian/Hindu vegetarian population)	Nutritional (commonest): old age, infancy, poverty, alcoholism, chronic invalids; scurvy/kwashiorkor	Antimetabolite drugs: cytarabine, hydroxyurea, 6-mercaptopurine, AZT
Pernicious anaemia (PA) — commonest severe cause in the West; autoimmune gastric atrophy with IF lack	Malabsorption: tropical sprue, coeliac (gluten-induced enteropathy), specific folate malabsorption (PCFT mutation)	Methotrexate / antifolates (DHF-reductase inhibitors)
Gastric: total/partial gastrectomy, congenital IF deficiency	Increased utilisation/loss: pregnancy & lactation, prematurity, chronic haemolysis (sickle cell, spherocytosis), myelofibrosis, malignancy, exfoliative dermatitis, haemodialysis	Orotic aciduria (responds to uridine)
Intestinal: stagnant/blind-loop syndrome, ileal resection (≥ 1.2 m) or Crohn's, tropical sprue, fish tapeworm (<i>Diphyllobothrium latum</i>), Imerslund-Gräsbeck syndrome	Antifolate/anticonvulsant drugs: phenytoin, primidone, barbiturates, sulfasalazine; alcohol	Thiamine-responsive (<i>SLC19A2</i>), myelodysplasia, acute myeloid leukaemia
Metabolic: transcobalamin (TC) II deficiency; N2O inactivation of methylcobalamin		

- ▶ **B12 stores** are 2–3 mg (3–4 years' reserve); deficiency develops slowly. **Folate stores** are only ~10 mg (3–4 months' reserve), so folate deficiency develops rapidly.
- ▶ B12 is **synthesised only by microorganisms**; human source is food of animal origin (meat, fish, dairy). Folate is abundant in liver, yeast and green vegetables but is **destroyed by cooking**.

Pathogenesis — biochemical basis

- ▶ The common final lesion is **impaired conversion of deoxyuridine monophosphate (dUMP) → deoxythymidine monophosphate (dTMP)**, the rate-limiting step of DNA synthesis, which requires **5,10-methylene-tetrahydrofolate (THF)** as coenzyme (thymidylate synthase). The

shortage of dTTP slows DNA replication; replicons fail to join, producing single-stranded breaks
→ **megaloblastic change and apoptotic intramedullary cell death.**

- ▶ **Only two reactions in humans require cobalamin:**
- ▶ **Methionine synthase** (uses **methylcobalamin** + 5-methyl-THF): homocysteine → methionine; methionine → **S-adenosyl-methionine (SAM)**, the universal methyl donor.
- ▶ **L-methylmalonyl-CoA mutase** (uses **adenosyl-cobalamin**): methylmalonyl-CoA → succinyl-CoA.
- ▶ **Methylfolate trap (THF starvation):** In B12 deficiency, methionine synthase fails, so folate is trapped as 5-methyl-THF in plasma (high serum folate) and cannot be converted to THF/polyglutamates inside the cell (low cell folate). This explains why B12 deficiency produces a **functional intracellular folate deficiency** and why the anaemia partly responds to large doses of folic acid (which bypass the trap) — but giving folate alone allows the **neuropathy to progress.**
- ▶ **Neuropathy** is attributed to defective methionine/SAM synthesis (impaired methylation of myelin), not to the megaloblastic process; methylmalonic acid (MMA) accumulates only with the mutase (B12) defect, not with TC II deficiency or N2O exposure.

Clinical features

- ▶ **General/anaemia:** insidious pallor, fatigue; “lemon-yellow” tint from combined pallor and mild **unconjugated jaundice** (ineffective erythropoiesis); anorexia, weight loss, low-grade fever; mild splenomegaly may occur.
- ▶ **Epithelial/GI:** **glossitis** (beefy-red, sore tongue), **angular cheilosis/stomatitis**, diarrhoea or constipation; reversible **melanin skin hyperpigmentation**; cervical smear abnormalities.
- ▶ **Neurological (B12 only)** — **subacute combined degeneration (SCD) of the cord:** symmetrical demyelination of the **posterior (dorsal) and lateral (pyramidal) columns** of the cervico-thoracic cord. Presents (more often in males) with **distal paraesthesiae**, loss of **vibration and proprioception**, positive **Romberg** and **Lhermitte** signs, ataxic-spastic gait with **hyperreflexia and extensor plantars**. Also peripheral neuropathy, optic atrophy, autonomic dysfunction (postural hypotension, incontinence, impotence). **Crucially, neuro-psychiatric features can occur with a normal CBC/MCV.**
- ▶ **Neuropsychiatric:** dementia, depression, psychosis, cognitive impairment, anosmia/loss of taste (“megaloblastic madness”).
- ▶ **Reproductive/obstetric:** infertility (both sexes); maternal folate deficiency → prematurity, recurrent fetal loss and **neural-tube defects (NTDs)**.
- ▶ **Infantile B12 deficiency** (B12-deficient mother, breast-fed): megaloblastic anaemia at 3–6 months with growth retardation, hypotonia and delayed myelination.

Haematological & laboratory findings / Diagnosis

- ▶ **Peripheral smear:** oval macrocytes, marked anisopoikilocytosis, **MCV usually >100 fL** (often 110–140 fL); **hypersegmented neutrophils (>5 lobes)** — an early, characteristic sign. Mild leucopenia and thrombocytopenia in severe cases (pancytopenia possible).
- ▶ **Reticulocyte count** is low/inappropriately normal (ineffective erythropoiesis).
- ▶ **Bone marrow:** hypercellular; **megaloblasts** with open, sieve-like (“stippled”) nuclear chromatin despite haemoglobinised cytoplasm (nuclear-cytoplasmic dissociation); **giant metamyelocytes/giant bands** and hypersegmented megakaryocytes.
- ▶ **Ineffective erythropoiesis markers:** raised **unconjugated bilirubin** and **serum LDH** (often markedly), raised urine urobilinogen, **reduced haptoglobin** (may mimic haemolysis/AIHA).
- ▶ **Vitamin assays:** serum B12 deficient if <74 pmol/L (~100 ng/L) — symptomatic patients <100 pg/mL; serum/RBC folate low (RBC folate <150 ng/mL is diagnostic, and reflects stores better). **Note:** serum folate is *high* in B12 deficiency (methylfolate trap).
- ▶ **Metabolite confirmation (for borderline values):** **MMA raised in B12 deficiency only;** **homocysteine raised in both B12 and folate deficiency.** (MMA also rises in renal failure.)
- ▶ **Establish the cause of B12 deficiency (PA work-up):** anti-**intrinsic-factor antibody** (specific; blocking type I ~55%, binding type II ~35%), anti-**parietal-cell antibody** (sensitive ~90%, less specific), raised **serum gastrin**, low **pepsinogen I**, gastric endoscopy/biopsy (body-fundus atrophy). The Schilling test is now obsolete.

Complications

- ▶ **Neurological:** irreversible SCD/peripheral neuropathy and dementia if B12 deficiency is untreated or if folate is given alone.
- ▶ **Obstetric/fetal:** NTDs (anencephaly, meningomyelocele, spina bifida), cleft lip/palate, prematurity, fetal loss.
- ▶ **Vascular:** hyperhomocysteinaemia → increased risk of arterial and **venous thrombosis** (including unusual sites e.g. cerebral venous sinus); severe homocystinuria causes premature vascular disease.
- ▶ **Malignancy:** PA carries an increased long-term risk of **gastric carcinoma** (and gastric carcinoid).
- ▶ **Haematological:** symptomatic anaemia, high-output failure; risk of severe **hypokalaemia and thrombocytosis** during early treatment.

Management / Treatment

- ▶ **Principle:** identify and treat the *correct* deficiency. In a critically ill patient, take samples for B12/folate (± marrow) and then treat with **both** vitamins; **never give folate alone until B12 deficiency is excluded/corrected** (precipitates/worsens neuropathy).
- ▶ **Cobalamin replacement (PA / B12 deficiency):**

- **Hydroxocobalamin** 1000 µg IM × 6 doses at 3–7 day intervals to replenish stores; **maintenance 1000 µg IM every 3 months**, usually lifelong. (Cyanocobalamin needs higher/more frequent dosing, e.g. monthly, due to poorer retention.)
 - CMDT regimen: 100–1000 µg IM/SC daily for 1 week, weekly for a month, then monthly.
 - **High-dose oral cyanocobalamin 1000–2000 µg/day** is effective even in PA (≈1% absorbed passively, IF-independent); ensure compliance. Parenteral preferred where neuropathy or severe anaemia is present.
 - Give B12 routinely after total gastrectomy or ileal resection; screen patients on long-term PPIs/metformin or after bariatric surgery.
- **Folate replacement: oral folic acid 1–5 mg daily** (Harrison: 5–15 mg/day; CMDT: 1 mg/day), continued ~4 months (until folate-deficient cells are replaced) or long-term if the cause is irreversible (haemolysis, dialysis). **Folinic acid (5-formyl-THF)** is the antidote to methotrexate/antifolates.
- **Response & monitoring:** sense of well-being within days; **reticulocytosis at 5–7 days**; haematology normalises in ~2 months. Watch for **hypokalaemia** (give K⁺ supplements) and a rebound thrombocytosis — consider antiplatelet therapy if platelets rise >800 × 10⁹/L. Transfusion is rarely needed and is hazardous (precipitates failure); if essential give packed cells slowly, 1–2 units, with diuretic cover.
- **Prophylaxis:** periconceptional **folic acid 400 µg/day** (5 mg/day in previous NTD, diabetes, sickle cell, on antiepileptics) reduces NTDs by ~80%; routine folate in chronic dialysis, prematurity, chronic haemolysis; food fortification programmes.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- **Methylfolate trap / one-carbon metabolism loop** — label: *dietary folate* → 5-methyl-THF (plasma); *methionine synthase (methylcobalamin)*; *homocysteine* → *methionine* → SAM; *THF* → 5,10-methylene-THF; *dUMP* → *dTMP (thymidylate synthase)* → DNA; *L-methylmalonyl-CoA* → *succinyl-CoA (adenosyl-cobalamin)*; arrows showing the block in B12 deficiency trapping folate as 5-methyl-THF.
- **Peripheral smear & marrow montage** — label: *oval macrocyte*, *hypersegmented neutrophil (>5 lobes)*, *megaloblast with open/stippled chromatin (nuclear-cytoplasmic asynchrony)*, *giant metamyelocyte*. Optional cord cross-section labelling *posterior columns* and *lateral (pyramidal) tracts* for subacute combined degeneration.

Clinical / Diagnostic significance

- **MCV + smear + hypersegmented neutrophils** give a rapid bedside diagnosis; confirm with B12/folate and, if borderline, **MMA (B12-specific) and homocysteine**.

- ▶ A **normal CBC does not exclude B12 neuropathy** — measure B12/MMA in any unexplained myelopathy, dementia or peripheral neuropathy.
- ▶ Distinguish from **non-megaloblastic macrocytosis** (alcohol, liver disease, hypothyroidism, MDS, reticulocytosis) — these lack megaloblastic marrow and hypersegmentation.
- ▶ Coexistent **iron deficiency** (common in PA from atrophic gastritis) can mask macrocytosis (“dimorphic” picture) — check iron studies.
- ▶ PA mandates a **single endoscopy** (atrophic gastritis, gastric carcinoma/carcinoid surveillance) and screening for associated autoimmune disease (thyroid, type 1 DM, Addison’s, vitiligo).

High-yield exam pointers

- ▶ Hallmark = **nuclear-cytoplasmic asynchrony** from defective DNA synthesis; anaemia is from **ineffective erythropoiesis** in a *hypercellular* marrow.
- ▶ **Two B12-dependent enzymes:** methionine synthase (methyl-B12) and methylmalonyl-CoA mutase (adenosyl-B12). MMA ↑ → B12; homocysteine ↑ → both.
- ▶ **Methylfolate trap** explains high serum folate + low cell folate in B12 deficiency.
- ▶ **Hypersegmented neutrophil (>5 lobes)** = earliest, most characteristic peripheral clue.
- ▶ **Never treat with folate alone** before excluding B12 — risk of subacute combined degeneration.
- ▶ **Pernicious anaemia:** elderly, anti-IF (specific) + anti-parietal-cell (sensitive) antibodies, ↑gastrin, ↓pepsinogen I; gastric carcinoma risk.
- ▶ Treatment response: **reticulocytosis day 5–7**; beware **hypokalaemia** and rebound **thrombocytosis** early.
- ▶ **Folic acid 400 µg periconception (5 mg high-risk)** prevents neural-tube defects.
- ▶ B12 store lasts **3–4 years**; folate store only **3–4 months**.

SOURCE & COVERAGE

- ▶ **Harrison’s Principles of Internal Medicine, 22e** — “Megaloblastic Anemias” (A.V. Hoffbrand): aetiology tables, cobalamin/folate biochemistry, methylfolate trap, clinical and haematological features, pernicious anaemia, diagnosis and treatment regimens (hydroxocobalamin $6 \times 1000 \mu\text{g}$ then 3-monthly; folate 5–15 mg).
- ▶ **CMDT 2026** — “Blood Disorders” (Vitamin B12 Deficiency; Folic Acid Deficiency): current diagnostic cut-offs (B12 <200/<100 pg/mL; RBC folate <150 ng/mL), MMA/homocysteine confirmation, parenteral and oral 1 mg replacement schedules, reticulocyte/hypokalaemia response.
- ▶ **Coverage note:** The assigned specialty text (DeVita’s *Cancer: Principles & Practice of Oncology*) covers haematological *malignancies*, not nutritional megaloblastic anaemia, and therefore was not a relevant source for this topic; grounding is from Harrison 22e and CMDT 2026, which cover it fully. The term *subacute combined degeneration* and the

standard 400 µg/5 mg NTD-prophylaxis doses are universally accepted internal medicine, consistent with Harrison's description of posterior/lateral-column demyelination and periconceptional folate.

Paroxysmal Nocturnal Hemoglobinuria: Etiology, Clinical Features, Evaluation and Management

Asked in: Paper IV May 2025 — RGUHS MD General Medicine

Definition / Introduction — Paroxysmal nocturnal hemoglobinuria (PNH) is an *acquired*, clonal hematopoietic stem-cell disorder characterised by **chronic complement-mediated intravascular hemolysis** with recurrent exacerbations, due to deficiency of glycosylphosphatidylinositol (GPI)-anchored complement-regulatory proteins on blood cells. The classic clinical triad is (1) **intravascular hemolysis**, (2) **a tendency to venous thrombosis**, and (3) **variable bone-marrow failure / pancytopenia** — a combination that makes PNH a unique entity. It is rare (prevalence ~5–10 per million), is *never inherited or congenital*, affects both sexes equally, and usually presents in young adults.

Etiology and Pathogenesis

- ▶ **Somatic mutation in the X-linked PIGA gene in a hematopoietic stem cell is the fundamental lesion. PIGA encodes an enzyme required for an early step in GPI biosynthesis*.*
- ▶ Loss of GPI means GPI-anchored surface proteins cannot be attached — most importantly the two complement regulators CD55 (decay-accelerating factor; blocks C3 convertase) and CD59 (membrane inhibitor of reactive lysis; blocks insertion of the C9 polymer / **membrane attack complex, MAC**).
- ▶ The marrow becomes a **mosaic** of mutant (GPI-negative, “PNH”) and normal (GPI-positive) cells; peripheral blood therefore always contains both populations, with PNH cells usually predominating.
- ▶ *PIGA* mutations occur in normal individuals too; clonal **expansion** requires a permissive marrow environment. PNH is closely linked to **aplastic anemia (AA)** — an organ-specific autoimmune attack (cytotoxic T cells) on stem cells, possibly directed at the GPI molecule itself, which spares (positively selects) the GPI-negative PNH clone. Thus PNH is a *clonal but non-malignant* disease arising from the combination of **failure of normal hematopoiesis + escape/expansion of the PNH clone**.
- ▶ **Hemolysis** is intravascular and complement-driven: chronic hemolysis is via the **alternative pathway**; the *classical* pathway (triggered by infection/inflammation) explains acute **exacerbations**. Free hemoglobin released into plasma **scavenges nitric oxide**, producing smooth-

muscle dystonia (abdominal pain, esophageal spasm, erectile dysfunction) and contributing to thrombosis.

- ▶ Rarely, PNH is caused by **biallelic mutations of the autosomal PIGT gene (20q) in the absence of a PIGA* mutation*; here GPI is made but cannot bind proteins, adding a chronic inflammatory picture.

Clinical Features

- ▶ **Hemoglobinuria** — the classic but inconstant presentation: passing “blood instead of urine,” typically the **first morning void** (nocturnal/early-morning acidosis from sleep hypoventilation lowers blood pH and facilitates complement activation — hence “*nocturnal*”). Urine is reddish-brown; hemoglobinuria fluctuates dramatically hour-to-hour and is often *not* noticed.
- ▶ **Anemia** — most patients present simply within the differential diagnosis of anemia (symptomatic or incidental); often associated fatigue.
- ▶ **Thrombosis** — the most immediately life-threatening and characteristic complication, typically **venous** and at **unusual sites**: intra-abdominal/mesenteric veins, **hepatic vein (Budd-Chiari syndrome** — hepatomegaly + ascites in absence of liver disease should raise suspicion of PNH), cerebral (sagittal sinus) veins, and dermal vessels (painful skin nodules).
- ▶ **Smooth-muscle dystonia** from NO depletion — recurrent severe **abdominal pain**, dysphagia/esophageal spasm, and **erectile dysfunction**.
- ▶ **Marrow failure features** — neutropenia and/or thrombocytopenia may be present from the outset (overlap with AA / MDS); patients may evolve from PNH → aplasia and vice-versa.
- ▶ **Iron deficiency** — from chronic urinary iron loss (hemoglobinuria/hemosiderinuria).
- ▶ **Natural history** — extends over decades; with supportive care only, median survival historically ~10–20 years, the commonest cause of death being **venous thrombosis** (then infection from neutropenia, hemorrhage from thrombocytopenia). Evolution to **acute myeloid leukemia is rare** (~1–2%); rare spontaneous remissions are documented.

Evaluation / Laboratory Diagnosis

- ▶ **Evidence of intravascular hemolysis**: normo- to macrocytic **anemia** (macrocytosis from reticulocytosis, up to ~20% / ~400,000/μL); **markedly elevated LDH** (often in thousands); **undetectable haptoglobin**; mildly–moderately raised **unconjugated bilirubin**; **hemoglobinuria** and **urine hemosiderin** (a useful marker of chronic intravascular hemolysis). Anemia may become **microcytic** if iron deficiency supervenes.
- ▶ **Direct antiglobulin (Coombs) test is characteristically NEGATIVE** — distinguishing PNH from autoimmune hemolytic anemia (it becomes positive only iatrogenically once C5 inhibitors are started).
- ▶ **Flow cytometry** — the **gold standard**: demonstrates a discrete population of CD59- and CD55-deficient cells on red cells *and* granulocytes/monocytes, giving a **bimodal distribution**. The

FLAER assay (fluorescein-labelled proaerolysin, which binds GPI directly) is more sensitive, especially on granulocytes/monocytes. Granulocyte clone size is more reliable than RBC clone size (the latter is lowered by ongoing hemolysis).

- **Diagnostic threshold:** a clinically meaningful diagnosis requires a *substantial* clone — roughly **≥5% of red cells and ≥20% of granulocytes** GPI-negative. Tiny clones (e.g. <2%) seen in aplastic anemia are *not* PNH per se.
- ▶ **Older tests:** the **acidified-serum (Ham) test** is reliable but now largely historical; the **sucrose hemolysis (sugar-water) test** is *unreliable*.
- ▶ **Bone marrow:** usually **cellular with erythroid hyperplasia** and mild dyserythropoietic features; may become hypocellular/aplastic at some stage; karyotype normal or clonal — performed to assess marrow failure and exclude MDS.
- ▶ **Screen for thrombophilia and complications** in those with thrombosis.

Management Options

Treatment is stratified by clone size, hemolysis severity, thrombosis, and degree of marrow failure. **Terminal/proximal complement inhibitors** have transformed prognosis; supportive care and transplantation retain key roles.

Agent	Target / class	Route & schedule	Key points
Eculizumab	Humanised anti-C5 mAb	IV every 14 days	First approved (2007); blocks MAC → abolishes intravascular hemolysis, reduces transfusion need & thrombosis; residual extravascular hemolysis (C3-opsonised RBCs cleared in spleen, Coombs becomes positive)
Ravulizumab	Anti-C5 (long-acting eculizumab derivative)	IV every 8 weeks	Fewer breakthrough hemolysis episodes; convenient dosing
Pegcetacoplan	C3 inhibitor	SC	Blocks <i>both</i> intra- and extravascular hemolysis → higher hemoglobin / fuller correction of anemia than C5 blockade
Iptacopan	Oral factor B inhibitor (alternative pathway)	Oral	Approved; proximal blockade

Agent	Target / class	Route & schedule	Key points
Danicipan	Oral factor D inhibitor	Oral	Add-on for inadequate response to C5 inhibitors

- ▶ **Mandatory before complement inhibitors: meningococcal vaccination** (serogroups ACWY and B) ± **penicillin prophylaxis**, because terminal-complement blockade markedly raises risk of *Neisseria meningitidis* infection.
- ▶ **Breakthrough hemolysis** can occur with incomplete blockade (more severe with proximal C3 blockade because of the large expanded PNH RBC mass) — abrupt cessation risks massive hemolysis.
- ▶ **Supportive care (essential where inhibitors are unaffordable):** leucodepleted red-cell transfusion; folic acid ≥ 3 mg/day (high marrow turnover); **iron supplementation** as needed (may transiently increase hemolysis); periodic monitoring for iron overload in transfused C5-inhibited patients.
- ▶ **Anticoagulation:** any patient with **venous thrombosis** or a thrombophilic risk factor needs **long-term anticoagulation**; **thrombolysis (tPA)** for refractory acute thrombosis.
- ▶ **Glucocorticoids:** *not* indicated for chronic hemolysis (no benefit + toxicity); a short course of prednisone may help an inflammatory exacerbation.
- ▶ **Allogeneic hematopoietic stem-cell transplantation (HSCT):** the only **curative** option; reserved for **severe PNH / PNH-AA syndrome**, especially young patients with an HLA-identical sibling (complement inhibitors do not correct marrow failure). **Immunosuppression** with **antithymocyte globulin + cyclosporine** is an alternative for the AA component.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Complement cascade on the PNH red cell** — label: *classical, lectin and alternative pathways* → C3 → C3 convertase → C5 → C5b-C9 = *membrane attack complex (MAC)*; show CD55 blocking the C3 convertase and CD59 blocking MAC on a normal RBC, and their **absence on the PNH RBC** → **intravascular hemolysis**. Mark drug sites: *eculizumab/ravulizumab at C5; pegcetacoplan at C3; iptacopan at factor B; danicipan at factor D*.
- ▶ **GPI-anchor schematic** — label: *PIGA mutation* → *no GPI anchor* → *loss of CD55 & CD59 (and other GPI-linked proteins) from cell surface*.

Clinical / Diagnostic significance

- ▶ Suspect PNH in any Coombs-negative intravascular hemolysis, hemolysis with pancytopenia, hemoglobinuria, unexplained venous thrombosis at unusual sites / Budd-Chiari, or aplastic anemia with hemolysis.

- ▶ Flow cytometry for CD55/CD59 (with FLAER) is the confirmatory test; markedly raised LDH with low haptoglobin and negative DAT is the screening signature.
- ▶ A PNH clone is found in ~50% of aplastic anemia patients at presentation — link the two diseases.
- ▶ Thrombosis drives mortality — early complement inhibition + anticoagulation are prognosis-changing.

High-yield exam pointers

- ▶ **Etiology = acquired somatic PIGA mutation (X-linked) → loss of GPI anchor → deficiency of CD55 + CD59 → complement-mediated intravascular hemolysis.**
- ▶ Triad: intravascular hemolysis + venous thrombosis + bone-marrow failure (pancytopenia).
- ▶ Coombs/DAT NEGATIVE intravascular hemolysis; LDH very high, haptoglobin absent, urine hemosiderin positive.
- ▶ Gold-standard diagnosis = flow cytometry (CD55/CD59 ± FLAER); clone ≥5% RBC / ≥20% granulocytes.
- ▶ Ham (acidified serum) test historically positive; sucrose lysis test unreliable.
- ▶ Hepatic vein thrombosis → Budd-Chiari; NO depletion → abdominal pain, dysphagia, erectile dysfunction.
- ▶ Eculizumab/ravulizumab (anti-C5), pegcetacoplan (C3), iptacopan (factor B), danicopan (factor D) — give meningococcal vaccine (ACWY + B) first.
- ▶ Folic acid ≥3 mg/day, iron, transfusion; allogeneic HSCT is the only cure (for severe PNH / PNH-AA).
- ▶ Thrombosis = leading cause of death; ~1–2% evolve to AML.

SOURCE & COVERAGE

- ▶ Harrison's Principles of Internal Medicine, 22e — "Hemolytic Anemias" (Paroxysmal Nocturnal Hemoglobinuria section, complement cascade and anticomplement therapy figures) and "Bone Marrow Failure Syndromes Including Aplastic Anemia and Myelodysplasia" (PNH–aplastic anemia relationship).
- ▶ CMDT 2026 — "Blood Disorders: Paroxysmal Nocturnal Hemoglobinuria" (FLAER assay, urine hemosiderin, meningococcal prophylaxis, current complement-inhibitor regimens).
- ▶ Coverage note: The assigned dedicated specialty text (*DeVita's Cancer: Principles & Practice of Oncology, 12e*) is an oncology/heme-malignancy reference and covers PNH only marginally (no dedicated section); the depth of this answer is therefore grounded in Harrison 22e + CMDT 2026, which between them carry the full etiology, evaluation and current management detail.

Disseminated intravascular coagulation

Asked in: Paper IV May 2019 — RGUHS MD General Medicine

Definition / Introduction — In 2001 the *International Society on Thrombosis and Haemostasis (ISTH)* defined DIC as “an acquired syndrome characterised by the **intravascular activation of coagulation with loss of localisation** arising from different causes that can originate from and cause damage to the microvasculature, which if sufficiently severe can produce **organ dysfunction**.” It is *never a primary disease* but always **secondary** to an underlying disorder. The central event is **uncontrolled, systemic generation of thrombin**, leading to widespread microvascular fibrin deposition (causing ischaemic organ failure) and simultaneous **consumption of platelets and clotting factors** with secondary hyperfibrinolysis (causing bleeding) — hence the older terms *consumptive coagulopathy* and *defibrination syndrome*.

Etiology — Common clinical triggers

DIC accompanies any condition that releases tissue factor into the circulation or causes diffuse endothelial injury.

Category	Representative causes
Sepsis / infection (commonest)	Gram-negative bacilli, <i>staphylococci</i> , <i>streptococci</i> , <i>pneumococci</i> , <i>meningococci</i> ; also viral, mycotic, parasitic, rickettsial
Trauma / tissue injury	Brain injury (gunshot), extensive burns, fat embolism, rhabdomyolysis
Obstetric	Abruptio placentae, amniotic fluid embolism, dead fetus (retained) syndrome, septic abortion; HELLP syndrome
Malignancy	Mucin-producing adenocarcinoma (prostate, pancreas); acute promyelocytic leukaemia (APL, AML-M3)
Vascular	Giant haemangioma (Kasabach-Merritt syndrome), large-vessel aneurysm (e.g. aorta)
Immunologic	Acute haemolytic transfusion reaction, transplant rejection, graft-versus-host disease, immunotherapy
Envenomation / drugs	Snake bite, insect venom; fibrinolytic agents, prothrombin complex concentrates, amphetamines
Liver / miscellaneous	Fulminant hepatic failure, fatty liver of pregnancy; shock, ARDS, massive transfusion

Pathophysiology

- ▶ **Initiation — uncontrolled thrombin generation:** Activation of inflammatory pathways markedly increases **tissue factor** expression, activates neutrophils/monocytes with **cytokine release**, forms **neutrophil extracellular traps (NETs)** and releases polyphosphates — collectively termed **thrombo-inflammation** — driving massive thrombin generation through the extrinsic pathway.
- ▶ **Amplification:** Simultaneous **disruption of physiological anticoagulants** (antithrombin, protein C/S, tissue factor pathway inhibitor) and **endothelial injury** (loss of native antithrombotic surface, prominent in sepsis and trauma) remove the normal brakes on coagulation.
- ▶ **Microvascular fibrin deposition:** Sustained fibrin formation in small and mid-size vessels compromises blood supply to **lung, kidney, liver and brain** → multi-organ ischaemia/failure (pulmonary microthrombosis contributes to ARDS).
- ▶ **Consumption → bleeding:** Continuous activation consumes platelets and coagulation factors faster than they are produced, producing systemic bleeding, aggravated in late stages by **secondary hyperfibrinolysis** (plasmin generation raising FDPs/D-dimer).
- ▶ **RBC fragmentation:** Fibrin strands across the microcirculation shear passing red cells → **schistocytes** and microangiopathic haemolysis.
- ▶ **SIRS / cytokine storm in the setting of infection drives this exuberant response and correlates with higher mortality. Purpura fulminans is the most severe form — extensive cutaneous thrombosis, classically in children after viral/bacterial infection or in neonates homozygous for protein C deficiency*.*

Clinical features

- ▶ **Bleeding (consumptive):** Petechiae, ecchymoses, oozing from venepuncture/catheter/incision sites; severe haemorrhage from the GI tract, lung, or CNS. Multiple simultaneous bleeding sites are characteristic.
- ▶ **Thrombosis (occlusive):** Microvascular occlusion → **organ failure** (oliguria/renal failure, hypoxia, hepatic dysfunction, delirium/coma); large-vessel thrombosis and cerebral embolism may occur. Malignancy-associated DIC may present chiefly as thrombosis (**Trousseau syndrome**, migratory thrombophlebitis).
- ▶ **Acute (decompensated) DIC:** Rapidly evolving, bleeding-dominant, with haemodynamic instability and **shock**; reported mortality 30 to >80%, largely driven by the underlying disease.
- ▶ **Chronic (compensated, low-grade) DIC:** Seen with giant haemangioma, metastatic carcinoma, or late-gestation fetal demise; compensated synthesis keeps PT/aPTT/fibrinogen normal or high with only mild thrombocytopenia and elevated D-dimer — *often thrombosis-predominant*.

Laboratory diagnosis & ISTH overt-DIC score

No single test is diagnostic; diagnosis rests on a **compatible clinical setting plus a panel of tests interpreted serially** (repeat every 6–8 h in the critically ill, as values change rapidly).

- ▶ **Platelet count** — low or progressively *falling* (a downward trend is more useful than a single value).
- ▶ **PT and aPTT** — prolonged (factor consumption).
- ▶ **Fibrinogen** — low or falling (an acute-phase reactant, so may be “normal” early — trend matters).
- ▶ **D-dimer / FDP** — elevated (the most sensitive marker of activation + secondary fibrinolysis).
- ▶ **Peripheral smear** — **schistocytes** (present in only ~10–20% of cases; their absence does not exclude DIC).

The ISTH overt-DIC scoring system (validated; *not for use in pregnancy* — a separate obstetric tool exists):

Parameter	Value	Points
Platelets	$>100 \times 10^9/L$	0
	$50-<100 \times 10^9/L$	1
	$<50 \times 10^9/L$	2
D-dimer / fibrin marker	Normal	0
	Moderate increase	2
	Severe increase	3
PT prolongation	<3 s	0
	$3-<6$ s	1
	>6 s	2
Fibrinogen	>1 g/L	0
	<1 g/L	1

- ▶ **Score ≥ 5 $\rightarrow$ overt DIC** (repeat labs *daily*). **Score <5 $\rightarrow$ suggests non-overt / low-grade DIC** (repeat every 1–2 days). A positive score should prompt a search for the underlying cause if not already evident.

Differential diagnosis

Condition	Discriminating features
Severe liver disease	Thrombocytopenia (hypersplenism), low factors, raised D-dimer — but parameters do not change rapidly on serial testing; FVIII normal/high (falls only if DIC superimposed); reduced FV reflects hepatocyte failure

Condition	Discriminating features
Thrombotic thrombocytopenic purpura (TTP)	Acute thrombocytopenia, schistocytes, organ failure, but PT/aPTT/fibrinogen near-normal; ADAMTS13 <10% with inhibitor is diagnostic
HIT	Thrombocytopenia + thrombosis after heparin; normal fibrinogen, positive anti-PF4 antibodies
Primary hyperfibrinolysis	Low fibrinogen, raised FDP but D-dimer relatively normal and platelets preserved

Treatment

- ▶ **Treat the underlying cause** — the single most important measure (antimicrobials for sepsis, delivery/uterine evacuation in obstetric DIC and HELLP, chemotherapy for malignancy). DIC will not resolve until the trigger is controlled; most overt cases need ICU support for shock physiology.
- ▶ **Blood-product/replacement support** — **only if active bleeding or high bleeding risk** (invasive procedure, post-chemotherapy); *do not transfuse merely to correct numbers*:
 - Platelets for counts <10,000–20,000/ μ L (or <50,000/ μ L with serious/intracranial bleeding or before procedures).
 - Cryoprecipitate / fibrinogen concentrate to keep fibrinogen >100–150 mg/dL.
 - FFP for bleeding with prolonged PT/aPTT; aim PT **no more than** ~3 s above ULN (target PT/aPTT <1.5 $\times$ normal).
 - Packed RBCs for symptomatic anaemia; give vitamin K.
- ▶ **Heparin (low-dose continuous infusion, 5–10 U/kg/h, no bolus)**: Indicated when **thrombosis predominates** — chronic/low-grade DIC with solid tumours, APL, Trousseau syndrome, and **purpura fulminans**. *Contraindicated/harmful in acute haemorrhagic DIC* and when platelets cannot be kept >20,000–50,000/ μ L, or with CNS/GI bleeding or placental abruption. It improves coagulation parameters but has **not shown a survival benefit** in severe DIC.
- ▶ **Anticoagulant concentrates** (antithrombin, recombinant thrombomodulin): little benefit overall, though post-hoc data in sepsis-confirmed DIC suggest possible advantage. *Activated protein C was withdrawn* after trial benefit was not reproduced.
- ▶ **Antifibrinolytics** (tranexamic acid, EACA): reserved for **primary-hyperfibrinolytic DIC with severe bleeding** (e.g. APL, giant haemangioma); risk of catastrophic thrombosis — often combined with heparin and used only with haematology input.
- ▶ **APL-associated DIC**: A haematological emergency — start **all-trans retinoic acid (ATRA)** at the *earliest suspicion* (do not wait for genetic confirmation) together with aggressive product support; modern induction is **ATRA + arsenic trioxide (ATO)**, which reduces early haemorrhagic death.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Pathophysiology flow diagram (Harrison Fig. 121-4):** Box-and-arrow cascade — *Trigger (sepsis/trauma/malignancy/obstetric)* → **Uncontrolled thrombin generation** → branch into (a) **Fibrin deposits in microcirculation** → *Ischaemic tissue damage + RBC damage/haemolysis (schistocytes)* → **Failure of multiple organs**; and (b) **Consumption of platelets and coagulation factors** → *Secondary fibrinolysis (↑FDP, ↑D-dimer)* → **Diffuse bleeding**. Add a side note: “Vessel patency vs occlusion = bleeding vs thrombosis balance.”
- ▶ **Coagulation cascade with test mapping (Fig. 121-1):** Intrinsic (XII→XI→IX→VIII, *aPTT*) and extrinsic (VIIa/tissue factor, *PT*) pathways converging on common pathway (X→Xa→prothrombin→**thrombin**→fibrinogen→fibrin, cross-linked by XIIIa, *TT*) — label PT, *aPTT*, *TT*, and “fibrin → FDP/D-dimer.”

Clinical / Diagnostic significance

- ▶ DIC is a **clinico-pathological diagnosis**: laboratory abnormalities must be interpreted *with* the clinical context and *serially* — an isolated abnormal value is non-specific.
- ▶ A **falling trend** in platelets and fibrinogen with a **rising D-dimer/PT** is more diagnostic than any single absolute value, especially in malignancy where baseline values may be normal.
- ▶ Recognising the **bleeding-vs-thrombosis phenotype** directs therapy: product replacement for the bleeding-dominant acute form, heparin for the thrombosis-dominant chronic/purpura fulminans form.
- ▶ The ISTH score gives an objective, reproducible threshold (≥ 5 = **overt DIC**) for diagnosis and serial monitoring — but is **not validated in pregnancy**.
- ▶ Distinguishing DIC from **liver disease** and **TTP** changes management entirely (TTP needs plasma exchange, not factor replacement); serial labs, FVIII level, and ADAMTS13 are the key discriminators.

High-yield exam pointers

- ▶ **ISTH 2001 definition** — acquired syndrome of intravascular activation of coagulation with loss of localisation. Always **secondary**; never primary.
- ▶ **Central mechanism** = **uncontrolled thrombin generation** via tissue factor + thrombo-inflammation (cytokines, NETs).
- ▶ **Commonest cause** = **sepsis** (esp. Gram-negative); other classics — **APL, abruptio placentae, amniotic fluid embolism, mucinous adenocarcinoma, snake bite, Kasabach-Merritt**.
- ▶ **Lab tetrad**: ↓platelets, ↑PT & *aPTT*, ↓fibrinogen, ↑D-dimer/FDP; **schistocytes in ~10–20%**.
- ▶ **ISTH overt-DIC score ≥ 5** = overt DIC (platelets, D-dimer, PT, fibrinogen).

- ▶ **Treat the underlying cause first**; transfuse only if bleeding/high risk — *don't treat numbers alone*.
- ▶ **Heparin** helps thrombotic/chronic DIC & purpura fulminans; **harmful in acute haemorrhagic DIC**.
- ▶ **APL** → start **ATRA** immediately on suspicion; **HELLP** → **deliver**; **Trousseau** → **LMWH/heparin** (warfarin ineffective).
- ▶ **DDx**: liver disease (parameters change slowly, FVIII normal/high) and **TTP** (ADAMTS13 <10% + inhibitor).
- ▶ Mortality of acute DIC **30 to >80%**, dictated by the underlying illness.

SOURCE & COVERAGE

Multiple Myeloma — Spectrum of Clinical Presentation and the Laboratory Investigations Aiding Diagnosis

Asked in: Paper IV Oct 2025 — RGUHS MD General Medicine

Definition / Introduction — Multiple myeloma (MM) is a malignant proliferation of a single clone of bone-marrow **plasma cells** that secrete a monoclonal immunoglobulin (**M-protein / paraprotein**) and produce end-organ damage. The clinical picture arises from three mechanisms: (1) **expansion of the neoplastic clone** in marrow and bone, (2) **secreted cell products** (intact immunoglobulin, free light chains, osteoclast-activating cytokines), and (3) the **host response** to the tumour. It is a disease of older adults (median age ~69 years, uncommon under 40), commoner in men and roughly twice as frequent in people of African descent. The cardinal clinical tetrad is captured by the mnemonic **CRAB** — hyperCalcaemia, Renal failure, Anaemia, Bone lesions.

Spectrum of clinical presentation — the cardinal (CRAB) features

Feature	Frequency / mechanism	Clinical manifestation
Bone pain / lytic disease	~70% (most common symptom); osteoclast activation by RANKL,	Back / rib / hip pain, pathological fracture (femoral neck, vertebrae), vertebral collapse,

Feature	Frequency / mechanism	Clinical manifestation
	MIP-1 α , IL-1, IL-6, TNF with osteoblast suppression by DKK-1	spinal cord / root compression; “punched-out” osteolytic lesions, diffuse osteopenia
Hyper-Calcaemia	Mobilisation of calcium from lysed bone	Lethargy, weakness, confusion, constipation, polyuria, dehydration, nephrocalcinosis; a leading cause of acute renal failure
Renal failure	~25% at presentation, some pathology in >50%	Light-chain cast nephropathy (“myeloma kidney”), hypercalcaemia, hyperuricaemia, light-chain deposition disease, AL amyloid, NSAIDs/contrast; earliest sign = adult Fanconi syndrome (type 2 proximal RTA)
Anaemia	~80%; marrow replacement, cytokine suppression of erythropoiesis, low erythropoietin, mild haemolysis	Fatigue, pallor, breathlessness; normocytic normochromic (occasionally megaloblastic from folate/B12 deficiency)

Other / less common presentations (must also be elaborated)

- ▶ **Recurrent bacterial infection** — second commonest problem; presenting feature in ~25%, and >75% suffer a serious infection. Due to **hypogammaglobulinaemia (immunoparesis)**, poor antibody response to polysaccharide antigens, T-cell and complement defects. Typical: pneumonia (*S. pneumoniae*, *S. aureus*, *K. pneumoniae*) and pyelonephritis (*E. coli*, gram-negatives).
- ▶ **Hyperviscosity syndrome** — headache, fatigue, visual disturbance, retinopathy, mucosal bleeding, ataxia, somnolence, heart failure, coma. Occurs above ~4 cP; most frequent with **IgM, IgG3 and IgA** paraproteins (IgM in ~50% vs 2–4% for IgG/IgA).
- ▶ **Neurological** — cord/root compression and radicular pain from bony collapse; carpal tunnel and sensorimotor neuropathy from **amyloid** infiltration; hypercalcaemic encephalopathy; treatment-related (thalidomide, bortezomib) neuropathy; IgM-associated neuropathy often directed against **myelin-associated glycoprotein (MAG)**.
- ▶ **Bleeding / thrombosis** — M-protein interferes with platelets and clotting factors (I, II, V, VII, VIII); DVT with immunomodulatory drugs (thalidomide/lenalidomide/pomalidomide); cryoglobulins → Raynaud’s.
- ▶ **Medical emergencies at presentation** — cord compression, pathological fracture, hyperviscosity, hypercalcaemic crisis, sepsis, acute kidney injury.

- ▶ **Variants / related syndromes** — **solitary bone plasmacytoma** (single lytic lesion, no marrow involvement) and **extramedullary plasmacytoma** (nasopharynx/paranasal sinuses); **POEMS syndrome** (Polyneuropathy, Organomegaly, Endocrinopathy, M-protein, Skin changes ± sclerotic bone lesions/Castleman's/raised VEGF); **plasma cell leukaemia** (circulating plasma cells >2000/ μ L); **nonsecretory** and **light-chain-only** myeloma. Notably, splenomegaly, lymphadenopathy and gut involvement are *rare*.

Laboratory investigations — detecting and characterising the M-protein

- ▶ **Serum protein electrophoresis (SPEP)** — sharp “*church-spire*” *M-spike*, usually in the γ (sometimes β_2/α_2) region; must be ≥ 5 g/L (0.5 g/dL) to be quantitated. M-protein level is an excellent **tumour-burden marker** for monitoring therapy.
- ▶ **Immunofixation electrophoresis (IFE) / immunoelectrophoresis** — confirms monoclonality and the heavy + light chain isotype; more sensitive than SPEP for low-level M-protein.
- ▶ **Serum free light-chain (FLC) assay (Freelite) and κ/λ ratio** — quantifies light chains; essential in **light-chain-only, nonsecretory and oligosecretory** myeloma; an **involved:uninvolved FLC ratio ≥ 100** is itself a myeloma-defining biomarker.
- ▶ **24-hour urine electrophoresis + IFE** — quantitates **Bence Jones protein** (free light chains). Urine dipstick is *unreliable* for light chains and the heat test is falsely negative in ~50%.
- ▶ **Quantitative immunoglobulins** — show suppression of uninvolved isotypes (immunoparesis).
M-protein distribution: IgG ~53%, IgA ~25%, IgD ~1%; ~20% secrete light chains only; <1% are truly non-secretory.

Laboratory investigations — marrow, end-organ and imaging workup

Purpose	Investigation	Expected finding
Clonal plasma cells	Bone-marrow aspirate and trephine biopsy with κ/λ immunostaining, flow cytometry / IHC	Plasmacytosis ($\geq 10\%$ for diagnosis); CD138+, monoclonal κ or λ ; binucleate/multinucleate forms
End-organ damage	CBC with film; ESR; serum calcium, creatinine/urea, uric acid; albumin	Anaemia, marked rouleaux , very high ESR; raised Ca^{2+} /creatinine; normal alkaline phosphatase despite bone disease
Biochemical clues	Electrolytes / protein	Decreased anion gap (cationic M-protein retains Cl^-); pseudohyponatraemia ; raised total protein with reversed A:G ratio

Purpose	Investigation	Expected finding
Skeletal imaging	Whole-body low-dose CT / skeletal survey, ¹⁸ F-FDG PET-CT, MRI spine & pelvis	Lytic “punched-out” lesions, osteopenia, focal marrow lesions; radionuclide bone scan is <i>unhelpful</i> (no osteoblastic reaction)
Prognosis / risk	Serum β 2-microglobulin + albumin, LDH; FISH / DNA sequencing	β 2M and LDH for staging; del(17p)/TP53, t(4;14), t(14;16), t(14;20), 1q gain/1p del = high-risk
Selected cases	Abdominal fat-pad aspirate; serum viscosity; MYD88/CXCR4 if IgM	Amyloid (Congo red, apple-green birefringence); confirm hyperviscosity

Diagnostic criteria — IMWG (CRAB + SLiM)

- Diagnosis requires **clonal bone-marrow plasma cells $\geq 10\%$ (or biopsy-proven plasmacytoma) PLUS ≥ 1 myeloma-defining event:**
- **C** — hyperCalcaemia: serum Ca > 2.75 mmol/L (> 11 mg/dL) or > 0.25 mmol/L (> 1 mg/dL) above ULN
- **R** — Renal: creatinine clearance < 40 mL/min or serum creatinine > 177 μ mol/L (> 2 mg/dL)
- **A** — Anaemia: Hb < 100 g/L or > 20 g/L below the lower limit of normal
- **B** — Bone: ≥ 1 osteolytic lesion on radiography, CT or PET-CT
- **SLiM biomarkers of malignancy** (added in 2014 to allow earlier treatment): **S** = clonal marrow plasma cells $\geq 60\%$; **Li** = involved:uninvolved serum FLC ratio ≥ 100 ; **M** = > 1 focal lesion ≥ 5 mm on MRI.
- **Distinguish from precursors:** MGUS (M-protein < 30 g/L, marrow plasma cells $< 10\%$, no CRAB/SLiM; $\sim 1\%$ /year progression) and **smoldering MM** (M-protein ≥ 30 g/L and/or 10–60% marrow plasma cells, no end-organ damage).

Staging and prognosis

ISS stage	Criteria	Median survival
I	β 2-microglobulin < 3.5 mg/L and albumin ≥ 3.5 g/dL	~ 62 months
II	Neither I nor III	~ 44 months
III	β 2-microglobulin > 5.5 mg/L	~ 29 months

- **Revised ISS (R-ISS)** adds **high-risk cytogenetics** [t(4;14), t(14;16), del(17p)] and **serum LDH** to the ISS: R-ISS I = ISS I + normal LDH + no high-risk FISH; R-ISS III = ISS III + (high-risk

cytogenetics or raised LDH). β 2-microglobulin is the single most powerful prognostic factor; the older Durie–Salmon system is no longer used.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ Labelled “spectrum-of-disease” spider/wheel centred on a myeloma plasma cell with spokes labelled: *Bone* (lytic lesions, fracture, cord compression), *Kidney* (cast nephropathy, Fanconi), *Blood* (anaemia, rouleaux, hyperviscosity), *Calcium* (hypercalcaemia), *Immune* (infection, immunoparesis), *Nerve* (amyloid neuropathy, MAG).
- ▶ SPEP tracing: x-axis = albumin $\rightarrow$ α 1 $\rightarrow$ α 2 $\rightarrow$ β $\rightarrow$ γ ; mark a tall narrow “M-spike / church-spire” in the γ region; contrast with a normal broad polyclonal γ hump. Label *albumin*, *γ -globulin region*, *M-component*.

Clinical / Diagnostic significance

- ▶ Suspect MM in any older patient with unexplained **back pain + anaemia + raised ESR/total protein**, lytic lesions, hypercalcaemia or acute renal failure — order SPEP/IFE, serum FLC and 24-h urine together.
- ▶ A **normal alkaline phosphatase with extensive lytic disease** and a **negative bone scan** are characteristic and help separate MM from metastatic carcinoma.
- ▶ The serum FLC assay rescues the diagnosis of **light-chain, oligo- and non-secretory** disease that SPEP misses; the κ/λ ratio also drives prognosis (MGUS $\rightarrow$ MM risk) and response monitoring.
- ▶ Light-chain cast nephropathy is potentially **reversible** — aggressive hydration, chemotherapy and (in selected oliguric cases) plasma exchange can recover renal function.
- ▶ Bone disease is managed with **bisphosphonates** (zoledronate/pamidronate) or **denosumab**, radiotherapy for cord compression/painful sites, and vertebroplasty/kyphoplasty.

High-yield exam pointers

- ▶ Bone pain is the commonest symptom (~70%); CRAB defines symptomatic disease.
- ▶ Anaemia ~80%, renal failure ~25%, hypercalcaemia and recurrent infection complete the classic picture.
- ▶ CRAB + SLiM = IMWG myeloma-defining events; $\geq 60\%$ plasma cells, FLC ratio ≥ 100 , >1 MRI lesion allow treatment before organ damage.
- ▶ Triad of tests: SPEP/IFE (serum) + 24-h urine IFE (Bence Jones) + serum free light chains.
- ▶ Decreased anion gap, pseudohyponatraemia, marked rouleaux, high ESR, normal ALP are signature lab clues.
- ▶ β 2-microglobulin + albumin = ISS; add cytogenetics + LDH for R-ISS.
- ▶ High-risk genetics: del(17p)/TP53, t(4;14), t(14;16), t(14;20), 1q gain — NOT t(11;14) or del(13).
- ▶ Radionuclide bone scan is useless; use skeletal survey/CT, MRI, or PET-CT.

Enumerate the triggers, clinical presentation and management of acute chest syndrome in sickle cell disease

Asked in: Paper IV Oct 2025 — RGUHS MD General Medicine

Definition / Introduction — *Acute chest syndrome (ACS)* is an acute, pneumonia-like, vaso-occlusive complication of sickle cell disease (SCD) defined by a **new pulmonary infiltrate on chest radiograph involving at least one complete lung segment**, together with respiratory symptoms and/or fever. It is the **second most frequent acute sickle cell-related event** (after the acute painful episode), occurs in **>50% of patients** (often recurrently), and is a **leading cause of death and ICU admission** in adults with SCD. It results from the interplay of pulmonary vaso-occlusion, fat embolism, infection and hypoventilation, and ranges from a mild self-limiting illness (especially in children) to fulminant multilobar disease with ARDS, multiorgan failure and rapid death.

Pathophysiology in brief

- ▶ HbS ($\beta 6 \text{ Glu} \rightarrow \text{Val}$) polymerises when deoxygenated; the rate of polymerisation depends on roughly the **30th power of HbS concentration**, so small falls in oxygen saturation, pH or cell hydration markedly accelerate sickling.
- ▶ Sickled, rigid erythrocytes and *irreversibly sickled cells (ISCs)* occlude the **pulmonary microvasculature**, producing in-situ thrombosis, regional hypoxia and a self-amplifying cycle of further sickling.
- ▶ Intravascular **haemolysis scavenges nitric oxide**, activates endothelium and platelets, and is pro-inflammatory and vasoconstrictive — promoting lung injury and pulmonary vasculopathy.
- ▶ A final common pathway is **ventilation-perfusion mismatch and worsening hypoxaemia**, which begets more polymerisation: the cardinal vicious cycle of ACS.

Triggers / precipitating factors

ACS is frequently **multifactorial**, and a single cause is identified in fewer than half of episodes. The recognised triggers are:

Category	Specific triggers
Infection	Any infection — viral (common in children), bacterial and atypical organisms; pneumonia is a classic precipitant
Vascular / embolic	In-situ pulmonary microvascular thrombosis; pulmonary infarction; fat / bone-marrow embolism from infarcted (necrotic) marrow — the cause of the most severe, often fatal episodes
Hypoventilation	Postoperative hypoventilation; splinting from rib/sternal or thoracic-bone infarction pain; opioid-induced respiratory depression during treatment of an acute painful episode
Iatrogenic / fluid	Over-hydration (pulmonary oedema) and excessive opioids compound dyspnoea and hypoxia
Antecedent painful crisis	ACS follows within 72 h in ~25% (about one-quarter) of admissions for an acute painful episode
Other	Asthma/bronchospasm (very common in SCD); surgery and general anaesthesia; cold exposure, dehydration and hypoxia (shared sickling triggers)

Clinical presentation

- ▶ **Cardinal features (major diagnostic criteria):** chest pain, cough, fever, hypoxia, and a new pulmonary infiltrate on chest x-ray.
- ▶ **Respiratory:** tachypnoea, dyspnoea, wheeze, pleuritic chest pain; falling SpO₂; in severe disease, multilobar consolidation with profound hypoxaemia.
- ▶ **Systemic:** fever (often ≥ 38.5 °C), tachycardia, leucocytosis; frequently superimposed on an ongoing acute painful episode involving ribs, sternum or spine.
- ▶ **Spectrum:** *mild* (children, often viral) → *devastating* (adults — multiple lobes affected, severe hypoxia, multiorgan failure and death).
- ▶ **Course:** because the infiltrate may lag behind symptoms, an initially normal CXR does **not** exclude ACS; serial radiographs and pulse oximetry are essential.
- ▶ **Differential diagnosis:** must be distinguished from **infective pneumonia** (overlapping and often coexistent), pulmonary thromboembolism, fluid overload/pulmonary oedema, and from sepsis/multiorgan failure.

Predictors of severe disease

- ▶ Thrombocytopenia, leucocyte count $>20,000/\mu\text{L}$, and a rapidly developing/drastic fall in haemoglobin portend severe ACS with ARDS and multiorgan failure.

- ▶ The most catastrophic cases are typically due to **embolisation of necrotic bone marrow (fat embolism)** and may progress to death even with prompt, correct treatment.
- ▶ Multiorgan failure (CNS, liver, muscle, lung, kidney) can accompany severe ACS and is easily confused with — and may coexist with — sepsis.

Management

General principle: **severity-driven**, supportive and pre-emptive, with the threshold for transfusion and ICU care kept deliberately low.

Intervention	Practical detail
Monitoring & disposition	Hypoxic, febrile patients may be admitted directly to the ICU ; continuous pulse oximetry / monitored beds for the first 48–72 h of any pain admission help detect early ACS
Oxygen	Supplemental O ₂ for SpO ₂ <95% (or hypoxaemia); titrate to maintain saturation
Antibiotics	Almost always given , even though a causative organism is seldom cultured; cover typical and atypical respiratory pathogens
Analgesia	Adequate pain control to permit deep breathing — but avoid excessive opioids (respiratory depression worsens hypoxia)
Fluids	Careful hydration; avoid over-hydration (precipitates/worsens pulmonary oedema)
Incentive spirometry	Used during painful episodes to forestall pulmonary complications/atelectasis and ACS
Transfusion	Indicated for hypoxic, febrile patients with leucocytosis and more than a trivial infiltrate . Simple (top-up) transfusion suffices for less severe cases. Automated red-cell exchange transfusion is the preferred modality in severe ACS (and in stroke / multiorgan failure). If exchange will take hours to arrange in a severely ill patient, start a simple/top-up transfusion first
Transfusion safety	Extended red-cell antigen phenotyping where possible; antigen-match for Rh (C/c, E/e) and K in addition to ABO/RhD to reduce alloimmunisation
Supportive / ICU	Bronchodilators for bronchospasm/asthma; VTE prophylaxis; treat multiorgan failure with exchange transfusion and full ICU support

Preventive (disease-modifying) therapy that reduces ACS:

- ▶ **Hydroxyurea** — standard of care for HbSS and HbS- β^0 thalassaemia; raises HbF and **reduces pain and ACS by about half** and long-term mortality by ~49%. Adult dosing titrated to maximum tolerated dose by neutrophil/platelet counts (CMDT: 15–35 mg/kg/day); start infants at ~20 mg/kg from 9 months of age.
- ▶ **L-glutamine** — reduces painful episodes (~25%) and favourably modulates ACS.
- ▶ **Crizanlizumab** (anti-P-selectin) and **voxelotor** (increases Hb-O₂ affinity) modulate vaso-occlusion; **chronic transfusion** is used for recurrent severe ACS.
- ▶ **Curative options**: HLA-matched allogeneic stem-cell transplant (event-free survival >95% with matched related donor) and approved **ex-vivo gene therapies** (lovotibeglogene autotemcel — HbA^{T87Q}; exagamglogene autotemcel — CRISPR/Cas9 disruption of *BCL11A* to raise HbF).

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Vicious cycle of ACS (flow diagram)**. Labels: *Trigger (infection / fat embolus / hypoventilation / pain) → Regional hypoxia & low pH → HbS polymerisation & sickling → Pulmonary microvascular vaso-occlusion + in-situ thrombosis → V/Q mismatch → Worsening hypoxaemia → (arrow looping back to HbS polymerisation); side-branch Intravascular haemolysis → NO depletion → endothelial activation/inflammation.*
- ▶ **Annotated chest radiograph schematic**. Labels: *new infiltrate involving ≥1 complete lung segment, multilobar consolidation, basal predominance, small pleural effusion* — captioned “ACS: new pulmonary infiltrate + respiratory symptom/fever/hypoxia.”

Clinical / Diagnostic significance

- ▶ **Definition (NHLBI/standard)**: a new radiodensity on CXR involving ≥1 complete lung segment, plus ≥1 of chest pain, fever ≥38.5 °C, tachypnoea/wheeze/cough, or hypoxia — operationalises the major criteria for the exam and the ward.
- ▶ **Investigations**: CBC (falling Hb, leucocytosis, platelet count), reticulocytes, ABG/pulse oximetry, chest radiograph (serial), blood and respiratory cultures, atypical-pathogen testing; consider CT-pulmonary angiography if thromboembolism is suspected.
- ▶ **Pearls**: an antecedent painful crisis is the commonest setting — anticipate ACS in the first 72 h; keep opioids and IV fluids restrained; transfuse early for hypoxia with infiltrate; **exchange (not simple) transfusion** for severe/multiorgan disease; antibiotics empirically despite negative cultures.
- ▶ ACS may leave a **chronic restrictive deficit with reduced DLCO** and contributes to pulmonary hypertension — both markers of poor long-term prognosis.

High-yield exam pointers

- ▶ ACS = new lung-segment infiltrate + (chest pain / fever / tachypnoea-cough-wheeze / hypoxia); second commonest acute SCD event, >50% lifetime incidence.

- ▶ Four classic trigger groups: **infection, fat/marrow embolism, in-situ pulmonary thrombosis, postoperative hypoventilation** — often multifactorial; cause unidentified in most.
- ▶ ~25% of acute pain admissions develop ACS within 72 h — monitor with pulse oximetry for 48–72 h.
- ▶ Severity predictors: **platelets ↓, WBC >20,000/μL, rapidly falling Hb** → ARDS/multiorgan failure; the worst cases are **bone-marrow fat embolism**.
- ▶ Treatment quartet: **oxygen (SpO₂ <95%), antibiotics, judicious analgesia/fluids, transfusion** — **exchange transfusion for severe disease**.
- ▶ **Avoid over-hydration and over-sedation with opioids** — both worsen hypoxia.
- ▶ **Incentive spirometry** prevents ACS during painful crises; **hydroxyurea halves ACS** as long-term prophylaxis.
- ▶ Transfuse with **Rh (C/c, E/e) and K antigen-matched** units to limit alloimmunisation.

SOURCE & COVERAGE

- ▶ **Harrison's Principles of Internal Medicine, 22e** — “Disorders of Hemoglobin” (sickle cell disease; complications — Acute Chest Syndrome; transfusion and disease-modifying therapy).
- ▶ **CMDT 2026** — “Blood Disorders” (Sickle Cell Anemia) for current management, drug regimens and the hemoglobin-distribution table.

Coverage note: The dedicated specialty text listed in the spec (DeVita's Cancer — haematological malignancies) contains only a single passing mention of ACS and is not the appropriate subspecialty source for this benign-haematology topic; depth was therefore drawn from Harrison 22e supplemented by CMDT 2026. The precise NHLBI consensus definition (“new radiodensity involving ≥1 complete lung segment plus a respiratory symptom/fever/hypoxia”) and the naming of atypical organisms (*Mycoplasma*, *Chlamydophila*) are universally accepted standard internal medicine stated for completeness beyond Harrison's exact “major diagnostic criteria” phrasing.

Flow cytometry: principle and application

Asked in: Paper I Nov 2019 — RGUHS MD General Medicine

Definition / Introduction — Flow cytometry is a laser-based technique that simultaneously measures multiple physical and antigenic characteristics of single cells as they flow, one at a time, in a fluid stream past a focused beam of light. Each cell is interrogated for its **size, internal complexity (granularity), and the panel of surface/intracytoplasmic molecules** bound by fluorochrome-labelled monoclonal antibodies — its *antigen footprint* or **immunophenotype**. Because it can characterise thousands of cells per second across several parameters at once (*multiparametric analysis*), it is indispensable in

haematology for diagnosing and sub-classifying leukaemias and lymphomas, detecting paroxysmal nocturnal haemoglobinuria (PNH), enumerating CD4 T-cells and CD34 stem cells, and tracking minimal residual disease (MRD). When the instrument also physically deflects and collects cells of interest it is called **fluorescence-activated cell sorting (FACS)**.

Principle and instrumentation

- ▶ **Pre-requisite — a single-cell suspension:** prepared from peripheral blood, bone marrow, body fluids (CSF, pleural/peritoneal), or *disaggregated solid tissue*; cells are stained with **fluorochrome-conjugated monoclonal antibodies** directed against the chosen antigens.
- ▶ Three integrated systems make up the cytometer:
 - **Fluidics** — *hydrodynamic focusing*: a fast outer sheath fluid constrains the sample core so cells file past the laser in **single line, one cell at a time**.
 - **Optics** — one or more **lasers** (e.g., 488 nm argon-blue) illuminate each cell; lenses, dichroic mirrors and band-pass filters separate the emitted light by wavelength onto detectors.
 - **Electronics** — **photodiodes/photomultiplier tubes (PMTs)** convert light pulses into digital voltage signals proportional to the parameter measured.
- ▶ **Two scatter (intrinsic) signals — require no antibody:**
 - **Forward scatter (FSC)** — light scattered in the direction of the beam; proportional to **cell size**.
 - **Side scatter (SSC)** — light scattered at $\sim 90^\circ$; proportional to **internal complexity/granularity** (e.g., high in granulocytes, low in lymphocytes).
- ▶ **Fluorescence (extrinsic) signals:** each bound fluorochrome absorbs laser light and re-emits at a longer wavelength; common dyes excited at 488 nm include **FITC (green)**, **PE (orange)**, **PerCP and PE-Cy5/APC tandems (red)** — allowing several antigens to be measured on one cell simultaneously.
- ▶ **Gating & display:** populations are electronically “gated” on dot-plots/histograms (classically **CD45 vs SSC** to resolve blasts, lymphocytes, monocytes and granulocytes), then analysed for their marker profile.
- ▶ **Cell sorting (FACS):** charged droplets containing target cells are deflected by electrostatic plates into collection tubes — used to purify CD34 stem cells or rare tumour cells (e.g., flow-sorting Hodgkin/Reed-Sternberg cells for sequencing).

Immunophenotyping — the antigen footprint

- ▶ The immunophenotype is *valuable diagnostically because it distinguishes specific tumour subtypes*, even though “stage of differentiation” itself does not predict natural history (Harrison).
- ▶ **Clonality** is the key malignant signature detectable by flow:

- **B-cell clonality** — *surface immunoglobulin light-chain restriction* (skewed kappa : lambda ratio) instead of the polyclonal mix of reactive lymphocytes.
 - **T-cell clonality** — aberrant antigen loss or an abnormal CD4:CD8 pattern (TCR clonality usually needs PCR).
- Antibodies may target **surface, cytoplasmic** (e.g., cytoplasmic CD3, CD79a, MPO) or **nuclear** antigens (e.g., TdT) after permeabilisation.

Lineage	Characteristic CD / marker profile
Haematopoietic stem/progenitor	CD34, CD117 (c-Kit), CD90 (Thy-1), CD133; TdT (lymphoblasts)
B-lymphoid	CD19, CD20, CD22, CD79a; surface Ig (kappa/lambda)
T-lymphoid	CD3, CD2, CD5, CD7, CD4, CD8
NK cell	CD16, CD56, CD57
Myeloid/monocytic	CD13, CD33, CD117, MPO; CD14, CD64 (monocytic)
Erythroid / megakaryocytic	CD71, glycophorin A; CD41, CD61
Plasma cell	CD138, CD38, CD56; cytoplasmic light-chain restriction
Common leucocyte / gating	CD45 (bright on lymphocytes, dim on blasts)

Applications in haematology and beyond

- **Acute leukaemia** — distinguishes AML (CD13, CD33, CD117, MPO+) from ALL, and B-ALL (CD19, CD10, TdT, cyto-CD79a) from T-ALL (cyto-CD3, CD7); identifies mixed-phenotype/biphenotypic acute leukaemia and acute promyelocytic leukaemia.
- **Chronic lymphocytic leukaemia (CLL)** — diagnostic immunophenotype is CD5+ CD19+ CD20(dim) CD23+ with light-chain restriction; a monoclonal B-cell count $\geq 5 \times 10^9/L$ defines CLL; flow confirms monoclonality in marrow/blood (DeVita).
- **Non-Hodgkin lymphoma sub-typing:**
 - *Follicular lymphoma* — CD19, CD20, CD10, BCL6 positive, CD5 and CD23 negative.
 - *Marginal-zone/MALT lymphoma* — CD19, CD20, CD22, CD79a positive; **negative for CD5, CD10, CD23 and cyclin D1**; light-chain restriction separates it from reactive infiltrates.
 - *Mantle cell* — CD5+, cyclin D1/t(11;14) (corroborated by FISH/IHC).
- **Hodgkin lymphoma** — flow-sorted Hodgkin/Reed-Sternberg cells express **bright CD30, CD15, CD40, CD95, CD64 but NOT CD20** (DeVita, Fig 66.4).
- **Paroxysmal nocturnal haemoglobinuria (PNH)** — flow is the **gold-standard** diagnostic test (replaces the old Ham/acidified-serum and sucrose lysis tests); see below.

- ▶ **Multiple myeloma / plasma-cell disorders** — peripheral-blood flow detects and quantifies circulating plasma cells; multiparametric flow estimates the **plasma-cell proliferative (S-phase) rate**; “absence of clonal plasma cells by 2- to 4-colour flow” is part of stringent CR; sensitive MRD assessment.
- ▶ **Minimal residual disease (MRD)** — multiparameter flow (alongside PCR/NGS) detects sub-microscopic residual leukaemia/lymphoma; uMRD status is independently prognostic in CLL and ALL.
- ▶ **CD4+ T-cell enumeration in HIV/AIDS** — flow cytometry is the standard method to count CD4 T-cells for staging (AIDS = CD4 <200/ μ L) and monitoring antiretroviral therapy.
- ▶ **CD34+ haematopoietic stem-cell enumeration** — quantifies the graft for autologous/allogeneic transplantation and apheresis adequacy.
- ▶ **DNA content / cell-cycle analysis** — DNA-binding dyes measure **ploidy (aneuploidy)** and **S-phase fraction** as prognostic markers in tumours.
- ▶ **Other uses** — lymphocyte subset quantitation in primary immunodeficiency (e.g., absent B and NK cells in GATA2 deficiency); **CSF flow cytometry** for lymphomatous/leukaemic meningitis; reticulocyte counting; fetomaternal haemorrhage (fetal Hb cells); platelet function/receptor disorders (CD41/CD61 in Glanzmann, CD42 in Bernard-Soulier); HLA-B27 typing; flow-based crossmatch in transplantation; increasing the sensitivity of antibody detection in autoimmune haemolytic anaemia to as few as 30–40 molecules per red cell.

PNH — the model “flow cytometry diagnosis”

- ▶ PNH arises from a somatic **PIGA** mutation → shortage of the **GPI anchor** → loss of GPI-linked complement-regulatory proteins **CD55 (DAF)** and **CD59 (MIRL)** from blood cells, causing complement-mediated intravascular haemolysis.
- ▶ Flow shows a **bimodal distribution**: a discrete population of cells that is **CD55 and CD59 negative** alongside normal cells.
- ▶ Run on **both granulocytes and red cells** (granulocytes avoid the confounding effect of haemolysis/transfusion on red cells); **FLAER** (fluorescein-labelled aerolysin, which binds GPI) is the preferred reagent for white cells.
- ▶ A diagnosis of PNH requires a *substantial* clone — roughly **≥5% of red cells and ≥20% of granulocytes** GPI-deficient (Harrison).
- ▶ Small PNH clones are detected by sensitive flow in **half or more of aplastic-anaemia patients** at presentation and signal an immune (immunosuppression-responsive) pathophysiology.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Schematic of a flow cytometer (label exactly)**: *Sample (single-cell suspension) → Sheath fluid → Flow cell / hydrodynamic focusing → Laser beam (488 nm) → Forward scatter*

detector (FSC = size) → Side scatter detector (SSC = granularity, 90°) → Dichroic mirrors/filters → Fluorescence PMTs (FITC / PE / APC) → Computer (dot-plot & histogram) → (FACS) charged-droplet deflection plates → collection tubes.

- ▶ A CD45-vs-SSC gating dot-plot labelling lymphocytes (CD45-bright, low SSC), monocytes, granulocytes (high SSC), and the blast gate (CD45-dim, low SSC); OR a PNH histogram showing the bimodal CD59-positive (normal) vs CD59-negative (PNH) red-cell populations.

Clinical / Diagnostic significance

- ▶ Provides **rapid, objective, quantitative** lineage assignment and clonality that, combined with morphology, cytochemistry, cytogenetics/FISH and molecular studies, completes the modern WHO classification of leukaemias and lymphomas.
- ▶ Works on **tiny / hypocellular samples** (CSF, fine-needle aspirates, “dry-tap” marrows) where histology may be insufficient.
- ▶ Enables **prognostication and MRD-guided therapy** (CLL, ALL, myeloma), **CD4-based HIV staging, stem-cell graft quantification**, and definitive, non-invasive diagnosis of PNH.
- ▶ Limitations: needs a viable single-cell suspension (poor for sclerotic/Hodgkin-rich tissue with few tumour cells), cannot show architecture (complementary to immunohistochemistry), is operator/panel-dependent, and degrades with delayed/old samples.

High-yield exam pointers

- ▶ FSC = cell size; SSC = granularity/internal complexity — the two antibody-independent parameters.
- ▶ **Hydrodynamic focusing** lines cells up singly; lasers + PMTs + fluorochromes (FITC/PE/APC) give multiparametric data.
- ▶ **CD45 vs SSC** is the standard gating plot; **light-chain (kappa:lambda) restriction** = B-cell clonality.
- ▶ PNH = flow is gold standard → **CD55 & CD59 negative**, bimodal, use **granulocytes + FLAER**; clone ≥5% RBC / ≥20% granulocytes.
- ▶ **CLL** = CD5+CD19+CD23+; **AML** = CD13/CD33/CD117/MPO; **B-ALL** = CD19/CD10/TdT.
- ▶ **Hodgkin/RS cells** = CD30+ CD15+ CD20– (flow-sorted).
- ▶ Flow enumerates **CD4 T-cells (HIV)** and **CD34 stem cells (transplant)**; tracks **MRD**.
- ▶ **FACS** = the sorting variant (charged-droplet deflection); also measures **DNA ploidy & S-phase**.

SOURCE & COVERAGE

- ▶ **Harrison's Principles of Internal Medicine, 22e** — “Non-Hodgkin's Lymphoma” (immunophenotype/antigen footprint, single-cell suspension method, FL/MZL markers,

light-chain restriction); “Hemolytic Anemias” (PNH flow cytometry, CD55/CD59, bimodal clone, $\geq 5\%$ / $\geq 20\%$ thresholds, AIHA antibody sensitivity); “Bone Marrow Failure Syndromes including Aplastic Anemia and Myelodysplasia” (PNH-clone detection, GATA2); “Hematopoietic Stem Cells” (CD34/CD90/CD117/CD133); “Hematopoietic Cell Transplantation”; “HIV Disease/AIDS” (CD4 staging).

- ▶ **DeVita, Hellman, and Rosenberg’s Cancer: Principles & Practice of Oncology, 12e** — CLL immunophenotype (CD5/CD19/CD23) and MRD by flow; Hodgkin/Reed-Sternberg flow immunophenotype (CD30/CD15/CD40/CD95/CD64, not CD20); multiple-myeloma circulating plasma cells, S-phase and clonal-PC CR criteria; CSF flow cytometry in leptomeningeal disease; DNA/ploidy analysis.
- ▶ **CMDT 2026** — “Blood Disorders” (PNH: flow cytometry demonstrates deficiencies of CD55 and CD59).
- ▶ *Coverage note:* This is a laboratory-technique topic and Harrison/DeVita cover it **applied within disease chapters** rather than as a stand-alone “method” section. The detailed instrument physics (hydrodynamic focusing, FSC/SSC definitions, named fluorochromes FITC/PE/APC, PMTs, droplet-based FACS) and a few standard application specifics (FLAER reagent for PNH white cells; CD41/CD61 and CD42 in platelet disorders; CD4 counting “by flow cytometry”; reticulocyte/fetomaternal-haemorrhage assays) are **universally accepted standard laboratory/internal-medicine knowledge** included to satisfy the “principle” half of the question, as they are not described verbatim in the available corpus. All disease-specific marker panels, the PNH thresholds, and the clonality concepts are corpus-grounded as cited above.

Hereditary Spherocytosis

Asked in: Paper IV Jul 2021 — RGUHS MD General Medicine

Definition / Introduction — Hereditary spherocytosis (HS) is the commonest inherited haemolytic anaemia due to a **defect of the red-cell membrane–cytoskeleton complex**, in which mutations affecting the *vertical* anchoring proteins (ankyrin, band 3, spectrin, band 4.2) uncouple the lipid bilayer from the underlying cytoskeleton. The resulting loss of membrane surface area produces rigid, poorly deformable **spherocytes** that are selectively trapped and destroyed in the spleen (extravascular haemolysis). It was first described by *Minkowski and Chauffard* in the late 19th century, who recognised spherocytes in the peripheral blood and their abnormal susceptibility to lysis in hypotonic media. Estimated prevalence is 1:2000–1:5000 in populations of European ancestry, making it the most common HS of this group.

Molecular basis and genetics

- ▶ The red-cell cytoskeleton is built on the **spectrin tetramer** (head-to-head association of two α -spectrin/ β -spectrin heterodimers), linked to the overlying membrane through two multiprotein bridges: the **ankyrin complex** (ankyrin + band 3 [AE1] + band 4.2) and the **junctional complex** (band 4.1R + actin + adducin + dematin).
- ▶ The ankyrin complex provides mainly **vertical (radial)** connections; the junctional complex provides **horizontal (tangential)** connections. Pathogenic changes that weaken *vertical* links cause **spherocytosis**, whereas defects of *horizontal* links cause elliptocytosis; spectrin defects can cause either.
- ▶ **Band 3** (anion exchanger, ~1.2 million copies/cell) is the most abundant membrane protein; its surface exposure with ageing creates the antigenic signal for macrophage clearance — a process accelerated in HS.
- ▶ HS is **genetically heterogeneous** — a single phenotype arising from mutations in any one of several genes. Inheritance is most often **autosomal dominant** (heterozygous), but the most severe forms are **autosomal recessive** (homozygous). A negative family history may reflect either a **de novo mutation** or a recessive form.

Gene	Protein	Inheritance in HS	Approx. share / comment
ANK1 (8p11.2)	Ankyrin	Dominant	May account for the majority of HS
SLC4A1 (17q21)	Band 3 (AE1)	Dominant	~25% of HS
SPTB (14q23–q24)	β -spectrin	Dominant	Rare
SPTA1 (1q22–q23)	α -spectrin	Recessive	Rare; severe biallelic forms
EPB42 (15q15–q21)	Band 4.2	Recessive	~3% of HS

Pathophysiology

- ▶ A *vertical* anchoring defect leaves regions of the lipid bilayer unsupported by the cytoskeleton → the membrane **vesiculates and is shed** → progressive **loss of surface area relative to volume** → the biconcave disc becomes a **spherocyte**.
- ▶ Spherocytes have reduced **deformability**. As they traverse the narrow fenestrations of the **splenic** red pulp cords, the metabolically stressed, low-glucose, acidic environment promotes further membrane loss (“splenic conditioning”), and the cells are ultimately phagocytosed by splenic macrophages.
- ▶ The spleen therefore plays a **dual role**: it both *worsens* the membrane lesion (vesiculation on transit) and is the *major site of destruction*. This explains why splenectomy is therapeutically effective even though it does not correct the underlying defect.

- ▶ Chronic extravascular haemolysis → unconjugated hyperbilirubinaemia, raised LDH, reduced haptoglobin, reticulocytosis, and a tendency to **pigment (bilirubinate) gallstones** and **splenomegaly**.

Clinical presentation

- ▶ **Wide spectrum of severity**. Severe cases present in **infancy** with neonatal jaundice or transfusion-dependent anaemia; mild cases may present in young adults or even later, sometimes only when gallstones are detected.
- ▶ The classic triad is **anaemia, jaundice and splenomegaly**; the discovery of **gallstones in a young person** frequently triggers diagnostic work-up.
- ▶ Haemolysis is often **compensated** (no anaemia) but may *decompensate* with intercurrent stress — pregnancy, infection, folate deficiency or renal impairment reducing erythropoietin.
- ▶ **Crises**: (1) *Aplastic crisis* from **parvovirus B19** infection causing transient red-cell aplasia and a precipitous fall in haemoglobin; (2) *Haemolytic crisis* with intercurrent infection; (3) *Megaloblastic crisis* from folate depletion. Chronic skull marrow expansion can cause frontal bossing in severe congenital cases.

Diagnosis and investigations

- ▶ **Full blood count / film**: normocytic anaemia with **spherocytes** (small, densely staining cells lacking central pallor) on the smear; **reticulocytosis**.
- ▶ **Red-cell indices** are highly suggestive: **MCHC >34 g/dL** (cells are dehydrated/spheroidal) with raised **RDW >14%** and a normal or slightly low MCV — a powerful screening clue from a routine blood count.
- ▶ **Haemolysis markers**: raised unconjugated bilirubin and AST, raised urinary/faecal urobilinogen; LDH increased and haptoglobin reduced when an intravascular component is present.
- ▶ **Confirmatory tests** (when family history is negative or a recessive form is suspected):
 - **Osmotic fragility test** — classically *increased* fragility in hypotonic saline (the historical diagnostic test); sensitivity improves after 24-h incubation.
 - **Acid glycerol lysis test (AGLT)** — accelerated lysis.
 - **Eosin-5'-maleimide (EMA)-binding test** by flow cytometry — *reduced* fluorescence (band 3 / Rh-related membrane protein deficiency); a sensitive, widely used screen.
 - **SDS-PAGE** of membrane proteins — quantifies the specific deficient protein.
 - **Ektacytometry** (osmotic gradient / laser diffraction) — measures deformability and reliably **distinguishes spherocytosis from stomatocytosis**.
 - **Molecular genetic studies** for a definitive answer in ambiguous cases.
- ▶ A negative **direct antiglobulin (Coombs) test** is essential to separate HS from **autoimmune haemolytic anaemia**, which can also produce spherocytes.

Treatment

- ▶ No causal therapy exists; management is supportive and directed at the spleen and its complications.
- ▶ Splenectomy abolishes or markedly reduces haemolysis. Current recommendations: perform at age 4–6 years in severe cases, delay to puberty in moderate cases, and avoid in mild cases; partial (subtotal) splenectomy is an option that preserves some splenic immune function. Knowledge of outcomes in affected relatives helps guide the decision.
- ▶ Pre-splenectomy vaccination against encapsulated organisms — *Streptococcus pneumoniae* and *Neisseria meningitidis* (and *Haemophilus influenzae* type b) — is imperative; penicillin prophylaxis afterwards is recommended in children though its value in older patients is debated.
- ▶ Cholecystectomy (usually laparoscopic) should be done — often at the same sitting as splenectomy — only when gallstones are symptomatic/clinically indicated, not automatically.
- ▶ Supportive care: folic acid supplementation for the increased erythropoietic demand; blood transfusion during aplastic/haemolytic decompensation; in the <10% of most severe (transfusion-dependent) infants, erythropoietin may be transfusion-sparing, and recurrent transfusion mandates iron-overload surveillance and chelation.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ Red-cell membrane–cytoskeleton complex (schematic). Labels: lipid bilayer; band 3 (anion exchanger AE1); glycophorin A; ankyrin; protein band 4.2; α -spectrin and β -spectrin (tetramer); actin; band 4.1R; adducin; dematin; mark the ankyrin (vertical) complex vs the junctional (horizontal) complex — annotate “vertical-link defect $\rightarrow$ spherocytosis.”
- ▶ Peripheral blood smear / surface-area concept. Draw a normal biconcave disc beside a spherocyte (small, round, loss of central pallor); annotate “membrane vesiculation $\rightarrow$ $\downarrow$ surface-area-to-volume ratio $\rightarrow$ $\downarrow$ deformability $\rightarrow$ splenic trapping.” Optionally an osmotic fragility curve with the HS curve shifted left (lysis at higher NaCl concentration).

Clinical / Diagnostic significance

- ▶ Triad to recognise: haemolytic anaemia + splenomegaly + pigment gallstones in a young patient with autosomal-dominant family history.
- ▶ The MCHC >34 g/dL + spherocytes + reticulocytosis + negative DAT quartet is effectively diagnostic at the bedside; EMA-binding/osmotic fragility confirm it.
- ▶ Parvovirus B19 is the classic cause of aplastic crisis — anticipate it during any abrupt fall in haemoglobin.
- ▶ Splenectomy decisions balance haemolysis control against lifelong risk of overwhelming post-splenectomy infection (OPSI) and thrombosis — hence vaccination, prophylaxis and age thresholds.

- ▶ Distinguish from AIHA (DAT-positive), G6PD/pyruvate-kinase deficiency, and from dehydrated/overhydrated stomatocytosis (ektacytometry), in which splenectomy is *contraindicated* due to thrombo-embolic risk.

High-yield exam pointers

- ▶ HS = **vertical** membrane-protein defect (ankyrin/band 3/spectrin/4.2); elliptocytosis = horizontal (band 4.1/spectrin) defect.
- ▶ ANK1 (ankyrin) = commonest gene; band 3 (SLC4A1) ~25%; mostly **autosomal dominant**.
- ▶ Hallmark lab clue: **MCHC >34 g/dL**, **RDW >14%**, normal/low MCV, spherocytes, reticulocytosis.
- ▶ Best screening confirmatory tests today: **EMA-binding (flow cytometry)** and **osmotic fragility**; **ektacytometry** separates HS from stomatocytosis.
- ▶ **DAT (Coombs)** is **NEGATIVE** — separates HS from immune spherocytosis.
- ▶ **Splenectomy** at **4–6 yr (severe)** / puberty (moderate); avoid in mild — vaccinate against pneumococcus, meningococcus, Hib first.
- ▶ Haemolysis is **extravascular** → unconjugated bilirubin↑, LDH↑, haptoglobin↓, **pigment gallstones**, splenomegaly.
- ▶ Complications: **aplastic crisis (parvovirus B19)**, gallstones, folate-deficiency megaloblastic crisis; give **folic acid**.
- ▶ No curative therapy; **erythropoietin** may spare transfusions in severe infants; the most severe ~<10% are transfusion-dependent.

SOURCE & COVERAGE

- ▶ **Harrison's Principles of Internal Medicine, 22e** — “**Hemolytic Anemias**” (red-cell membrane–cytoskeleton complex; Hereditary Spherocytosis section, Table of inherited membrane-cytoskeleton diseases, diagnostic tests and treatment). Primary source for this answer.
- ▶ **CMDT 2026** — “**Blood Disorders**” (haemolytic-anaemia classification and supportive context).
- ▶ *Coverage note:* The dedicated specialty text listed in the spec (**DeVita's Cancer**) covers haematologic *malignancies* and does **not** address hereditary spherocytosis, so it was not used. CMDT covers HS only briefly within its haemolysis classification; depth is therefore drawn from Harrison. Universally accepted standard points not stated verbatim in the corpus — *H. influenzae* type b vaccination, negative direct Coombs test, and folate/gallstone associations — are included as established internal-medicine teaching.

Hypoproliferative Anemias

Asked in: Paper IV Nov 2019 — RGUHS MD General Medicine

Definition / Introduction — *Hypoproliferative (underproduction) anemias* are those in which anemia results from **inadequate red-cell production by the bone marrow** rather than from blood loss or accelerated destruction. They are characterised by an **inappropriately low reticulocyte response** for the degree of anemia (low absolute reticulocyte count; reticulocyte production index $<2-2.5$) with a marrow that fails to amplify erythropoiesis. They are the **largest group of anemias** — **at least 75% of all cases** — the commonest being iron deficiency and anemia of inflammation. The functional erythron requires three things: **renal erythropoietin (EPO)**, a **competent erythroid marrow**, and **adequate substrate (iron, folate, vitamin B12)**; a defect in any one produces a hypoproliferative anemia.

Pathophysiology — why production fails

- ▶ Erythropoiesis is driven by EPO, a glycoprotein made by renal peritubular interstitial cells; its synthesis is governed by **hypoxia-inducible factor (HIF)-1 α** . When haemoglobin falls below 100–120 g/L (10–12 g/dL), plasma EPO rises **logarithmically**.
- ▶ The pronormoblast undergoes **4–5 divisions** → **16–32 mature red cells**; with EPO stimulation, production can rise **4–5 fold in 1–2 weeks** — but *only if iron supply is adequate*.
- ▶ Hypoproliferation occurs when EPO is deficient, when the marrow cannot respond (aplasia, infiltration, dysplasia), or when substrate (chiefly iron) is unavailable or sequestered.
- ▶ The reticulocyte count is the **physiological pivot**: an elevated count signals haemolysis/haemorrhage (hyperproliferation), whereas a low/inappropriately normal count defines the hypoproliferative mechanisms.

Classification by mechanism (cause-based)

Mechanism	Representative causes
Nutritional / substrate deficiency	Iron, vitamin B12, folate, copper, vitamin C deficiency
Lack of erythropoietin	Chronic kidney disease, anemia of inflammation, anemia of aging; ACE-inhibitor effect
Anemia of inflammation (iron sequestration)	Infection, autoimmunity, malignancy, CHF, CKD — hepcidin-driven
Absence of red-cell precursors	Aplastic anemia (pancytopenia), pure red-cell aplasia (parvovirus B19)
Marrow replacement (myelophthisis)	Metastatic carcinoma, lymphoma/myeloma, granuloma (TB, histoplasmosis), myelofibrosis
Stem-cell / clonal defects	Myelodysplastic syndrome, acute/chronic leukemia

- ▶ A complementary morphological scheme (Wintrobe) groups anemia by **MCV**: *microcytic* (iron deficiency, thalassemia, sideroblastic, inflammation), *normocytic* (renal, aplastic, marrow invasion, endocrine), and *macrocytic* (B12/folate deficiency, MDS, alcohol/liver disease). Most hypoproliferative anemias are **normocytic-normochromic** or microcytic.

Iron-restricted hypoproliferation: deficiency vs inflammation

- ▶ **Iron metabolism** is governed by **hepcidin**, a 25-amino-acid hepatic peptide that degrades the iron exporter **ferroportin**, throttling iron release from enterocytes, macrophages and hepatocytes. Hepcidin is **suppressed** in iron deficiency (maximising absorption) and **raised by IL-6 (STAT3 pathway)** in inflammation.
- ▶ **Iron-deficiency anemia (IDA)**: absolute store depletion → low ferritin → iron-restricted erythropoiesis → **microcytic, hypochromic** cells with **high RDW**. Clues: pica, koilonychia, cheilosis, atrophic glossitis, and oesophageal webs (**Plummer-Vinson syndrome**). Severe IDA may cause **reactive thrombocytosis**.
- ▶ **Anemia of inflammation (chronic disease)**: the second commonest anemia worldwide; mild–moderate, **normocytic-normochromic** (microcytic if long-standing) with **low reticulocytes**. It is fundamentally a **disorder of iron distribution** — high hepcidin sequesters iron in macrophages (functional iron deficiency) with **reduced EPO production and blunted EPO response** (IL-1 β , TNF- α , IFN- γ).

Parameter	Iron deficiency	Anemia of inflammation	Thalassemia trait
Serum ferritin	Low ($\leq 15\text{--}30\text{ }\mu\text{g/L}$)	Normal–high (>100)	Normal–high
Serum iron	Low	Low	Normal–high
Transferrin saturation	Low ($<15\text{--}20\%$)	Low ($<20\%$)	Normal–high
MCV	Low ($<80\text{ fL}$)	Low–normal	Low
RDW	High	Normal	Low–normal
Soluble transferrin receptor (sTfR)	High	Low–normal	Normal–high
Hepcidin	Very low	Normal–high	Low–normal

(Normal serum iron 50–150 $\mu\text{g/dL}$; TIBC 300–360 $\mu\text{g/dL}$; transferrin saturation 25–50%; ferritin $<30\text{ }\mu\text{g/L}$ = depleted stores, sensitivity 92% / specificity 98%.)

Selected entities of marrow failure

- ▶ **Aplastic anemia**: bone-marrow failure from stem-cell injury/immune (T-cell) suppression → **pancytopenia with a hypocellular marrow** and no abnormal cells. Causes: idiopathic/autoimmune, drugs (chloramphenicol, sulfonamides, phenytoin, carbamazepine, gold), benzene/toluene, radiation, viral hepatitis, parvovirus/EBV/CMV, PNH, pregnancy;

inherited telomere/DNA-repair defects (**Fanconi anemia**, **dyskeratosis congenita**). **Severe aplastic anemia (Camitta criteria)**: marrow cellularity <20% **plus** ≥ 2 of — neutrophils <500/ μL , platelets <20,000/ μL , reticulocytes <1%.

- ▶ **Pure red-cell aplasia**: isolated erythroid precursor loss with severe reticulocytopenia; classic trigger **parvovirus B19** (also thymoma, autoimmune, drugs).
- ▶ **Anemia of CKD**: EPO deficiency once >50% renal function is lost; anemia is near-universal at $\text{GFR} < 30 \text{ mL/min/1.73 m}^2$, compounded by absolute and functional iron deficiency.
- ▶ **Anemia of aging**: roughly **one-third nutritional (iron)**, **one-third inflammation/CKD**, **one-third “unexplained”** (low EPO-for-Hb; associated with clonal hematopoiesis of indeterminate potential, CHIP).
- ▶ **Marrow infiltration / clonal disease**: carcinoma, lymphoma, myeloma, myelofibrosis or leukemia produce a **leukoerythroblastic (myelophthasic) smear** — nucleated RBCs, teardrop cells and immature myeloid forms — mandating marrow examination. **MDS** may present as an isolated macrocytic anemia or pancytopenia.

Diagnostic approach

- ▶ **Step 1 – CBC + reticulocyte count**: correct the percentage for anemia — *Corrected reticulocyte count = measured retic $\times$ (patient Hct / 45)*; a low/inappropriately normal value confirms hypoproliferation.
- ▶ **Step 2 – Blood smear**: microcytic-hypochromic (IDA), macro-ovalocytes + hypersegmented neutrophils (megaloblastic), teardrop/nRBC (myelophthasis), dimorphic with basophilic stippling (sideroblastic).
- ▶ **Step 3 – MCV-guided tests**: *low MCV* $\rightarrow$ ferritin/iron studies (IDA vs inflammation vs thalassemia, RDW helps); *normal MCV* $\rightarrow$ renal function, EPO level, SPEP/light chains; *high MCV* $\rightarrow$ B12/folate, then marrow for suspected MDS.
- ▶ **Step 4 – Bone marrow aspirate + biopsy** (biopsy first) for pancytopenia, very low reticulocytes (<0.1%), nRBC/teardrops, or suspected infiltration/aplasia/MDS; assess cellularity, **myeloid:erythroid ratio (normal $\approx 2.5:1$, range 2:1–5:1)** and iron stores (Perls stain — absent stainable iron is the gold standard for iron deficiency).

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Physiological classification algorithm**: box “Anemia $\rightarrow$ CBC + reticulocyte count” branching to “High absolute reticulocyte count $\rightarrow$ haemolysis / haemorrhage” and “Low absolute reticulocyte count $\rightarrow$ HYPOPROLIFERATIVE $\rightarrow$ assess MCV”; under MCV draw three arms — *Low* $\rightarrow$ Ferritin (*low* = iron deficiency; *normal/high* = inflammation, thalassemia, sideroblastic), *Normal* $\rightarrow$ EPO level, BUN/creatinine, SPEP, marrow exam,

High → smear (hypersegmentation? Yes = B12/folate deficiency; No = MDS / drug effect).

Labels: CBC, reticulocyte count, MCV, ferritin, EPO, marrow exam.

- ▶ **Hepcidin–ferroportin axis:** liver hepcidin acting on ferroportin in **duodenal enterocyte, splenic macrophage, hepatocyte**; arrows “IL-6 → ↑hepcidin → ↓iron release (anemia of inflammation)” and “iron deficiency/erythroferrone → ↓hepcidin → ↑iron release.” Labels: *Hepcidin, Ferroportin, Transferrin, IL-6/STAT3, Erythroferrone.*

Clinical / Diagnostic significance

- ▶ The reticulocyte count is the single most useful triage test — it separates underproduction from increased destruction before any expensive workup.
- ▶ A low ferritin is **diagnostic of iron deficiency**, but ferritin is an acute-phase reactant; in inflammation use a higher cut-off (<100 µg/L) and transferrin saturation <20%.
- ▶ In **males and postmenopausal women**, IDA mandates GI evaluation (endoscopy) to exclude occult malignancy/bleeding.
- ▶ A **leukoerythroblastic smear or unexplained pancytopenia** is an absolute indication for bone-marrow biopsy.
- ▶ Distinguish **aplastic anemia (hypocellular marrow)** from **MDS and hypocellular leukemia** by morphology, blast percentage and cytogenetics.

Treatment (cause-directed)

- ▶ **Iron deficiency:** oral iron salts (iron sulfate, 65–100 mg elemental iron); **alternate-day single morning dose maximises absorption** (avoids the hepcidin peak of daily dosing) and is better tolerated; continue ≥3 months to refill stores. **IV iron** (ferric carboxymaltose, derisomaltose, ferumoxytol) for intolerance, malabsorption, severe anemia (Hb ≤8 g/dL), CKD, CHF, pregnancy 2nd–3rd trimester, or surgery within 6 weeks; watch for **hypophosphataemia** (FGF-23, with carboxymaltose).
- ▶ **Anemia of inflammation:** treat the underlying disorder; ESAs in CKD targeting Hb <11.5 g/dL, with IV iron to keep transferrin saturation 30–40% and ferritin 200–700 µg/L; HIF prolyl-hydroxylase inhibitors are an oral alternative.
- ▶ **Megaloblastic anemia:** replace B12/folate.
- ▶ **Aplastic anemia:** allogeneic HSCT for patients <40 yr with an HLA-matched donor; otherwise **immunosuppression** — equine ATG 40 mg/kg/day ×4 days + cyclosporine 6 mg/kg BID + eltrombopag 150 mg/day (response ~90%) with corticosteroid cover for serum sickness.
- ▶ **Transfusion** is reserved for haemodynamic instability or symptomatic anemia; use **restrictive thresholds** (7–8 g/dL) in stable patients. IDA itself should not be transfused unless decompensated.

High-yield exam pointers

- ▶ Hypoproliferative = low reticulocyte response; constitutes $\geq 75\%$ of all anemias.
- ▶ Reticulocyte production index $< 2\text{--}2.5$ = inadequate marrow response = hypoproliferative.
- ▶ Commonest two causes: iron deficiency and anemia of inflammation.
- ▶ Ferritin $< 30\text{ }\mu\text{g/L}$ = absolute iron deficiency; high hepcidin + hyperferritinaemia + hypoferremia = functional iron deficiency of inflammation.
- ▶ Plummer-Vinson = IDA + dysphagia + oesophageal web; koilonychia, pica, atrophic glossitis are IDA signs.
- ▶ Severe aplastic anemia (Camitta): cellularity $< 20\%$ + 2 of (ANC < 500 , platelets $< 20,000$, retics $< 1\%$).
- ▶ Parvovirus B19 $\rightarrow$ pure red-cell aplasia / transient aplastic crisis.
- ▶ CKD anemia = EPO deficiency, prominent once GFR $< 30\text{ mL/min}$.
- ▶ Leukoerythroblastic (myelophthistic) smear $\rightarrow$ suspect marrow infiltration $\rightarrow$ biopsy.
- ▶ Normal M:E ratio $\approx 2.5:1$; absent marrow stainable iron is the gold standard for iron deficiency.

- ▶ Harrison's Principles of Internal Medicine, 22e — "*Anemia and Polycythemia*" (physiological classification, reticulocyte interpretation, smear morphology, marrow indications) and "*Iron Deficiency and Other Acquired Anemias Due to Decreased Erythrocyte Production*" (iron metabolism, hepcidin, iron studies, anemia of inflammation, CKD and aging).
- ▶ CMDT 2026 — "*Blood Disorders*" (aplastic anemia causes, Camitta severity criteria, ATG/cyclosporine/eltrombopag regimen; iron-restricted anemia management).
- ▶ Coverage note: The dedicated specialty text assigned in the spec (DeVita's Cancer: Principles & Practice of Oncology) is oriented to haematological malignancies and contributes only peripherally here — to the *marrow-replacement / clonal stem-cell* causes (MDS, leukemia, lymphoma, myeloma). The spine of this benign-haematology topic is Harrison's two hematology chapters supplemented by CMDT 2026 for management; this is reflected in the citations above.

Light chain amyloidosis (AL)

Asked in: Paper III Nov 2022 — RGUHS MD General Medicine

Definition / Introduction — Amyloidosis is a group of protein-misfolding disorders defined by the extracellular deposition of insoluble, antiparallel β -pleated-sheet-rich protein fibrils that distort tissue architecture and impair organ function. AL (light-chain) amyloidosis is the form in which the

fibril precursor is a **monoclonal immunoglobulin light chain** produced by a clonal bone-marrow plasma-cell (or B-lymphoproliferative) disorder; it was formerly called *primary systemic amyloidosis*. It is the **most common systemic amyloidosis in North America** and is rapidly progressive and fatal if untreated. (The term *amyloid* was coined around 1854 by **Rudolf Virchow**, who thought the deposits resembled starch — Latin *amylum*.)

Classification & nomenclature context

- ▶ Amyloid diseases are named by the convention **A + X**, where **A** = amyloid and **X** = the fibril precursor protein; they are classed as **systemic vs localized** and **acquired vs inherited**.
- ▶ AL sits among the **systemic amyloidoses**; the major systemic types are contrasted below.

Type	Precursor protein	Clinical setting	Typical organ involvement
AL	Immunoglobulin light chain	Primary / myeloma-associated (plasma-cell dyscrasia)	Renal, heart, nerve, GI, soft tissue
AH	Immunoglobulin heavy chain	Rare variant of primary/myeloma-associated	Renal
AA	Serum amyloid A (SAA)	Secondary / reactive (chronic inflammation, infection, FMF)	Hepatic, renal
A β 2M	β 2-microglobulin	Long-term dialysis-associated	Synovium, bone, carpal tunnel
ATTR	Transthyretin (mutant / wild-type)	Familial / age-related	Cardiac, peripheral & autonomic nerve

- ▶ **Localized AL** can occur in skin, conjunctiva, urinary bladder and the tracheobronchial tree, produced by *local* clonal plasma cells.

Etiopathogenesis

- ▶ A **clonal plasma-cell expansion** secretes a **monoclonal light chain** whose primary sequence (and other genetic/epigenetic factors) predisposes it to **misfold** rather than fold normally; the misfolded protein forms oligomers → higher-order polymers → fibrils that deposit in tissues.
- ▶ The **amyloid hypothesis** holds that soluble **oligomeric intermediates are the most toxic species** (direct proteotoxicity, reactive oxygen species, stress signalling), while fibrillar deposits cause architectural disruption.
- ▶ Fibrils are composed of **full-length 23-kDa monoclonal light chains** plus fragments; **λ (lambda) subtypes predominate** (λ light chains are more amyloidogenic and more nephrotoxic than κ — *Ch 116*).

- ▶ Accessory molecules co-deposited with fibrils: **serum amyloid P component**, apolipoproteins E and A-IV, glycosaminoglycans, and metal ions.
- ▶ May coexist with **multiple myeloma**, **non-Hodgkin lymphoma**, or **Waldenström macroglobulinemia**. Estimated incidence 8–12 per 100,000; usually presents after age 40.

Clinical features (multisystem, pleiotropic)

Recognition of the *constellation* of syndromes — unexplained nephropathy, cardiomyopathy, neuropathy, enteropathy, arthropathy, macroglossia — is the key to early diagnosis.

Organ system	Frequency / features
Kidney	60–70%; proteinuria , often nephrotic-range → hypoalbuminemia, secondary hypercholesterolemia/triglyceridemia, edema/anasarca. Interstitial (vs glomerular) deposition → azotemia without proteinuria
Heart	70–80%; leading cause of death . ECG: low limb-lead voltage with pseudo-infarct pattern . Echo: concentrically thickened ventricles, diastolic dysfunction , abnormal global longitudinal strain , “sparkly” myocardium; poor atrial contractility (atrial thrombi/thromboembolism even in sinus rhythm). Cardiac MRI: increased wall thickness, delayed subendocardial gadolinium enhancement
Nervous system	Peripheral sensorimotor neuropathy and/or autonomic dysfunction — orthostatic hypotension, GI dysmotility (early satiety, diarrhea, constipation), dry eyes/mouth, impotence, neurogenic bladder
GI / liver / spleen	Hepatomegaly with cholestasis (raised alkaline phosphatase, preserved transaminases/synthetic function); splenic involvement with functional hyposplenism
Skin / soft tissue	Periorbital ecchymoses (“ raccoon-eye ” sign) and easy bruising (capillary amyloid ± acquired factor X deficiency); macroglossia (~10%); nail dystrophy, alopecia, amyloid arthropathy of wrists/shoulders

- ▶ **Macroglossia** and periorbital “**raccoon-eye**” ecchymoses are **pathognomonic** (each seen in a minority of patients).
- ▶ Endocrine deposition may cause **hypothyroidism**, **hypoadrenalism**, or **hypopituitarism**.

Diagnosis & investigations

Diagnosis requires (1) **histologic proof of amyloid**, (2) **accurate typing**, and (3) demonstration of an underlying **clonal plasma-cell disorder + a clonal light chain**.

- ▶ Tissue biopsy + Congo red stain → apple-green birefringence under polarized light; 10-nm fibrils on electron microscopy. Abdominal subcutaneous fat aspirate (16-gauge needle) is positive in >80% of systemic cases and avoids organ biopsy.
- ▶ **Typing** (essential — wrong type = wrong treatment): **laser-capture microdissection + tandem mass spectrometry is the diagnostic standard** (sensitivity 88%, specificity 96%); immunoelectron microscopy is more reliable than routine immunohistochemistry (commercial antibodies may mistype).
- ▶ **Plasma-cell / light-chain workup:**
 - SPEP/UPEP are poor screening tests in AL (an M-spike is often absent). >90% have monoclonal light chain/immunoglobulin detectable by serum/urine immunofixation (SIFE/UIFE) or by serum free light-chain (FLC) nephelometry.
 - Assess both the κ : λ FLC ratio AND the absolute FLC level — renal insufficiency reduces clearance and non-specifically raises both isotypes.
 - Bone marrow shows clonal plasma cells (typically 5–30% of nucleated cells in ~90%); demonstrate κ or λ restriction by flow cytometry, immunohistochemistry, or *in situ* hybridization.
- ▶ A monoclonal protein alone is **not** diagnostic (MGUS is common in the elderly) — but in biopsy-proven amyloid, AL must be **actively excluded/confirmed**.

Staging & prognosis

- ▶ **Mayo 2004 cardiac stage** — based on NT-proBNP and cardiac troponin (European modification identifies very-high-risk patients); most widely used.
- ▶ **Mayo 2012 stage** — adds dFLC (difference between involved and uninvolved circulating free light chains) as an independent survival predictor; dFLC <50 mg/L confers a better outcome regardless of cardiac stage.
- ▶ **Boston University stage** — incorporates BNP and troponin I.
- ▶ A validated **renal staging system** (24-h urine protein + eGFR) predicts progression to dialysis at 2 years.
- ▶ **High-risk patients** (~15–20%): advanced cardiac stage IIIb or severe heart failure (NYHA III–IV).

Treatment

Therapy targets the **clonal plasma cells** (myeloma-style regimens) to abolish the amyloidogenic light chain; **organ-function recovery lags 6–12 months** behind hematologic response.

- ▶ **High-dose IV melphalan + autologous stem-cell transplant (HDM/SCT)** — complete hematologic response in ~40%; durable remissions (sometimes >15 years). Only ~20–30% are eligible (cardiac stage, performance status limit candidacy).

- ▶ Transplant-ineligible (standard): FDA-approved CyBorD (cyclophosphamide + bortezomib + dexamethasone) plus daratumumab (anti-CD38).
- ▶ Bortezomib + melphalan-dexamethasone (MDex) can overcome the adverse genetics of gain of 1q21 and t(11;14).
- ▶ If bortezomib is contraindicated (pre-existing peripheral neuropathy): MDex or immunomodulatory drugs (lenalidomide, pomalidomide).
- ▶ Novel antifibril monoclonal antibodies are in trials, combined with anti-plasma-cell therapy.
- ▶ Localized AL: surgical excision or low-dose radiotherapy (~20 Gy); systemic chemotherapy is *not* appropriate.
- ▶ Supportive care:
 - *Nephrotic syndrome*: diuretics, support stockings, albumin infusion to aid diuresis; ACE inhibitors with caution (no proven renal benefit).
 - *Cardiac*: diuretics are mainstay; **digoxin, calcium-channel blockers and β -blockers are relatively contraindicated** (bind amyloid fibrils $\rightarrow$ heart block, worsening failure). Amiodarone for arrhythmia; **atrial ablation** for AF; **ventricular pacing** for conduction block; AICDs are less effective (thickened myocardium); consider **anticoagulation even without AF** (atrial thrombi).
 - *Autonomic*: **midodrine** (α -agonist) for orthostatic hypotension; motility/bulk agents for GI dysmotility; nutritional support.
- ▶ **Prognosis**: untreated median survival historically only ~1–2 years; markedly improved over four decades with modern therapy and earlier diagnosis.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Pathogenesis flow diagram**: *Clonal plasma cells $\rightarrow$ monoclonal λ/κ light chain $\rightarrow$ misfolding $\rightarrow$ oligomers (toxic) $\rightarrow$ β -pleated-sheet fibrils $\rightarrow$ tissue deposition*. Labels: Clonal plasma cell, Free light chain, Misfolded monomer, Toxic oligomer, Amyloid fibril (β -sheet), Tissue deposit (heart/kidney/nerve), Serum amyloid P component.
- ▶ **Clinical signs sketch** (face/hand): label Macroglossia, Periorbital “raccoon-eye” ecchymoses, Nail dystrophy — alongside ECG strip showing low-voltage + pseudo-infarct pattern.

Clinical / Diagnostic significance

- ▶ Suspect AL in any patient with **unexplained nephrotic-range proteinuria**, “hypertrophic” cardiomyopathy with low ECG voltage, peripheral/autonomic neuropathy, hepatomegaly, or macroglossia — especially when **multiple** systems are involved.
- ▶ Fat-pad aspirate + Congo red + mass-spectrometry typing + serum FLC + bone marrow is the practical diagnostic quartet.

- ▶ Cardiac biomarkers (NT-proBNP, troponin) and dFLC drive staging, prognosis and monitoring — remember renal failure falsely elevates them.
- ▶ An acquired factor X deficiency explains the bleeding/bruising and must be checked before biopsy.

High-yield exam pointers

- ▶ AL = monoclonal light chain, formerly *primary systemic amyloidosis*; $\lambda > \kappa$, fibril = 23-kDa light chain.
- ▶ Congo red → apple-green birefringence; abdominal fat-pad aspirate positive in >80%.
- ▶ Kidney 60–70%, Heart 70–80% (commonest cause of death).
- ▶ Macroglossia and periorbital “raccoon-eye” ecchymoses = pathognomonic signs.
- ▶ ECG low voltage + pseudo-infarct; echo with concentric thickening + abnormal global longitudinal strain.
- ▶ Mass spectrometry typing is the gold standard (88%/96%); SPEP/UPEP unreliable — use FLC + SIFE/UIFE.
- ▶ Staging: Mayo 2004/2012 (NT-proBNP, troponin, dFLC); dFLC <50 mg/L = better outcome.
- ▶ Treatment: HDM/SCT (eligible ~20–30%) or CyBorD + daratumumab; β -blockers, CCBs, digoxin relatively contraindicated in cardiac amyloid.

SOURCE & COVERAGE

Harrison’s Principles of Internal Medicine, 22e — Ch 117 “Amyloidosis” (Berk & Sanchorawala); cross-reference Ch 116 “Plasma Cell Disorders” (light-chain physiology, λ amyloidogenicity, free light-chain ratio). Coverage note: the topic is fully supported by the provided chapters; specific Mayo/BU staging cut-off values (exact NT-proBNP/troponin thresholds, Roman-numeral substages) are referenced by name in Harrison but the numeric thresholds are not tabulated in the provided text, so only the named systems and the dFLC <50 mg/L threshold are stated here.

Management of Multiple Myeloma

Asked in: Paper IV Jun 2024 — RGUHS MD General Medicine

Definition / Introduction — Multiple myeloma (MM) is a malignant proliferation of a single clone of plasma cells derived from the late B-lymphocyte lineage, characterised by clonal bone-marrow plasmacytosis, a serum and/or urine monoclonal (M) protein, and myeloma-defining end-organ damage (CRAB — hyperCalcaemia, Renal insufficiency, Anaemia, Bone lesions). It is incurable but highly treatable: with modern triplet/quadruplet induction, autologous transplantation and continuous maintenance, median overall survival now exceeds 8 years. Management is risk-adapted and rests on

three pillars — accurate diagnosis/staging, sequential anti-myeloma therapy, and vigorous supportive care.

Diagnosis, staging and risk stratification (the basis for treatment)

- **Diagnosis (IMWG):** clonal bone-marrow plasma cells $\geq 10\%$ (or biopsy-proven plasmacytoma) plus ≥ 1 myeloma-defining event — either CRAB features or a SLiM biomarker of malignancy: clonal marrow plasma cells $\geq 60\%$, involved:uninvolved serum **free light chain (FLC) ratio** ≥ 100 , or **>1 focal lesion on MRI** (each ≥ 5 mm).
- **CRAB thresholds:** Calcium >11 mg/dL (or >1 mg/dL above normal); creatinine >2 mg/dL or creatinine clearance <40 mL/min; haemoglobin <10 g/dL (or >2 g/dL below normal); ≥ 1 osteolytic lesion on skeletal survey, CT or PET-CT.
- **Distinguish from precursors:** MGUS (M-protein <30 g/L, marrow PCs $<10\%$, no MDE) and *smoldering MM* (M-protein ≥ 30 g/L and/or marrow PCs 10–60%, no MDE) — these are **observed, not treated** (except high-risk SMM, see below).
- **Workup:** SPEP + immunofixation, serum FLC and quantitative immunoglobulins, 24-h urine for Bence Jones protein; marrow aspirate/biopsy with κ/λ clonality (CD138⁺); FISH/DNA-sequencing; $\beta 2$ -microglobulin, albumin, LDH; whole-body low-dose CT / PET-CT or MRI (radionuclide bone scan is **not** useful — lesions are purely lytic).

System	Parameters	Strata
ISS	$\beta 2$ -microglobulin + albumin	I: $\beta 2M <3.5$ + alb ≥ 3.5 (median ~62 mo); II: intermediate (~44 mo); III: $\beta 2M >5.5$ (~29 mo)
R-ISS	ISS + high-risk cytogenetics + LDH	I: ISS-I, normal LDH, no high-risk FISH; III: ISS-III with high-risk FISH or high LDH; II: rest
High-risk FISH	—	t(4;14), t(14;16), t(14;20), del(17p)/TP53, gain/amp 1q, del 1p
Standard-risk FISH	—	t(11;14), t(6;14), hyperdiploidy; del(13q) & t(11;14) are NOT high-risk

- **mSMART/Mayo:** “double-hit” = any 2 high-risk lesions, “triple-hit” = ≥ 3 — confer the worst prognosis (median OS ~3 yr vs >7 –10 yr for standard risk).

Goals and overall framework of therapy

- Two parallel aims: (1) **systemic anti-myeloma therapy** to achieve the deepest possible response, and (2) **supportive care** for complications and treatment toxicity.

- ▶ Therapy is sequenced as **induction** → **high-dose therapy/ASCT (consolidation)** → **maintenance** → **therapy of relapse**, partitioned by **transplant eligibility** (age, performance status, comorbidity).
- ▶ The three backbone drug classes for newly diagnosed MM are **immunomodulatory drugs (IMiDs)**, **proteasome inhibitors (PIs)** and **anti-CD38 monoclonal antibodies**, almost always combined with **dexamethasone**.

Class	Representative agents (dose)	Key toxicity
IMiD	Lenalidomide (5–25 mg PO × 21/28 d); thalidomide; pomalidomide (2–4 mg)	VTE, cytopenias, neuropathy (thalidomide), teratogenicity
Proteasome inhibitor	Bortezomib (1.3 mg/m ² SC d1,4,8,11); carfilzomib (20–56 mg/m ²); ixazomib (4 mg PO, oral)	Bortezomib → peripheral neuropathy, HZV reactivation; carfilzomib → cardiac/pulmonary
Anti-CD38 mAb	Daratumumab (16 mg/kg IV or SC); isatuximab (10 mg/kg)	Infusion reactions, infection
Other antibody/ADC	Elotuzumab (anti-SLAMF7); belantamab mafodotin (anti-BCMA ADC)	Belantamab → keratopathy (ocular)
Alkylator / steroid	Melphalan (high-dose conditioning); cyclophosphamide; dexamethasone 40 mg/wk	Marrow toxicity, secondary MDS/leukaemia

Front-line therapy

- ▶ **Smoldering MM**: generally observed; **high-risk SMM** — early **lenalidomide ± dexamethasone** delays progression to active disease and may prolong survival.
- ▶ **Transplant-ELIGIBLE (newly diagnosed)**:
 - **Induction**: a PI + IMiD + dexamethasone triplet — **VRd** (bortezomib–lenalidomide–dexamethasone) or **KRd** (carfilzomib-based) achieves ~100% overall and >50% complete response (CR); alternatives VTd, VCd. **Adding daratumumab/isatuximab as a quadruplet** (e.g. **Dara-VRd**) gives deeper responses and is now becoming standard of care. Give **4–6 cycles** to achieve maximal cytoreduction.
 - **Stem-cell collection**: harvest **within ~6 months** as prolonged lenalidomide impairs stem-cell yield.
 - **High-dose therapy + autologous SCT (ASCT)**: conditioning with **high-dose melphalan**; adds 25–40% further CRs and prolongs PFS/OS. **Tandem ASCT** benefits only patients failing

to reach $\geq$ VGPR after the first. Delayed (relapse) transplant is an acceptable alternative as upfront ASCT showed no OS difference vs delayed in a randomised trial.

- **Maintenance: lenalidomide** (continuous) prolongs PFS and OS — small increased risk of second primary malignancy is outweighed by benefit. **Add bortezomib or ixazomib (a PI)** for high-risk cytogenetics; **daratumumab** maintenance is also beneficial.
- ▶ **Transplant-INELIGIBLE (age >70, significant cardiopulmonary disease, comorbidity):** the same triplets with frailty-adjusted dosing — **DRd** (daratumumab–lenalidomide–dexamethasone, ORR ~93%) or **RVD-lite** (ORR ~86%); fit older patients may receive quadruplets. Older melphalan-prednisone (MP)-based regimens (MPT, VMP) are now largely superseded but retain a role where novel agents are unavailable.

Relapsed / refractory disease and immunotherapy

- ▶ Treatment of relapse uses **alternate combinations** incorporating agents not previously used or to which the patient is not refractory.
- ▶ **Salvage agents:** carfilzomib and pomalidomide (active even in lenalidomide/bortezomib-refractory disease); all-oral **IRd** (ixazomib-Rd); anti-CD38 **daratumumab/isatuximab** combinations; **elotuzumab** + Rd; **belantamab mafodotin** (BCMA ADC — needs ophthalmologic monitoring); **selinexor** (first-in-class XPO1/exportin nuclear-export inhibitor); **panobinostat** (HDAC inhibitor) + bortezomib-dexamethasone; melflufen.
- ▶ **BCMA-directed cellular therapy (CAR-T):** **idecabtagene vicleucel (Ide-cel)** — after ≥ 2 prior lines (IMiD + PI + anti-CD38); **ciltacabtagene autoleucel (Cilta-cel)** — after ≥ 1 prior line and lenalidomide-refractory; response rates ~81–98% with high CR rates.
- ▶ **Bispecific T-cell engagers** (after ≥ 4 prior lines): **teclistamab** and **elranatamab** (anti-BCMA $\times$ CD3); **talquetamab** (anti-GPRC5D $\times$ CD3); ORR ~60–70%.
- ▶ **Class toxicities of immunotherapy:** cytokine-release syndrome, neurotoxicity (ICANS), and prolonged hypogammaglobulinaemia/infection — may need IVIG support.

Supportive and adjunctive care (often as important as anti-tumour therapy)

- ▶ **Bone disease:** monthly **bisphosphonate** — zoledronate 4 mg or pamidronate 90 mg (12–24 months) — reduces skeletal events; **denosumab 120 mg SC monthly** is the alternative (preferred in renal impairment). Watch for **osteonecrosis of the jaw**. **Vertebroplasty/kyphoplasty** for painful vertebral collapse; **local radiotherapy** (~40 Gy) for focal painful lesions and solitary plasmacytomas.
- ▶ **Renal protection:** hydration, avoid NSAIDs/iodinated contrast/nephrotoxins; treat hypercalcaemia and hyperuricaemia; rapid M-protein reduction with **bortezomib-based therapy** can recover renal function; **plasma exchange** considered for cast nephropathy/light-chain-induced AKI.

- ▶ **Hypercalcaemia:** hydration + natriuresis, bisphosphonates, glucocorticoids ($\pm$ calcitonin).
- ▶ **Hyperviscosity:** plasmapheresis.
- ▶ **Infection prophylaxis:** pneumococcal (conjugate) and influenza vaccination; **herpes-zoster prophylaxis** with bortezomib or anti-CD38 therapy; **IVIG** for recurrent serious infection or post CAR-T/bispecific hypogammaglobulinaemia.
- ▶ **VTE prophylaxis** with IMiDs: **aspirin** (low risk) or **LMWH/warfarin/DOAC** (high risk).
- ▶ **Anaemia:** erythropoietin with haematinics.

Response assessment (IMWG)

- ▶ Hierarchy of depth: **MRD-negative** > **stringent CR (sCR)** > **CR** > **VGPR** > **PR** > **minor response** > **stable** > **progressive disease**.
- ▶ **CR** = negative serum/urine immunofixation, no soft-tissue plasmacytoma, marrow plasma cells <5%; **sCR** adds normal FLC ratio and absence of clonal plasma cells; **VGPR** = M-protein detectable by immunofixation but not electrophoresis, or $\geq 90\%$ serum reduction.
- ▶ **MRD** by next-generation flow/sequencing at 10^{-5} **sensitivity** is the deepest endpoint and predicts longer PFS and OS.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Risk-adapted treatment algorithm of MM** — boxes/arrows: *Newly diagnosed MM* $\rightarrow$ assess MDE $\rightarrow$ (Smoldering $\rightarrow$ observe / high-risk SMM $\rightarrow$ Len $\pm$ Dex) and (Symptomatic $\rightarrow$ split by Transplant-eligible vs ineligible) $\rightarrow$ **Induction (triplet/quadruplet)** $\rightarrow$ eligible arm: **HDT + autologous SCT** $\rightarrow$ **consolidation** $\rightarrow$ both arms: **Maintenance (lenalidomide $\pm$ PI)** $\rightarrow$ **Relapse** $\rightarrow$ **alternate regimens** $\rightarrow$ **CAR-T / bispecifics**. Label drug classes IMiD/PI/anti-CD38.
- ▶ **Pathophysiology / CRAB wheel** — central *clonal plasma cell* with spokes labelled: **RANKL $\uparrow$ /OPG $\downarrow$** $\rightarrow$ osteoclast activation $\rightarrow$ lytic bone lesions & hyperCalcaemia; **light chains** $\rightarrow$ cast nephropathy/Renal failure; **marrow infiltration** $\rightarrow$ Anaemia; **immunoparesis** $\rightarrow$ infection; **M-protein** $\rightarrow$ hyperviscosity/amyloid.

Clinical / Diagnostic significance

- ▶ The **serum M-component** is the **best tumour marker** for monitoring; serum/urine FLC fall faster ($t_{1/2} \sim 6$ h) than intact Ig ($t_{1/2} \sim 3$ wk) and track tumour kill earlier.
- ▶ Recognise **myeloma emergencies**: spinal cord compression, pathological fracture, hypercalcaemia, hyperviscosity, sepsis and AKI — each alters immediate management priorities.
- ▶ Cytogenetics (FISH/sequencing) drive both **prognosis (R-ISS)** and **treatment intensity** (add a PI to maintenance in high-risk disease).

- ▶ Achieving and sustaining **MRD negativity** is the emerging therapeutic goal and a powerful surrogate for survival.

High-yield exam pointers

- ▶ **Diagnosis** = $\geq 10\%$ clonal marrow PCs + M-protein + ≥ 1 MDE (CRAB or SLiM biomarker).
- ▶ **SLiM**: Sixty% PCs, Light-chain ratio ≥ 100 , MRI > 1 focal lesion.
- ▶ **R-ISS** = ISS ($\beta 2M$ + albumin) + **high-risk cytogenetics** + LDH.
- ▶ **High-risk FISH**: $t(4;14)$, $t(14;16)$, $t(14;20)$, $del(17p)$, 1q gain — *$t(11;14)$ and $del(13q)$ are standard-risk.*
- ▶ **Backbone classes**: IMiD + PI + anti-CD38 + dexamethasone; quadruplet (Dara-VRd) is the modern standard induction.
- ▶ **ASCT conditioning** = **high-dose melphalan**; lenalidomide is standard **maintenance**.
- ▶ **BCMA targets**: CAR-T (Ide-cel, Cilta-cel) and bispecifics (teclistamab, elranatamab); talquetamab targets GPRC5D.
- ▶ **Bone disease**: monthly zoledronate/pamidronate or denosumab; beware osteonecrosis of jaw.
- ▶ IMiD $\rightarrow$ **mandatory VTE prophylaxis**; bortezomib $\rightarrow$ **HZV prophylaxis** + **give SC/weekly** to cut neuropathy.
- ▶ Median OS now > 8 years; **MRD negativity (10^{-5})** = deepest response.

Microangiopathic Haemolytic Anaemia (MAHA)

Asked in: Paper IV Nov 2021 — RGUHS MD General Medicine

Definition / Introduction — Microangiopathic haemolytic anaemia (MAHA) is a form of acquired, predominantly **intravascular haemolysis** caused by **mechanical fragmentation of red cells** as they are sheared in a microvasculature distorted by platelet/fibrin microthrombi, abnormal endothelium or turbulent flow. It is defined by the combination of **thrombocytopenia** and **fragmented RBCs (schistocytes)** on the peripheral smear with laboratory evidence of haemolysis (raised LDH and

unconjugated bilirubin, low/absent haptoglobin) and microvascular thrombosis. The thrombotic microangiopathies — **thrombotic thrombocytopenic purpura (TTP)** and **haemolytic-uraemic syndrome (HUS)** — are the prototype causes; disseminated intravascular coagulation (DIC), malignant hypertension, pregnancy syndromes, prosthetic-valve haemolysis, drugs and vasculitis also produce a microangiopathic picture.

Pathophysiology — why red cells fragment

- ▶ Red cells normally survive ~120 days and are remarkably deformable, squeezing through capillaries narrower than themselves thousands of times. MAHA occurs when they **succumb to shear stress** in an abnormal microcirculation, producing intravascular haemolysis and haemoglobinuria.
- ▶ **Mechanical trauma** to the cell membrane generates **schistocytes** (helmet cells, fragmented RBCs) and microspherocytes; the freed haemoglobin saturates haptoglobin and spills into urine (haemoglobinuria ± haemosiderinuria).
- ▶ In the thrombotic microangiopathies, **platelet-rich microthrombi** deposited in arterioles/capillaries create the fibrin/platelet strands against which circulating RBCs are lacerated, simultaneously **consuming platelets** (hence thrombocytopenia).
- ▶ **TTP mechanism:** the plasma metalloprotease **ADAMTS13** normally cleaves the ultra-large von Willebrand factor (VWF) multimers secreted by endothelium into smaller multimers. Deficiency of, or **antibodies to, ADAMTS13** allow ultra-large VWF multimers to persist, driving pathological platelet adhesion and aggregation and widespread microvascular thrombosis. **ADAMTS13 activity <10% is diagnostic of TTP.** (ADAMTS13 deficiency alone is insufficient — congenital deficiency causes disease only episodically, e.g., a first pregnancy — so a trigger is required.)
- ▶ **HUS mechanism:** endothelial injury — by **Shiga toxin** (*E. coli* O157:H7) in typical/diarrhoea-associated HUS, or by **uncontrolled complement alternative-pathway activation** in atypical HUS (aHUS) — initiates the microangiopathy, with the kidney bearing the brunt.
- ▶ **Common pathophysiologic theme:** increased red-cell turnover. Chronic intravascular haemolysis causes urinary iron loss (and may need iron replacement), whereas recurrent haemolysis raises folate demand and bilirubin (pigment gallstones).

Classification / Causes of MAHA

- ▶ In Harrison's classification of haemolytic anaemias, MAHA falls under **acquired, extracorporeal** causes — “**Mechanical destruction (microangiopathic)**” — alongside toxic agents, drugs, infection and autoimmune mechanisms (the lone inherited extracorporeal exception being familial/atypical HUS).

Category	Representative causes
Primary thrombotic microangiopathies	TTP (ADAMTS13 deficiency/inhibitor); HUS (Shiga toxin); atypical HUS (complement dysregulation)
Pregnancy-associated	HELLP syndrome, pre-eclampsia/eclampsia; pregnancy may unmask TTP
Drug-induced	Antibody-mediated: ticlopidine (possibly clopidogrel). Direct endothelial toxicity: cyclosporine, tacrolimus, gemcitabine, mitomycin C
Infection	Shiga-toxin <i>E. coli</i> O157:H7; systemic sepsis (often with DIC); HIV
Consumptive coagulopathy	Disseminated intravascular coagulation (DIC)
Mechanical / cardiac	Prosthetic (especially leaky/paraprosthetic-regurgitant) heart valves; cardiac haemangioma
Transplant / systemic	Haematopoietic stem-cell (bone-marrow) transplantation; vasculitis; (malignant hypertension, disseminated malignancy — standard textbook additions)

Peripheral smear and laboratory diagnosis

- ▶ **Peripheral blood smear is the cornerstone:** schistocytes/fragmented RBCs + thrombocytopenia define MAHA (Fig. 120-1D). Polychromasia, macrocytosis and occasional nucleated RBCs reflect the brisk reticulocyte response.
- ▶ **Haemolysis markers** (largely intravascular pattern):

Parameter	Finding in MAHA
Haemoglobin	Reduced (may fall acutely)
Reticulocytes / MCV	Increased
Peripheral smear	Schistocytes , helmet cells, low platelets
Bilirubin	Increased, mostly unconjugated
LDH	Markedly increased (up to ~10× normal with intravascular haemolysis)
Haptoglobin	Reduced to absent
Urine	Haemoglobinuria ± haemosiderinuria
Direct antiglobulin (Coombs) test	Negative (mechanical, not immune — key distinguishing point)

Parameter	Finding in MAHA
Platelet count	Low (consumption)

- **Distinguishing MAHA mechanism by coagulation profile:** in DIC, although thrombocytopenia and microangiopathy occur, a **coagulopathy predominates** — consumption of clotting factors and fibrinogen prolongs the PT and often the aPTT. By contrast, PT and aPTT are **characteristically normal in TTP and HUS**. This single distinction is high-yield.
- A complete diagnostic panel in suspected TTP/MAHA: CBC with platelet count and smear, ADAMTS13 activity ($\pm$ inhibitor assay), LDH, bilirubin, haptoglobin, PT/aPTT/fibrinogen, direct antiglobulin test and renal function.

Differentiating TTP vs HUS vs DIC

Feature	TTP	HUS (typical)	DIC
Core defect	ADAMTS13 deficiency / inhibitor $\rightarrow$ ultra-large VWF	Shiga-toxin (E. coli O157:H7) endothelial injury	Systemic coagulation activation
Classic age/setting	Adults; women > men; HIV, pregnancy	Children; preceded by (often bloody) diarrhoea	Sepsis, malignancy, obstetric catastrophe
Predominant organ	CNS (neurologic findings)	Kidney (acute renal failure)	Multi-organ
Renal failure	Variable	Prominent	Variable
PT / aPTT	Normal	Normal	Prolonged
Fibrinogen	Normal	Normal	Low (consumed)
ADAMTS13	<10% (diagnostic)	Generally normal	Normal
First-line therapy	Therapeutic plasma exchange	Supportive ($\pm$ dialysis)	Treat cause; replace factors

- The classic TTP “pentad” (first described by *Eli Moschcowitz, 1924*): **microangiopathic haemolytic anaemia, thrombocytopenia, renal failure, neurologic findings and fever**. The full pentad is now seen less often because of earlier diagnosis — do not wait for all five before treating.

Specific syndromes and management

- TTP — a medical emergency. Inherited TTP is *Upshaw-Schulman syndrome*; idiopathic TTP (more common in women, and in HIV/pregnancy) is autoantibody-mediated against ADAMTS13.

- **Therapeutic plasma exchange (TPE)** is the mainstay — it transformed mortality from 85–100% down to 10–30%. Continue TPE until the platelet count normalises and signs of haemolysis resolve for at least **2 days**.
- **Glucocorticoids** are a reasonable adjunct to TPE. **Rituximab** added to initial therapy reduces relapse. **Caplacizumab** (anti-VWF nanobody) reduces mortality and care burden in patients with ADAMTS13 <10% or high clinical probability. ISTH guidance: start caplacizumab and rituximab in those with diagnostic ADAMTS13 (usually <10%), and rituximab additionally where an inhibitor is demonstrated.
- **Relapse** is significant: 25–45% within 30 days of remission and 12–40% late relapses, more frequent with severe ADAMTS13 deficiency. Treat suspected relapse **before** confirmatory assays return.
- ▶ **HUS**. Triad of acute renal failure, MAHA and thrombocytopenia, typically following haemorrhagic diarrhoea in children (*E. coli* O157:H7). Treatment is **primarily supportive**; ~40% of diarrhoea-associated cases need dialysis but overall mortality is <5%. Non-diarrhoeal HUS carries higher mortality (~26%). Plasma infusion/exchange has **not** been shown to alter the course of HUS/aHUS, **except** where anti-factor-H antibodies are present.
- ▶ **Atypical HUS (aHUS)**. Due to dysregulation of the **complement alternative pathway** — anti-factor-H autoantibodies in some, but mostly germline mutations in **CFH, CFI, CD46 (MCP), C3, CFB, THBD (thrombomodulin)** — inherited (autosomal dominant) with incomplete penetrance, needing a trigger (usually infection). Shiga-toxin HUS is regarded as a *phenocopy* of aHUS. The anti-C5 inhibitor **eculizumab** markedly ameliorates the microangiopathy, improving platelet counts and renal function and largely abrogating the need for plasma exchange; aHUS remains a **diagnosis of exclusion**.
- ▶ **Drug-induced MAHA**: withdrawing or reducing the endothelial-toxic agent usually settles the microangiopathy.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Diagram 1 — Peripheral blood smear in MAHA (label exactly)**: *Schistocytes (fragmented RBC) / helmet cells, microspherocyte, polychromatic macrocyte (reticulocyte), nucleated RBC, markedly reduced platelets*. Caption: “Schistocytes + thrombocytopenia = MAHA.”
- ▶ **Diagram 2 — Pathogenesis of TTP (Fig. 120-4 style; label exactly)**: *Endothelial cell, ultra-large VWF multimers, ADAMTS13 (cleaving protease), normal multimers (protease present) vs ultra-large multimers (no protease → TTP), platelet aggregation / microthrombus, sheared/fragmented red cell*.

Clinical / Diagnostic significance

- ▶ The triad **schistocytes + thrombocytopenia + negative Coombs** in a patient with haemolysis (high LDH, low haptoglobin, unconjugated hyperbilirubinaemia) mandates urgent evaluation for a thrombotic microangiopathy.
- ▶ **PT/aPTT** rapidly separate TTP/HUS (normal) from DIC (prolonged, low fibrinogen) — order them early.
- ▶ **ADAMTS13 <10%** confirms TTP and predicts relapse risk; send the sample **before** starting plasma exchange but **do not delay TPE** awaiting the result.
- ▶ Recognise **secondary settings**: malignant hypertension, HELLP/pre-eclampsia, prosthetic-valve dysfunction, sepsis-DIC and drugs — management is of the cause, not blind plasma exchange.
- ▶ Eculizumab has reframed aHUS therapy; correctly distinguishing aHUS from TTP and Shiga-toxin HUS changes treatment entirely (complement blockade vs TPE vs supportive care).

High-yield exam pointers

- ▶ **MAHA = mechanical, intravascular haemolysis** → schistocytes + thrombocytopenia + raised LDH + low haptoglobin + **negative direct Coombs**.
- ▶ **TTP pentad (Moschcowitz, 1924)**: MAHA, thrombocytopenia, renal failure, neurologic signs, fever — treat before the pentad is complete.
- ▶ **ADAMTS13 <10% is diagnostic of TTP**; inherited form = **Upshaw-Schulman syndrome**.
- ▶ **TTP: TPE is life-saving** (mortality 85–100% → 10–30%); adjuncts rituximab, caplacizumab, steroids.
- ▶ **HUS**: children, bloody diarrhoea, **E. coli O157:H7**, kidney-predominant; treatment mainly supportive, mortality <5%.
- ▶ **aHUS**: complement alternative-pathway mutations (CFH, CFI, CD46, C3, CFB, THBD) → **eculizumab**.
- ▶ **DIC vs TTP/HUS**: PT/aPTT **prolonged in DIC, normal in TTP/HUS**; fibrinogen low in DIC.
- ▶ Drug culprits: **ticlopidine** (immune); **gemcitabine, mitomycin C, cyclosporine, tacrolimus** (endothelial toxicity).

SOURCE & COVERAGE

Harrison's Principles of Internal Medicine, 22e (2025) — Ch 120 "Disorders of Platelets and Vessel Wall" (TTP/HUS/aHUS, MAHA definition, ADAMTS13–VWF pathogenesis, treatment) and Ch 105 "Hemolytic Anemias" (classification, mechanical/microangiopathic destruction, intravascular-haemolysis laboratory features, familial/atypical HUS complement genes). Coverage note: A few standard exam additions not explicitly named as MAHA causes in the provided chapters — HELLP/pre-eclampsia, malignant hypertension, disseminated malignancy and the universally taught point that the **direct Coombs test is negative** in MAHA — are included

as accepted textbook internal medicine; all eponyms, drug names, gene names and numerical values are grounded in the two chapters above.

Myelodysplastic Syndromes

Asked in: Paper I Sep 2025 — RGUHS MD General Medicine

Definition / Introduction — The myelodysplastic syndromes (MDS) are a heterogeneous group of acquired clonal haematopoietic stem-cell neoplasms defined by two hallmarks: (1) peripheral cytopenias due to ineffective, dysplastic haematopoiesis (a bone-marrow failure phenotype), and (2) a variable but substantial risk of progression to acute myeloid leukaemia (AML). The marrow is typically normo- or hypercellular (hypocellular in ~20%) yet produces too few mature cells, and the disease is characterised by morphological dysplasia plus recurrent cytogenetic and somatic-mutational abnormalities. MDS is fundamentally a disease of the elderly arising from age-related genomic instability.

Epidemiology and Aetiology

- **Disease of older adults:** mean age at onset >70 years, slight male predominance; incidence 35 to >100 per million in the general population and 120 to >500 per million in older adults (~30,000–40,000 new US cases/year). Overall 5-year survival is poor (~30%).
- **Rare in children/young adults** — when MDS occurs before age 40 it is frequently constitutional/germline, mandating predisposition gene screening.

Aetiological category	Key features
Primary (de novo)	Most cases; no identifiable exposure or antecedent haematologic disease
Therapy-related (t-MDS)	Alkylating agents (busulfan, melphalan, chlorambucil, nitrosourea, procarbazine) — 5–7 yr latency, complex karyotype/–5/–7; topoisomerase-II inhibitors — ~2 yr latency, 11q23 (MLL) lesions. Age-independent, very poor prognosis
Environmental	Ionising radiation (atomic-bomb survivors), benzene, tobacco smoking, pesticides
Germline predisposition	GATA2 deficiency (MonoMAC), familial RUNX1 (familial platelet disorder), DDX41, SAMD9/SAMD9L (MIRAGE/ataxia-pancytopenia), ETV6, ANKRD26; inherited marrow-failure syndromes — Fanconi anaemia, telomere biology disorders (dyskeratosis congenita), Shwachman-Diamond

Aetiological category	Key features
Evolution	Acquired aplastic anaemia and other marrow-failure states may transform to MDS

Pathophysiology and Molecular Genetics

- ▶ MDS is a **clonal stem-cell disorder** with disordered proliferation, impaired differentiation and aberrant maturation, producing **ineffective haematopoiesis** — cytopenias despite a cellular marrow (intramedullary apoptosis).
- ▶ **Cytogenetic abnormalities** in ~50% of patients; non-random and aneuploidy (loss/gain) predominates over translocations — **del(5q)**, **-7/del(7q)**, **del(20q)**, **trisomy 8**; type and number of lesions strongly predict leukaemic transformation and survival.
- ▶ **Somatic mutations** are detectable in **80–90%** across ~100 recurrently mutated myeloid genes, grouped by function:

Functional class	Genes (frequency)	Prognostic note
Spliceosome (commonest)	SF3B1 (20–25%; up to 80% of ring-sideroblast cases), SRSF2 (~20–30% MDS, ~55% CMML), U2AF1, ZRSR2	SF3B1 favourable; SRSF2/U2AF1 adverse
DNA methylation / epigenetic	TET2 (~30%), DNMT3A (R882), IDH1/IDH2 (→ 2-hydroxyglutarate oncometabolite)	EZH2/ASXL1 adverse
Chromatin / transcription factors	ASXL1 (20–25%), EZH2 (~10%), RUNX1, ETV6	EZH2, RUNX1, ASXL1 adverse
Tumour suppressor	TP53 (17p13.1)	Biallelic/"multi-hit" = complex karyotype, very poor
Signal transduction	FLT3, NRAS, KRAS, CBL	Drive secondary-AML transformation
Cohesin	STAG2	Adverse

- ▶ **Genotype–phenotype links:** *SF3B1* → ring sideroblasts; *del(5q)* → heterozygous ribosomal-protein loss mimicking red-cell aplasia. Distinguish **clonal haematopoiesis of indeterminate potential (CHIP)** (mutation without cytopenia/dysplasia, ~10% of those ≥70 yr) and **CCUS** (clonal cytopenia of undetermined significance) from frank MDS.

Clinical Features and Laboratory Diagnosis

- ▶ **Anaemia** dominates the early course (fatigue, dyspnoea, pallor); ~50% are asymptomatic, diagnosed incidentally on a blood count. Bleeding (thrombocytopenia *and* platelet dysfunction; ~50% have a bleeding event) and **infection** (neutropenia + impaired neutrophil function; ~40%

of deaths, mostly pneumonia) occur. **Splenomegaly** in ~20%. Fever/weight loss favour a myeloproliferative process.

- ▶ **Autoimmune/inflammatory associations** (e.g. *Sweet's syndrome*); MDS with inflammation should prompt consideration of **VEXAS syndrome** (somatic *UBA1* mutation; cytoplasmic vacuoles in myeloid/erythroid precursors).
- ▶ **Peripheral blood**: macrocytic anaemia with **macro-ovalocytes**, reticulocytopenia; **pseudo-Pelger-Huët** neutrophils (hypogranular, hyposegmented, Döhle bodies); large hypogranular platelets; circulating blasts mirror marrow blast count.
- ▶ **Bone marrow** (hyper- or normocellular; hypocellular in ~20%): **dyserythroidopoiesis** (nuclear budding/multinuclearity, megaloblastoid change, **ring sideroblasts** on Prussian-blue), **dysgranulopoiesis** (hypogranular/hyposegmented), **dysmegakaryopoiesis** (**micromegakaryocytes**, dwarf megakaryocytes with unilobed nuclei) — megakaryocyte changes are the most reliable. Blast percentage is enumerated manually and by flow cytometry; cytogenetics/FISH and an NGS myeloid panel are integral.
- ▶ **Diagnostic criteria**: persistent unexplained cytopenia(s) **plus** dysplasia in ≥10% of cells in ≥1 myeloid lineage, **or** an MDS-defining cytogenetic lesion, **or** **5–19% blasts**. Ring-sideroblast threshold is ≥15% (or ≥5% if *SF3B1* mutated). Exclude **B12/folate/copper deficiency**, HIV/parvovirus B19, alcohol, drugs and copper depletion.

Classification

- ▶ **FAB (1983)** — five subtypes: refractory anaemia (RA), RA with ring sideroblasts (RARS), RA with excess blasts (RAEB), RAEB in transformation (RAEB-t), and chronic myelomonocytic leukaemia (CMML). WHO later moved RAEB-t into AML and reclassified CMML as an **MDS/MPN-overlap (myeloproliferative)** neoplasm (monocytosis >1000/μL).
- ▶ Two current schemes — **WHO 5th edition (2022)** and the **International Consensus Classification (ICC 2022)** — both integrate morphology, cytopenias, blast %, cytogenetics and molecular data; **≥20% marrow/blood blasts separates AML from MDS** (ICC adds an MDS/AML category at 10–19% blasts, emphasising the continuum).

WHO 2022 category	Blasts / defining feature
MDS with isolated del(5q)	<5% BM, <2% PB; del(5q) alone or +1 other (not -7/7q)
MDS with <i>SF3B1</i> mutation	<5% BM, <2% PB; ≥15% ring sideroblasts may substitute
MDS with biallelic TP53 inactivation	<20% blasts; usually complex karyotype
MDS with low blasts	<5% BM, <2% PB
MDS, hypoplastic	≤25% cellularity

WHO 2022 category	Blasts / defining feature
MDS with increased blasts-1 (IB1)	5–9% BM or 2–4% PB
MDS with increased blasts-2 (IB2)	10–19% BM or 5–19% PB, or Auer rods
MDS with fibrosis	5–19% BM; 2–19% PB

Prognosis — IPSS-R / IPSS-M

- ▶ The IPSS (1997) was refined to the Revised IPSS (IPSS-R, 2012) using: marrow blast %, five cytogenetic risk subgroups (very good → very poor), and depth of each cytopenia (Hb <80 / 80–<100 / ≥100 g/L; platelets <50 / 50–100 / ≥100 ×10⁹/L; ANC <800 vs ≥800/μL).
- ▶ Five IPSS-R risk categories with median overall survival:

IPSS-R category	Median OS
Very low	8.8 years
Low	5.3 years
Intermediate	3.0 years
High	1.6 years
Very high	0.8 years

- ▶ The molecular IPSS-M (2022) adds ~2 dozen genes (notably multi-hit *TP53*) and re-stratifies ~45% of patients (mostly upstaged) — now the emerging standard. For management, patients are dichotomised into **lower-risk** (very-low/low/intermediate) vs **higher-risk** (high/very-high) disease.
- ▶ **Favourable:** isolated del(5q), *SF3B1*/ring-sideroblast disease. **Adverse:** complex karyotype, chromosome-7 lesions, *TP53*. Most patients die of **cytopenia complications** (infection, bleeding) or comorbidity rather than overt leukaemia.

Risk-adapted Treatment

Setting	Therapy
All patients (supportive)	RBC transfusion (+ iron chelation — deferasirox/deferrioxamine/deferiprone — when ferritin >2500 ng/mL or ≥20 units); platelet transfusion if <10 ×10 ⁹ /L; aggressive infection management
Lower-risk, anaemia	ESA (epoetin/darbepoetin) if serum EPO ≤500 U/L (~50% response) ± G-CSF; luspatercept (TGF-β/SMAD2-3 ligand trap) after ESA failure, esp. <i>SF3B1</i> /RS — RBC-independence ~38%; imetelstat (telomerase inhibitor) for transfusion-dependent low/int-1 with EPO >500

Setting	Therapy
Lower-risk, del(5q)	Lenalidomide 10 mg/day — 55–80% erythroid response + cytogenetic remission; watch myelosuppression and VTE (aspirin prophylaxis)
Lower-risk, hypoplastic/young	Immunosuppression — ATG ± cyclosporine; responders <60 yr, absent 5q–, HLA-DR15; TPO mimetics (eltrombopag/romiplostim) for thrombocytopenia
Higher-risk	Hypomethylating agents — azacitidine 75 mg/m ² ×7 days q28 (AZA-001: median OS 24.5 months); decitabine; oral decitabine-cedazuridine; ± venetoclax; ivosidenib (IDH1)
Curative	Allogeneic HSCT — only curative option (cure ~30–60% by risk); reduced-intensity conditioning extends eligibility to older/fit patients; aim marrow blasts <5% pre-transplant

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Dysplasia montage (peripheral smear + marrow)** — label: *pseudo-Pelger-Huët neutrophil (hypogranular, bilobed), ring sideroblast (perinuclear iron granules, Prussian blue), micromegakaryocyte / unilobed “dwarf” megakaryocyte, macro-ovalocyte, dyserythropoiesis with nuclear budding, myeloblast with Auer rod.*
- ▶ **Risk-adapted treatment algorithm (flowchart)** — MDS diagnosis → IPSS-R/IPSS-M risk → **Lower-risk:** ESA / luspatercept / lenalidomide (del5q) / IST / imetelstat → **Higher-risk:** hypomethylating agent (azacitidine) → **allogeneic HSCT** if fit.

Clinical / Diagnostic significance

- ▶ A bone-marrow aspirate **plus trephine biopsy with iron stain, cytogenetics/FISH and an NGS myeloid panel** is mandatory; megakaryocyte dysplasia and *SF3B1/TP53* status drive both classification and therapy.
- ▶ Always **exclude reversible mimics** — B12/folate/copper deficiency, HIV, alcohol, drugs — before labelling MDS; transient dysplasia is common in these.
- ▶ **Hypoplastic MDS vs aplastic anaemia:** clonal cytogenetic/molecular lesions and dysplasia favour MDS; some (del13q/del20q, *DNMT3A/ASXL1*) overlap and respond to immunosuppression.
- ▶ *TP53* multi-hit and complex karyotype predict transplant relapse; pre-HSCT cyto-reduction to <5% blasts improves outcome.

High-yield exam pointers

- ▶ MDS = **acquired clonal stem-cell neoplasm** → ineffective haematopoiesis (cytopenias with cellular marrow) + AML risk; mean age >70.

- ▶ $\geq 20\%$ blasts = AML; MDS blast range 5–19%; IB1 = 5–9%, IB2 = 10–19% (or Auer rods).
- ▶ **Commonest mutation** = SF3B1 (spliceosome) → ring sideroblasts, **good prognosis**; TP53 / complex karyotype / -7 = worst.
- ▶ **Pseudo-Pelger-Huët** neutrophils, **ring sideroblasts**, **micromegakaryocytes** — classic dysplastic triad.
- ▶ **del(5q) syndrome**: macrocytic anaemia, normal/high platelets, hypolobated megakaryocytes → **lenalidomide**; 5-yr survival $>90\%$.
- ▶ IPSS-R (blasts, cytogenetics, cytopenias) → 5 groups, median OS 8.8 to 0.8 yr; IPSS-M adds molecular data.
- ▶ Lower-risk → ESA/luspatercept/lenalidomide/IST; higher-risk → **azacitidine**; **allogeneic HSCT is the only cure**.
- ▶ Suspect **germline predisposition** (GATA2, RUNX1, DDX41) if MDS at <40 years or strong family history; consider **VEXAS** (UBA1) when MDS coexists with systemic inflammation.

SOURCE & COVERAGE

Neuroendocrine Tumors

Asked in: Paper III May 2022 · Paper IV Jul 2020 (2×) — RGUHS MD General Medicine

Definition / Introduction — Neuroendocrine tumors (NETs) are neoplasms arising from cells of the diffuse neuroendocrine system that retain the ability to synthesize and ectopically secrete peptides, growth factors and bioactive amines, giving rise to characteristic clinical syndromes. Gastrointestinal NETs are broadly grouped by site of origin as **extrapancreatic** NETs (historically called *carcinoid tumors*) or **pancreatic** NETs. They classically pursue a more indolent course than most other malignancies, though behavior ranges from benign to highly aggressive. Diagnosed incidence has risen markedly (≈ 6.4 -fold in U.S. SEER data, 1973–2012), partly reflecting improved diagnosis and classification.

Classification

NETs are categorized along three axes — anatomic site, functional status, and histologic differentiation/grade. Histologic grade (mitotic count and Ki-67 index) is the single most important determinant of behavior and treatment.

Axis		Categories		
Anatomic		Pancreatic NETs; extrapancreatic GI (“carcinoid”) — stomach, small intestine (terminal ileum), appendix, rectum; bronchial/thymic		
Functional		<i>Functional</i> (hormone-secretion symptoms) vs <i>non-functional</i> ($\approx 80\%$ of pancreatic NETs; silent or anatomic symptoms)		
Histologic (WHO/Table 89-1)		See grading table below		
Tumor	Differentiation	Grade	Mitoses /10 HPF	Ki-67
NET	Well-differentiated	Low (G1)	<2	<3%
NET	Well-differentiated	Intermediate (G2)	2–20	3–20%
NET	Well-differentiated	High (G3)	>20	>20%
Neuroendocrine carcinoma	Poorly differentiated	High (G3)	>20	>20%

- **Histology:** monotonous sheets of small round cells with uniform nuclei; immunostaining positive for **chromogranin A** and **synaptophysin**; ultrastructural electron-dense neurosecretory granules.
- **Molecular:** sporadic pancreatic NETs — *MEN1* mutated in 44%, *DAXX/ATRX* in 43%, mTOR-pathway genes in 15%. Small-intestinal NETs — recurrent *CDKN1B* (p27^{Kip1}) mutation in 8% and loss of chromosome 18.
- **Inherited syndromes (minority):** MEN 1 (*menin*, 11q13 — commonest), von Hippel–Lindau (*VHL*, 3p25), neurofibromatosis type 1 (*NF1*, von Recklinghausen), tuberous sclerosis (*TSC1* hamartin / *TSC2* tuberin).

Functional pancreatic NET syndromes

Tumor	Syndrome / features	Key marker	Symptom control
Insulinoma (commonest)	Fasting hypoglycemia — confusion, coma, weight gain	↑Fasting insulin + proinsulin + C-peptide	Diazoxide, everolimus (SSA with caution)
Glucagonoma	<i>Necrolytic migratory erythema</i> , glucose	Glucagon >1000 pg/mL	Somatostatin analogue (SSA)

Tumor	Syndrome / features	Key marker	Symptom control
	intolerance, weight loss; hypercoagulable ($\approx 33\%$)		
Gastrinoma	Zollinger-Ellison syndrome — peptic ulcers, GERD, diarrhea	Fasting hypergastrinemia	PPIs, SSA
VIPoma	Verner-Morrison / WDHA / pancreatic cholera — watery diarrhea, hypokalemia, achlorhydria	$\uparrow$ VIP (28-aa peptide)	SSA + fluid/electrolyte replacement
Somatostatinoma	Diabetes, cholelithiasis, diarrhea, steatorrhea	$\uparrow$ Plasma somatostatin	Surgery (SSA value questionable)
ACTHoma	Ectopic Cushing's — hyperglycemia, hypokalemia	$\uparrow$ ACTH/cortisol	Ketoconazole, metyrapone, $\pm$ adrenalectomy

- **Gastrinomas** mostly arise in the **gastrinoma triangle** (bounded by duodenum, pancreas and confluence of cystic and common bile ducts); 50–90% of sporadic ZES gastrinomas are duodenal; up to 25% of ZES patients have MEN 1.
- **Insulinomas** are usually <2 cm and best localized by **endoscopic ultrasound (EUS)**; enucleation is the primary surgical option. SSAs may worsen hypoglycemia by suppressing counter-regulatory hormones.

Extrapancreatic (“carcinoid”) NETs and the carcinoid syndrome

- **Gastric NETs:** *type 1* (chronic atrophic gastritis/pernicious anemia, high gastrin, multifocal, benign — commonest); *type 2* (gastrinoma/ZES); *type 3* (sporadic, normal gastrin, aggressive).
- **Small-intestinal NETs:** terminal ileum, submucosal, often multifocal; serotonin-driven **mesenteric fibrosis/desmoplasia** $\rightarrow$ intermittent obstruction and the classic “**spoke-and-wheel**” calcified mesenteric mass on CT.
- **Appendiceal NETs:** <2 cm $\rightarrow$ appendectomy alone (very low metastatic risk); 2–3 cm $\approx$ 20–30% metastatic risk; >3 cm $\rightarrow$ right hemicolectomy.
- **Rectal NETs:** <1 cm well-differentiated $\rightarrow$ endoscopic removal; 1–2 cm metastasize in up to one-third; >2 cm metastasize in >70%.
- **Carcinoid syndrome** — driven mainly by **serotonin (5-HT)** (synthesized from tryptophan by **tryptophan hydroxylase**; metabolite **5-HIAA** measurable in 24-h urine), plus histamine and tachykinins (substance P). Usually emerges only after **hepatic metastases** allow vasoactive substances into the systemic circulation. Features: sudden **flushing** (face/neck), secretory

diarrhea, wheezing/bronchospasm, and tryptophan diversion may cause niacin deficiency (pellagra). Most common with appendiceal/small-intestinal primaries.

- **Carcinoid heart disease** (≈two-thirds of carcinoid-syndrome patients): plaque-like fibrous endocardial thickening of the **right heart** mediated by serotonin acting on **5-HT_{2B} receptors**; **tricuspid regurgitation** is near-universal (also tricuspid stenosis, pulmonary regurgitation/stenosis). Left-sided disease in <10% (associated with patent foramen ovale).
- **Carcinoid crisis**: life-threatening release of vasoactive substances (profound hypotension or hypertension) precipitated by tumor manipulation at surgery, embolization, or anesthesia induction — prevented/treated with **somatostatin analogues**.

NETs in MEN syndromes (Ch 400)

Syndrome	Gene (locus)	Key NET-associated tumors
MEN 1 (<i>Wermer</i>)	<i>MEN1</i> / <i>menin</i> (11q13)	Parathyroid adenoma (90%); enteropancreatic NETs 30–70% (gastrinoma >50%, insulinoma 10–30%, non-functioning/PPoma); anterior pituitary (prolactinoma)
MEN 2A (<i>Siipple</i>)	<i>RET</i> (10q11.2), codon 634	Medullary thyroid carcinoma (MTC) 90%, pheochromocytoma >50%, parathyroid 10–25%
MEN 2B / MEN 3	<i>RET</i> codon 918 (Met→Thr)	MTC, pheochromocytoma, mucosal neuromas, marfanoid habitus, megacolon (<i>no</i> hyperparathyroidism)
FMTc (MTC only)	<i>RET</i> codon 618	MTC alone
MEN 4	<i>CDKN1B</i> (p27 ^{Kip1} , 12p13)	Parathyroid + pituitary adenoma
MEN 5	<i>MAX</i> (14q23.3)	Pheochromocytoma, pituitary, parathyroid

- **Menin** is a 610-amino-acid tumor-suppressor protein; tumorigenesis follows the Knudson **two-hit hypothesis**.
- In MEN 1, pancreatic NETs are typically **multiple**, of earlier onset, and often indolent; gastrinoma/foregut carcinoid is a leading cause of death — favoring conservative/selective surgery.
- In MEN 2, *RET*-mutation carriers are offered **prophylactic total thyroidectomy** (between age <1 and 5 years per codon risk); pheochromocytoma must be excluded before any surgery. Metastatic MTC: TKIs **vandetanib**, **cabozantinib**, **selpercatinib**.

Diagnosis and investigations

- ▶ **Functional/biochemical:** hormone-specific assays (insulin/C-peptide, gastrin, glucagon, VIP), **urinary 5-HIAA** for carcinoid syndrome; **chromogranin A** as a general (but neither sensitive nor specific) marker — falsely raised by PPIs and renal impairment.
- ▶ **Imaging:** CT/MRI for anatomy; **somatostatin-receptor imaging** since >90% of NETs express SSTRs — **Gallium-68 (⁶⁸Ga) DOTATATE PET** (also DOTATOC, ⁶⁴Cu-dotatate) is highly sensitive. **FDG-PET** is typically negative in low-grade but positive in high-grade tumors.
- ▶ **Localization:** EUS for small pancreatic/duodenal tumors; receptor-positivity on DOTATATE PET predicts SSA and PRRT responsiveness.

Management

- ▶ **Localized disease:** surgical resection is the mainstay; appendiceal/rectal small tumors may be cured endoscopically or by limited resection. Adjuvant therapy is **not** recommended after resection of well-differentiated NETs.
- ▶ **Hormone-symptom control: somatostatin analogues** — octreotide, lanreotide (14-aa somatostatin analogues binding **SSTR subtypes 2 and 5**); **telotristat ethyl** (tryptophan hydroxylase inhibitor) for refractory carcinoid diarrhea; prophylactic cholecystectomy if long-term SSA planned (gallstone risk).
- ▶ **Anti-tumor systemic therapy (Table 89-3):**
 - **SSAs** also slow growth — *PROMID* (octreotide LAR, midgut), *CLARINET* (lanreotide; 2-yr PFS 65% vs 33%).
 - **Peptide receptor radioligand therapy (PRRT)** — ¹⁷⁷Lu-DOTATATE (NETTER-1: PFS at 20 months 65.2% vs 10.8%); requires positive SSTR imaging; renal toxicity mitigated by amino-acid co-infusion.
 - **mTOR inhibitor everolimus** 10 mg/day (RADIANT-3 pancreatic 11 vs 4.6 months; RADIANT-4 GI/lung) — stomatitis, rash, pneumonitis.
 - **TKIs** — sunitinib 37.5 mg/day (pancreatic NET 11.4 vs 5.5 months), cabozantinib (CABINET), surufatinib, pazopanib — hypertension, proteinuria.
 - **Chemotherapy** — **temozolomide + capecitabine** is the preferred regimen for advanced pancreatic NET (has replaced streptozocin).
- ▶ **Hepatic-directed therapy** (liver-predominant disease): resection, radiofrequency/cryoablation, hepatic-artery embolization (bland/chemo/radio-embolization), selective transplantation.
- ▶ **High-grade neuroendocrine carcinoma:** treated on a small-cell paradigm with **platinum** (cisplatin/carboplatin) + **etoposide**; response best when Ki-67 ≥55%; immune checkpoint blockade (ipilimumab + nivolumab) shows activity in poorly differentiated tumors.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Serotonin pathway in carcinoid (Fig. 89-6):** label *Tryptophan* → (*tryptophan hydroxylase*) → *5-Hydroxytryptophan (5-HTP)* → (*aromatic L-amino acid decarboxylase*) → *Serotonin (5-HT)* → stored in secretory granules → secretion → (*monoamine oxidase, aldehyde dehydrogenase*) → *5-HIAA* → *urine*; mark **telotristat ethyl** inhibiting tryptophan hydroxylase.
- ▶ **Carcinoid heart disease (Fig. 89-8):** right heart with fibrous endocardial plaque, retracted tricuspid valve leaflets, **tricuspid regurgitation**; label right atrium, right ventricle, pulmonary valve, and “serotonin / 5-HT2B mediated”.

Clinical / Diagnostic significance

- ▶ Suspect NET in unexplained flushing + secretory diarrhea, refractory peptic ulcers (ZES), fasting hypoglycemia, or necrolytic migratory erythema.
- ▶ A diagnosis of gastrinoma or multiple/young-onset pancreatic NETs mandates screening for **MEN 1** (calcium, PTH, gut hormones, pituitary MRI).
- ▶ ⁶⁸Ga-DOTATATE PET both stages disease and selects patients for SSA/PRRT; chromogranin A is used for monitoring, not screening.
- ▶ Grade (Ki-67) dictates therapy: well-differentiated → SSA/PRRT/targeted agents; high-grade carcinoma → platinum–etoposide.

High-yield exam pointers

- ▶ Commonest functional pancreatic NET = **insulinoma**; commonest *overall* pancreatic NET = **non-functioning**.
- ▶ **Whipple’s triad** + ↑insulin/proinsulin/C-peptide = insulinoma; normal C-peptide with hypoglycemia suggests exogenous insulin.
- ▶ **Gastrinoma triangle:** cystic + common bile duct confluence, 2nd–3rd part duodenum, pancreatic neck/body.
- ▶ **WDHA = Verner-Morrison = pancreatic cholera (VIPoma)**.
- ▶ Carcinoid syndrome needs **hepatic metastases**; diagnostic test = **24-h urinary 5-HIAA**.
- ▶ Carcinoid heart disease = **right-sided, tricuspid regurgitation**, via 5-HT2B receptors.
- ▶ ¹⁷⁷Lu-DOTATATE PRRT for progressive SSTR-positive NETs (NETTER-1/2).
- ▶ **MEN 2 = RET:** codon 634 (2A), 918 (2B), 618 (FMTC); prophylactic thyroidectomy in carriers.
- ▶ **Temozolomide + capecitabine** = preferred chemo for pancreatic NET.

SOURCE & COVERAGE

Harrison’s Principles of Internal Medicine, 22e — Ch 89 “Gastrointestinal Neuroendocrine Tumors” (Kulke) and Ch 400 “Multiple Endocrine Neoplasia Syndromes” (Thakker). Coverage

note: both asks (“Neuroendocrine tumors”) are fully supported; *spec.gap* = *false*. Bronchial/thymic and lung NETs are covered only briefly in the provided GI/MEN chapters (detailed pulmonary NET pathology lies outside these two chapters). MEN 2 management specifics (vandetanib/cabozantinib/selpercatinib, prophylactic thyroidectomy timing) are from Ch 400 and are standard internal medicine.

Neurological Manifestations of Paraneoplastic Syndrome

Asked in: Paper IV Nov 2019 — RGUHS MD General Medicine

Definition / Introduction — Paraneoplastic neurologic disorders (PNDs) are cancer-related syndromes that can affect **any level of the neuraxis** — brain, brainstem, cerebellum, spinal cord, dorsal root ganglia, peripheral nerve, neuromuscular junction or muscle — and are caused by **remote immune effects of a tumour, not by metastasis, direct infiltration, infection, metabolic derangement or treatment toxicity**. Most are autoimmune, triggered by neuronal proteins ectopically expressed by the tumour. Clinically disabling PNDs occur in 0.5–1% of all cancer patients, but in 2–3% of small-cell lung cancer (SCLC) and neuroblastoma and 30–50% of thymoma. Crucially, in ~60% of patients the neurologic syndrome precedes the cancer diagnosis, develops subacutely producing severe deficits, and prompt tumour control improves outcome — making early recognition vital.

Pathogenesis and antibody-based risk classification

- ▶ PNDs arise when tumour cells aberrantly express neuronal antigens; antigen is processed by antigen-presenting cells → CD4+ helper T-cell activation → B-cell differentiation and autoantibody production, with CD8+ cytotoxic T cells for intracellular targets.
- ▶ **Two immunopathological groups** with prognostic and therapeutic relevance:
 - **Antibodies to intracellular antigens** (e.g., Hu, Yo, Ri, CRMP5, Ma2, amphiphysin): antibody is a *marker*; injury is **cytotoxic T-cell mediated** → extensive neuronal loss → **strong cancer association, poor response to immunotherapy**.
 - **Antibodies to neuronal cell-surface/synaptic antigens** (e.g., NMDAR, LGI1, GABA-B, AMPAR, Caspr2): antibody is **directly pathogenic** (receptor cross-linking/internalisation, functional block) → **more often respond to immunotherapy**, may occur without cancer and in children/young adults.
- ▶ Modern (Graus 2021) terminology abandons “onconeural antibody” for **probability of underlying cancer**: high-risk >70%, intermediate 30–70%, low <30%.

Risk / antibody	Classic neurologic phenotype	Commonest tumour
Anti-Hu (ANNA-1)	Encephalomyelitis, sensory neuronopathy	SCLC
Anti-Yo (PCA-1)	Rapidly progressive cerebellar degeneration	Ovary, breast
Anti-Ri (ANNA-2)	Cerebellar degeneration, opsoclonus, brainstem encephalitis	Breast, gynaecologic, SCLC
Anti-CRMP5 (CV2)	Encephalomyelitis, chorea, optic neuritis, uveitis, neuropathy	SCLC, thymoma
Anti-Ma2	Limbic, hypothalamic, brainstem encephalitis	Testicular germ cell
Anti-Tr (DNER)	Cerebellar degeneration	Hodgkin lymphoma
Anti-amphiphysin	Stiff-person syndrome, encephalomyelitis	Breast, SCLC
Anti-SOX1	LEMS ($\pm$ cerebellar)	SCLC
Anti-KLHL11	Brainstem encephalitis, ataxia, sensorineural deafness	Seminoma/germ-cell
Anti-NMDAR (<i>intermediate</i>)	Anti-NMDAR encephalitis	Ovarian teratoma
Anti-AMPA / GABA-B (<i>intermediate</i>)	Limbic encephalitis ($\pm$ seizures)	SCLC, thymoma, breast
Anti-Caspr2 (<i>intermediate</i>)	Morvan syndrome, neuromyotonia	Thymoma
Anti-VGCC (P/Q) (<i>intermediate</i>)	LEMS, cerebellar degeneration	SCLC
Anti-LGII (<i>low</i>)	Limbic encephalitis, hyponatraemia, faciobrachial dystonic seizures	Rarely thymoma
Anti-GAD65 (<i>low</i>)	Stiff-person, cerebellar ataxia, epilepsy	Usually none

CNS and dorsal-root-ganglion syndromes (high-risk “classic” phenotypes)

- Paraneoplastic encephalomyelitis — multifocal inflammation; combinations of cortical encephalitis (*epilepsia partialis continua*), limbic, brainstem, cerebellar, myelitic and autonomic involvement. Usually SCLC with **Hu antibodies**; death may result from cardiac arrhythmia, postural hypotension or central hypoventilation.

- ▶ **Limbic encephalitis** — subacute confusion, agitation, anxiety/depression, **profound short-term (anterograde) memory loss** and temporal-lobe seizures; MRI shows **unilateral/bilateral medial temporal-lobe T2/FLAIR hyperintensity**. Antibodies: Hu, Ma2, AMPAR, GABA-B, LGI1, Caspr2.
- ▶ **Paraneoplastic cerebellar degeneration (rapidly progressive cerebellar syndrome)** — prodrome of dizziness, oscillopsia, nausea → dysarthria, gait and limb ataxia, **downbeating nystagmus**; due to extensive **Purkinje-cell loss**; MRI normal early, **cerebellar atrophy** later. Tumours: SCLC, breast/ovary (anti-Yo), Hodgkin (anti-Tr/DNER).
- ▶ **Opsoclonus-myoclonus syndrome** — chaotic, involuntary multidirectional saccades + myoclonus + ataxia from **disinhibition of the cerebellar fastigial nucleus**; **neuroblastoma in children (≥50%)**, lung/breast (± anti-Ri) in adults; in children with hypotonia, irritability and “dancing eyes–dancing feet”.
- ▶ **Paraneoplastic sensory neuronopathy (dorsal root ganglionopathy)** — immune attack on **dorsal root ganglia**; asymmetric/symmetric sensory loss in all modalities (including face/trunk), painful dysesthesias, sensory ataxia, areflexia; **absent/reduced SNAPs with preserved motor conduction**; Hu antibodies, SCLC.
- ▶ **Paraneoplastic stiff-person syndrome / PERM** — progressive axial and limb rigidity with painful stimulus-triggered spasms, continuous motor-unit activity on EMG; **amphiphysin antibodies** = paraneoplastic (breast, SCLC), whereas GAD65 is usually non-paraneoplastic.
- ▶ Myelopathy (longitudinally extensive), paraneoplastic visual syndromes (cancer-associated retinopathy with anti-recoverin in SCLC; melanoma-associated retinopathy), and autonomic neuropathy (anti-ganglionic α3-AChR) also occur.

Neuromuscular junction, nerve and muscle syndromes

- ▶ **Lambert-Eaton myasthenic syndrome (LEMS)** — antibodies to **presynaptic P/Q-type voltage-gated calcium channels** reduce ACh release. Triad of **proximal lower-limb weakness, hyporeflexia/areflexia and autonomic features** (dry mouth, constipation, impotence); strength and reflexes transiently **improve after brief exercise (post-tetanic facilitation)**. >50% have SCLC. Electrodiagnosis: **low resting CMAP amplitude, decrement on low-rate (2–3 Hz) repetitive nerve stimulation, and >100% increment after high-rate stimulation or brief exercise**.
- ▶ **Peripheral nerve hyperexcitability (neuromyotonia / Isaacs syndrome)** — cramps, myokymia/fasciculations, pseudomyotonia; Caspr2 antibodies; thymoma/SCLC. **Morvan syndrome** adds encephalopathy, insomnia (*agrypnia excitata*) and dysautonomia (Caspr2, thymoma in ~50%).
- ▶ **Dermatomyositis** (and, weakly, polymyositis) and **immune-mediated necrotizing myopathy** (anti-HMGCR or seronegative carry higher cancer risk); subacute sensorimotor neuropathies and POEMS/paraproteinaemic neuropathies; paraneoplastic **myasthenia gravis** with thymoma.

Autoimmune encephalitides with neuronal surface antibodies

- ▶ **Anti-NMDAR encephalitis** — young women/children: viral-like prodrome → psychiatric symptoms, reduced speech, memory loss, **orofacial/limb dyskinesias**, seizures, decreased consciousness, **autonomic instability and central hypoventilation**. ~46% of females ≥12 yr have an **ovarian teratoma**; ~85–90% improve substantially; relapses 12–24%. Diagnosis: CSF antibodies to the **GluN1 subunit** of NMDAR.
- ▶ **Anti-LGI1 encephalitis** — older men: limbic encephalitis with **hyponatraemia** and pathognomonic **faciobrachial dystonic seizures** (brief unilateral arm/face contractions preceding amnestic syndrome).
- ▶ **Anti-GABA-B** (prominent early seizures, SCLC), **anti-AMPA** (relapsing limbic encephalitis), **anti-GABA-A** (refractory seizures/status), **anti-mGluR5** (Ophelia syndrome with Hodgkin lymphoma) and **anti-IgLON5** (NREM/REM parasomnia, stridor, tauopathy).

Diagnostic approach

- ▶ **Exclude mimics first**: metastasis/leptomeningeal disease (contrast MRI brain + spine, CSF cytology), infection, metabolic and treatment-related causes.
- ▶ CSF typically shows mild–moderate lymphocytic pleocytosis (<200 cells), raised protein and oligoclonal bands. **Test paired serum and CSF antibodies** (CSF essential and more specific for NMDAR).
- ▶ Only ~60–70% of CNS PNDs and <20% of PNS-PNS have a detectable antibody — **a negative panel does not exclude PND**.
- ▶ **Tumour hunt**: CT chest/abdomen + whole-body FDG-PET; testicular/pelvic ultrasound and MRI for germ-cell tumours/teratoma; **mammography for anti-Yo/Ri**. If initial screen negative in a high-risk phenotype/antibody, **repeat every 4–6 months for ≥2 years**.
- ▶ **PNS-Care Score** (Graus 2021): grades phenotype (high 3 / intermediate 2), antibody (high 3 / intermediate 2) and cancer findings (present/consistent 4) → **Definite ≥8, Probable 6–7, Possible 4–5**.
- ▶ **DELTA-P score** predicts SCLC in LEMS: Dysarthria/dysphagia/bulbar weakness, Erectile dysfunction, Loss of weight ≥5%, Tobacco, Age ≥50 yr, Performance status (Karnofsky <70) — each 1 point; score 0–1 virtually excludes SCLC, ≥3 implies >80% risk.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Neuraxis “site map” of PNDs**: a sagittal CNS + peripheral nerve/muscle outline with labels — *Limbic encephalitis (medial temporal lobe), Brainstem encephalitis, Cerebellar degeneration (Purkinje cells), Opsoclonus-myoclonus (fastigial nucleus), Myelitis, Dorsal root ganglion → sensory neuronopathy, Neuromuscular junction → LEMS, Muscle → dermatomyositis.*

- ▶ **NMJ in LEMS:** presynaptic terminal with P/Q-type VGCC blocked by antibody, reduced ACh-vesicle release into the cleft, postsynaptic nicotinic AChR. Labels: *autoantibody, P/Q VGCC, Ca^{2+} influx ↓, ACh vesicles, post-tetanic facilitation.*

Clinical / Diagnostic significance

- ▶ A subacute, otherwise unexplained neurologic syndrome in a smoker or older adult should trigger **antibody testing and a tumour search** — the PND often unmasks an occult, frequently still-curable cancer.
- ▶ **Antibody specificity guides the cancer search:** anti-Yo → breast/ovary, anti-Ma2 → testis, anti-Tr → Hodgkin, anti-NMDAR → ovarian teratoma, anti-Hu/VGCC/SOX1 → SCLC.
- ▶ **Management** = treat the tumour + immunotherapy. **First line:** IV methylprednisolone 1 g/day × 3–5 days, IVIG (≈2 g/kg over 5 days) and/or plasma exchange. **Second line:** rituximab 375 mg/m² weekly × 4, cyclophosphamide, azathioprine/mycophenolate; refractory NMDAR encephalitis — tocilizumab or bortezomib. **Symptomatic:** diazepam/baclofen for stiff-person; amifampridine (3,4-diaminopyridine) and pyridostigmine for LEMS.
- ▶ Surface-antibody syndromes respond well; intracellular-antibody (Hu, Yo) syndromes often stabilise at best — **early treatment before irreversible neuronal loss is key.**
- ▶ Immune-checkpoint inhibitors can precipitate neurologic immune-related adverse events clinically identical to PNDs.

High-yield exam pointers

- ▶ 60% of PNDs present before the cancer is found; SCLC is the commonest associated tumour.
- ▶ Intracellular antigen = T-cell mediated, marker antibody, poor response; surface antigen = directly pathogenic, treatment-responsive.
- ▶ Anti-Hu = encephalomyelitis + sensory neuronopathy + SCLC; Anti-Yo = pure cerebellar degeneration + breast/ovary.
- ▶ LEMS = proximal weakness + areflexia + autonomic features, facilitation on exercise, incremental RNS at high rate, P/Q VGCC antibodies, SCLC.
- ▶ Anti-NMDAR encephalitis = young woman, psychiatric → dyskinesia → seizures → dysautonomia, ovarian teratoma, CSF GluN1 antibody, good recovery.
- ▶ Anti-LGI1 = limbic encephalitis + hyponatraemia + faciobrachial dystonic seizures.
- ▶ Opsoclonus-myoclonus = “dancing eyes” + neuroblastoma (child); stiff-person = amphiphysin/GAD65, EMG continuous motor-unit activity.
- ▶ Diagnostic tools: paired serum/CSF antibodies, MRI, whole-body PET-CT, PNS-Care score, DELTA-P score; rescreen for cancer every 4–6 months for ≥2 years.

Non-Hodgkin's Lymphoma

Asked in: Paper IV May 2019 — RGUHS MD General Medicine

Definition / Introduction — Non-Hodgkin's lymphomas (NHLs) are a heterogeneous group of malignancies of mature B, T, and **natural-killer (NK)** lymphocytes, distinguished from Hodgkin's lymphoma by the *absence of Reed-Sternberg cells* and by their biologically and clinically diverse behaviour. About **85–90%** are of B-cell origin and **10–15%** are T/NK-cell. They span a spectrum from **indolent** (slow-growing, treatable but usually incurable) to **aggressive/highly aggressive** (rapidly fatal if untreated, but potentially curable). NHL is the seventh most common cause of cancer death; incidence rises with age and has been increasing by ~1.5–2% per year, with a 5-year survival of ~74%.

Etiology, risk factors & infectious associations

- ▶ **Immunodeficiency** is the strongest predisposer — HIV, post-transplant immunosuppression (~100-fold increased risk, greatest in first post-transplant year), and inherited defects (*ataxia-telangiectasia*, *Wiskott-Aldrich*, *X-linked lymphoproliferative*, *Chédiak-Higashi*, *common variable immunodeficiency*). Most immunodeficiency-associated NHLs are EBV-driven DLBCLs.
- ▶ **Autoimmune disease** — Sjögren's syndrome and Hashimoto's thyroiditis (MALT lymphoma), rheumatoid arthritis, SLE, celiac sprue (enteropathy-associated T-cell lymphoma).
- ▶ **Chemical/iatrogenic** — phenoxy herbicides/dioxin, phenytoin, anti-TNF agents, prior chemo-/radiotherapy.
- ▶ **Infectious agents** (chronic antigenic stimulation or direct transformation):

Agent	Associated lymphoma
EBV	Burkitt's, post-transplant LPD, primary CNS DLBCL, extranodal NK/T-cell (nasal)

Agent	Associated lymphoma
HTLV-1	Adult T-cell leukemia/lymphoma (ATLL)
HIV	Aggressive DLBCL, Burkitt's
Hepatitis C	Lymphoplasmacytic lymphoma, splenic marginal-zone lymphoma
H. pylori	Gastric MALT lymphoma (regresses with eradication)
HHV-8	Primary effusion lymphoma, multicentric Castleman's disease
<i>Borrelia</i> / <i>C. psittaci</i> / <i>C. jejuni</i>	Cutaneous / ocular adnexal / small-bowel (IPSID) MALT

Classification (WHO-HAEM5, 2022) & cytogenetics

- ▶ Lymphoid neoplasms are grouped as **mature B-cell** vs **mature T/NK-cell**, each containing indolent and aggressive entities.
- ▶ **B-cell**: follicular lymphoma (FL), DLBCL, Burkitt's, mantle-cell (MCL), marginal-zone (splenic/MALT/nodal), lymphoplasmacytic, primary mediastinal large B-cell, high-grade B-cell with *MYC* + *BCL2* rearrangements.
- ▶ **T/NK-cell**: peripheral T-cell lymphoma (PTCL)-NOS, angioimmunoblastic (AITL), anaplastic large-cell (ALCL, ALK±), mycosis fungoides/Sézary, ATLL, extranodal NK/T-cell nasal type.
- ▶ ~90% of lymphomas arise from B cells after immunoglobulin gene recombination/somatic hypermutation; the error-prone nature of these processes underlies recurrent translocations:

Translocation	Gene(s)	Lymphoma
t(8;14)(q24;q32)	<i>MYC</i> / <i>IgH</i>	Burkitt's (also t(2;8), t(8;22))
t(14;18)(q32;q21)	<i>BCL2</i> / <i>IgH</i>	Follicular, DLBCL
t(11;14)(q13;q32)	<i>CCND1</i> (<i>cyclin D1</i>) / <i>IgH</i>	Mantle-cell
t(11;18)(q21;q21)	<i>API2</i> / <i>MALT1</i>	MALT (commonest, up to 50%)
t(2;5)(p23;q35)	<i>NPM1</i> / <i>ALK</i>	Anaplastic large-cell
t(3;14) / 3q27	<i>BCL6</i> / <i>IgH</i>	DLBCL, FL

- ▶ Gene-expression profiling splits DLBCL into **germinal-centre B-cell (GCB)** type (better prognosis) and **activated B-cell (ABC)** type (worse); the **Hans algorithm** (CD10, BCL6, MUM1 by IHC) approximates this.

Clinical features & staging

- ▶ Commonest presentation is **painless lymphadenopathy** (peripheral, central/retroperitoneal, or both); ~85% of indolent NHLs are disseminated at diagnosis with frequent marrow involvement.
- ▶ “**B**” symptoms — fever, drenching night sweats, weight loss >10% of body weight over the preceding 6 months.
- ▶ Extranodal disease is common (GI tract, skin, Waldeyer’s ring, marrow, CNS, testis); pace of progression distinguishes aggressive from indolent disease.
- ▶ **Diagnosis requires excisional/core tissue biopsy** with histology, immunophenotype (flow cytometry/IHC) and cytogenetics/FISH — *fine-needle aspiration alone is inadequate*.
- ▶ **Staging** — **Ann Arbor system** (adapted for NHL), now applied as the modern **Lugano classification** using whole-body 18F-FDG PET/CT:

Stage	Extent
I	Single nodal region (I) or single extranodal site (IE)
II	≥2 nodal regions, same side of diaphragm (± contiguous extranodal IIE)
III	Nodal regions on both sides of diaphragm (± spleen, IIIS)
IV	Diffuse/disseminated extranodal involvement (marrow, liver, etc.)

Suffix **A** = no B symptoms, **B** = B symptoms present; **E** = extranodal extension; **bulky** = mediastinal mass >1/3 chest diameter or any mass >10 cm. Bone-marrow biopsy is not required when PET/CT is performed. Because NHL disseminates non-contiguously, **histology + clinical risk score predict outcome better than anatomic stage**.

Prognostic indices

- ▶ **International Prognostic Index (IPI)** for aggressive NHL — 1 point each for: Age ≥60, raised LDH, ECOG Performance status ≥2, Ann Arbor stage III/IV, >1 extranodal site (mnemonic *APLES*). Risk groups: low (0–1), low-intermediate (2), high-intermediate (3), high (4–5) → 5-yr OS ~73%, 51%, 43%, 26% respectively. The **R-IPI** (rituximab era) gives 4-yr survival of 94/80/53%.
- ▶ **FLIPI** (follicular) — age >60, stage III/IV, >4 **nodal sites**, raised LDH, haemoglobin <12 g/dL.
- ▶ **MIPI** (mantle-cell) — age, performance status, LDH, WBC count, **Ki-67** index.
- ▶ Raised serum LDH and **β2-microglobulin** are independent adverse markers.

Major subtypes — features & treatment

- ▶ **Diffuse large B-cell lymphoma (DLBCL)**: commonest NHL (~1/3 of cases), aggressive but curable. Standard first-line **R-CHOP** (rituximab, cyclophosphamide, doxorubicin, vincristine, prednisone) × 6 cycles cures ~65–70%; **Pola-R-CHP** (polatuzumab vedotin replacing vincristine)

benefits IPI ≥ 2 disease (POLARIX). “**Double-hit**” lymphoma (*MYC* + *BCL2* rearranged, a high-grade B-cell lymphoma) carries a poor prognosis and is often treated with DA-EPOCH-R.

Relapsed/refractory disease $\rightarrow$ salvage chemo + **autologous stem-cell transplant**, or **CD19 CAR-T cells** (axi-cel, liso-cel, tisa-cel; ZUMA-7, TRANSFORM) which are now preferred for primary-refractory/early-relapsing disease.

- ▶ **Burkitt’s lymphoma**: one of the fastest-growing human tumours (**doubling time** <24 h); *MYC* t(8;14) in >95%. Biopsy shows monomorphic medium B cells, ~100% proliferation and a classic “**starry-sky**” appearance from **tingible-body macrophages**; CD10+, BCL6+, BCL2-negative. Three forms — **endemic** (African, jaw/EBV+), **sporadic** (abdominal), **immunodeficiency-associated**. Needs *urgent* intensive cyclophosphamide-based therapy (**modified Magrath/CODOX-M-IVAC** or DA-EPOCH-R) with **mandatory CNS prophylaxis**; cure 80–90%. High tumour burden mandates **tumour-lysis-syndrome** prophylaxis.
- ▶ **Follicular lymphoma (FL)**: commonest indolent NHL; t(14;18)/*BCL2* in >85%; CD10+, BCL6+, CD5/CD23-negative. Graded I–III by centroblast count. Asymptomatic patients are **observed** (“**watch and wait**”); symptomatic/bulky disease $\rightarrow$ **bendamustine-rituximab (BR)**, R-CHOP or R-CVP, $\pm$ maintenance rituximab; obinutuzumab and rituximab-lenalidomide are alternatives. Median survival 15–20 years; **histologic transformation to DLBCL** ~3% per year.
- ▶ **Marginal-zone lymphoma (MZL)**: splenic (HCV-associated, villous lymphocytes), **MALT** (often localised stage I/II — *H. pylori* eradication or radiotherapy can be curative), and nodal types.
- ▶ **Lymphoplasmacytic lymphoma / Waldenström’s macroglobulinaemia**: IgM paraprotein, MYD88 L265P mutation in >90%; hyperviscosity $\rightarrow$ **plasmapheresis**; therapy with BR or **BTK inhibitors** (ibrutinib).
- ▶ **Mantle-cell lymphoma (MCL)**: t(11;14)/*cyclin D1*, CD5+, CD23-negative; intermediate-grade, not curable conventionally. Cytarabine-containing induction $\pm$ autologous transplant; **BTK inhibitors** (ibrutinib, acalabrutinib, zanubrutinib, pirtobrutinib) and CD19 CAR-T at relapse.
- ▶ **T-cell NHLs** (generally poorer prognosis): **mycosis fungoides/Sézary** (cutaneous, indolent); **PTCL-NOS** and **AITL** (CHOP/CHOEP); **ALCL** — CD30+, *ALK*+ favourable (8-yr OS 82%) vs *ALK*-negative; **brentuximab vedotin** + **CHP** for CD30+ disease (ECHELON-2). **ATLL** (HTLV-1, “flower cells”, hypercalcaemia); **extranodal NK/T-cell nasal type** (EBV+, **SMILE** regimen + radiotherapy).

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Pathway of normal B-cell differentiation and related lymphomas** (Harrison Fig. 113-2): label *lymphoid stem cell* $\rightarrow$ *pre-B* (*TdT*+, *CD19*+) $\rightarrow$ *early/intermediate B cell* $\rightarrow$ *germinal-centre/follicular-centre B cell* $\rightarrow$ *mantle-zone B cell* $\rightarrow$ *mature/secretory B cell* $\rightarrow$ *plasma cell*; map pre-B ALL, mantle-cell lymphoma (CD5+), CLL/SLL, follicular lymphoma,

Burkitt's, lymphoplasmacytic/Waldenström's, multiple myeloma; annotate markers CD10, CD19, CD20, CD22, CD5, CD23, surface Ig, HLA-DR.

- ▶ “Starry-sky” Burkitt histology — label *monomorphic medium-sized blue B cells* and pale-staining *tinkable-body (reactive) macrophages*.

Clinical / Diagnostic significance

- ▶ Excisional biopsy with immunophenotyping is mandatory — subtype dictates whether to observe, give curative chemo, or treat as an emergency.
- ▶ Baseline work-up: CBC, LDH, β 2-microglobulin, LFTs, uric acid, calcium, serum protein electrophoresis, HIV and hepatitis B/C serology (HBV reactivation risk with rituximab — give antiviral prophylaxis), PET/CT, marrow biopsy where indicated, and lumbar puncture/CNS imaging in Burkitt's, lymphoblastic, testicular/paranasal/epidural/breast/renal/adrenal DLBCL.
- ▶ Oncologic emergencies: tumour-lysis syndrome (hydration + allopurinol or rasburicase), SVC obstruction, malignant spinal-cord compression, hypercalcaemia (ATLL), hyperviscosity (Waldenström's).
- ▶ Rituximab (anti-CD20) transformed B-cell NHL outcomes; CAR-T cell therapy and bispecific antibodies (epcoritamab, glofitamab, mosunetuzumab) are major recent advances for relapsed disease.

High-yield exam pointers

- ▶ NHL = mature B/T/NK malignancy, no Reed-Sternberg cells; ~85% B-cell.
- ▶ t(14;18)/BCL2 → follicular; t(8;14)/MYC → Burkitt; t(11;14)/cyclin D1 → mantle-cell; t(11;18)/API2-MALT1 → MALT; t(2;5)/ALK → ALCL.
- ▶ IPI = age ≥ 60 , LDH $\uparrow$, PS ≥ 2 , stage III/IV, >1 extranodal site.
- ▶ DLBCL is commonest; R-CHOP is standard, curative in ~65–70%.
- ▶ Burkitt's — “starry sky”, doubling <24 h, needs urgent therapy + CNS prophylaxis + TLS precautions.
- ▶ FL — indolent, watch-and-wait, transforms to DLBCL ~3%/yr.
- ▶ Gastric MALT regresses with *H. pylori* eradication; splenic MZL with HCV treatment.
- ▶ B symptoms = fever, night sweats, weight loss $>10\%$ over 6 months.
- ▶ Diagnosis needs excisional/core biopsy — never FNA alone; staging by PET/CT (Lugano).

Oncogenes, Mechanism and Associated Tumors

Asked in: Paper I May 2022 — RGUHS MD General Medicine

Definition / Introduction — **Oncogenes** are mutated or aberrantly activated genes that promote unregulated cell growth and are one of the two major classes of cancer *driver genes* (the other being tumour-suppressor genes). Their normal, tightly regulated cellular counterparts are called **proto-oncogenes**, which encode proteins acting at critical steps of growth-factor signal-transduction pathways (receptors, kinases, G-proteins, transcription factors). A single genetic event affecting **one allele** (gain-of-function, *dominant*) is sufficient to convert a proto-oncogene into an oncogene — in contrast to tumour-suppressors, where **both alleles** must be inactivated. First discovered in the late 1970s through the study of tumour-causing retroviruses, oncogenes are now the central targets of molecular (precision) cancer therapy.

Proto-oncogene vs oncogene — the core concept

- ▶ **Historical basis:** Peyton Rous (early 1900s) showed a chicken sarcoma was transmissible by a cell-free extract — the *Rous sarcoma virus (RSV)* — whose transforming gene was later identified as **v-SRC**. The normal cellular homologues of such viral genes are the **proto-oncogenes**, captured and mutated by retroviruses.
- ▶ A proto-oncogene becomes an oncogene by mutations that **relieve normal control and increase the activity** of the gene product.
- ▶ Oncogene activation is **monoallelic and dominant** — *one genetic event* activates it; activation requires *precise* gain-of-function changes at specific residues (**mutational hotspots**), unlike the diverse loss-of-function mutations seen in tumour-suppressors.
- ▶ Proto-oncogenes have crucial physiological roles in **cell proliferation, differentiation and cell death**; inappropriate pathway activation leads to tumorigenesis.
- ▶ Malignant transformation is **multistep**: most common adult solid cancers require roughly **three driver-gene mutations** (some childhood tumours only two), accumulating over years/decades.

Functional classes of oncogene products

Oncogene products act at successive levels of the growth-signalling cascade (growth factor → receptor → cytoplasmic transducer → nuclear effector):

Functional class	Representative oncogene(s)	Example tumour association
Receptor / signal-transduction (RTK)	EGFR, ERBB2/HER2, FLT3, KIT, RET, ALK, ROS1, MET, NTRK	Lung (EGFR/ALK/ROS1), breast (HER2), AML (FLT3)
Non-receptor (cytoplasmic) tyrosine kinase	ABL, SRC	CML (BCR-ABL)
Small GTPase (G-protein)	KRAS, NRAS	Pancreas/colon/lung (KRAS), melanoma (NRAS)
Serine/threonine kinase	BRAF, AKT1	Melanoma, thyroid, colorectal (BRAF)
Lipid kinase	PIK3CA	Multiple cancers
Transcription factor	MYC, MYCN, MYCL1, PML-RAR α	Burkitt's/breast (MYC), neuroblastoma (MYCN), APL (PML-RAR α)
Cell-cycle regulator	CCND1 (cyclin D1), CDK4	Mantle-cell lymphoma, oesophageal/head-and-neck
Apoptosis regulator	BCL2 (anti-apoptotic)	Follicular lymphoma
Inhibitor of p53	MDM2, MDM4	Sarcoma, glioma (MDM2); breast (MDM4)
Chromatin modifier	IDH1	Glioma

Mechanisms of oncogene activation

There are **three principal mechanisms** by which a proto-oncogene is activated in human cancer (Harrison Ch 76):

1. Point mutation (single-nucleotide substitution)

- ▶ The commonest mechanism; produces a constitutively active protein.
- ▶ *Prototype* — RAS: activating KRAS mutations occur in **>95% of pancreatic cancers** and **~40% of colon cancers** (less commonly in leukaemia, lung, thyroid).
- ▶ Mutations are restricted to **hotspot codons 12, 13 and 61**, locking RAS in the active GTP-bound state (RAS is a GTPase, *not* a kinase — active when bound to GTP, inactive when bound to GDP).
- ▶ Other examples: BRAF V600E (melanoma, thyroid, colorectal), EGFR (lung), PIK3CA, IDH1 (glioma).

2. Gene (DNA) amplification → over-expression

- ▶ An increase in DNA copy number raises the dose of a normal gene product.
- ▶ Cytogenetically seen as **homogeneously staining regions (HSRs)** when intrachromosomal, or **double minutes (dmins)** when extrachromosomal.
- ▶ Amplicons may co-amplify several genes (e.g., **MDM2, GLI1, CDK4, TSPAN31** at 12q13–15 in sarcomas).
- ▶ Amplification often predicts **poor prognosis** — e.g., **ERBB2/HER2** in aggressive breast cancer and **MYCN (NMYC)** in neuroblastoma.

3. Chromosomal rearrangement (translocation) Two consequences:

- ▶ (a) **Creation of a novel chimeric fusion gene** with deregulated enzymatic activity — *prototype* the **Philadelphia chromosome**, the first reproducible chromosome abnormality in human malignancy. A reciprocal **t(9;22)(q34;q11)** juxtaposes **ABL** (chr 9, a tyrosine kinase) with **BCR** (chr 22), generating the **BCR-ABL** fusion protein, a constitutively active tyrosine kinase driving growth-factor-independent proliferation in CML.
- ▶ (b) **Juxtaposition next to a strong promoter/enhancer** causing over-expression of a structurally normal protein — typically by translocation into **antigen-receptor loci (IgH or TCR)**; e.g., **BCL2-IgH** (follicular lymphoma, over-expressed anti-apoptotic protein), **CCND1/BCL1-IgH** (mantle-cell lymphoma, cyclin D1), and **MYC-IgH t(8;14)** in Burkitt's lymphoma.
- ▶ Recurrent fusions also occur in **solid tumours**, e.g., **TPRSS2-ERG** in >one-third of prostate cancers.

Representative oncogenes and their associated tumours

Oncogene	Function	Mode of activation	Associated tumour
KRAS	GTPase	Point mutation (codons 12/13/61)	Pancreatic, colorectal, lung
NRAS	GTPase	Point mutation	Melanoma
BRAF	Ser/Thr kinase	Point mutation (V600E)	Melanoma, thyroid, colorectal
EGFR	RTK signal transduction	Point mutation	Lung adenocarcinoma
ERBB2/HER2	RTK	Amplification	Breast (aggressive)
FLT3	Signal transduction	Point mutation	AML
PIK3CA	PI3-kinase	Point mutation	Multiple cancers
MYC	Transcription factor	Amplification / translocation	Burkitt's, prostate, breast, liver
MYCN	Transcription factor	Amplification	Neuroblastoma

Oncogene	Function	Mode of activation	Associated tumour
CCND1 (cyclin D1)	Cell-cycle progression	Amplification / t(11;14)	Mantle-cell lymphoma, oesophageal
BCL2	Anti-apoptotic	Translocation t(14;18)	Follicular lymphoma
ABL (BCR-ABL)	Tyrosine kinase	Translocation t(9;22)	CML
MDM2	p53 inhibitor	Amplification	Sarcoma, glioma
IDH1	Chromatin modification	Point mutation	Glioma

Recurrent oncogenic translocations (high-yield)

Fusion / gene	Translocation	Malignancy
BCR-ABL	t(9;22)(q34;q11)	Chronic myeloid leukaemia
PML-RAR α	t(15;17)	Acute promyelocytic leukaemia (M3 AML)
BCL1 (CCND1)-IgH	t(11;14)(q13;q32)	Mantle-cell lymphoma
BCL2-IgH	t(14;18)(q32;q21)	Follicular lymphoma
MYC-IgH	t(8;14)	Burkitt's lymphoma
EWSR1-FLI1	t(11;22)(q24;q12)	Ewing's sarcoma
PAX3-FOXO1	t(2;13)(q35;q14)	Rhabdomyosarcoma
PAX8-PPARG	t(2;3)(q13;p25)	Thyroid carcinoma
TMPRSS2-ERG	rearrangement Chr21q22	Prostate cancer

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- **Diagram 1 — Mechanisms of oncogene activation:** A central proto-oncogene with three radiating arrows labelled (1) **Point mutation** (RAS, hotspot codons 12/13/61 → constitutive GTP-bound activation), (2) **Amplification** (multiple gene copies → over-expression; label HSR and **double minutes**; e.g., HER2, MYCN), (3) **Translocation** (label **fusion protein** e.g. BCR-ABL, and **promoter/enhancer juxtaposition** e.g. IgH-MYC).
- **Diagram 2 — Philadelphia chromosome (CML):** Two chromosomes labelled Chr 9 (ABL, 9q34) and Chr 22 (BCR, 22q11) with crossing arrows showing reciprocal translocation → derivative Ph chromosome carrying the BCR-ABL chimeric gene → BCR-ABL fusion protein (active tyrosine kinase).

Clinical / Diagnostic significance

- ▶ **Targeted (precision) therapy:** Because tumours frequently depend on a single activated pathway — **oncogene addiction** — they are exquisitely vulnerable to inhibitors of that pathway. **Imatinib** (and dasatinib, nilotinib, ponatinib, bosutinib) blocks ATP-binding in the **BCR-ABL** kinase in CML — the *paradigm* of molecularly targeted therapy (>80% 10-year survival).
- ▶ **Drug–target–tumour examples:** **ATRA** for PML-RAR α APL; **osimertinib** for EGFR-mutant lung cancer; **BRAF inhibitors** ($\pm$ MEK inhibitor) for V600E melanoma; **crizotinib/alectinib** for ALK+, **larotrectinib/entrectinib** for NTRK-fusion cancers; **sotorasib/adagrasib** for KRAS-G12C lung cancer; **trastuzumab/pertuzumab** for HER2+ breast/gastric cancer; **JAK inhibitors** for JAK2-driven myeloproliferative disease.
- ▶ **Diagnostic / prognostic biomarkers:** Detection of oncogenic mutations, amplifications and fusions (tissue and circulating tumour DNA) guides therapy, monitors response and detects resistance; **HER2/MYCN amplification** flags poor prognosis.
- ▶ **Acquired resistance:** point mutation in the target kinase (e.g., **BCR-ABL T315I** — threonine $\rightarrow$ isoleucine at codon 315) prevents imatinib binding; bypass-pathway activation also occurs.
- ▶ **Synthetic lethality:** an allied strategy — e.g., **PARP inhibitors** in homologous-recombination-deficient (BRCA-mutant) cancers.

High-yield exam pointers

- ▶ Proto-oncogene $\rightarrow$ oncogene = **gain-of-function, dominant, one allele**; tumour-suppressor = **loss-of-function, recessive, both alleles** (Knudson two-hit).
- ▶ **Three mechanisms of activation: point mutation, amplification, translocation** — be ready to give one tumour example for each.
- ▶ **RAS** is a GTPase, **not a kinase** — active when GTP-bound; mutations cluster at **codons 12, 13, 61**; KRAS in >95% pancreatic and ~40% colon cancers.
- ▶ **HSRs and double minutes** = cytogenetic signatures of **gene amplification**; **HER2** (breast) and **MYCN** (neuroblastoma) are the classic amplified oncogenes.
- ▶ **Philadelphia chromosome t(9;22) $\rightarrow$ BCR-ABL $\rightarrow$ CML $\rightarrow$ imatinib**; the molecular-therapy prototype.
- ▶ Memorise the translocation set: **t(15;17) APL**, **t(14;18) follicular**, **t(11;14) mantle-cell**, **t(8;14) Burkitt's**, **t(11;22) Ewing's**.
- ▶ **Oncogene addiction** explains the dramatic responses to targeted agents; **T315I** explains imatinib resistance.
- ▶ **v-SRC** (Rous sarcoma virus) = first oncogene concept; **Vogelstein “three-strikes”** = multistep colorectal carcinogenesis (APC $\rightarrow$ KRAS $\rightarrow$ SMAD4/TP53).

SOURCE & COVERAGE

Harrison 22e — Ch 76 “Cancer Genetics” (mechanisms of oncogene activation, Tables 76-1 oncogenes and 76-2 translocations, BCR-ABL) and Ch 77 “Cancer Cell Biology” (signal-transduction classes, RAS biology, oncogene addiction, targeted agents Table 77-2). *Coverage note:* The specific MYC-IgH t(8;14) translocation of Burkitt’s lymphoma and the **Knudson two-hit / Vogelstein three-strikes** eponyms are standard, universally accepted internal medicine (and appear elsewhere in Harrison 22e, e.g. Ch 113) but are not detailed verbatim within the two provided chapters; all other specifics (gene names, codons, percentages, translocation notations, drug–target pairs) are taken directly from Ch 76 and Ch 77.

Paraneoplastic Syndromes Associated with Bronchogenic Carcinoma

Asked in: Paper III Jul 2021 — RGUHS MD General Medicine

Definition / Introduction — Paraneoplastic syndromes are disorders that accompany a malignancy but are **not** caused by the local mass effect, invasion, or distant metastasis of the tumour; rather they result from tumour-elaborated peptide hormones, cytokines and growth factors, or from tumour-triggered autoimmunity. Bronchogenic (lung) carcinoma — especially the neuroendocrine **small-cell lung cancer (SCLC)** and carcinoids — is the single most prolific solid-tumour cause of these syndromes. They are clinically important because they may be the **presenting feature**, may herald **recurrence**, can mimic metastatic (incurable) disease, and frequently regress when the primary tumour is treated.

Classification (by organ system) and histological associations

System	Syndrome	Mediator / mechanism	Commonest lung histology
Endocrine	SIADH (hyponatraemia)	Ectopic vasopressin (± ANP)	SCLC
Endocrine	Hypercalcaemia of malignancy	PTHrP (humoral); rarely 1,25-(OH) ₂ D, ectopic PTH	Squamous cell
Endocrine	Ectopic ACTH (Cushing’s)	POMC → ACTH; rarely CRH	SCLC, bronchial carcinoid
Neurological	Lambert-Eaton myasthenic syndrome (LEMS)	Anti-P/Q-type VGCC, anti-SOX1	SCLC
Neurological	Encephalomyelitis, sensory neuronopathy, limbic/brainstem	Anti-Hu, anti-CRMP5, anti-AMPA, anti-GABA-B, anti-recoverin	SCLC

System	Syndrome	Mediator / mechanism	Commonest lung histology
	encephalitis, cerebellar degeneration, opsoclonus, CAR (retinopathy)		
Haematologic	Granulocytosis, thrombocytosis, eosinophilia, anaemia	G-CSF/GM-CSF, IL-6, IL-5	NSCLC > SCLC
Vascular	Migratory thrombophlebitis (Trousseau), marantic endocarditis, DIC, VTE	Tumour procoagulants	Adenocarcinoma
Skeletal/cutaneous	Clubbing, hypertrophic pulmonary osteoarthropathy (HPOA) , dermatomyositis, acanthosis nigricans	Unknown / autoimmune	Adenocarcinoma (HPOA)

- ▶ *Rule of thumb*: SCLC drives the endocrine (SIADH, ectopic ACTH) and neurological (LEMS, encephalomyelitis) syndromes; **squamous cell** drives hypercalcaemia (PTHrP); **adenocarcinoma** drives HPOA/clubbing and is the most thrombogenic.

Endocrine / metabolic syndromes

- ▶ **SIADH (ectopic vasopressin)** — occurs in *at least half* of SCLC patients (clinically apparent in ~11%). Hyponatraemia with **low serum osmolality**, **inappropriately concentrated urine (urine osmolality not maximally dilute)**, **urine Na⁺ normal/high**, and clinical euvolaemia; exclude renal/adrenal/thyroid causes. Symptoms (lethargy, confusion, seizures) reflect *rate* and *severity* of fall in Na⁺. **Treatment**: fluid restriction (first line); **demeclocycline** 150–300 mg PO 3–4×/day; V2-receptor antagonists **tolvaptan** 15 mg PO OD or **conivaptan**; hypertonic (3%) saline + furosemide for Na⁺ <115 meq/L or seizures. Correct **slowly (0.5–1 meq/L/h)** to avoid central pontine myelinolysis. SIADH usually resolves within 1–4 weeks of effective chemotherapy.
- ▶ **Humoral hypercalcaemia of malignancy (HHM)** — seen in ~10–25% of lung cancers, most often **advanced squamous cell carcinoma**. Mediated chiefly by PTHrP (structurally related to PTH, acts on the PTH receptor → hypercalcaemia, hypophosphataemia, hypercalciuria). Features favouring HHM over primary hyperparathyroidism: known malignancy, recent/abrupt onset, very high Ca²⁺, **metabolic alkalosis**, and a **suppressed PTH** with **elevated PTHrP** (raised in ~80% of hypercalcaemic cancer patients). Symptoms: polyuria, dehydration, constipation, confusion; ECG shows **short QT**. **Treatment**: IV saline rehydration (200–500 mL/h), IV **bisphosphonates**

(zoledronate 4 mg, pamidronate 60–90 mg), **denosumab** if refractory, calcitonin, glucocorticoids (lymphoma/myeloma), loop diuretics only after rehydration.

- **Ectopic ACTH (Cushing's syndrome)** — accounts for 10–20% of all Cushing's; SCLC is the commonest cause, followed by **bronchial and thymic carcinoids**. Due to aberrant POMC expression. Because exposure is brief and cachexia coexists, the classic centripetal phenotype is often *absent*; instead patients show **hypokalaemic metabolic alkalosis, hypertension, oedema, hyperglycaemia, hyperpigmentation** (high MSH) and steroid psychosis. **Diagnosis:** urine free cortisol $>2-4\times$ normal, plasma ACTH usually >100 pg/mL, **failure to suppress on high-dose (8 mg) dexamethasone in ~90%** (bronchial carcinoid is a notable exception that may suppress); inferior petrosal sinus sampling (central:peripheral ACTH $\geq 3:1$ favours pituitary source) localises ambiguous cases. **Treatment:** steroidogenesis inhibitors — ketoconazole, metyrapone, mitotane, etomidate; mifepristone; treat the tumour; bilateral adrenalectomy in extreme refractory cases.

Neurological paraneoplastic syndromes

- **Lambert-Eaton myasthenic syndrome (LEMS)** — the classic neuromuscular-junction paraneoplastic syndrome of SCLC; antibodies against **presynaptic P/Q-type voltage-gated calcium channels (VGCC)** (and **anti-SOX1**, a high-risk SCLC marker) reduce quantal acetylcholine release. *Triad:* **proximal lower-limb weakness, autonomic dysfunction** (dry mouth, impotence), and **hyporeflexia/areflexia**. Distinguishing point from myasthenia gravis: **strength and reflexes augment after brief sustained/repeated effort** (post-exercise facilitation); on repetitive nerve stimulation there is an **incremental response at high frequency** (vs decrement in MG). Treat the SCLC (chemotherapy is the initial treatment of choice); symptomatic relief with **3,4-diaminopyridine (amifampridine)** and pyridostigmine; immunotherapy (IVIg, steroids) for refractory cases.
- **CNS / antibody-mediated syndromes** ($\approx$ SCLC, antibodies often precede cancer diagnosis):

Antibody	Syndrome
Anti-Hu (ANNA-1)	Encephalomyelitis, subacute sensory neuronopathy (dorsal-root ganglionopathy)
Anti-CRMP5 (CV2)	Encephalomyelitis, chorea, optic neuritis/uveitis, peripheral neuropathy
Anti-AMPA / anti-GABA-B	Limbic encephalitis (GABA-B $\rightarrow$ early prominent seizures)
Anti-VGCC / P/Q, anti-Yo	Subacute cerebellar degeneration
Anti-recoverin	Cancer-associated retinopathy (CAR) — photosensitivity, night blindness, ring scotomata, attenuated ERG

- ▶ Other reported syndromes: opsoclonus-myoclonus, brainstem encephalitis, polymyositis/dermatomyositis and stiff-person syndrome (anti-amphiphysin). Neurological syndromes occur in ~1% of lung cancers but are dramatic; antibodies against **intracellular** antigens (Hu, CRMP5, Yo) carry a high tumour probability but respond *poorly* to immunotherapy.

Haematologic, vascular and skeletal/cutaneous syndromes

- ▶ **Haematologic** (usually asymptomatic, parallel tumour course): **granulocytosis** (G-CSF/GM-CSF/IL-6; ~40% of lung cancers), **thrombocytosis** (IL-6; ~17–40%, poorer prognosis), **eosinophilia** (IL-5), anaemia, and leukoerythroblastosis with marrow invasion.
- ▶ **Hypercoagulability / vascular** — the most consequential haematologic effect. **Migratory/recurrent superficial thrombophlebitis with visceral carcinoma = Trousseau's syndrome** (classically pancreatic, also lung); also deep vein thrombosis, pulmonary embolism, **non-bacterial thrombotic (marantic) endocarditis** with arterial emboli, and DIC. Lung scores 1 point on the **Khorana VTE risk score**. Treat with LMWH or a DOAC (e.g., apixaban) — generally preferred over warfarin in cancer-associated VTE.
- ▶ **Skeletal / cutaneous** — **digital clubbing** (~30%, usually NSCLC) and **hypertrophic pulmonary osteoarthropathy (HPOA)** (1–10%, classically adenocarcinoma): symmetrical periostosis of long bones with painful arthropathy and a positive bone scan. Cutaneous: **dermatomyositis** (heliotrope rash, Gottron's papules — strong cancer association), acanthosis nigricans, erythema gyratum repens. Renal ($\leq 1\%$): membranous nephropathy / nephrotic syndrome.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Schematic of a bronchogenic carcinoma with labelled paraneoplastic “satellites”** radiating by system: *Endocrine* — SIADH (vasopressin), Hypercalcaemia (PTHrP), Ectopic ACTH (POMC); *Neurological* — LEMS (anti-P/Q VGCC), Encephalomyelitis (anti-Hu), Cerebellar degeneration; *Haematologic/Vascular* — Trousseau's thrombophlebitis, marantic endocarditis; *Skeletal* — Clubbing + HPOA. Label each satellite with **mediator + commonest histology**.
- ▶ **LEMS neuromuscular junction diagram** — label: *presynaptic terminal*, *P/Q-type voltage-gated Ca^{2+} channel*, *anti-VGCC antibody blocking Ca^{2+} entry*, *reduced acetylcholine vesicle release*, *post-synaptic AChR*, and an inset RNS tracing showing **incremental response at high-frequency stimulation**.

Clinical / Diagnostic significance

- ▶ A paraneoplastic syndrome may be the **first clue** to an occult bronchogenic carcinoma — e.g., unexplained hyponatraemia, hypercalcaemia, hypokalaemic alkalosis, or new proximal weakness in a smoker should trigger imaging (CT chest, PET-CT) and onconeural antibody panels.

- ▶ Distinguishing paraneoplastic effects from true metastasis is **prognostically critical** — paraneoplastic syndromes **do not preclude curative-intent treatment**, whereas mislabelling them as metastatic disease wrongly relegates the patient to palliation.
- ▶ **Management hierarchy**: treat the underlying tumour (often produces the most durable response) **plus** syndrome-specific therapy (vaptans for SIADH, bisphosphonates for hypercalcaemia, steroidogenesis inhibitors for ectopic ACTH, 3,4-DAP for LEMS, anticoagulation for VTE).
- ▶ Antibody profiling both **localises the likely primary** (SCLC for anti-Hu/VGCC/SOX1) and **prognosticates** (intracellular-antigen antibodies = poor neurological recovery).

High-yield exam pointers

- ▶ SCLC = the **paraneoplastic powerhouse** of the lung: SIADH, ectopic ACTH, LEMS, anti-Hu encephalomyelitis.
- ▶ Squamous cell → hypercalcaemia (PTHrP); adenocarcinoma → HPOA/clubbing and the most thrombogenic histology.
- ▶ SIADH: euvolaemic hyponatraemia, low serum osmolality, inappropriately concentrated urine, urine $\text{Na}^+ > 20\text{--}40$; correct Na^+ at **0.5–1 meq/L/h** to prevent osmotic demyelination.
- ▶ HHM: suppressed PTH + **elevated PTHrP**, hypophosphataemia, metabolic alkalosis, short QT; treat with saline + bisphosphonate.
- ▶ Ectopic ACTH: hypokalaemic metabolic alkalosis + hyperpigmentation; **fails high-dose dexamethasone suppression**; ACTH > 100 pg/mL.
- ▶ LEMS vs MG: LEMS = proximal weakness, areflexia, autonomic features, **post-exercise facilitation**, **incremental** RNS response, anti-P/Q VGCC; MG = fatigable ocular/bulbar weakness, **decremental** response, anti-AChR.
- ▶ Trousseau's syndrome = migratory thrombophlebitis with visceral (lung/pancreatic) cancer; consider occult malignancy in recurrent/migratory/unusual-site thrombosis.
- ▶ Dermatomyositis (heliotrope rash + Gottron's papules) carries a strong association with internal malignancy including lung.
- ▶ Onconeural antibodies **precede the cancer diagnosis in ~60%** of paraneoplastic neurological disorders.

SOURCE & COVERAGE

- ▶ **Harrison's Principles of Internal Medicine, 22e** — “Paraneoplastic Syndromes: Endocrinologic/Hematologic”; “Neoplasms of the Lung”; “Paraneoplastic Neurologic Syndromes and Autoimmune Encephalitis”; “Myasthenia Gravis and Other Diseases of the Neuromuscular Junction” (LEMS).

- ▶ DeVita, Hellman, and Rosenberg's Cancer: Principles & Practice of Oncology, 12e — lung cancer paraneoplastic syndromes (HHM 10–25%, SIADH ~11% SCLC, HPOA, leukocytosis/thrombocytosis, VTE data).
- ▶ CMDT 2026 — current management framing (SIADH, hypercalcaemia, cancer-associated VTE).
- ▶ *Coverage note:* The “P/Q-type” VGCC subtype and the high-frequency **incremental** RNS response in LEMS are universally accepted standard neuromuscular medicine; Harrison states the antibody as anti-voltage-gated calcium channel / P/Q calcium channel and contrasts it with the decremental MG response.

Paraneoplastic syndromes

Asked in: Paper IV Nov 2020 — RGUHS MD General Medicine

Definition / Introduction — Paraneoplastic syndromes are disorders that accompany benign or malignant tumours but are **not** caused by the local mass effect, invasion, or distant metastasis of the tumour. They arise from substances elaborated by the tumour (peptide hormones, cytokines, growth factors) or from tumour-triggered immune responses (onconeural antibodies). Neuroendocrine tumours — particularly **small-cell lung carcinoma (SCLC)** and carcinoids — are the commonest culprits. They are important because they are more frequent than appreciated, may be the **presenting feature** of an occult malignancy, can cause major morbidity independent of tumour burden, and characteristically wax and wane with the activity of the underlying cancer.

Pathogenesis / Mechanisms

- ▶ **Ectopic hormone production** — *Eutopic* = hormone from its normal tissue (e.g., ACTH from pituitary corticotropes); *ectopic* = hormone from an atypical source (e.g., ACTH from SCLC). Mechanisms include cellular **dedifferentiation** (re-expression of fetal genes such as hCG, PTHrP, α-fetoprotein), epigenetic derepression, and rarely gene rearrangement bringing a hormone gene under an atypical promoter.
- ▶ **Loss of normal feedback regulation and aberrant peptide processing** — e.g., ectopic ACTH arises from unregulated proopiomelanocortin (POMC) expression and is released largely as inactive precursor fragments.
- ▶ **Immune-mediated (neurologic syndromes)** — neuronal proteins ectopically expressed by the tumour break immune tolerance, generating **onconeural antibodies** and cytotoxic T-cell responses that cross-react with the nervous system.
- ▶ **General criteria confirming an ectopic hormone syndrome** — (1) hormone excess from an atypical source; (2) demonstration of tumour hormone production (immunostaining, mRNA,

in-vitro secretion); (3) arteriovenous hormone gradient across the tumour; (4) fall in hormone levels after tumour debulking.

Endocrine paraneoplastic syndromes

Treatment of the **underlying tumour** is the mainstay; specific measures relieve symptoms but rarely alter survival.

Syndrome	Ectopic mediator	Typical tumours	Key points
Humoral hypercalcaemia of malignancy (HHM)	PTHrP; rarely 1,25-(OH) ₂ D (lymphoma), PTH	Squamous (lung, head & neck, skin), breast, GU, oesophagus; myeloma, lymphoma	Commonest endocrine PNS; ~20–30% of cancers; PTHrP raised in ~80%; PTH suppressed , hypophosphataemia, metabolic alkalosis
SIADH (ectopic ADH/vasopressin)	Arginine vasopressin	SCLC (≥50%), carcinoid, head & neck, GU	Euvolaemic hyponatraemia; low serum osmolality with inappropriately concentrated urine
Ectopic Cushing's syndrome	ACTH (POMC); rarely CRH	SCLC (commonest), bronchial/thymic carcinoid, islet cell, pheochromocytoma, medullary thyroid Ca	10–20% of Cushing's; hypokalaemia, metabolic alkalosis, oedema, hyperpigmentation; ACTH usually >100 pg/mL, fails high-dose dexamethasone suppression
Non-islet-cell tumour hypoglycaemia	IGF-II precursor (big IGF-II)	Large mesenchymal tumours, sarcoma, hepatic, adrenal	Fasting hypoglycaemia with suppressed insulin; IGF-II : IGF-I ratio >10:1
hCG-related (gynaecomastia, precocious puberty)	hCG	Testicular germ cell, choriocarcinoma, lung, hepatic, islet	Leydig-cell stimulation → oestrogen excess
Oncogenic (tumour-induced) osteomalacia	FGF23 (phosphatonin)	Haemangiopericytoma, fibroma, giant-cell tumour	Renal phosphate wasting, hypophosphataemia, low 1,25-(OH) ₂ D; normal Ca/PTH; treat with phosphate/vit D, burosumab (anti-FGF23 mAb)

Syndrome	Ectopic mediator	Typical tumours	Key points
Others (rare)	GHRH (acromegaly), renin (hypertension), calcitonin, VIP, TSH	Carcinoids, islet cell, juxtaglomerular tumour	—

Haematologic paraneoplastic syndromes

Usually asymptomatic and self-limited; severity parallels tumour course. The most consequential is hypercoagulability.

Syndrome	Mediator	Associated cancers
Erythrocytosis	Erythropoietin	Renal cell (~3%), hepatoma (~10%), cerebellar haemangioblastoma (~15%)
Granulocytosis	G-CSF, GM-CSF, IL-6	Lung, GI, ovary, GU, Hodgkin's (no left shift)
Thrombocytosis	IL-6, thrombopoietin	Lung, GI, breast, ovary, lymphoma (marker of poorer prognosis)
Eosinophilia	IL-5	Lymphoma, leukaemia, lung
Thrombophlebitis / VTE	Procoagulants, tissue factor	Pancreatic, lung, GI, breast, ovary, GU, brain

- ▶ **Trousseau's syndrome** = migratory/recurrent superficial thrombophlebitis with visceral carcinoma, classically **pancreatic** cancer; may be the heralding sign of malignancy.
- ▶ Cancer-associated VTE risk is stratified by the **Khorana score** (site of cancer, platelets $\geq 350\,000/\mu\text{L}$, Hb $< 10\text{ g/dL}$ or use of ESAs, leucocytes $> 11\,000/\mu\text{L}$, BMI ≥ 35). Treat with LMWH or a DOAC (e.g., **apixaban**, noninferior to dalteparin).

Neurologic paraneoplastic syndromes (PNS) and autoimmune encephalitis

Disabling PNS occur in 0.5–1% of all cancer patients, but in 2–3% with SCLC/neuroblastoma and 30–50% with thymoma. In ~60% the neurologic syndrome **precedes** the cancer diagnosis; syndromes typically evolve subacutely. Antibodies are classified by their probability of an underlying tumour.

Antibody	Target	Classic syndrome	Tumour
Anti-Hu (ANNA-1)	intracellular	Encephalomyelitis, sensory neuronopathy	SCLC
Anti-Yo (PCA-1)	intracellular	Subacute cerebellar degeneration	Ovary, breast

Antibody	Target	Classic syndrome	Tumour
Anti-Ri (ANNA-2)	intracellular	Opsoclonus, cerebellar/brainstem	Breast, gynaecologic, SCLC
Anti-CRMP5 (CV2)	intracellular	Encephalomyelitis, chorea, optic neuritis, uveitis, neuropathy	SCLC, thymoma
Anti-Tr (DNER)	cell-surface	Cerebellar degeneration	Hodgkin's lymphoma
Anti-Ma2	intracellular	Limbic/hypothalamic/brainstem encephalitis	Testicular germ cell
Anti-amphiphysin	(synaptic)	Stiff-person syndrome	Breast, SCLC
Anti-NMDAR	cell-surface	Psychiatric prodrome → seizures, dyskinesias, dysautonomia, hypoventilation	Ovarian teratoma (young women)
Anti-VGCC	cell-surface	Lambert-Eaton myasthenic syndrome (LEMS) , cerebellar	SCLC
Anti-LGI1	cell-surface	Limbic encephalitis, hyponatraemia, faciobrachial dystonic seizures	Rarely thymoma
Anti-Caspr2	cell-surface	Morvan syndrome , neuromyotonia	Thymoma

- ▶ **Classic (“high-risk”) syndromes** — encephalomyelitis, limbic encephalitis, subacute cerebellar degeneration, opsoclonus-myoclonus, sensory neuronopathy, LEMS, gastrointestinal pseudo-obstruction, dermatomyositis.
- ▶ **Therapeutic dichotomy** — antibodies to **intracellular antigens** (Hu, Yo, Ri, CRMP5, Ma2) act via cytotoxic T cells, cause neuronal loss, and respond **poorly** to immunotherapy (focus on treating the tumour). Antibodies to **cell-surface/synaptic antigens** (NMDAR, LGI1, Caspr2, AMPAR, GABA-B) are **directly pathogenic** and **respond well** to tumour removal plus immunotherapy — first-line steroids, IVIg, plasma exchange; second-line **rituximab**, **cyclophosphamide**. ~85–90% of anti-NMDAR patients improve substantially.
- ▶ LEMS: proximal weakness with **post-tetanic facilitation** and autonomic features; if positive, screen for SCLC with CT/PET and continue surveillance ≥3 years.

Dermatologic and rheumatologic paraneoplastic syndromes

- ▶ **Acanthosis nigricans** (esp. gastric adenocarcinoma) and **tripe palms** (thickened velvety palms).
- ▶ **Sign of Leser-Trélat** — sudden eruption of multiple seborrheic keratoses (GI adenocarcinoma).
- ▶ **Erythema gyratum repens** (lung), **necrolytic migratory erythema** (glucagonoma), **Bazex syndrome / acrokeratosis paraneoplastica** (aerodigestive squamous cancers), **paraneoplastic pemphigus** (lymphoproliferative disease).

- ▶ **Dermatomyositis / polymyositis** (Gottron papules, heliotrope rash) — strongest cancer link with dermatomyositis, highest risk within the first 5 years.
- ▶ **Hypertrophic pulmonary osteoarthropathy (HPOA)** — triad of **digital clubbing, symmetrical large-joint arthropathy, and radiographic periostosis**; most often non-small-cell (adenocarcinoma) lung cancer.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Schematic of mechanisms of paraneoplastic syndromes** — central tumour cell with three labelled arrows: (1) *Ectopic hormone* → PTHrP, ADH, ACTH, IGF-II → target organs (bone/kidney, kidney, adrenal, muscle); (2) *Cytokines* → IL-6, G-CSF, IL-5, EPO → marrow (thrombocytosis, granulocytosis, eosinophilia, erythrocytosis); (3) *Onconeural antibodies / T cells* → CNS, dorsal root ganglion, neuromuscular junction. Label **eutopic vs ectopic** and “effects not due to mass/metastasis.”
- ▶ **Antibody–antigen location diagram** — two panels: *Intracellular antigens* (Hu, Yo, Ri, CRMP5) → cytotoxic T-cell attack → poor response; *Cell-surface antigens* (NMDAR, LGI1, VGCC) → antibody-mediated → good response to immunotherapy. Label the neuron, surface receptor, antibody, and T cell.

Clinical / Diagnostic significance

- ▶ **Recognition value** — atypical metabolic/neurologic features in a cancer patient, or an unexplained syndrome (hyponatraemia, hypercalcaemia, subacute cerebellar ataxia) in a patient without known cancer, should prompt a search for malignancy (CT/PET; testicular/pelvic USS or MRI for germ-cell tumours and teratomas).
- ▶ **Endocrine work-up** — suppressed PTH with raised PTHrP confirms HHM; ACTH >100 pg/mL with failure of high-dose dexamethasone suppression and absent petrosal:peripheral gradient indicates ectopic ACTH; IGF-II:IGF-I ratio >10:1 supports IGF-II hypoglycaemia.
- ▶ **Neurologic work-up** — only ~60–70% of CNS PNS and <20% of peripheral PNS have a detectable antibody; MRI (mesial temporal FLAIR change in limbic encephalitis) and CSF (lymphocytic pleocytosis, oligoclonal bands) support the diagnosis and exclude metastatic/leptomeningeal disease.
- ▶ **Management of HHM** — IV **0.9% saline 100–300 mL/h** for rehydration and calciuresis, then **bisphosphonate** (zoledronic acid/pamidronate) or **denosumab** (anti-RANKL; preferred in renal impairment or bisphosphonate-refractory cases); calcitonin or glucocorticoids as adjuncts; treat the tumour.
- ▶ **Management of SIADH** — fluid restriction, **vaptans** (tolvaptan) or demeclocycline; correct sodium slowly (0.5–1 mEq/L/h) to avoid osmotic demyelination.

High-yield exam pointers

- ▶ SCLC is the single commonest cause of paraneoplastic syndromes (SIADH, ectopic ACTH, LEMS, Hu/encephalomyelitis).
- ▶ Commonest **endocrine** PNS = **hypercalcaemia** (PTHrP); commonest cause of **paraneoplastic SIADH** = SCLC.
- ▶ **Ectopic ACTH** → hyperpigmentation, hypokalaemic metabolic alkalosis, *less* central obesity; ACTH not suppressed by high-dose dexamethasone.
- ▶ **Trousseau's syndrome** = migratory thrombophlebitis ↔ visceral (pancreatic) cancer.
- ▶ **Anti-Yo** → cerebellum (ovary/breast); **anti-Hu** → sensory neuronopathy/encephalomyelitis (SCLC); **anti-Ri** → opsoclonus; **anti-Ma2** → limbic/brainstem (testicular); **anti-Tr** → cerebellar (Hodgkin's).
- ▶ **Anti-NMDAR encephalitis** → young woman + **ovarian teratoma**; psychiatric → seizures → dyskinesias → autonomic instability; rituximab-responsive.
- ▶ **LEMS** → anti-VGCC, SCLC, proximal weakness with facilitation; **Lambert-Eaton precedes the cancer** in most.
- ▶ **Surface-antigen** antibodies respond to immunotherapy; **intracellular-antigen** antibodies do not — treat the tumour.
- ▶ Cutaneous clues: **Leser-Trélat**, **acanthosis nigricans**, **tripe palms**, **erythema gyratum repens**, **necrolytic migratory erythema** (glucagonoma); rheumatologic: **HPOA** (clubbing + periostosis), dermatomyositis.

Paroxysmal nocturnal haemoglobinuria

Asked in: Paper IV Nov 2020 — RGUHS MD General Medicine

Definition / Introduction — Paroxysmal nocturnal hemoglobinuria (PNH) is an **acquired, clonal hematopoietic stem-cell disorder** caused by a somatic mutation in the X-linked *PIGA* gene, leading to

deficiency of the **glycosylphosphatidylinositol (GPI) anchor** and of the GPI-linked complement-regulatory proteins **CD55 and CD59** on the surface of blood cells. The result is a chronic, complement-mediated **intravascular hemolytic anemia** with recurrent exacerbations. The classic clinical triad is (1) **intravascular hemolysis**, (2) **a marked tendency to venous thrombosis**, and (3) **a variable degree of bone marrow failure (pancytopenia)** — a combination that makes PNH a uniquely recognisable entity. It is a rare disease (estimated prevalence **5–10 per million**, perhaps somewhat commoner in Southeast Asia and the Far East), affects men and women equally, is **never inherited/congenital**, and usually presents in young adults. It is the prime example of a *clonal but non-malignant* disorder.

Molecular pathogenesis — the PIGA mutation and GPI anchor

- ▶ The fundamental lesion is an **acquired somatic mutation of the PIGA gene (located on the X chromosome) in a hematopoietic stem cell*. PIGA encodes an enzyme needed for an early step in GPI biosynthesis*.
- ▶ Because the gene is X-linked, a single inactivating hit (one active X in each cell) abolishes function, producing a clone of progeny cells deficient in the GPI glycolipid.
- ▶ GPI is a glycolipid that, through a peptide bond, **anchors numerous proteins to the cell-surface membrane**; these proteins possess only an extracellular domain. Loss of GPI therefore removes a whole family of surface proteins, the critical ones being the **complement regulators CD55 and CD59**.
 - **CD55 (decay-accelerating factor)** — prevents assembly/accelerates decay of the C3 and C5 convertases, i.e., limits C3-fragment deposition.
 - **CD59 (membrane inhibitor of reactive lysis / protectin)** — the **most important** regulator; it blocks insertion of C9 polymers, preventing formation of the **membrane attack complex (MAC, C5b-9)**.
- ▶ The marrow becomes a **mosaic** of mutant (GPI-negative, “PNH”) and normal (GPI-positive) cells; the peripheral blood always contains both populations, and in most patients the PNH clone predominates.
- ▶ Rarely, PNH arises from **biallelic mutations of the autosomal PIGT gene (chromosome 20q) without a PIGA mutation; here GPI is made but cannot bind proteins, and the picture is complicated by a chronic inflammatory state**.

Mechanism of hemolysis — complement on an unprotected cell

- ▶ Hemolysis is **mainly intravascular** and results from the *intrinsic* hypersensitivity of CD55/CD59-deficient red cells to **activated complement**.
- ▶ **Alternative pathway** activation (continuous low-grade “tick-over”) drives the **chronic** baseline hemolysis; **classical pathway** activation (antigen–antibody) during **infection or inflammation** triggers the dramatic acute **exacerbations** (“paroxysms”).

- ▶ Without CD59, the MAC inserts freely into the membrane → lysis → **hemoglobinemia and hemoglobinuria**.
- ▶ Free plasma hemoglobin scavenges **nitric oxide**, producing smooth-muscle dystonia — **esophageal spasm/dysphagia, abdominal pain, erectile dysfunction**, and contributing to thrombotic risk and kidney damage.

Relationship with bone marrow failure (PNH–aplastic anemia syndrome)

- ▶ PNH and aplastic anemia (AA) are pathogenetically linked. AA is regarded as a T-cell-mediated organ-specific autoimmune attack on hematopoietic stem cells; the autoantigen in PNH may be the GPI molecule itself, so that **GPI-negative (PNH) stem cells are spared** the immune attack and undergo positive (negative against normal cells) selection* and clonal expansion.
- ▶ Thus PNH results from **two factors acting together: (i) failure of normal hematopoiesis and (ii) escape/expansion of the GPI-deficient clone**.
- ▶ **Clinical overlap:** many patients with overt PNH have antecedent (often unnoticed) BMF; a patient with PNH may evolve into frank AA, and a patient with AA may develop hemolytic PNH years later. Small GPI-deficient (PNH) clones are detectable by flow cytometry in **≥50% of patients with aplastic anemia** at presentation — a small clone (<2%) without reticulocytosis or thrombosis is **not** true PNH.
- ▶ Useful clinical categories: (a) **classic hemolytic PNH**, (b) **PNH in the setting of another marrow-failure disorder (AA/MDS)** — the “PNH-AA syndrome”, and (c) **subclinical PNH** (a small clone, no clinical hemolysis).

Clinical features

Component of the triad	Manifestations
Intravascular hemolysis	Episodic hemoglobinuria — classically “passing blood instead of urine”; reddish-brown urine typically in the first morning void (nocturnal hypoventilation lowers blood pH and facilitates hemolysis). Anemia, fatigue; NO depletion → dysphagia/esophageal spasm, abdominal pain, erectile dysfunction . Hemoglobinuria varies dramatically hour-to-hour.
Thrombosis (venous, characteristically unusual sites)	Most life-threatening complication and the leading cause of death. Hepatic vein → Budd-Chiari syndrome (acute hepatomegaly + ascites without liver disease should raise suspicion of PNH); mesenteric/abdominal veins (recurrent severe abdominal pain); cerebral veins (sagittal sinus) ; dermal vessels (painful nodules).

Component of the triad	Manifestations
Bone marrow failure / cytopenias	Anemia with neutropenia and/or thrombocytopenia signalling marrow failure; may evolve to overt aplasia.

- ▶ **Natural history** spans decades; with supportive care only, historical **median survival ~10–20 years**, death mainly from thrombosis, then infection (neutropenia) and hemorrhage (thrombocytopenia). **Transformation to AML is rare (~1–2%)**; rare spontaneous remissions occur.

Laboratory diagnosis

- ▶ **Hemolysis profile:** normo- to macrocytic anemia with **reticulocytosis** (up to ~20% / 400,000/ μ L); **LDH markedly elevated** (values in the thousands); unconjugated bilirubin mildly–moderately raised; **haptoglobin undetectable**.
- ▶ **Intravascular hemolysis markers:** **urine hemosiderin positive** (chronic loss), **hemoglobinuria** on dipstick (serial samples help because it fluctuates); **iron deficiency** is common from chronic urinary iron loss (may make the anemia microcytic).
- ▶ **Direct antiglobulin (Coombs) test is characteristically NEGATIVE** — a key point distinguishing PNH from autoimmune hemolytic anemia. (It can turn *positive* once a patient is on anti-C5 therapy because of C3 opsonisation.)
- ▶ **Flow cytometry = gold standard:** demonstrates a discrete population of cells deficient in CD55 and CD59 on red cells AND granulocytes/monocytes, giving a **bimodal distribution**. The FLAER assay (fluorescein-labelled proaerolysin, which binds the GPI anchor directly) on granulocytes/monocytes is **more sensitive**.
- ▶ **Diagnostic threshold:** do not diagnose PNH unless the GPI-deficient population is *substantial* — in first approximation **$\geq 5\%$ of red cells and $\geq 20\%$ of granulocytes**.
- ▶ **Older tests:** the **acidified-serum (Ham) test** is highly reliable; the **sucrose hemolysis test** is **unreliable** (both now superseded by flow cytometry).
- ▶ **Bone marrow:** usually **cellular with marked erythroid hyperplasia** $\pm$ mild dyserythropoiesis; may become **hypocellular/aplastic** at some stage.

Management

- ▶ **Supportive** (essential everywhere, as **complement inhibitors are very expensive/often inaccessible**): mandatory **folic acid ≥ 3 mg/day**; periodic serum iron with **iron replacement** as needed (may transiently increase hemolysis); transfusion of **leukocyte-depleted red cells**; treat/anticipate iron overload if transfusion-dependent.
- ▶ **Anticoagulation:** any patient with prior venous thrombosis (or a thrombophilia risk factor on screening) should receive **regular anticoagulant prophylaxis**; thrombolysis (tPA) for refractory thrombosis.

- ▶ **Glucocorticoids:** not indicated for chronic hemolysis (contraindicated long-term); a short prednisone course may help an inflammation-driven flare.
- ▶ **Complement inhibitors** (transform hemolysis, reduce transfusion need and thrombosis):

Agent	Target	Comment
Eculizumab	C5	Humanized anti-C5 mAb (introduced 2007); blocks C5 cleavage → no MAC → abolishes intravascular hemolysis; IV every 14 days. Residual <i>extravascular</i> hemolysis from C3 opsonisation persists (Coombs becomes positive).
Ravulizumab	C5	Longer-acting eculizumab derivative; IV every 8 weeks; fewer breakthrough episodes.
Pegcetacoplan	C3	Proximal blockade prevents both intravascular and extravascular hemolysis → can fully correct anemia (higher Hb than C5 blockade).
Iptacopan	Factor B	Oral; blocks alternative-pathway C3 convertase.
Danicopan	Factor D	Oral; add-on for inadequate response to C5 blockade.

- ▶ **Meningococcal risk:** terminal-complement blockade predisposes to **Neisseria meningitidis* infection — *vaccinate against serogroups ACWY and B** (plus antibiotic prophylaxis, e.g., penicillin) before starting.
- ▶ **Breakthrough hemolysis** can occur with incomplete blockade (more abrupt/severe with proximal C3 blockade because of the larger surviving PNH red-cell mass).
- ▶ **Allogeneic HSCT** is the only curative option — reserved for young patients with severe PNH or PNH-AA syndrome (complement inhibitors do not treat the marrow failure); immunosuppression with **antithymocyte globulin + ciclosporin** is an alternative for the AA component.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Diagram 1 — Complement cascade and the GPI-protected red cell (with drug targets).**
Labels: *Classical / Lectin / Alternative pathways* → C3 → C3 convertase → C5 convertase → C5 → C5b–C9 = Membrane Attack Complex (MAC); CD55 (DAF) blocking the convertases; CD59 (protectin) blocking MAC; GPI anchor tethering CD55/CD59;

Normal RBC (protected) vs PNH RBC (CD55/CD59 negative → lysis); drug arrows — Eculizumab/Ravulizumab at C5, Pegcetacoplan at C3, Iptacopan at factor B, Danicopan at factor D.

- ▶ **Diagram 2 — GPI anchor on the red-cell membrane.** Labels: *lipid bilayer, GPI glycolipid anchor, CD55, CD59, PIGA gene* → GPI biosynthesis; show **normal cell** (anchor + proteins present) vs PNH cell (anchor and proteins absent due to PIGA mutation).

Clinical / Diagnostic significance

- ▶ **Suspect PNH in:** Coombs-negative intravascular hemolytic anemia; hemolysis **with** unexplained cytopenia/pancytopenia or aplastic anemia; **venous thrombosis at unusual sites** (especially Budd-Chiari syndrome or abdominal/cerebral vein thrombosis) in a young patient; and unexplained iron-deficiency with hemoglobinuria.
- ▶ **LDH very high + haptoglobin absent + urine hemosiderin positive + DAT negative** is the classic biochemical signature; confirm with **flow cytometry** (CD55/CD59, FLAER).
- ▶ Screen all **aplastic anemia and hypoplastic MDS** patients for a PNH clone, and **monitor PNH patients** for evolving marrow failure.
- ▶ Recognising the **NO-depletion symptoms** (dysphagia, abdominal pain, erectile dysfunction) and **thrombotic risk** drives early complement inhibition and anticoagulation, which markedly improve quality of life and survival.

High-yield exam pointers

- ▶ PNH = **acquired clonal stem-cell disease**; somatic ***X-linked PIGA* mutation** → GPI-anchor deficiency → **loss of CD55 & CD59** → **complement-mediated** intravascular hemolysis**.
- ▶ **Triad:** hemolysis + **venous thrombosis** (leading cause of death) + **bone-marrow failure/pancytopenia**.
- ▶ **CD59** is the most important protector (blocks MAC); **CD55** accelerates convertase decay.
- ▶ **DAT/Coombs NEGATIVE** — distinguishes PNH from AIHA.
- ▶ **Diagnosis** = **flow cytometry** for GPI-deficient red cells *and* granulocytes; **FLAER** most sensitive; threshold **≥5% RBC / ≥20% granulocytes**; **Ham (acidified serum) test** classic, sucrose test unreliable.
- ▶ **First morning urine** is darkest (nocturnal acidosis); **LDH markedly raised, haptoglobin absent, urine hemosiderin positive**; iron deficiency common.
- ▶ **Budd-Chiari syndrome without liver disease** → think PNH.
- ▶ **Eculizumab (anti-C5, q2w) and ravulizumab (q8w)** abolish intravascular hemolysis; **pegcetacoplan (C3)/iptacopan (factor B)/danicopan (factor D)** also block extravascular hemolysis; **meningococcal vaccination mandatory** before complement blockade.

- ▶ **Allogeneic HSCT** is the only cure (for severe PNH / PNH-AA syndrome); **folic acid ≥ 3 mg/day** is mandatory supportive care; **AML transformation ~ 1 –2%**.

SOURCE & COVERAGE

- ▶ **Harrison's Principles of Internal Medicine, 22e** — “Hemolytic Anemias” (Acquired/PNH section: PIGA, GPI anchor, CD55/CD59, complement cascade Figs 105-10/105-11, diagnosis, anti-complement therapy) and “**Bone Marrow Failure Syndromes Including Aplastic Anemia and Myelodysplasia**” (PNH–aplastic anemia relationship).
- ▶ **CMDT 2026** — “Blood Disorders” (Paroxysmal Nocturnal Hemoglobinuria) — essentials of diagnosis, FLAER assay, nitric-oxide–mediated symptoms, thrombosis sites, and current complement-inhibitor regimens including meningococcal prophylaxis.
- ▶ Standard nomenclature CD55 = *decay-accelerating factor* and CD59 = *membrane inhibitor of reactive lysis/protectin* is universally accepted textbook hematology (the functional roles are as described in Harrison).
- ▶ *Coverage note:* The assigned specialty text (**DeVita's Cancer: Principles & Practice of Oncology 12e*) *does not** substantively cover PNH (search matches were incidental, e.g., author names/“epigastric”); depth here is therefore drawn from Harrison 22e plus CMDT 2026, both of which cover PNH comprehensively.

Screening Strategies for Colorectal Cancer

Asked in: Paper II May 2019 — RGUHS MD General Medicine

Definition / Introduction — Screening for colorectal cancer (CRC) is the systematic application of tests to *asymptomatic, average-risk or increased-risk* individuals to detect either pre-malignant adenomatous/serrated polyps (so they can be removed) or early, curable cancers. CRC is an ideal target for screening because it is common, is fatal in nearly 50% of cases yet highly curable when localized, and arises from benign polyps that progress to cancer over many years through the *adenoma–carcinoma sequence*. Removal of these polyps has been shown to prevent the majority of cancers; consequently, the U.S. Preventive Services Task Force (USPSTF, 2021), American Cancer Society (ACS, 2018), ACG and US Multi-Society Task Force all endorse offering organized screening to **all adults aged 45–75 years**.

Rationale and risk stratification (who, and when to start)

- ▶ **Twin rationale:** (1) endoscopic removal of adenomatous polyps *prevents* cancer; (2) detection of localized, superficial cancers in asymptomatic people raises the surgical cure rate.
- ▶ **Starting age lowered to 45 years (USPSTF 2021)** because of the rising incidence of CRC in adults <50 years. Grade B at 45–49 years (qualified) and grade A at 50–75 years (strong).

- ▶ **76–85 years:** individualize (“C”) — consider overall health, life expectancy, prior screening and preferences. **>85 years:** discourage screening.
- ▶ Screening intensity is **risk-tiered**: average risk vs increased risk (family history, IBD/PSC) vs high risk (hereditary syndromes).

Risk category	Defining feature	When to begin / interval
Average risk	No personal/family history, no IBD	Age 45 y; modality-dependent interval (see below)
Single FDR, CRC at ≥ 60 y	One first-degree relative	Begin age 40 y; colonoscopy every 10 y (as average risk)
FDR with CRC/advanced adenoma < 60 y, or two FDRs	Stronger family history	Begin age 40 y or 10 y before youngest case; colonoscopy every 5 y
IBD (UC / Crohn colitis), PSC	Chronic colitis	Surveillance colonoscopy 8–10 y after symptom onset
FAP / MUTYH-associated	APC / biallelic MUTYH	Endoscopic surveillance from puberty; prophylactic colectomy
Lynch syndrome (HNPCC)	MMR gene variant	Colonoscopy every 1–2 y from age 25 y

Stool-based (non-invasive) tests

- ▶ **Guaiac faecal occult blood test (gFOBT, e.g. Hemoccult SENSА):** detects pseudoperoxidase activity of haem; **annual**. Affected by diet/medications. ~50% of proven CRCs give a negative test (intermittent bleeding); of asymptomatic “positives” <10% have cancer, 20–30% have benign polyps. Meta-analysis: **22% relative reduction** in CRC mortality with biennial testing (up to 32% with annual) — benefit emerges only after years of follow-up via downstream colonoscopy.
- ▶ **Faecal immunochemical test (FIT):** detects human globin; **annual**. Higher sensitivity than gFOBT with similar specificity and **not affected by diet or medication** — it has largely replaced gFOBT and is the *preferred* stool test (US Multi-Society Task Force, ACG). Pooled sensitivity ~74%, specificity ~94% for CRC; may detect proximal tumours less reliably.
- ▶ **Multi-target stool DNA test (mt-sDNA; Cologuard = FIT + methylated/mutated DNA markers):** every 1–3 years. Single-test sensitivity for CRC 92.3% vs 73.8% for FIT alone, and for large/serrated adenomas 42.4% vs 23.8%; but **lower specificity** → more false positives and follow-up colonoscopies. High sensitivity/specificity (>90%) for established adenocarcinoma but <50% sensitivity for advanced precancerous lesions.
- ▶ **Blood-based test (methylated SEPT9):** lower sensitivity and specificity than FIT, costlier — **not recommended as a first-line screening test**.

- **Key principle:** *any positive stool/blood/imaging test mandates colonoscopy*; a non-invasive test is only the first step of a two-step pathway.

Structural / visual (endoscopic and imaging) tests

Test	Interval	Strengths	Limitations
Colonoscopy	every 10 y	Examines <i>entire</i> colon; diagnostic + therapeutic (polypectomy); most sensitive	Bowel prep + sedation; perforation ~0.1% ($\approx 4/10\,000$), bleeding ~0.25%, death $\approx 2.9/100\,000$; operator-dependent
Flexible sigmoidoscopy	every 5 y (or 10 y + annual FIT)	No sedation, no full enema, fewer perforations ($\approx 1/10\,000$); RCT-proven ↓ incidence & mortality	Only rectosigmoid/descending colon; misses proximal lesions ($\approx 1.5\%$ have proximal advanced neoplasia despite normal scope)
CT colonography (virtual)	every 5 y	Sensitivity >95% for cancer, 86% for polyps ≥ 6 mm; option if colonoscopy declined/incomplete	Bowel prep; radiation; extracolonic findings (5–37%); flat/serrated lesions missed; positive → colonoscopy
Capsule colonoscopy	—	Non-invasive imaging of colon	Lower sensitivity (polyps >6 mm 64% vs 84%; CRC 74% vs 100%); FDA-approved only for unsuitable/incomplete colonoscopy

- **Sigmoidoscopy evidence:** meta-analyses of RCTs show an **18% relative reduction in incidence** and a **28% reduction in mortality**; benefit of a single screen persists >15 years. Any adenoma found at sigmoidoscopy → complete the examination with **full colonoscopy**.
- **Colonoscopy quality matters:** benefit is greater in the **distal** ($\approx 80\%$) than proximal colon ($\approx 40\text{--}60\%$); withdrawal time $\geq 7\text{--}9$ min and an adequate adenoma detection rate are key quality metrics.
- **Digital rectal examination (DRE)** is **NOT** an effective CRC screening test and is not recommended by any society.

Screening in high-risk / hereditary syndromes

- **Familial adenomatous polyposis (FAP):** autosomal dominant, APC gene ($\sim 90\%$); **MUTYH-associated polyposis** is autosomal recessive ($\sim 8\%$). Hundreds–thousands of adenomas; polyps by mean age 15 y, cancer often by 40 y, **inevitable by 50 y** if untreated. Management: genetic counselling/testing, endoscopic surveillance from puberty, and **prophylactic**

proctocolectomy/colectomy (usually before age 20 y); plus upper-GI endoscopy every 1–3 y for duodenal/peripapillary adenomas. *MUTYH-associated polyposis* — colonoscopic surveillance annually-to-biennially from age 25–30 y.

- ▶ **Lynch syndrome (HNPCC)**: autosomal dominant MMR gene defect (**MLH1, MSH2, MSH6, PMS2, EPCAM**) causing microsatellite instability; ~3% of all CRC, up to 17-fold risk; accelerated adenoma→cancer (1–2 y). **Universal tumour testing** (IHC for MMR proteins or MSI) is recommended for *all* CRCs. Carriers: **colonoscopy every 1–2 years from age 25 y** (or 5 y younger than youngest case); plus endometrial/ovarian surveillance from 30–35 y and consideration of risk-reducing hysterectomy ± BSO at 40 y.
- ▶ **IBD**: risk rises ~0.5–1% per year after the first decade; surveillance colonoscopy with biopsies begins 8–10 years after symptom onset (earlier with concurrent PSC).

Surveillance after polypectomy / curative resection

- ▶ After curative CRC resection: history, examination and **CEA** every 3–6 months for 2 years then 6-monthly to 5 years; CT chest/abdomen/pelvis 6–12 monthly in high-risk stage II / all stage III.
- ▶ **Colonoscopy 1 year** after resection (or after completing adjuvant therapy if not fully scoped pre-op); if clear, repeat **every 3–5 years** for metachronous lesions.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Adenoma–carcinoma sequence flow diagram**: *Normal colonic mucosa → APC loss → small adenoma → KRAS activation → large/advanced adenoma → TP53 / DCC loss → invasive carcinoma*, with a parallel arrow “polypectomy interrupts the sequence.” Label the multi-year timeline and the accelerated 1–2 year pathway in Lynch syndrome.
- ▶ **CRC screening algorithm**: Box “Average-risk adult, age 45 y” → two branches: *Stool-based (FIT annual / mt-sDNA q1–3 y)* and *Structural (colonoscopy q10 y / FS q5 y / CT colonography q5 y)*; any **positive non-invasive test → COLONOSCOPY**. Side box: “Increased/high risk → tailored earlier, more frequent colonoscopy.” Label start age 45, stop 75 (individualize 76–85).

Clinical / Diagnostic significance

- ▶ Choice of test is a shared decision — “*the best test is the one the patient will actually complete.*” FIT and colonoscopy are the preferred stool-based and structural modalities respectively.
- ▶ Unexplained **iron-deficiency anaemia** in any adult (except a menstruating multiparous woman) mandates full colonic evaluation — it is not a screening scenario but the commonest presentation of a right-sided cancer.
- ▶ Stool tests reduce mortality chiefly by triggering colonoscopy and polypectomy; their value is realized only when positives are followed up.

- ▶ **Primary prevention** adjuncts: regular **aspirin/NSAIDs** reduce adenoma/cancer incidence (individualized owing to bleeding risk); antioxidant vitamins and fibre supplements are *not* protective.

High-yield exam pointers

- ▶ **Start screening at age 45 y** (USPSTF 2021); continue to 75; individualize 76–85; discourage >85.
- ▶ **Average-risk menu:** FIT annual · gFOBT (Hemoccult SENSa) annual · mt-sDNA q1–3 y · flexible sigmoidoscopy q5 y · **colonoscopy q10 y** · CT colonography q5 y.
- ▶ **Colonoscopy = gold standard** (most sensitive, therapeutic); FIT = **preferred non-invasive test** (replaced gFOBT, diet-independent).
- ▶ **DRE is not a screening test.** Any positive non-invasive test → **colonoscopy**.
- ▶ **FAP:** APC, AD, colectomy before age 20 y; **MUTYH** is AR. **Lynch:** MMR genes, colonoscopy q1–2 y from age 25 y; universal MSI/IHC testing of all CRCs.
- ▶ **IBD/PSC:** surveillance colonoscopy 8–10 y after onset.
- ▶ Family history of CRC → begin at **age 40 y** or 10 y before youngest affected relative.
- ▶ Sigmoidoscopy misses the proximal colon; complete with colonoscopy if any adenoma found.
- ▶ Post-resection: colonoscopy at **1 year**, then q3–5 y.

Sickle cell anemia

Asked in: Paper I May 2019 — RGUHS MD General Medicine

Definition / Introduction — Sickle cell anemia (SCA) is the **autosomal-recessive** hemoglobinopathy caused by *homozygosity* for the sickle β -globin gene (HbSS, $\alpha_2\beta S_2$). A single point mutation produces an abnormal hemoglobin (HbS) that **polymerizes when deoxygenated**, deforming the red cell into the classic sickle shape. The result is a **chronic hemolytic anemia** punctuated by **vaso-occlusive** events and progressive multi-organ damage. It is the most prevalent of the “sickle cell disease” (SCD) phenotypes and one of the commonest Mendelian disorders worldwide.

Molecular genetics, epidemiology & inheritance

- ▶ **Mutation:** point mutation in the β -globin gene (HBB, chromosome 11p15) — GAG→GTG in **codon 6**, substituting **valine for glutamic acid** ($\beta 6 \text{ Glu} \rightarrow \text{Val}$; Harrison numbers it residue 7 by counting the initiator methionine), generating βS . The mutant tetramer is $\alpha_2\beta S_2$ (HbS).
- ▶ **Inheritance:** autosomal recessive — homozygote ($\beta S/\beta S$) = sickle cell anemia; heterozygote ($\beta A/\beta S$) = **sickle cell trait**; compound heterozygotes (HbS- β -thal, HbSC, HbSE) give the broader sickle cell disease spectrum.
- ▶ **Heterozygote advantage:** HbS arose in Africa ~7,000–22,000 years ago and reached high frequency because carriers are relatively protected against *Plasmodium falciparum* malaria (balanced polymorphism).
- ▶ **HbS haplotypes** (Senegal, Benin, Bantu, Cameroon, **Arab-Indian**) modulate severity via their average HbF level — *Senegal* and *Arab-Indian* haplotypes have higher HbF and a milder, often Indian-relevant course.
- ▶ **Burden:** sickle cell trait affects 2–15% of emigrant populations and up to ~half the population in parts of Africa, India and the Middle East; carriers outnumber patients ~25:1. Median age of death in SCA is now in the **5th–6th decade** (CMDT: ~40–50 years).

Pathophysiology (the two interlinked sub-phenotypes)

- ▶ **Polymerization:** HbS behaves like HbA when oxygenated but on **deoxygenation** polymerizes into fibres; the process is exquisitely concentration-dependent — proportional to roughly the **30th power of intracellular Hb concentration**, so small rises in MCHC or cell dehydration markedly accelerate sickling.
- ▶ **Promoters of sickling:** hypoxia, acidosis, dehydration, hyperosmolarity, cold, infection and stasis. HbF **cannot enter the polymer** and therefore powerfully retards sickling (basis of HbF-inducing therapy).
- ▶ **Membrane injury:** repeated sickling causes K^+/Cl^- co-transport and Gardos-channel activation with cellular dehydration, phosphatidylserine externalization and oxidative damage → **irreversibly sickled cells (ISCs)** permanently deformed regardless of oxygenation.

- ▶ **Vaso-occlusion (viscosity arm):** rigid, adhesive sickle cells, leukocytes and platelets occlude the microvasculature → tissue ischemia/infarction and the acute painful episode.
- ▶ **Hemolysis (endothelial arm):** sickle red cells survive <20 days (normal ~120). **Intravascular hemolysis** depletes haptoglobin/hemopexin and releases free hemoglobin, heme and arginase, which scavenge **nitric oxide (NO)**, activate platelets/endothelium and drive vasoconstriction, a pro-inflammatory/pro-thrombotic state and **pulmonary hypertension, priapism, leg ulcers, stroke and nephropathy.**

Genotypes (classification of sickle hemoglobinopathies)

Genotype	Hb fractions (typical)	Clinical severity
Sickle cell trait (HbAS)	HbA 60–70%, HbS 30–40%	Benign; usually normal life expectancy
Sickle cell anemia (HbSS)	HbS >75%, HbF 2–15%, HbA2 ~3–4%, no HbA	Most severe; reference phenotype
HbS-β ⁰ thalassemia	HbS >75%, HbF 2–15%, HbA2 5–6%, no HbA ; low MCV	Clinically like HbSS
HbS-β ⁺ thalassemia	HbS 60–90%, HbA 5–40%, low MCV	~half the complication rate; spleen often palpable
HbSC disease	HbS ~50%, HbC ~50%	Milder; ↑ proliferative retinopathy , target cells
HbSE	HbS ~65%, HbE ~35%	Mild; often Asian/Indian ancestry
HbSS-α thalassemia	high HbA2, low MCV	~30% of HbSS; fewer strokes/leg ulcers, less PHT/renal disease

Clinical features & complications

- ▶ **Onset:** in the first year of life as protective HbF declines and the γ→β switch completes.
- ▶ **Constitutional:** chronic hemolytic anemia with **jaundice, pigment (calcium-bilirubinate) gallstones (~40%),** early splenomegaly then **autosplenectomy,** and **delayed puberty/growth.**
- ▶ **Acute painful (vaso-occlusive) episode:** commonest acute event — severe, often symmetrical/stereotyped pain in back, chest and long bones; lasts days–weeks; provoked by infection, dehydration, hypoxia, cold. **Dactylitis (hand-foot syndrome)** is the typical first presentation in infants.
- ▶ **Acute chest syndrome (ACS):** 2nd commonest acute event, occurs in >50% — fever, chest pain, cough, hypoxia and a **new pulmonary infiltrate**; causes include in-situ thrombosis, infection, **fat embolism from necrotic marrow** and hypoventilation; a leading cause of death.
- ▶ **Neurological:** **stroke/silent infarction in 10–15%** (ischemic in childhood, may be hemorrhagic in adults); neurocognitive decline.

- ▶ **Bone/joint:** osteonecrosis (avascular necrosis, esp. bilateral femoral heads, ~half of patients) and *Salmonella* > *Staphylococcus osteomyelitis*.
- ▶ **Genitourinary:** priapism (~30% of males); nephropathy in ~30% of adults (hyperfiltration → albuminuria → CKD); papillary infarction → hematuria and **hyposthenuria**.
- ▶ **Other:** leg ulcers (over the malleoli), proliferative **retinopathy**, **pulmonary hypertension** (5–10%, **poor prognosis**), hepatopathy/intrahepatic cholestasis.
- ▶ **Acute anemic crises:** aplastic crisis (parvovirus B19), **splenic sequestration** (children), hyperhemolytic and delayed hemolytic transfusion reactions, folate deficiency.
- ▶ **Infection:** functional **hyposplenism** → overwhelming infection with **encapsulated organisms** (*pneumococcus*, *Haemophilus*, *Salmonella*); a major cause of childhood death.

Diagnosis / investigations

- ▶ **CBC & film:** normocytic anemia (Hct usually 20–30%), ISCs, target cells, **nucleated RBCs**, **Howell-Jolly bodies** (hyposplenism), reticulocytosis (10–25%), leukocytosis ($12\text{--}15 \times 10^9/\text{L}$), reactive thrombocytosis; raised indirect bilirubin and LDH, low/absent haptoglobin.
- ▶ **Sickle solubility test:** rapid screen — positive in both trait and disease (cannot distinguish them).
- ▶ **Confirmatory:** **Hb electrophoresis / HPLC** — in HbSS, **HbS 85–98% with no HbA**; HbF often raised (**HbF 15–20% confers a milder course**). Differentiates HbSS from trait, HbSC and HbS- β -thal (see table).
- ▶ **DNA-based testing:** for definitive genotype, genetic counseling and antenatal diagnosis.
- ▶ **Screening:** newborn/cord-blood screening; **antenatal diagnosis** by chorionic villus sampling or cell-free fetal DNA; partner testing when either carries HbS/ β -thal trait.

Management

Modality	Mechanism / indication	Key detail
Hydroxyurea	Induces HbF (anti-polymerization); disease-modifying	Standard of care for all HbSS & HbS- β^0 ; start infants from ~9 months at ~20 mg/kg, titrate to max tolerated (CMDT 15–35 mg/kg/day); halves pain & ACS; mortality reduced ~49% at 17.5 yr
Voxelotor	Increases Hb-O ₂ affinity, inhibits HbS polymerization	1500 mg/day; raises Hb ~1 g/dL; reduces hemolysis (≥ 12 yr)
Crizanlizumab	Anti-P-selectin mAb ; blocks cell-endothelial adhesion	IV monthly; reduces painful episodes ~45%
L-glutamine	Reduces RBC oxidative stress	~25% fewer painful episodes, ~33% fewer hospitalizations

Modality	Mechanism / indication	Key detail
Transfusion / exchange	Severe anemia, stroke prevention/treatment, severe ACS, multiorgan failure, pre-op to Hb ~10 g/dL	Prefer automated red-cell exchange; antigen-match Rh (C, E/c, e) and K; avoid in routine pain
Allogeneic HSCT	Potentially curative	HLA-identical sibling event-free survival >95%; only ~15% have a matched donor; haploidentical improving
Gene therapy (ex vivo)	Two FDA-approved curative options	Lentiviral β A-T87Q (anti-sickling Hb) and CRISPR/Cas9 BCL11A disruption to de-repress HbF $\rightarrow$ 30–50% HbF/HbAT87Q, near-total VOC prevention

- **Acute painful episode:** identify/treat precipitant; IV opioids by PCA or fixed schedule (not “as-needed”) with breakthrough dosing; hydration with **half-normal saline (avoid over-hydration)**; VTE prophylaxis, incentive spirometry, laxatives/antihistamines; O₂ only if hypoxic; monitor first 48–72 h for evolving ACS.
- **Preventive package:** prophylactic penicillin (125 mg <3 yr, 250 mg $\geq$ 3 yr, twice daily until age 5), pneumococcal/Hib/meningococcal vaccination, folic acid 1 mg/day, transcranial Doppler screening annually ages 2–16 with transfusion for high-risk velocities, microalbuminuria screen by age 10 (ACE inhibitor/ARB for albuminuria, avoid NSAIDs), annual retinal screen from age 10.
- **Referral:** to a Comprehensive Sickle Cell Centre with multidisciplinary follow-up.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- “Pathophysiology of sickle cell disease” (Harrison Fig. 103-3): *Oxygenated HbS (solution) $\rightarrow$ Deoxygenation $\rightarrow$ HbS polymer / sickled RBC $\rightarrow$ branch into (1) Vaso-occlusion (endothelial + leukocyte/platelet adhesion $\rightarrow$ ischemia/pain/ACS) and (2) Hemolysis (RBC survival <20 days $\rightarrow$ free Hb + arginase $\rightarrow$ NO depletion $\rightarrow$ vasoconstriction, pulmonary HTN, platelet activation). Label: β S codon-6 GAG $\rightarrow$ GTG (Glu $\rightarrow$ Val), ISC (irreversibly sickled cell), Arginine $\rightarrow$ NO via NO synthase.*
- **Inheritance (Punnett) square:** two carrier parents (AS $\times$ AS) $\rightarrow$ 25% AA (normal), 50% AS (trait), 25% SS (disease). Label genotypes and 1-in-4 affected ratio.

Clinical / Diagnostic significance

- Distinguish trait vs disease: solubility test positive in both; electrophoresis/HPLC is decisive (trait HbA>HbS and asymptomatic; disease HbS>>HbA or no HbA).

- ▶ **HbF level** is the single best modifier of severity — the rationale for hydroxyurea and HbF-reactivating gene therapy.
- ▶ A febrile sickle patient is a **medical emergency** (hyposplenic sepsis); ACS and acute stroke mandate **exchange transfusion**.
- ▶ **Sickle cell trait** is largely benign but linked to exertional rhabdomyolysis/sudden death, hematuria, hyposthenuria, VTE and the rare aggressive **renal medullary carcinoma**.

High-yield exam pointers

- ▶ $\beta 6 \text{ Glu} \rightarrow \text{Val}$ (GAG $\rightarrow$ GTG), βS , tetramer $\alpha 2 \beta \text{S} 2$; autosomal recessive; chromosome 11.
- ▶ HbS polymerizes only when **deoxygenated**; polymerization $\propto \sim 30\text{th}$ power of Hb concentration; HbF **cannot polymerize** (protective).
- ▶ Heterozygote advantage against **falciparum malaria**.
- ▶ **Dactylitis (hand-foot syndrome)** = often the earliest manifestation in infants.
- ▶ **Acute chest syndrome** = leading cause of death; new infiltrate + hypoxia $\pm$ fat embolism from marrow.
- ▶ **Aplastic crisis** = parvovirus B19; osteomyelitis = **Salmonella**; smear shows **Howell-Jolly bodies** (autosplenectomy).
- ▶ **Hydroxyurea** is disease-modifying for all HbSS/HbS- β^0 (works by raising HbF; $\sim 49\%$ mortality reduction).
- ▶ Curative options: **HLA-matched sibling HSCT** (EFS $>95\%$) and **FDA-approved gene therapy** (lentiviral $\beta \text{A-T87Q}$ and CRISPR-edited BCL11A).
- ▶ **Penicillin prophylaxis + pneumococcal vaccine + TCD screening + folic acid** form the pediatric preventive bundle.

SOURCE & COVERAGE

- ▶ **Harrison's Principles of Internal Medicine, 22e** — “Disorders of Hemoglobin” (HbS mutation, polymerization, pathophysiology Fig. 103-3, genotype/Hb-fraction tables, complications, hydroxyurea/voxelotor/crizanlizumab/L-glutamine, transfusion, HSCT and gene therapy, preventive screening).
- ▶ **CMDT 2026** — “Blood Disorders” (**Sickle Cell Anemia & Related Syndromes**) (clinical findings, laboratory criteria, Hb-distribution Table 15-9, supportive care and current drug management).
- ▶ **DeVita's Cancer: Principles & Practice of Oncology, 12e** (hydroxyurea/ESCORT-HU and the sickle-cell-trait association of **renal medullary carcinoma**).

Coverage note: The corpus covers this topic richly; the cited HbF-percentage cut-off for a benign course (15–20%) and exact drug doses are taken verbatim from CMDT/Harrison. Harrison labels

the substituted residue “7” (counting the initiator methionine); the universally taught designation β6 is used here, both being the same valine substitution.

Spleen: Structure and Function

Asked in: Paper I Nov 2021 — RGUHS MD General Medicine

Definition / Introduction — The **spleen** is the largest secondary lymphoid organ of the body and the major **reticuloendothelial (mononuclear phagocyte) organ**, lying in the left upper quadrant (LUQ) entirely within the rib cage. It is uniquely positioned in the **portal (low-pressure) circulation** and is functionally divided into **red pulp** (a blood-filtering compartment) and **white pulp** (lymphoid, immune compartment) — terms coined by *Malpighi*. It serves dual roles as a fastidious blood filter (quality control of red cells) and an immune organ (antibody synthesis and clearance of opsonised pathogens). The normal adult spleen weighs <250 g and is not normally palpable.

Development, gross anatomy and accessory spleens

- ▶ **Embryology:** arises from the **dorsal mesogastrium** at ~5 weeks' gestation as a series of *hillocks* (mesenchymal condensations) that coalesce and migrate to the LUQ. It is mesodermal in origin yet remains a lymphoid/RE organ.
- ▶ **Failure of the hillocks to fuse** leaves rests of splenic tissue → **accessory spleens (splenunculi)** in ~20% of persons; important to recognise, as they cause relapse after splenectomy for haematologic disease and must be sought (often hilar or pancreatic-tail).
- ▶ **Peritoneal attachments (ligaments):** *gastrosplenic* (gastrosplenic) *ligament* anchors spleen to the stomach (carries short gastric vessels), and the *splenorenal* (splenorenal) *ligament* anchors it to the left kidney (carries the splenic artery/vein and pancreatic tail).
- ▶ **Vascular supply:** the **splenic artery** (a branch of the coeliac trunk) carries ~150 mL/min of blood and ramifies into **central arterioles**; venous drainage is via the splenic vein into the portal system.
- ▶ **Normal dimensions:** weight <250 g (decreases with age); maximum **cephalocaudal diameter** 13 cm by **ultrasonography**, or maximum length 12 cm / width 7 cm by **radionuclide scan**.

Microscopic architecture — red pulp and white pulp

Compartment	Components	Principal function
White pulp	Periarteriolar lymphoid sheath (PALS) = T-cell zone sheathing central arteriole; primary follicles and secondary follicles with germinal centres = B-cell zones; surrounding marginal zone	Immune surveillance, antigen presentation, antibody synthesis, marginal-zone B-cell response to encapsulated organisms

Compartment	Components	Principal function
Marginal zone	Lymphoid zone at the white-pulp/red-pulp interface, rich in specialised B cells and macrophages	First contact with blood-borne antigens; T-independent responses to polysaccharide capsular antigens
Red pulp	Pulp cords (cords of Billroth) lined by RE/macrophages — anatomical “dead ends”; venous sinuses with slit-like inter-endothelial pores	Mechanical and immunologic filtration of erythrocytes; culling and pitting

- ▶ The “open” circulation / filtration mechanism: most blood leaving the central arterioles empties into the macrophage-lined cords. To re-enter the circulation, red cells must **squeeze through narrow slits in the cord lining into the sinuses** → venules. **Old, rigid, damaged or antibody-coated red cells are too poorly deformable to pass and are retained and destroyed** — this is the structural basis of red-cell quality control.
- ▶ The low portal pressure and slow transit minimise damage to normal erythrocytes while exposing abnormal cells to prolonged macrophage scrutiny.

Physiologic functions of the spleen

- ▶ 1. Quality control of erythrocytes (red pulp):
 - **Culling** — removal of senescent and defective red cells.
 - **Pitting** — removal of intra-erythrocytic inclusions without destroying the cell: **Howell-Jolly bodies (nuclear remnants)**, **Heinz bodies (denatured haemoglobin)**, **Pappenheimer/basophilic-stippling (siderotic) granules**, and intracellular parasites (e.g., malaria) are “pinched off” as the cell traverses the slits.
- ▶ 2. Immune function (white pulp): synthesis of **antibodies** (notably IgM by germinal-centre and marginal-zone B cells) and generation of immune responses to blood-borne pathogens; antigen presentation in PALS and follicles.
- ▶ 3. Clearance of opsonised material: removal of **antibody-coated bacteria and antibody-coated blood cells**, and of poorly opsonised **encapsulated organisms** and particulates from the circulation.
- ▶ 4. Reservoir/sequestration: the normal human spleen holds about **one-third of the total body platelet mass** plus a pool of **marginated neutrophils**, available to mobilise during bleeding or infection. (Unlike some animals, the *normal human spleen does not store or contract to autotransfuse red cells*.)
- ▶ 5. Extramedullary haematopoiesis (EMH): a latent fetal function reactivated when marrow cannot meet demand (e.g., myelofibrosis) — a cause of splenomegaly.

Splenomegaly — mechanisms and the concept of hypersplenism

- ▶ **Pathogenic mechanisms of enlargement** (a useful exam framework):
 - **Work hypertrophy / RE hyperplasia** — for removal of defective red cells (*hereditary spherocytosis, thalassemia, early sickle cell, haemoglobinopathies*).
 - **Immune hyperplasia** — response to infection (*infectious mononucleosis, subacute bacterial endocarditis, malaria*) or immune disease (*ITP, SLE, Felty's syndrome*).
 - **Congestive (passive congestion)** — portal hypertension (*cirrhosis, Budd-Chiari, splenic/portal vein obstruction, CHF*); chronic congestion = “*Banti's disease*.”
 - **Infiltration** — lymphomas, leukaemias, metastases (melanoma commonest), amyloidosis, and storage disorders (*Gaucher's, Niemann-Pick*).
 - **Extramedullary haematopoiesis** — myelofibrosis with myeloid metaplasia.
- ▶ **Hypersplenism** is a clinico-pathologic syndrome defined by: (1) **splenomegaly**, (2) **cytopenia(s) of one or more lineages**, (3) **normal or hyperplastic bone marrow**, and (4) **correction (or improvement) of cytopenias after splenectomy**. Cytopenias arise from increased pooling/destruction in congested cords or by immune mechanisms; red cells may become **spherocytic** from membrane loss during prolonged transit.
- ▶ **Massive splenomegaly** (spleen >8 cm below the costal margin or drained weight ≥ 1000 g) markedly narrows the differential: *chronic myeloid leukaemia, myelofibrosis with myeloid metaplasia, lymphomas, chronic lymphocytic leukaemia, hairy cell leukaemia, polycythaemia vera, Gaucher's disease, sarcoidosis, autoimmune haemolytic anaemia, diffuse splenic hemangiomatosis*.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Diagram 1 — Schematic spleen unit** (Fig. 70-1): draw a central artery/arteriole with concentric zones — label **periarteriolar lymphoid sheath** (T-cell area), **primary follicle** (B-cell), **secondary follicle with germinal centre** (B-cell), **marginal lymphoid zone**, then the **red pulp** showing **pulp cords** (cords of Billroth, RE cells) as dead-ends and **pulp sinuses** with **sinusoidal pores** draining to the **splenic venous system**. Annotate the arrow: “stiff/old/damaged red cells cannot enter the sinuses — culled.”
- ▶ **Diagram 2 — Surface markings / palpation**: outline the LUQ spleen behind ribs 9–11; mark **Traube's space** (borders: *6th rib superiorly, left midaxillary line laterally, left costal margin inferiorly*) and show the line of bimanual palpation from the right lower quadrant towards the left costal margin.

Clinical / Diagnostic significance

- ▶ **Examination**: percussion (**Castell's sign**, **Nixon's method**, **Traube's space dullness**) is best done first, then **bimanual palpation** / ballottement / **Middleton manoeuvre** (palpation from above). Palpation sensitivity 56–71%, percussion 59–82%; both are unreliable in obesity or post-prandially. **Ultrasonography is the imaging investigation of choice** (normal craniocaudal

diameter ≤ 13 cm); CT/MRI better define focal lesions and infarcts; radionuclide scans demonstrate accessory splenic tissue.

- ▶ **Peripheral-smear clues to hyposplenism/post-splenectomy state:** Howell-Jolly bodies, Heinz bodies, basophilic stippling, target cells, acanthocytes, nucleated RBCs, anisocytosis and poikilocytosis; thrombocytosis (up to $1 \times 10^6/\mu\text{L}$) and leukocytosis (up to $25,000/\mu\text{L}$) transiently after splenectomy. Such changes appearing in a patient with an *intact* spleen suggest **splenic infiltration by tumour** interfering with culling/pitting.
- ▶ **Splenectomy — indications:** therapeutic control of symptomatic massive splenomegaly, traumatic/iatrogenic rupture, correction of cytopenias in hypersplenism or immune destruction (e.g., refractory ITP, hereditary spherocytosis, autoimmune haemolytic anaemia), and as effective secondary/tertiary therapy for hairy cell leukaemia, prolymphocytic leukaemia and splenic marginal-zone / mantle-cell lymphoma. Splenic marginal-zone lymphoma characteristically presents with massive splenomegaly and responds to splenectomy or rituximab (DeVita). The only real contraindication is **marrow failure where the spleen is the sole haematopoietic site**.
- ▶ **Overwhelming post-splenectomy infection (OPSI):** the gravest sequela. Susceptibility to **encapsulated organisms** — *Streptococcus pneumoniae* (most important), *Haemophilus influenzae* type b, *Neisseria meningitidis* — and to **Babesia** (avoid endemic areas) and *Capnocytophaga*. Overall sepsis risk $\sim 7\%$ over 10 years; **case-fatality of pneumococcal sepsis 50–80%**; risk highest in the **first 3 years** and in those aged <20 . Mechanism: failure to clear opsonised bacteria + impaired antibody response to **T-independent polysaccharide antigens**.
- ▶ **Prevention:** pneumococcal (PCV13/conjugate $\pm$ PPSV23), Hib and meningococcal vaccines, given ideally ≥ 2 weeks before elective splenectomy (repeat pneumococcal at ~ 5 years); patient education that **any unexplained fever is a medical emergency**; antibiotic standby.
Autosplenectomy occurs in sickle cell disease from repeated infarction — a palpable spleen after age 5 in SCD suggests a coexisting haemoglobinopathy.

High-yield exam pointers

- ▶ Spleen = largest **secondary lymphoid organ**; embryology = **dorsal mesogastrium, 5 weeks**; accessory spleens in $\sim 20\%$.
- ▶ **Red pulp = filter** (cords of Billroth + sinuses $\rightarrow$ *culling & pitting*); **white pulp = immunity** (PALS = T cells, follicles + marginal zone = B cells).
- ▶ **Pitting** removes inclusions $\rightarrow$ their reappearance (**Howell-Jolly bodies**) is the cardinal smear sign of hyposplenism.
- ▶ Normal weight <250 g; US **craniocaudad ≤ 13 cm**; spleen holds $\sim 1/3$ of body platelets.
- ▶ **Hypersplenism tetrad:** splenomegaly + cytopenia + hypercellular marrow + response to splenectomy.

- ▶ **Massive splenomegaly** (>1000 g / >8 cm): think CML, myelofibrosis, CLL, hairy cell leukaemia, lymphoma, PV, Gaucher's, kala-azar.
- ▶ **OPSI** by encapsulated organisms — vaccinate **2 weeks pre-elective splenectomy**; case-fatality 50–80%.
- ▶ **Traube's space dullness** and **Castell's sign** = bedside tests for splenomegaly; **ultrasound** is confirmatory.
- ▶ **Banti's syndrome** = congestive splenomegaly of portal hypertension; **autosplenectomy** = sickle cell disease.

SOURCE & COVERAGE

- ▶ **Harrison's Principles of Internal Medicine, 22e** — “Enlargement of Lymph Nodes and Spleen” (structure/function of the spleen, red/white pulp, culling and pitting, hypersplenism, massive splenomegaly, splenectomy and OPSI, vaccination); cross-referenced with Harrison's chapters on **non-Hodgkin's lymphoma / immune system** for white-pulp lymphoid architecture and marginal-zone B-cell biology.
- ▶ **DeVita, Hellman and Rosenberg's Cancer: Principles & Practice of Oncology, 12e** — splenic marginal-zone lymphoma and the role of splenectomy in indolent B-cell neoplasms.
- ▶ *Coverage note:* This topic is **flagged thin** in the corpus — Harrison covers splenic **function, hypersplenism and splenectomy** in depth but gives only a **brief account of detailed histological/anatomical structure**; the white-pulp microanatomy (PALS, marginal zone, cords of Billroth) and surgical/peritoneal anatomy above are standard, universally-accepted textbook internal medicine/anatomy added for completeness and are faithful to the source where present (e.g., Fig. 70-1 labels). CMDT was not used (spec flag cmdt = false).

Stages in neutrophil development

Asked in: Paper I Sep 2025 — RGUHS MD General Medicine

Definition / Introduction — *Granulopoiesis* is the bone-marrow production of neutrophils from the pluripotent haematopoietic stem cell (HSC) through a series of committed progenitors and morphologically recognisable precursors. In the normal adult, neutrophils are produced **only in the marrow**, where roughly three-fourths of nucleated cells are committed to leukocyte production. The system generates about 1.3×10^{11} **neutrophils per 80-kg person per day** and maintains a large marrow reserve that can be mobilised during inflammation. The entire journey from the first recognisable precursor to a mature segmented neutrophil takes **about 2 weeks**.

1. Progenitor hierarchy and lineage commitment

- ▶ Neutrophils and monocytes arise from a **common stem cell** under the control of **colony-stimulating factors (CSFs)** and **interleukins**; the minimum number of HSCs needed to sustain haematopoiesis is estimated at **400–500** at any time.
- ▶ Differentiation pathway (Harrison Fig. 101-2): **HSC** → **multipotent progenitor** → **common myeloid progenitor (CMP)** → **granulocyte-monocyte progenitor (GMP)** → **granulocyte progenitor** → **myeloblast**.
- ▶ **Soluble growth-factor regulation**: stem-cell factor (SCF) and IL-3 act early; GM-CSF and G-CSF drive granulocytic commitment and terminal maturation. G-CSF and GM-CSF are described as critical to the whole developmental process.
- ▶ **Transcription-factor control**: *C/EBPα* governs the granulocyte-monocyte branch point; *C/EBPε* (gene CEBPE) directs the granulocyte progenitor and specifically controls packaging of secondary-granule contents.

2. Morphologic maturation stages (the answer's core)

The morphologic sequence is **myeloblast** → **promyelocyte** → **myelocyte** → **metamyelocyte** → **band (stab) form** → **segmented (mature) neutrophil** (Harrison Fig. 67-2). The myeloblast is the first recognisable precursor.

Stage	Division	Key morphology	Granule event	Surface markers (cumulative)
Myeloblast	Yes (mitotic)	Large cell, prominent nucleoli , fine chromatin, agranular cytoplasm	No specific granules yet	CD33, CD13, CD15
Promyelocyte	Yes (mitotic)	Largest of the series; nucleolus still present	Primary (azurophil) granules appear	CD33, CD13, CD15
Myelocyte	Yes (last dividing cell)	Round/oval nucleus, no nucleolus; “dawn of neutrophilia”	Secondary (specific) granules appear	CD33, CD13, CD15, CD14, CD11b
Metamyelocyte	No (post-mitotic)	Kidney-bean / indented nucleus	Granule synthesis complete	CD33, CD13, CD15, CD14, CD11b
Band (stab) form	No	Sausage / band-shaped non-	—	+ CD10, CD16

Stage	Division	Key morphology	Granule event	Surface markers (cumulative)
		segmented nucleus		
Segmented neutrophil	No	Condensed multilobed nucleus (up to 4 lobes), clumped chromatin	—	CD33, CD13, CD15, CD14, CD11b, CD10, CD16

- ▶ **Two functional compartments:** the **proliferative (mitotic) pool** comprises the myeloblast, promyelocyte and myelocyte; the **myelocyte is the last cell capable of mitosis**. From the **metamyelocyte onward no cell division occurs** — these constitute the **post-mitotic maturation / storage pool**.
- ▶ As the band matures, the nucleus assumes a lobulated configuration; the physiologic role of the multilobed nucleus is uncertain but may permit the marked deformation needed for tissue migration and neutrophil extracellular trap (NET) formation.

3. Granule formation during maturation

Granule genesis is **stage-specific** and is the morphologic hallmark used to distinguish precursors:

- ▶ **Primary / azurophil granules** — synthesised at the **promyelocyte** stage; true lysosomes containing **myeloperoxidase, neutrophil elastase, cathepsin G, hydrolases, cationic proteins, bactericidal/permeability-increasing protein (BPI)** (kills gram-negative bacteria) and **defensins** (broad antimicrobial cysteine-rich peptides).
- ▶ **Secondary / specific granules** — synthesised at the **myelocyte** stage; contain **lactoferrin, vitamin B₁₂-binding protein, membrane components of the NADPH oxidase (NOX2), histaminase, the laminin receptor and receptors for chemoattractants and adherence factors (e.g., CR3/CD11b)**. They lack acid hydrolases, so are **not classic lysosomes**, and their contents are readily released extracellularly to modulate inflammation.
- ▶ (*Standard hematology adds a third, late tertiary/gelatinase granule pool; Harrison Ch. 67 itself describes only the primary and secondary granules.*)

4. Kinetics, marrow release and circulating pools

- ▶ **Transit time:** the proliferation phase **through the metamyelocyte** takes ~1 week, and the maturation phase **from metamyelocyte to mature neutrophil** takes another ~1 week.
- ▶ Marrow release is triggered by **IL-1, TNF- α , CSFs, complement fragments (C3a/C5a) and chemokines**, delivering cells to blood in an unstimulated state.
- ▶ **Anatomic distribution:** under normal conditions **~90% of the neutrophil pool is in the bone marrow, 2–3% in the circulation**, and the remainder in tissues.

- ▶ **Circulating pool** has two dynamic compartments: a **freely flowing pool** (~half the cells) and a **marginated pool** in contact with endothelium; *epinephrine* (exercise, stress) demarginates cells and can double the count in minutes, whereas *glucocorticoids* increase marrow release.
- ▶ **Lifespan**: circulating half-life is only **6–7 hours**; after entering tissues neutrophils survive **1–4 days** before apoptosis (prolonged by G-CSF and IFN- γ). Most are lost across the gut mucosa; senescent cells are cleared by lung and splenic macrophages.
- ▶ **Functional acquisition mirrors morphology**: adhesion and chemotactic machinery appears late — selectin ligand sialyl-Lewis^x (CD15s), L-selectin (CD62L) and the β_2 -integrins (CD11a/b/c with common CD18) become functional in the band/segmented stages, enabling rolling, tight adhesion and diapedesis only in the mature cell.

5. Disordered development — quick correlations

- ▶ **Neutropenia** can arise from *depressed production* (cytotoxic drugs, B₁₂/folate deficiency, congenital marrow failure), *peripheral destruction* (autoimmune, Felty syndrome) or *excess pooling*.
- ▶ **Neutrophilia** reflects increased production, increased marrow release, or **demargination** — the basis for the rapid rises seen with infection, glucocorticoids, epinephrine and exercise.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Maturation ladder** (label each stage left-to-right): *Myeloblast* → *Promyelocyte* → *Myelocyte* → *Metamyelocyte* → *Band form* → *Segmented neutrophil*. Annotate: “prominent nucleoli” (myeloblast); “primary/azurophil granules appear” (promyelocyte); “secondary/specific granules appear + last mitotic division” (myelocyte); “kidney-bean nucleus” (metamyelocyte); “band-shaped nucleus” (band); “multilobed (≤ 4 lobes)” (neutrophil). Bracket *Myeloblast–Myelocyte* as “mitotic / proliferative pool” and *Metamyelocyte–segmented* as “post-mitotic maturation–storage pool.”
- ▶ **Pool distribution pie/box**: three compartments labelled **Marrow ~90%**, **Circulating 2–3%** (freely flowing + marginated), **Tissue (remainder)**, with arrows for *G-CSF / steroids / endotoxin* (marrow release) and *epinephrine* (demargination).

Clinical / Diagnostic significance

- ▶ **Left shift**: appearance of immature forms (bands, metamyelocytes) in blood signals accelerated marrow release in infection/inflammation; a **leukemoid reaction** is persistent neutrophilia $\geq 30,000$ – $50,000/\mu\text{L}$ with **mature, non-clonal** cells (distinguishes from CML).
- ▶ **Maturation arrest** underlies several neutropenias: **severe congenital neutropenia** (*ELANE*-encoded neutrophil elastase, *HAX-1*/Kostmann), and **WHIM syndrome** (*CXCR4* mutation) shows marrow **myeloid arrest with hypersegmentation and myelokathexis**.

- ▶ **Acute promyelocytic leukaemia (APL)** is a clonal arrest at the **promyelocyte** stage; CML expands the entire granulocytic series across all maturation stages.
- ▶ **Nuclear clues: hypersegmentation (>5 lobes)** suggests **vitamin B₁₂/folate deficiency** (or WHIM); the **Pelger-Hüet anomaly** (LBR mutation) gives benign **bilobed “pince-nez”** nuclei that mimic bands; acquired *pseudo-Pelger-Hüet* occurs in MDS.
- ▶ **Cytoplasmic clues of toxicity: toxic granulation** (prominent azurophil granules), **Döhle bodies** (rough-ER aggregates) and cytoplasmic vacuoles indicate severe infection/sepsis (and COVID-19).
- ▶ **Absolute neutrophil count (ANC = bands + mature neutrophils)**: infection risk rises sharply <1000/ μ L; endogenous-flora control is lost <500/ μ L; the local inflammatory response is **absent** <200/ μ L.

High-yield exam pointers

- ▶ Sequence to memorise: Myeloblast → Promyelocyte → Myelocyte → Metamyelocyte → Band → Segmented neutrophil.
- ▶ **Promyelocyte = primary (azurophil/MPO-containing) granules; Myelocyte = secondary (specific/lactoferrin) granules; myelocyte is the last dividing cell.**
- ▶ Total marrow transit **~2 weeks** ($\approx$ 1 week proliferative + $\approx$ 1 week maturation); blood half-life 6–7 h; tissue survival 1–4 days.
- ▶ Distribution: **~90% marrow, 2–3% blood, rest tissues**; circulating = **freely flowing + marginated** halves.
- ▶ Marker progression: CD33/CD13/CD15 throughout; **CD14/CD11b from myelocyte; CD10/CD16 from band stage.**
- ▶ Daily output $\sim 1.3 \times 10^{11}$; G-CSF/GM-CSF are the master cytokines; C/EBP α and C/EBP ϵ the key transcription factors.
- ▶ Production $\sim 1.3 \times 10^{11}$ /day, regulated reserve mobilised by endotoxin/steroids; epinephrine causes demargination (pseudo-neutrophilia).

SOURCE & COVERAGE

- ▶ **Harrison’s Principles of Internal Medicine, 22e** — “Disorders of Granulocytes and Monocytes” (neutrophil maturation sequence, Fig. 67-2 stage/marker table, granule contents, marrow pools and kinetics, ANC thresholds, morphologic anomalies); “Hematopoietic Stem Cells” (progenitor hierarchy HSC→CMP→GMP and growth-factor/transcription-factor regulation, Fig. 101-2).
- ▶ **DeVita, Hellman & Rosenberg’s Cancer: Principles & Practice of Oncology, 12e** — consulted for myeloid-malignancy correlation (maturation-arrest leukaemias).

Coverage note (spec gap = true): Harrison 22e covers granulopoiesis and the full morphologic staging well within Ch. 67 and Ch. 101; DeVita (an oncology text) does **not** carry dedicated normal granulopoietic morphology, so the developmental detail here is drawn from Harrison. Classic “mitotic vs maturation-storage pool” terminology and the **tertiary/gelatinase granule** are universally accepted standard haematology but are only partially explicit in the corpus, so they are flagged rather than over-attributed.

Summarize the management of acute promyelocytic leukemia

Asked in: Paper IV May 2025 — RGUHS MD General Medicine

Definition / Introduction — Acute promyelocytic leukemia (APL) is the distinct subtype of acute myeloid leukemia (AML) defined by the balanced translocation **t(15;17)(q22;q12)** generating the **PML::RARA** fusion gene, whose chimeric protein blocks myeloid differentiation at the promyelocyte stage. It is both the most curable AML (≈85–90%+ long-term survival) *and* the most dangerous at presentation because of a life-threatening **disseminated intravascular coagulation (DIC)/hyperfibrinolysis** that causes early haemorrhagic death. The therapeutic revolution lies in two **differentiating/targeting** agents — **all-trans retinoic acid (ATRA, tretinoin) and arsenic trioxide (ATO)* — *which have converted APL into a largely chemotherapy-free, curable disease. APL is therefore managed as a medical emergency**: treat first on morphological suspicion, do not wait for genetic confirmation.

Why APL is managed differently — biology and diagnosis

- ▶ **PML::RARA** is both the diagnostic marker and the drug target. ATRA binds RARα and forces terminal differentiation of leukaemic promyelocytes; ATO degrades the PML::RARA oncoprotein, induces apoptosis, causes G1–S/G2–M arrest and has anti-angiogenic activity (per the DeVita drug data).
- ▶ **Hallmark morphology**: hypergranular promyelocytes with bundles of **Auer rods** (“faggot cells”); the microgranular (hypogranular) variant has a bilobed nucleus and high WBC.
- ▶ **Diagnostic confirmation**: rapid **PML::RARA RT-PCR** and/or **FISH** for t(15;17); immunophenotype typically **HLA-DR-negative**, **CD34-negative**, **CD33/CD13/myeloperoxidase strongly positive**.
- ▶ **Coagulopathy is the killer**: release of granule procoagulants/annexin-II-driven hyperfibrinolysis produces DIC; early death from intracranial or pulmonary haemorrhage is the main cause of treatment failure. Rare ATRA-resistant variants (e.g. **ZBTB16(PLZF)::RARA**, lacking classic t(15;17)) must be recognised because they respond poorly to ATRA/ATO.

Risk stratification (Sanz) — drives the regimen choice

The corpus splits APL for treatment into **low-risk** (presenting $\text{WBC} \leq 10 \times 10^9/\text{L}$) and **high-risk** ($\text{WBC} > 10 \times 10^9/\text{L}$), the latter requiring immediate cytoreduction. The widely used three-tier **Sanz score** refines this:

Risk group	Presenting WBC	Platelet count
Low	$\leq 10 \times 10^9/\text{L}$	$> 40 \times 10^9/\text{L}$
Intermediate	$\leq 10 \times 10^9/\text{L}$	$\leq 40 \times 10^9/\text{L}$
High	$> 10 \times 10^9/\text{L}$	any

- ▶ Low- and intermediate-risk are managed together as “**low/standard-risk**” and treated with chemotherapy-free ATRA + ATO.
- ▶ High-risk disease carries the greatest early-death risk (differentiation syndrome + haemorrhage) and warrants added cytoreductive chemotherapy.

Emergency supportive care (start immediately, before genetics)

- ▶ **Begin ATRA on clinical suspicion** of APL — it reduces the frequency of DIC and buys time while PCR/FISH is pending; the persistently high early-death rate is the rationale for not delaying.
- ▶ **Aggressive correction of coagulopathy:** transfuse to keep platelets $> 30\text{--}50 \times 10^9/\text{L}$ and fibrinogen $> 100\text{--}150 \text{ mg/dL}$ using platelets, cryoprecipitate and fresh frozen plasma; monitor PT/aPTT, fibrinogen and D-dimer at least twice daily until the coagulopathy resolves.
- ▶ **Avoid leukapheresis** in APL (worsens coagulopathy/precipitates fatal haemorrhage); avoid central lines/invasive procedures while coagulopathy persists.
- ▶ **Tumour-lysis prophylaxis:** hydration and allopurinol (rasburicase if marked hyperuricaemia/renal injury, avoiding G6PD deficiency).

Induction therapy — by risk group

Risk	Standard induction regimen	Key points
Low/standard-risk ($\text{WBC} \leq 10$)	ATRA $45 \text{ mg/m}^2/\text{day}$ PO + ATO 0.15 mg/kg/day IV until complete remission (chemotherapy-free)	ATRA + ATO proved superior to ATRA + idarubicin in EFS and OS (APL0406); CR approaches ~100% with excellent long-term survival
High-risk ($\text{WBC} > 10$)	ATRA + ATO plus cytoreductive chemotherapy — an anthracycline (idarubicin) or gemtuzumab ozogamicin	Immediate cytoreduction needed because of the rapidly rising WBC and severe differentiation-syndrome/haemorrhage risk after starting ATRA (APML4, AML17)

Risk	Standard induction regimen	Key points
		support ATO across all risk groups)

- ▶ The historical AIDA-type backbone (ATRA + idarubicin) remains an alternative where ATO is unavailable, but **ATRA + ATO is now standard of care** for low-risk disease and reduces cumulative chemotherapy toxicity.
- ▶ **Oral ATO** formulations (validated in China) are non-inferior to IV ATO in non-high-risk APL and improve convenience.

Differentiation (APL) syndrome — recognise and treat early

- ▶ **Onset:** typically within the **first 1–3 weeks** of ATRA (or ATO) therapy; caused by adhesion of differentiating neoplastic cells to pulmonary vascular endothelium and cytokine release.
- ▶ **Features:** unexplained **fever, fluid retention/weight gain, dyspnoea, chest pain, pulmonary infiltrates, pleural and pericardial effusions, hypoxaemia**, and rising leukocyte count; renal impairment in severe cases. **Mortality ≈10% if unrecognised.**
- ▶ **Management:** **dexamethasone 10 mg IV twice daily** at first suspicion, plus diuresis/supportive care and cytoreductive chemotherapy if hyperleukocytosis; **temporarily discontinue ATRA (and/or ATO)** only in severe cases (renal failure or ICU admission for respiratory distress) and resume once resolved.
- ▶ **Prophylaxis:** consider prednisone/dexamethasone prophylaxis especially in high-risk patients to blunt the syndrome.

Consolidation, maintenance and monitoring

- ▶ **Consolidation:** continue ATRA + ATO in repeating cycles after CR — e.g. ATO 0.15 mg/kg/day, 5 days/week for weeks 1–4 of an 8-week cycle × 4 cycles, with intermittent ATRA — to achieve **molecular (PCR-negative) remission.**
- ▶ **Maintenance:** with the chemotherapy-free ATRA + ATO regimen, prolonged maintenance is generally **not required**; in chemotherapy-containing (AIDA-type) protocols, maintenance uses ATRA ± 6-mercaptopurine + methotrexate, particularly for high-risk patients.
- ▶ **Measurable residual disease (MRD):** serial RT-PCR for PML::RARA is the standard tool — disappearance of the transcript predicts durable remission, while persistence or re-emergence reliably predicts **molecular relapse**, allowing pre-emptive re-treatment before overt relapse, especially in high-risk patients.
- ▶ **Drug monitoring:** ATO prolongs the **QT interval** — baseline and serial ECG, and aggressive repletion of **potassium and magnesium**; ATRA can cause headache/**pseudotumour cerebri**, dryness and hypertriglyceridaemia.

Relapsed/refractory disease

- ▶ ATO is highly active in relapse; for patients not previously exposed, ATO ± ATR-A (± gemtuzumab ozogamicin) can re-induce remission.
- ▶ Achieve a **second molecular remission**, then consolidate with **autologous HSCT** if PCR-negative, or **allogeneic HSCT** if PCR-positive/poor reserve. (In contrast to other AML subtypes, transplant is reserved for relapse, not first remission.)

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Box 1 — Risk-adapted treatment algorithm (flow diagram):** “Suspected APL (faggot cells / coagulopathy)” → “Start ATRA + correct DIC immediately” → “Confirm PML::RARA (PCR/FISH)” → branch to **Low-risk** (WBC ≤10): ATRA + ATO and **High-risk** (WBC >10): ATRA + ATO + anthracycline/gemtuzumab → “Consolidation (ATRA+ATO cycles)” → “PML::RARA RT-PCR MRD monitoring” → “Molecular CR = cure / PCR re-emergence = pre-emptive salvage”. Side-arrow label: “Differentiation syndrome → dexamethasone 10 mg BD, hold ATRA if severe.”
- ▶ **Box 2 — Molecular target:** label **chromosome 15 (PML)** and **chromosome 17 (RARA)** → t(15;17) → **PML::RARA fusion protein** → blocked promyelocyte differentiation; arrows showing ATRA → differentiation and ATO → degradation of PML::RARA + apoptosis.

Clinical / Diagnostic significance

- ▶ APL is an **oncological emergency**: the leading preventable cause of death is **early haemorrhage from DIC**, so empirical ATRA and blood-product support precede genetic confirmation.
- ▶ **PML::RARA RT-PCR** is uniquely valuable both diagnostically and for MRD-directed therapy — APL is the paradigm of molecular monitoring in leukaemia.
- ▶ The cure of APL with **non-cytotoxic targeted differentiation therapy** is a landmark proof of concept in precision oncology; recognition of **ATRA-resistant RARA variants** prevents mismanagement.
- ▶ Vigilance for **differentiation syndrome** and **ATO-induced QT prolongation** is essential during induction.

High-yield exam pointers

- ▶ APL = AML with t(15;17) / PML::RARA; morphology = hypergranular promyelocytes with **faggot (multiple Auer-rod) cells**; immunophenotype HLA-DR-/CD34- **negative**.
- ▶ **Treat on suspicion** — start ATRA **immediately**; do not await cytogenetics; **avoid leukapheresis**.
- ▶ **Low-risk** = WBC ≤10 × 10⁹/L → **chemo-free ATRA** (45 mg/m²/d) + ATO (0.15 mg/kg/d); CR ~100% (APL0406 trial, superior to ATRA + idarubicin).
- ▶ **High-risk** = WBC >10 × 10⁹/L → **add anthracycline (idarubicin) or gemtuzumab ozogamicin** for immediate cytoreduction.

- ▶ **Differentiation syndrome:** first 1–3 weeks, fever/dyspnoea/effusions/infiltrates/hypoxaemia → dexamethasone 10 mg IV BD, hold ATRA if severe; ~10% mortality if missed.
- ▶ **DIC management:** keep fibrinogen >100–150 mg/dL and platelets >30–50 × 10⁹/L with cryoprecipitate/FFP/platelets.
- ▶ **ATO toxicity = QT prolongation** → monitor ECG, K⁺ and Mg²⁺; **ATRA toxicity = pseudotumour cerebri/headache, hypertriglyceridaemia, differentiation syndrome.**
- ▶ **MRD by PML::RARA PCR** directs cure (negativity) and pre-emptive salvage (re-emergence); relapse salvage uses **ATO-based re-induction** → **autologous HSCT (PCR-neg) or allogeneic HSCT (PCR-pos).**

SOURCE & COVERAGE

- ▶ **Harrison's Principles of Internal Medicine, 22e** — “Acute Myeloid Leukemia” (Treatment of Acute Promyelocytic Leukemia section; t(15;17)/PML::RARA, ATRA + arsenic trioxide, APL/differentiation syndrome, DIC, PML-RARA PCR monitoring; content spans the ch109–ch110 page-bleed).
- ▶ **DeVita, Hellman, and Rosenberg's Cancer: Principles & Practice of Oncology, 12e** — “Management of Acute Leukemias” (Acute Promyelocytic Leukemia: ATRA/ATO, standard- vs high-risk, ATRA + ATO vs ATRA + idarubicin, oral ATO; APML4/AML17 trials) and the arsenic-trioxide drug profile (mechanism, induction/consolidation dosing, QT-prolongation/differentiation-syndrome toxicity).
- ▶ **CMDT 2026** — “Blood Disorders” (Acute Promyelocytic Leukemia: t(15;17)/PML-RARα, >90% curable with ATRA + ATO across induction/consolidation/maintenance; DIC; supportive care).

Coverage note: The corpus stratifies APL by a **low-risk** (WBC ≤10 × 10⁹/L) vs **high-risk** (>10 × 10⁹/L) dichotomy; the three-tier **Sanz** classification (adding a platelet >40 × 10⁹/L cut-off to define the intermediate group), the precise DIC transfusion thresholds (fibrinogen >100–150 mg/dL; platelets >30–50 × 10⁹/L), the dexamethasone 10 mg BID dose for differentiation syndrome, and the AIDA maintenance schedule (ATRA + 6-mercaptopurine + methotrexate) are universally accepted standard haematology included to satisfy the “summarize management” ask, consistent with the corpus framework.

Thrombocytopenia

Asked in: Paper IV May 2022 — RGUHS MD General Medicine

Definition / Introduction — Thrombocytopenia is a **platelet count <150,000/μL** (normal 150,000–450,000/μL). It results from one or more of three processes: (1) **decreased bone-marrow production,**

(2) sequestration (usually in an enlarged spleen), and (3) increased platelet destruction. It is the commonest cause of abnormal bleeding, ranging from incidental laboratory finding to life-threatening mucocutaneous and intracranial haemorrhage. The single most important first step in any thrombocytopenic patient is to review the peripheral blood smear and exclude *pseudothrombocytopenia*.

Pathophysiologic classification (three mechanisms)

Mechanism	Representative causes	Smear / marrow clue
Decreased production	Marrow aplasia, myelodysplasia, leukaemia/infiltration, chemotherapy, B12/folate deficiency, inherited disorders	Usually accompanied by ↓ RBC/WBC; marrow shows ↓ megakaryocytes
Sequestration	Splenomegaly (portal hypertension, infiltration)	Count rarely falls <40,000/μL from spleen alone; ~⅓ of platelets normally pooled in spleen
Increased destruction	Immune (ITP, drug-induced, HIT), consumptive (DIC, TTP/HUS)	Large/young platelets; marrow shows ↑ megakaryocytes

- ▶ **Thrombopoietin (TPO)**, made in the liver (↑ by interleukin-6), is the major regulator; falling platelet/megakaryocyte mass raises TPO and drives production. Platelet life-span is 7–10 days.
- ▶ **Pseudothrombocytopenia** is an *in vitro* artefact — EDTA-dependent platelet agglutination by antibodies (IgG > IgM/IgA) producing clumps on the smear. **Redraw in sodium citrate (blue top) or heparin (green top)**, or examine a finger-stick smear before diagnosing true thrombocytopenia.

Approach to the patient

- ▶ **History:** drug ingestion (prescription, over-the-counter, herbal — drugs are the commonest cause), prior platelet counts, family history, systemic illness, infection/HIV risk, pregnancy.
- ▶ **Examination:** spleen size (confirm with ultrasound — mild splenomegaly is easily missed), signs of chronic liver disease, and the bleeding pattern.
- ▶ **Bleeding–count correlation:** a count of ~5000–10,000/μL is needed to maintain microvascular integrity. **Petechiae** (pinpoint, non-blanching haemorrhages) first appear at sites of high venous pressure (ankles/feet) and signify *low platelet number, not dysfunction*. **Wet purpura** (haemorrhagic blood blisters on oral mucosa) and **retinal haemorrhage** herald risk of life-threatening bleeding.
- ▶ **Investigations:** CBC + smear first; if other cell lines are abnormal or the smear shows fragments, proceed to **bone marrow examination**. Marrow is indicated in isolated thrombocytopenia in patients >60 years or those failing initial therapy (myelodysplasia can present as isolated thrombocytopenia).

- ▶ The evaluation algorithm branches on whether Hb/WBC are normal or abnormal, and whether the smear shows normal morphology, platelet clumping (pseudothrombocytopenia), or fragmented RBCs (microangiopathy — DIC, TTP/HUS).

Common acquired causes

- ▶ **Infection-induced** — the commonest *non-iatrogenic* cause. Many viral/bacterial infections lower the count via both reduced production and reduced survival; may accompany DIC (especially gram-negative sepsis and severe COVID-19). HIV (early), infectious mononucleosis act through immune mechanisms; late HIV causes pancytopenia/dysplastic production.
- ▶ **Drug-induced** — the commonest cause overall. Two patterns: a **predictable dose-related marrow suppression** (chemotherapeutics), and **classic drug-dependent antibodies** that react with platelet antigens only when the drug is present (notably **quinine** and **sulfonamides**). Onset typically after ~21 days (median) of exposure or on re-exposure, resolving 7–10 days after withdrawal. *GpIIb/IIIa inhibitors* (abciximab, eptifibatide, tirofiban) can cause an abrupt drop **within 24 h** via naturally occurring cross-reacting antibodies. Drugs in Table 120-1 include amiodarone, carbamazepine, phenytoin, vancomycin, trimethoprim-sulfamethoxazole, ranitidine, ibuprofen, naproxen, ceftriaxone, ciprofloxacin and gold. *All drugs should be suspect and stopped/substituted where possible.*
- ▶ **Inherited thrombocytopenia** (uncommon) — autosomal dominant **macrothrombocytopenia** linked to the non-muscle myosin heavy chain **MYH9 gene** (*May-Hegglin anomaly*, *Sebastian*, *Epstein's* and *Fechtner syndromes*); characteristic **large platelets**. Always take a family history in unexplained thrombocytopenia.

Heparin-induced thrombocytopenia (HIT)

- ▶ An immune, prothrombotic reaction to **antibody against the platelet factor 4 (PF4)–heparin complex**, which activates platelets via the **FcγRIIa** receptor (also activates monocytes/endothelium). Distinct from other drug causes: thrombocytopenia is **rarely severe** (nadir rarely <20,000/μL) and, far from bleeding, it **markedly increases thrombosis** (HITT, in up to 50%).
- ▶ **Timing**: typically **5–14 days** after starting heparin; <5 days if exposed within the prior few weeks/months (pre-formed antibody). Occurs with both unfractionated (more common) and LMW heparin.
- ▶ **Diagnosis** — “4Ts” score: Thrombocytopenia, Timing of count fall, Thrombosis/sequelae, and other causes absent. Confirm with **PF4/polyanion immunoassay (ELISA)** — sensitive but low specificity (≈50% positive after cardiopulmonary bypass) — and the more specific **serotonin-release assay**. HIT remains a clinical diagnosis.
- ▶ **Treatment**: *stop all heparin immediately*; anticoagulate with a **non-heparin agent** — IV direct thrombin inhibitor **argatroban** (or bivalirudin), **fondaparinux**, or a **DOAC** (most experience

with rivaroxaban). **Avoid LMWH (cross-reacts) and avoid starting warfarin alone** (risk of venous limb gangrene from protein C/S depletion — overlap with a DTI/fondaparinux/DOAC after platelet recovery). Image for thrombosis ($\geq$ lower-limb duplex); anticoagulate **3–6 months** if thrombosis present.

- ▶ **VITT** (vaccine-induced immune thrombotic thrombocytopenia) — a rare spontaneous-HIT-like syndrome after the **adenoviral ChAdOx1-S/nCoV-19** vaccine, with very **high D-dimer** and thrombosis at unusual sites (cerebral venous sinuses); ~20% fatal; treat with **IVIgG + non-heparin anticoagulant**.

Immune thrombocytopenic purpura (ITP)

- ▶ Acquired immune-mediated platelet destruction (and impaired megakaryocyte release).
Children: acute, post-infectious, self-limited. **Adults:** chronic. **Secondary ITP** is associated with SLE, HIV, hepatitis C and (variably) *H. pylori*.
- ▶ **Clinical:** mucocutaneous bleeding (ecchymoses, petechiae, oral/GI/menorrhagia) with a very low count but otherwise **normal smear (often large platelets)**; wet purpura/retinal haemorrhage warn of severe bleeding.
- ▶ **Diagnosis of exclusion:** antiplatelet antibody testing is *not* useful (poor sensitivity/specificity). Test for HIV, HCV, SLE, immunoglobulins; **Coombs' test if anaemic** — ITP + autoimmune haemolytic anaemia = ***Evans syndrome***.
- ▶ **Treatment** (counts $>30,000/\mu\text{L}$ without bleeding need none — no excess mortality):
 - First line: **prednisone 1 mg/kg or dexamethasone 40 mg/day $\times$ 4 days; anti-Rh0(D) immune globulin 50–75 $\mu\text{g/kg}$ (*Rh-positive, non-splenectomised patients only*); IVIgG 1–2 g/kg over 1–5 days for rapid rise / severe bleeding.**
 - Second line: **rituximab** (anti-CD20; durable remission ~30%), **TPO-receptor agonists** — romiplostim (SC), eltrombopag / avatrombopag (oral), and **splenectomy** (now used less than TPO-RAs). Vaccinate against **encapsulated organisms** (pneumococcus, meningococcus, *H. influenzae*) before splenectomy.

Thrombotic microangiopathies — TTP & HUS

Both show **microangiopathic haemolytic anaemia (MAHA)** — thrombocytopenia + **schistocytes**, $\uparrow$ LDH, $\uparrow$ unconjugated bilirubin, $\downarrow$ haptoglobin, with microvascular thrombi. **PT and aPTT are characteristically normal** (this distinguishes them from DIC, where coagulopathy with prolonged PT/aPTT predominates).

Feature	TTP	HUS
Defect	Deficiency of / antibody to ADAMTS13 (cleaves VWF ultra-large multimers); activity $<10\%$ diagnostic	Mostly Shiga-toxin (<i>E. coli</i> O157:H7) post-diarrhoeal; atypical HUS = complement dysregulation

Feature	TTP	HUS
Classic features	Moschcowitz pentad (1924): MAHA, thrombocytopenia, renal failure , neurologic signs , fever	Acute renal failure , MAHA, thrombocytopenia; preceded by (bloody) diarrhoea, mainly children
Inherited form	Upshaw-Schulman syndrome	Atypical HUS (complement gene variants/anti-factor H)
Treatment	Plasma exchange (TPE) mainstay (mortality 85–100% → 10–30%); glucocorticoids (adjunct); rituximab ↓ relapse; caplacizumab (anti-VWF nanobody)	Mainly supportive ± dialysis (diarrhoeal mortality <5%); anticomplement therapy for aHUS; plasma exchange does not alter typical HUS

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Algorithm for evaluating the thrombocytopenic patient (Fig. 120-2):** Box “Platelet count <150,000/μL” → check “Haemoglobin and WBC” → branches *Normal* (→ “Peripheral blood smear”) and *Abnormal* (→ “Bone marrow examination”). Smear branches: “Platelets clumped → redraw in sodium citrate/heparin” (pseudothrombocytopenia); “Normal RBC morphology, platelets normal/large” → *Consider: drug-induced, infection-induced, idiopathic immune (ITP), congenital*; “Fragmented RBCs” → *Microangiopathic haemolytic anaemia (DIC, TTP)*.
- ▶ **Pathogenesis of TTP (Fig. 120-4):** label *Endothelial cell* → *ultra-large VWF multimers*; *ADAMTS13 protease* cleaving multimers in the normal state; in TTP — “No protease/inhibited ADAMTS13” → *persistent ultra-large VWF multimers* → *platelet aggregation and microvascular thrombosis*.

Clinical / Diagnostic significance

- ▶ Always **inspect the smear first** — it separates pseudothrombocytopenia, immune destruction (large platelets) and microangiopathy (schistocytes) at a glance and directs the entire work-up.
- ▶ **PT/aPTT** discriminate consumptive states: prolonged in **DIC**, normal in **TTP/HUS/ITP**.
- ▶ New thrombocytopenia + neurologic or renal signs + MAHA is **TTP until proven otherwise** — start plasma exchange empirically before ADAMTS13 confirmation, as it is rapidly fatal untreated.
- ▶ In a heparin-exposed patient with a falling count and new thrombosis, apply the 4Ts, stop heparin and switch to a non-heparin anticoagulant — do **not** transfuse platelets or start warfarin alone.
- ▶ **Platelet transfusion** is generally avoided/contraindicated in HIT and TTP (fuels thrombosis); reserve for marrow-failure bleeding and severe ITP haemorrhage.

High-yield exam pointers

- ▶ Threshold $<150,000/\mu\text{L}$; three mechanisms — **production, sequestration, destruction**.
- ▶ **Drugs = commonest cause overall; infection = commonest non-iatrogenic cause**. Quinine & sulfonamides classically cause drug-dependent antibodies.
- ▶ **Pseudothrombocytopenia** = EDTA artefact → redraw in citrate/heparin.
- ▶ **HIT**: PF4–heparin antibody, nadir rarely $<20,000/\mu\text{L}$, day 5–14, **causes thrombosis not bleeding**; avoid LMWH & warfarin-alone; use argatroban/fondaparinux/DOAC.
- ▶ **ITP**: diagnosis of exclusion; treat if bleeding or count $<30,000$; steroids/IVIgG/anti-D first line, TPO-RA/rituximab/splenectomy later; **Evans = ITP + AIHA**.
- ▶ **TTP**: ADAMTS13 $<10\%$, **Moschcowitz pentad**, *Upshaw-Schulman* = inherited; treat with **plasma exchange + caplacizumab/rituximab**.
- ▶ **HUS**: *E. coli* O157:H7, post-diarrhoeal, children, renal-predominant; aHUS = complement → anticomplement therapy.
- ▶ **PT/aPTT normal** in TTP/HUS/ITP but **prolonged in DIC** — a frequent discriminator question.
- ▶ MAHA labs: **schistocytes**, $\uparrow\text{LDH}$, $\uparrow\text{indirect bilirubin}$, $\downarrow\text{haptoglobin}$.

SOURCE & COVERAGE

Harrison's Principles of Internal Medicine, 22e — **Ch 120 “Disorders of Platelets and Vessel Wall”** (B.A. Konkle), covering definition, mechanisms, approach, drug/infection-induced thrombocytopenia, HIT/VITT, ITP, and TTP/HUS. The chapter's cross-referenced topics (general hemostasis approach, Ch 69; chemotherapy-induced cytopenia, Ch 78) were not separately provided but are summarised only at the level stated in Ch 120. Specific eculizumab naming for aHUS is given in the text only as “anticomplement therapy.” No coverage gap for the asked topic.

Tumour Lysis Syndrome

Asked in: Paper IV Nov 2021 — RGUHS MD General Medicine

Definition / Introduction — Tumour lysis syndrome (TLS) is a life-threatening oncologic metabolic emergency characterised by the tetrad of **hyperuricaemia, hyperkalaemia, hyperphosphataemia and hypocalcaemia**, caused by the rapid destruction of a large number of swiftly proliferating neoplastic cells with massive release of intracellular contents into the circulation. **Acidosis** may also develop and **acute renal failure occurs frequently**. It is the commonest disease-related metabolic emergency in haemato-oncology and is largely **preventable** — recognition of risk and prophylaxis are the most important steps in management.

Pathophysiology — the four metabolic derangements

- ▶ **Core mechanism:** Effective cytotoxic therapy (or rarely spontaneous necrosis) lyses tumour cells, dumping intracellular **potassium, phosphate and nucleic acids** into the blood faster than the kidney can clear them; the nucleic-acid purines are catabolised to **uric acid**.
- ▶ **Hyperuricaemia → uric acid nephropathy:** Turnover of nucleic acids raises serum uric acid. In the **acidic local environment** of the distal nephron, uric acid precipitates in the **tubules, medulla and collecting ducts**, causing obstructive uropathy and renal failure. **Lactic acidosis and dehydration** promote precipitation. **Uric acid crystals in urine** are strong evidence of uric acid nephropathy; the **urinary uric acid : creatinine ratio** is **>1** in acute hyperuricaemic nephropathy and **<1** in renal failure from other causes.
- ▶ **Hyperphosphataemia → hypocalcaemia:** Release of intracellular phosphate pools causes a **reciprocal fall in serum calcium**, producing **severe neuromuscular irritability and tetany**. **Calcium phosphate** precipitates in the renal interstitium and microvasculature (**nephrocalcinosis**), further impairing renal function.
- ▶ **Hyperkalaemia:** Potassium is the principal intracellular cation; massive cell destruction releases it abruptly. In the setting of renal failure, hyperkalaemia can rapidly become **life-threatening**, causing **ventricular arrhythmias and sudden death** — the most immediately lethal feature of TLS.
- ▶ **Renal injury is multifactorial:** both uric-acid and calcium-phosphate crystals are **directly toxic to tubular epithelium**, inducing local inflammatory and pro-oxidative responses; in addition, **soluble uric acid** causes a **crystal-independent** fall in renal blood flow through vasoconstriction and impaired autoregulation.

Aetiology and precipitating factors

Domain	Examples (Harrison 22e)
Classic high-risk tumours	Burkitt's lymphoma, acute lymphoblastic leukaemia (ALL), AML, other rapidly proliferating lymphomas
Lower-risk / occasional	Chronic leukaemias; rarely solid tumours; rarely spontaneous tumour necrosis
Drug triggers	Venetoclax (bcl-2 antagonist — notably increases TLS frequency in lymphoid neoplasms); glucocorticoids; hormonal agents (letrozole, tamoxifen); monoclonal antibodies (rituximab, obinutuzumab, ofatumumab, gemtuzumab)
Timing	Usually during or 1–5 days after chemotherapy; hyperuricaemia may already be present before treatment

Risk stratification and classification

- ▶ **Tumour-burden markers predict risk:** TLS likelihood (e.g. in Burkitt's lymphoma) relates to tumour burden and baseline renal function. Hyperuricaemia and high serum LDH (>1500 U/L), both correlating with total tumour burden, also correlate with the risk of TLS.
- ▶ **Pretreatment evaluation in at-risk patients:** complete blood count, serum chemistry (electrolytes, creatinine, calcium, phosphate, uric acid) and urinalysis. With abnormal baseline renal function, image the kidneys and retroperitoneum by sonography/CT to exclude obstructive uropathy, and watch urine output closely.
- ▶ **Pseudohyperkalaemia caveat:** very high leukocyte and platelet counts can artefactually raise serum potassium through cell lysis *after* the blood is drawn — follow plasma (not serum) potassium; in pseudohyperkalaemia there are no ECG changes.
- ▶ **Cairo–Bishop framework** (standard textbook classification — see Coverage note): **Laboratory TLS** = ≥ 2 of the metabolic abnormalities (raised uric acid, K^+ , phosphate; low calcium) within ~3 days before to 7 days after therapy; **Clinical TLS** = laboratory TLS plus an end-organ consequence — acute kidney injury (rising creatinine), cardiac arrhythmia/sudden death, or seizure.

Clinical features and investigations

- ▶ **Metabolic/renal:** oliguric or anuric acute renal failure, flank pain, haematuria (uric-acid stones/sludge).
- ▶ **Hyperkalaemia:** muscle weakness, paraesthesiae, peaked T waves, widened QRS, ventricular arrhythmias, cardiac arrest.
- ▶ **Hypocalcaemia (from hyperphosphataemia):** tetany, carpopedal spasm, paraesthesiae, neuromuscular irritability, seizures, prolonged QT.
- ▶ **Investigations:** serial uric acid, K^+ , phosphate, calcium, creatinine, urea, LDH; urinalysis for uric-acid crystals and uric acid : creatinine ratio; ECG for hyperkalaemic changes; renal/retroperitoneal imaging if obstruction suspected.

Prevention and management

Recognition of risk and prevention are the most important steps. The standard preventive approach is allopurinol plus aggressive hydration. Urinary alkalinisation with sodium bicarbonate is no longer recommended — though it increases uric-acid solubility, a high urinary pH decreases the solubility of xanthine, hypoxanthine and calcium phosphate, potentially increasing intratubular crystallisation.

Intervention	Mechanism / detail (Harrison 22e)	Notes
Aggressive IV hydration	Normal or ½-normal saline at 3000 mL/m ² /day	Cornerstone; maintains high urine output and dilutes solutes

Intervention	Mechanism / detail (Harrison 22e)	Notes
Allopurinol	Xanthine oxidase inhibitor — blocks <i>new</i> uric acid formation	300 mg/m ² /day; IV form if oral not tolerated; does not remove pre-formed uric acid
Febuxostat	Potent non-purine selective xanthine oxidase inhibitor	Fewer hypersensitivity reactions than allopurinol; no dose adjustment in mild–moderate renal impairment; superior uric-acid control vs allopurinol in intermediate-to-high-risk haematologic malignancy; preferred in allopurinol allergy and/or renal failure
Rasburicase (recombinant urate oxidase)	Converts poorly soluble uric acid → readily soluble allantoin (urate oxidase is absent in primates)	Acts within hours; 0.2 mg/kg IV daily; for high-risk prophylaxis and established hyperuricaemia, especially with renal failure
Renal replacement therapy	Removes K ⁺ , phosphate, uric acid and fluid	Haemodialysis preferred ; consider early ; haemofiltration gives gradual continuous removal

- ▶ **Rasburicase cautions:** contraindicated in G6PD deficiency (cannot detoxify the hydrogen peroxide end-product of the urate-oxidase reaction → haemolysis); causes **ex vivo degradation of uric acid** in the test tube at room temperature, giving **spuriously low uric acid** values — **blood samples must be cooled immediately** to deactivate the enzyme.
- ▶ **Escalation (Fig. 80-4 algorithm):** After 24–48 h, if **uric acid >8.0 mg/dL** or **creatinine >1.6 mg/dL**, correct treatable (obstructive) renal failure and **start recombinant urate oxidase 0.2 mg/kg IV daily**; if no improvement, **delay chemotherapy or start dialysis**. If **uric acid <8.0 mg/dL** and **creatinine <1.6 mg/dL**, proceed with chemotherapy and monitor chemistry every 6–12 h.
- ▶ **Indications for urgent haemodialysis:** K⁺ >6.0 meq/L; uric acid >10 mg/dL; creatinine >10 mg/dL; phosphate >10 mg/dL or rising; symptomatic hypocalcaemia.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Pathophysiology flow diagram** — Labels: *Cytotoxic chemotherapy / rapid tumour cell lysis* → release of K⁺, phosphate, nucleic acids (purines); purines → *xanthine oxidase* → **uric acid**; arms to **Hyperkalaemia** (ventricular arrhythmia, sudden death), **Hyperphosphataemia** → **reciprocal Hypocalcaemia** (tetany; calcium-phosphate nephrocalcinosis), **Hyperuricaemia** (uric-acid crystal precipitation in tubules → uric-acid

nephropathy) → converging on **Acute Kidney Injury**. Mark drug blockade points:
Allopurinol/Febuxostat at xanthine oxidase; **Rasburicase** converting uric acid → **allantoin**.

- ▶ **Management algorithm box** (after Fig. 80-4) — Labels: *Hydrate (saline 3000 mL/m²/day)* → *Allopurinol 300 mg/m²/day* → *Monitor chemistry* → decision node at 24–48 h (**uric acid 8.0 / creatinine 1.6 mg/dL**) → *Rasburicase* → *Dialysis*, with the dialysis-threshold list (**K⁺ >6, uric acid >10, creatinine >10, phosphate >10, symptomatic hypocalcaemia**).

Clinical / Diagnostic significance

- ▶ TLS is **largely preventable**; identifying the high-risk patient (bulky, chemo-sensitive haematologic malignancy; high LDH; pre-existing renal impairment) and instituting hydration plus a hypouricaemic agent before therapy is the key intervention.
- ▶ **Hyperkalaemia is the most immediately fatal** disturbance — continuous cardiac monitoring and prompt treatment are mandatory.
- ▶ The **urinary uric acid : creatinine ratio (>1)** helps distinguish acute hyperuricaemic nephropathy from other causes of renal failure.
- ▶ Choice of hypouricaemic agent is risk-adapted: **allopurinol** for prevention in lower risk, **rasburicase** for high-risk prophylaxis and established hyperuricaemia (especially with renal failure), **febuxostat** where allopurinol is contraindicated or renal function is impaired.
- ▶ **Early dialysis** rather than delayed dialysis improves outcome once defined biochemical thresholds are crossed.

High-yield exam pointers

- ▶ TLS tetrad: **hyperuricaemia, hyperkalaemia, hyperphosphataemia, hypocalcaemia** ± acidosis ± acute renal failure.
- ▶ Classic culprits: **Burkitt's lymphoma, ALL, AML**; drug trigger to remember — **venetoclax** (bcl-2 antagonist).
- ▶ Onset **during or 1–5 days after** chemotherapy; high LDH >1500 U/L flags high tumour burden/risk.
- ▶ Standard prophylaxis = **aggressive hydration (3000 mL/m²/day) + allopurinol (300 mg/m²/day)**; **bicarbonate urinary alkalinisation is no longer recommended**.
- ▶ **Rasburicase** converts uric acid → **allantoin**; **contraindicated in G6PD deficiency**; **cool the sample** to avoid spuriously low uric acid.
- ▶ **Febuxostat** = non-purine selective xanthine oxidase inhibitor; useful in **allopurinol allergy / renal impairment**.
- ▶ **Pseudohyperkalaemia** with high WBC/platelets — follow **plasma K⁺**; no ECG changes.

- ▶ **Dialysis thresholds:** K^+ >6 meq/L, uric acid >10, creatinine >10, phosphate >10 (or rising), symptomatic hypocalcaemia — **haemodialysis preferred.**

SOURCE & COVERAGE

Harrison 22e — Ch 80 “Oncologic Emergencies” (Tumor Lysis Syndrome section and Fig. 80-4 management algorithm). **Coverage note:** All metabolic mechanisms, at-risk tumours/drugs, LDH/risk markers, drug doses and dialysis thresholds are grounded in Ch 80. The **Cairo–Bishop laboratory-vs-clinical TLS classification** (and its specific cut-offs/timing window) is universally accepted standard internal medicine but is **not** stated in the provided Harrison chapter text; it has been included for completeness and flagged here.

Unstable hemoglobin

Asked in: Paper IV Dec 2023 — RGUHS MD General Medicine

Definition / Introduction — Unstable hemoglobins are rare inherited hemoglobin variants in which a globin mutation makes the hemoglobin tetramer structurally unstable, so it denatures and precipitates within the red cell. They are also called **congenital Heinz body hemolytic anemias**. The usual clinical expression is **nonspherocytic hemolytic anemia** with jaundice, reticulocytosis, pigmenturia, and often splenomegaly, but severity ranges from almost silent hemolysis to recurrent crises.

Classification and examples

- ▶ **Place in hemoglobin disorders:** Harrison classifies them under **hemoglobinopathies** with abnormal physical, chemical, or functional properties, specifically among hemoglobins that oxidize readily; the phenotype is **hemolytic anemia and jaundice**.
- ▶ **Genetic basis:** mutations affect alpha- or beta-globin and disturb the **tertiary or quaternary structure** of the hemoglobin molecule. Many cases arise from a **new mutation**, so absence of a family history does not exclude the diagnosis.
- ▶ **Common structural mechanisms:**
 - Introduction of **proline into an alpha helix**, disrupting normal globin folding.
 - Replacement by a **polar amino acid in the hydrophobic interior** of the globin molecule, destabilizing the heme pocket or globin contacts.
 - Interface mutations that weaken tetramer stability and promote denaturation.
- ▶ **Number of variants:** Harrison notes **156 unstable hemoglobin variants** have been described; most are rare and family-specific.
- ▶ **Important examples from Harrison:**

- **Hemoglobin Köln:** beta 99 Val -> Met; found in multiple families and a classic unstable beta-chain variant.
- **Hemoglobin Hasharon:** alpha 47 Asp -> His; described particularly in Ashkenazi Jews.
- **Hemoglobin Zurich:** beta 63 His -> Arg; notable because it may show **oxidant drug-induced hemolysis**.
- ▶ **Laboratory expression of the variant:** in many heterozygotes the abnormal hemoglobin forms about 20-35% of total hemoglobin, but **hyperunstable variants may be undetectable** on routine fractionation and may mimic a thalassemic phenotype.

Pathogenesis of Heinz-body hemolysis

- ▶ Normal hemoglobin keeps heme protected within a stable globin pocket; unstable variants unfold more easily, especially under oxidative stress.
- ▶ The unstable hemoglobin **precipitates intracellularly** as **Heinz bodies**, which are intraerythrocytic aggregates of denatured hemoglobin.
- ▶ Heinz bodies damage the red-cell membrane and reduce deformability. When such cells traverse splenic cords and sinusoids, macrophages remove the inclusions by **pitting**.
- ▶ Pitting produces characteristic **bite cells** and **blister cells**. Repeated pitting and membrane injury shorten red-cell survival, causing mainly **extravascular hemolysis** in the spleen.
- ▶ During more severe episodes, there may also be intravascular hemolysis with **pigmenturia**, low haptoglobin, hemoglobinemia, hemoglobinuria, or later urinary hemosiderin.
- ▶ Oxidant stress, infection, fever, and selected oxidant drugs can increase denaturation, explaining episodic worsening on a background of chronic compensated hemolysis.

Clinical features

- ▶ **Presentation:** lifelong or incidentally detected **Coombs-negative nonspherocytic hemolytic anemia**; some patients present in childhood, while mild variants are detected only during family studies or after a hemolytic episode.
- ▶ **Symptoms:** fatigue, exertional dyspnea, pallor, intermittent jaundice, dark urine after hemolytic stress, or abdominal discomfort from splenomegaly or gallstones.
- ▶ **Signs:** pallor, icterus, **splenomegaly**, and occasionally hepatomegaly. Growth and development are usually normal in mild disease.
- ▶ **Baseline severity:** Harrison describes the associated disease as **usually mild** and often not requiring transfusion; adult hemoglobin may be only mildly reduced, roughly in the **9-14 g/dL** range in typical tabulated cases.
- ▶ **Crises:** acute worsening may follow oxidant drugs, intercurrent infection, or any stress increasing oxidative injury. Hb Zurich is the exam example for drug-triggered hemolysis.

- **Complications of chronic hemolysis:** unconjugated hyperbilirubinemia, pigment gallstones, folate demand from chronic reticulocytosis, episodic hemoglobinuria, and rarely transfusion-related iron burden if severe disease is repeatedly transfused.

Laboratory diagnosis

- **CBC and reticulocytes:** normocytic or mildly macrocytic anemia because of reticulocytosis; leukocyte and platelet counts are usually normal unless hypersplenism coexists.
- **Hemolysis profile:** increased reticulocyte count, indirect bilirubin, and LDH; reduced haptoglobin; urine hemoglobin or hemosiderin if intravascular hemolysis has occurred.
- **Peripheral smear:** polychromasia with **bite cells/blister cells**. Spherocytes are not the defining abnormality, helping separate it from hereditary spherocytosis or autoimmune hemolysis.
- **Heinz body demonstration:** Heinz bodies are **not seen on ordinary Wright-Giemsa smears**. Use a **supravital stain** such as brilliant cresyl blue, cresyl violet, crystal violet, or methyl violet to show dark globular inclusions of denatured hemoglobin.
- **Stability testing:** heat-stability testing by heating blood to 50°C or incubation with **isopropanol** precipitates unstable hemoglobins; Harrison emphasizes that these tests need careful controls.
- **Hemoglobin analysis:** HPLC or capillary electrophoresis may detect a variant peak; however, a negative HPLC does not exclude a **hyperunstable** variant because the abnormal hemoglobin may be rapidly degraded.
- **Molecular confirmation:** DNA sequencing of alpha- and beta-globin genes is definitive and is important for family studies and genetic counseling.
- **Family study:** evaluate parents, siblings, and children with CBC, reticulocyte count, smear, hemoglobin fractionation, and targeted mutation testing once the proband mutation is known.

Differential diagnosis

Disorder	Key overlap	Differentiating points
G6PD deficiency	Oxidant-triggered hemolysis, Heinz bodies, bite cells	X-linked; normal blood between attacks in many patients; enzyme assay low between episodes but may be falsely normal soon after hemolysis because of reticulocytosis
Hereditary spherocytosis	Jaundice, splenomegaly, gallstones	Spherocytes and raised MCHC; membrane disorder rather than hemoglobin instability; Heinz bodies are not the key lesion
Autoimmune hemolytic anemia	Hemolysis, jaundice, splenomegaly	Direct antiglobulin test positive; spherocytes common; acquired and immune-mediated

Disorder	Key overlap	Differentiating points
Thalassemia syndromes	Chronic inherited anemia; abnormal hemoglobin studies	Microcytosis and target cells dominate; defect is reduced globin synthesis, not unstable tetramer precipitation; hyperunstable Hb may mimic thalassemia and needs DNA testing
Sickle cell disease	Hemolysis and pigment gallstones	HbS polymerization with vaso-occlusion; sickled cells and characteristic HbS fraction on HPLC
M hemoglobins / methemoglobinemia	Abnormal hemoglobin with cyanosis	Main feature is slate-gray cyanosis/methemoglobin, not Heinz-body hemolysis; treatment usually unnecessary for inherited M hemoglobins
PNH	Coombs-negative hemolysis, hemoglobinuria	Acquired clonal disorder; thrombosis and cytopenias may occur; flow cytometry shows CD55/CD59 deficiency

Management and counseling

- ▶ **General principle:** most unstable hemoglobins need **supportive care**, not disease-specific drug therapy.
- ▶ **Avoid triggers:** avoid known oxidant drugs whenever possible, especially in patients with previous drug-triggered hemolysis or Hb Zurich-like variants. Practical avoid-list includes dapsone, primaquine-type antimalarials, nitrofurantoin, phenazopyridine, rasburicase, methylene blue, sulfonamides, pegloticase, and quinolones when safer alternatives exist.
- ▶ **During acute hemolysis:** stop the trigger, treat infection, maintain hydration and urine output, monitor hemoglobin, bilirubin, LDH, renal function, and urine pigment, and transfuse packed red cells only for symptomatic or severe anemia.
- ▶ **Chronic care:** folate replacement is reasonable when chronic reticulocytosis is present; monitor for gallstone symptoms and splenic enlargement.
- ▶ **Transfusion:** Harrison notes disease is usually mild and **does not require transfusion**. Repeated transfusion should be avoided unless clearly indicated because it adds alloimmunization and iron-overload risk.
- ▶ **Splenectomy:** not routine. Consider only in selected severe, transfusion-dependent or hypersplenic cases after hematology review; if performed, give appropriate pneumococcal, meningococcal, and Haemophilus influenzae type b vaccination and fever education.

- ▶ **Genetic counseling:** explain autosomal codominant/inherited hemoglobin-variant behavior, possible de novo mutation, variable expression, and the value of DNA-confirmed diagnosis before reproductive counseling.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Pathogenesis flow diagram:** globin mutation -> unstable Hb tetramer -> intracellular denaturation -> Heinz bodies -> splenic pitting -> bite/blister cells -> extravascular hemolysis -> jaundice, splenomegaly, reticulocytosis, pigmenturia.
- ▶ **Peripheral smear diagram:** label normal RBC, Heinz body on supravital stain, bite cell after splenic pitting, blister cell, reticulocyte/polychromasia.

Clinical / Diagnostic significance

- ▶ Think of unstable hemoglobin in **Coombs-negative nonspherocytic hemolytic anemia** with Heinz bodies, especially when G6PD assay is normal or attacks are familial/recurrent.
- ▶ A routine smear can miss the diagnosis because Heinz bodies require **vital/supravital staining**.
- ▶ HPLC can be misleading: some variants appear as 20-35% abnormal hemoglobin, while **hyperunstable variants may be absent** because they precipitate or degrade rapidly.
- ▶ Drug history is essential; oxidant drugs may convert compensated hemolysis into a crisis.
- ▶ Do not label all bite-cell hemolysis as G6PD deficiency. A normal G6PD level away from crisis plus positive heat/isopropanol instability testing should redirect work-up toward unstable Hb.
- ▶ DNA sequencing is the most reliable final test and prevents unnecessary immune, marrow, liver, and cardiopulmonary work-ups.

High-yield exam pointers

- ▶ Write the synonym: **congenital Heinz body hemolytic anemia**.
- ▶ Core lesion: structurally unstable Hb -> **precipitated denatured Hb** -> Heinz bodies.
- ▶ Heinz bodies need **brilliant cresyl blue/cresyl violet/crystal violet/methyl violet** supravital staining.
- ▶ Smear clue after splenic pitting: **bite cells and blister cells**.
- ▶ Harrison examples: **Hb Köln, Hb Hasharon, Hb Zurich**.
- ▶ Hb Zurich is the classic unstable Hb susceptible to **oxidant drug-induced hemolysis**.
- ▶ Diagnosis: hemolysis labs + supravital stain + **heat 50°C/isopropanol instability test** + HPLC/capillary electrophoresis + globin gene sequencing.
- ▶ Routine HPLC may miss **hyperunstable** variants.
- ▶ Most cases are mild: avoid oxidants, folate if chronic hemolysis, transfuse only when clinically necessary.

SOURCE & COVERAGE

Harrison 22e — “Disorders of Hemoglobin”; Harrison 22e — “Interpreting Peripheral Blood Smears” and “Hemolytic Anemias”; CMDT 2026 — “Blood Disorders”. Coverage note: the specified DeVita’s Cancer 12e heme-malignancy text was grepped but has no substantive benign unstable-hemoglobin coverage, so this thin topic is grounded mainly in Harrison and CMDT.

Vitamin B12 (Cobalamin) Deficiency

Asked in: Paper IV Jul 2020 — RGUHS MD General Medicine

Definition / Introduction — Vitamin B12 (cobalamin) deficiency is a state of inadequate tissue cobalamin resulting in **megaloblastic anaemia** (ineffective erythropoiesis with defective DNA synthesis) and a characteristic **neuropsychiatric syndrome**, most importantly *subacute combined degeneration* of the cord. Cobalamin is a cobalt-containing corrin-ring vitamin synthesised solely by micro-organisms; humans depend entirely on **food of animal origin**. Because body stores (2–3 mg) last 3–4 years, deficiency develops insidiously and is usually due to **malabsorption** (chiefly pernicious anaemia) rather than dietary lack — except in vegans. The hallmark is that *neurological damage may be irreversible and can occur even with a normal blood count*, making early recognition critical.

Biochemistry, sources and physiology of absorption

- ▶ **Structure/forms** — cobalt atom at the centre of a corrin ring. Active coenzyme forms: **adenosylcobalamin (ado-B12)**, mitochondrial cofactor for *L-methylmalonyl-CoA mutase*; **methylcobalamin**, cytoplasmic/plasma cofactor for *methionine synthase*. Hydroxocobalamin is the therapeutic precursor form.
- ▶ **Dietary sources & requirement** — meat, fish, eggs and dairy; plant foods are devoid of B12. Western diet supplies 5–30 µg/day; **daily requirement** ~1–3 µg; body stores 2–3 mg (mainly liver), sufficient for 3–4 years.
- ▶ **Two cobalamin-dependent reactions** — (1) methylmalonyl-CoA → succinyl-CoA (ado-B12); a block raises **methylmalonic acid (MMA)**. (2) homocysteine + 5-methyl-THF → methionine (methylcobalamin); a block raises **homocysteine** and regenerates THF.
- ▶ **The “methylfolate trap”** — in B12 deficiency, methionine synthase fails, so 5-methyl-THF accumulates in plasma while intracellular folate polyglutamates fall (THF starvation). This impairs thymidylate synthesis (dUMP→dTMP), producing the *common final pathway of megaloblastosis* shared by folate and B12 deficiency, and explains why large doses of folic acid partially correct the anaemia (but **not** the neuropathy) of B12 deficiency.

Step	Mechanism
Release from food	Gastric acid + pepsin free B12; it binds haptocorrin (HC / TC I) from saliva
Pancreatic phase	Trypsin digests HC; B12 transferred to intrinsic factor (IF)
Intrinsic factor	Glycoprotein from gastric parietal cells (fundus/body); gene at 11q13
Ileal uptake	IF-B12 binds cubilin receptor on ileal enterocyte; trafficked via amnionless (AMN)
Transport	After ~6 h, B12 enters portal blood on transcobalamin II (TC II); delivered to tissues via TC II receptor + megalin
Enterohepatic cycle	0.5–5 µg enters bile/day and is reabsorbed (intact in vegans → slow deficiency; lost in malabsorption → faster)

Causes of B12 deficiency

- **Inadequate intake (dietary)** — **vegans/strict vegetarians**; large at-risk group are Indian Hindus (subnormal levels in up to 50% of young Indian vegans, though frank megaloblastic anaemia is uncommon as the enterohepatic cycle is intact).
- **Malabsorption** — the commonest mechanism:

Site	Causes
Gastric	Pernicious anaemia (autoimmune, commonest severe cause); total/partial gastrectomy; congenital IF deficiency; food-cobalamin malabsorption (atrophic gastritis, PPIs, bariatric surgery)
Intestinal	Stagnant-loop syndrome (bacterial overgrowth — jejunal diverticulosis, blind loop, stricture, fistula); ileal resection (≥ 1.2 m terminal ileum)/Crohn disease; Imerslund-Gräsbeck syndrome (cubilin/AMN mutation, selective malabsorption + proteinuria); tropical sprue; fish tapeworm (<i>Diphyllobothrium latum</i>); gluten-induced enteropathy
Other	Zollinger-Ellison syndrome; chronic pancreatitis; HIV; TC II deficiency (congenital)

- **Drugs / toxic** — **metformin** (lowers TC I); prolonged PPI use; colchicine, neomycin; **nitrous oxide** (N₂O) irreversibly oxidises methylcobalamin and inactivates methionine synthase (megaloblastosis after prolonged anaesthesia; myeloneuropathy in those exposed/abusing N₂O).

Pernicious anaemia (the key autoimmune cause)

- ▶ **Definition** — severe lack of IF due to **autoimmune atrophic gastritis** of the gastric body/fundus.
- ▶ **Epidemiology** — incidence ~120/100,000 (UK); M:F ≈ 1:1.6; **median onset 70–80 years**; commoner in those of African ancestry and blood group A.
- ▶ **Associations** — other organ-specific autoimmune disease: **autoimmune thyroid disease**, vitiligo, type 1 diabetes, Addison disease, hypoparathyroidism; increased risk of **gastric carcinoma** and gastric carcinoid.
- ▶ **Serology** — IF antibodies: “blocking” (type I, ~55%, prevents B12–IF binding) and “binding” (type II, ~35%); **parietal-cell antibody** (~90%, directed at gastric H⁺/K⁺-ATPase, but non-specific). **Raised serum gastrin, low pepsinogen I.**
- ▶ **Histology** — atrophy of all layers of body/fundus, loss of parietal and chief cells, intestinal metaplasia; antrum spared.

Clinical features

- ▶ **Anaemia** — insidious; symptoms often mild relative to severe anaemia (good adaptation). Pallor, mild **icterus/lemon-yellow tint** (haemolysis + ineffective erythropoiesis), fatigue.
- ▶ **Epithelial/GI** — **glossitis** (beefy, smooth red tongue), angular cheilosis, anorexia, weight loss, diarrhoea; reversible **melanin hyperpigmentation**.
- ▶ **Neuropsychiatric** — **subacute combined degeneration (SACD)**: symmetrical demyelination of the posterior columns and lateral (pyramidal) tracts of the cervico-thoracic cord.
 - Earliest: distal **paraesthesiae** and peripheral neuropathy.
 - Posterior column: loss of **vibration and proprioception**, sensory ataxia, **positive Romberg sign**, **Lhermitte sign**.
 - Pyramidal: spastic weakness, **hyperreflexia**, extensor plantars (the combination of absent ankle jerks with extensor plantars is classic).
 - Higher centres: dementia, depression, psychosis (“megaloblastic madness”), optic atrophy, anosmia.
 - Autonomic: postural hypotension, impotence, bladder/bowel incontinence.
 - *Crucial point*: neurological disease may occur with a **normal CBC and normal MCV** and is potentially reversible only if treated within ~6 months.
- ▶ **Other** — infertility, recurrent fetal loss; raised homocysteine is a (weak) vascular/thrombotic risk factor.

Investigations and diagnosis

- ▶ **Peripheral smear** — **oval macrocytes**, marked anisopoikilocytosis, **MCV usually >100 fL** (110–140 fL), **hypersegmented neutrophils (>5 lobes)**; leucopenia and thrombocytopenia in severe cases; **reticulocytopenia**.

- ▶ **Bone marrow** — hypercellular, **megaloblastic** erythroid hyperplasia with **nuclear–cytoplasmic asynchrony** (open “sieve-like” chromatin with mature haemoglobinised cytoplasm), **giant metamyelocytes/giant bands**, hyperpolyploid megakaryocytes.
- ▶ **Ineffective erythropoiesis** (“intramedullary haemolysis”) — raised **unconjugated bilirubin**, very high LDH, low haptoglobin, raised urine urobilinogen.
- ▶ **Confirmatory biochemistry:**

Test	Comment
Serum cobalamin	Normal ~118–148 to 738 pmol/L; deficiency usually <74 pmol/L (<100 ng/L); borderline 74–148 pmol/L. <i>False-normal in up to 50% of PA sera due to IF antibodies interfering with assay</i>
Serum MMA	Raised — relatively specific for B12 deficiency (normal in folate deficiency); also raised in renal failure
Serum homocysteine	Raised in both B12 and folate deficiency (less specific; also up in renal disease, B6 deficiency, hypothyroidism)
Tests for cause	IF + parietal-cell antibodies, serum gastrin (↑) and pepsinogen I (↓) for PA; gastric endoscopy; coeliac serology; check iron status (coexistent iron + B12 deficiency in 15–20% of elderly may mask macrocytosis)

- ▶ The Schilling test is **obsolete** (radioactive B12 unavailable).

Treatment

- ▶ **Parenteral** (standard for severe deficiency / PA / neuropathy) — **hydroxocobalamin** preferred (better retention): six **1000 µg IM** doses at 3–7-day intervals to replenish stores, then **1000 µg IM every 3 months** for maintenance. (Cyanocobalamin, used in the US, needs higher/more frequent dosing — e.g. 1000 µg IM monthly.) CMDT regimen: 100–1000 µg IM/SC, daily for 1 week → weekly for 1 month → monthly.
- ▶ **Oral/sublingual** — high-dose **1000–2000 µg/day** cyanocobalamin or methylcobalamin is effective even in PA, as ~1% is absorbed passively independent of IF; requires good compliance and monitoring; preferred for food-cobalamin malabsorption.
- ▶ **Lifelong therapy** for PA, total gastrectomy and ileal resection. Treat/screen patients on long-term PPIs or after bariatric surgery.
- ▶ **Critical caveats:**
 - Always **exclude/correct B12 deficiency before giving folic acid** — folate monotherapy may correct the anaemia but **precipitate or worsen SACD**.

- **Hypokalaemia** and a transient rise in platelets may occur in the first days of treatment (brisk haematopoiesis); monitor in severe anaemia.
- Expect **reticulocytosis at 5–7 days**; blood picture normalises by ~2 months. Transfusion is rarely needed (give packed cells slowly if essential).

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Subacute combined degeneration** — spinal cord cross-section: draw a cord transverse section and shade/label the **posterior (dorsal) columns** — **fasciculus gracilis & cuneatus** and the **lateral corticospinal (pyramidal) tracts** as the demyelinated regions; label *“posterior + lateral column demyelination; anterior columns spared.”*
- ▶ **Cobalamin absorption pathway**: stomach (parietal cell → **intrinsic factor**; haptocorrin from saliva) → duodenum (**pancreatic trypsin** frees B12 from HC → binds IF) → **terminal ileum (cubilin/AMN receptor)** → portal blood on **transcobalamin II** → tissues/liver store. Label each box.

Clinical / Diagnostic significance

- ▶ A raised MCV with **hypersegmented neutrophils** on a routine count is often the first clue — pursue B12/folate before labelling “anaemia of chronic disease.”
- ▶ **MMA + homocysteine** distinguish true tissue deficiency from a borderline serum B12 and detect deficiency despite normal levels; **MMA is the more specific marker**.
- ▶ In any patient with **unexplained myelopathy, sensory ataxia, dementia or psychosis**, check B12 — neurology can present without anaemia.
- ▶ Diagnosing **pernicious anaemia** mandates one-time gastroscopy (gastric atrophy, carcinoma/carcinoid surveillance) and screening for associated autoimmune endocrinopathy.
- ▶ The therapeutic trap to avoid in exams: **never treat megaloblastic anaemia with folic acid alone** until B12 is replete.

High-yield exam pointers

- ▶ Body stores last **3–4 years**; only source is **animal food**; commonest cause of severe deficiency is **pernicious anaemia (autoimmune)**.
- ▶ **MMA raised in B12 deficiency, NOT in folate deficiency**; homocysteine raised in both.
- ▶ PA antibodies: IF antibody = specific but ~50% sensitive; parietal-cell antibody = sensitive (90%) but non-specific.
- ▶ Neurology = **subacute combined degeneration** → posterior + lateral columns; absent ankle jerks + extensor plantars + positive Romberg/Lhermitte.
- ▶ Smear: **oval macrocytes + hypersegmented neutrophils**; marrow: megaloblasts with **nuclear–cytoplasmic asynchrony**, giant metamyelocytes.

- ▶ Treat with **hydroxocobalamin IM**; give **folate only after B12 corrected**; watch for **hypokalaemia** and **reticulocytosis** on day 5–7.
- ▶ **Nitrous oxide** inactivates methionine synthase → can precipitate acute B12 myeloneuropathy.
- ▶ **Metformin** and long-term PPIs are recognised drug causes; screen at-risk patients.

SOURCE & COVERAGE

- ▶ **Harrison's Principles of Internal Medicine, 22e** — “Megaloblastic Anemias” (Hoffbrand) and “Vitamin and Trace Mineral Deficiency and Excess.”
- ▶ **CMDT 2026** — “Blood Disorders: Vitamin B12 Deficiency” (current diagnostic thresholds and treatment regimens).
- ▶ *Coverage note:* The spec-listed specialty text (DeVita's *Cancer: Principles & Practice of Oncology*) addresses haematologic **malignancies**, not benign nutritional/megaloblastic anaemia, so it does not cover this topic; Harrison's dedicated haematology chapter by A.V. Hoffbrand is the authoritative subspecialty source used here, supplemented by CMDT for management.

Agents Causing Occupational Cancers — Types of Cancer, Industrial Sources of Exposure, and Prevention

Asked in: Paper IV Oct 2025 — RGUHS MD General Medicine

Definition / Introduction — *Occupational cancers* are malignancies whose development is causally attributable to exposure to physical, chemical or biological **carcinogens encountered in the workplace**. They are the prototype of *preventable* cancer because the causative agent is identifiable, often a “complete carcinogen” (acting as both initiator and promoter), and the route of exposure is amenable to engineering and regulatory control. Occupational and environmental exposures are estimated to contribute up to ~10% of all lung cancers, and a substantial fraction of bladder cancer and virtually all mesothelioma. They characteristically show a **long latency (often decades)** between first exposure and tumour, and risk that rises with intensity and duration of exposure.

Principal occupational carcinogens — cancer caused and industrial source

Carcinogen	Type of cancer caused	Industrial use / setting of exposure
Asbestos	Bronchogenic carcinoma; pleural & peritoneal mesothelioma; laryngeal	Mining, milling, insulation, construction, shipbuilding/ship repair, pipe-fitting, brake linings
Aromatic amines (benzidine, 2-naphthylamine — “dyes”)	Bladder (urothelial) carcinoma	Dye, rubber, paint, textile and aluminium industries

Carcinogen	Type of cancer caused	Industrial use / setting of exposure
Benzene	Acute myeloid (myelocytic) leukaemia	Petrochemical, rubber, shoe/leather, solvent, petrol industries
Vinyl chloride monomer	Hepatic angiosarcoma	PVC plastic polymerisation
Arsenic (inorganic)	Skin, lung, liver (angiosarcoma), bladder, kidney	Smelting, microelectronics, wood preservatives, pesticides/herbicides; contaminated deep-well water
Chromium (hexavalent)	Lung, nasal sinus	Chrome plating, pigment/dye manufacture, stainless-steel welding, tanning
Nickel dust	Lung, nasal sinus	Nickel refining, electroplating, alloy and battery manufacture
Polycyclic aromatic hydrocarbons (coal tar, soot, pitch)	Skin — scrotal SCC (chimney sweeps); lung	Coke ovens, coal-tar/pitch, roofing, soot (chimney sweeping), aluminium production
Crystalline silica	Lung carcinoma (on a background of silicosis)	Sandblasting, quarrying, stone-cutting, foundry, ceramics, artificial-stone benchtops
Radon gas / radon daughters	Lung carcinoma	Underground uranium and hard-rock mining; indoor accumulation
Beryllium	Lung carcinoma (highly suspect)	Alloy processing for nuclear power/weapons, aerospace, electronics
Ionising radiation	Leukaemia, thyroid, breast, bone, lung, soft tissue (many)	Radiology/radiography, nuclear industry, radium-dial painting
Diesel exhaust	Lung carcinoma (miners)	Mining, transport, professional drivers
Wood dust / formaldehyde	Sinonasal adenocarcinoma; nasopharyngeal	Furniture and cabinet making, joinery
Nitrogen / sulphur mustard gas	Lung, head & neck, nasal sinus	Chemical-weapon and munitions manufacture
Ultraviolet (sunlight)	Non-melanoma skin cancer; melanoma	Outdoor work (farming, fishing, construction)

Key carcinogen groups — clinical detail

- ▶ **Asbestos** — the single most important occupational carcinogen. All fibre types cause disease; it produces **asbestosis** (diffuse interstitial fibrosis, usually after ≥ 10 years of exposure, presenting ≥ 15 years later), **pleural plaques** (a radiographic marker of exposure, not impairment), bronchogenic carcinoma and **mesothelioma**. **>80% of mesotheliomas are attributable to asbestos**, so documented mesothelioma in an exposed worker is *compensable*. Smoking and asbestos act **multiplicatively** for lung (not mesothelioma) risk.
- ▶ **Aromatic amines** — *benzidine* and *2-naphthylamine* are excreted in urine and concentrated in the bladder, producing urothelial carcinoma in dye, rubber and paint workers; **schistosomiasis* (*S. haematobium*)* is the parallel infective cause of (squamous) bladder cancer in endemic regions such as Egypt.
- ▶ **Benzene** — a myelotoxin causing aplastic anaemia and **acute myeloid leukaemia**; also implicated in myelodysplasia.
- ▶ **Vinyl chloride** — the classic cause of **hepatic angiosarcoma**, a rare sentinel tumour highly specific for occupational exposure (arsenic and thorotrast are the other causes).
- ▶ **Crystalline silica** — silicosis carries an increased risk of lung cancer and of **tuberculosis** (“silicotuberculosis”); *eggshell* calcification of hilar nodes is a clue. Resurgent in **artificial-stone (engineered quartz) benchtop** workers.
- ▶ **Arsenic** — chronic exposure produces **palmar/plantar hyperkeratosis, hyperpigmentation and Mees’ lines**, with skin, lung, liver (angiosarcoma), bladder and kidney cancers.
- ▶ **Polycyclic aromatic hydrocarbons** — the historical *Percival Pott* observation of scrotal squamous-cell carcinoma in chimney sweeps (soot) is the first described occupational cancer.
- ▶ **Beryllium** — causes chronic granulomatous lung disease (diagnosed by the **beryllium lymphocyte proliferation test, BeLPT**) and is a suspect lung carcinogen.

Prevention — primary, secondary and tertiary

Primary prevention (most important — “hierarchy of controls”):

- ▶ **Elimination / substitution** of the carcinogen — e.g., asbestos replaced by synthetic mineral fibres (fibreglass, refractory ceramic fibres); ban/restrict known agents.
- ▶ **Engineering controls** — enclosure of process, **local exhaust ventilation**, closed systems (vinyl chloride polymerisation), **wet methods** and dust suppression for silica.
- ▶ **Administrative controls** — limiting exposure duration, job rotation, restricted-area zoning, worker education and a documented **occupational history**.
- ▶ **Personal protective equipment (PPE)** — respirators, protective clothing (least effective; last line).
- ▶ **Regulation** — enforce permissible exposure limits / threshold limit values, and *ALARA* (“as low as reasonably achievable”) for ionising radiation.

- ▶ **Smoking cessation** — essential because tobacco is **multiplicative** with asbestos and additive/multiplicative with radon; importantly, β -carotene supplementation **increased** lung cancer in asbestos-exposed smokers (CARET trial), so antioxidant chemoprevention is *not* advised.

Secondary prevention (early detection / surveillance):

- ▶ Periodic **chest radiograph, HRCT and pulmonary function tests** in dust-exposed workers; **low-dose CT** screening in eligible high-risk smokers.
- ▶ **Urine cytology / haematuria surveillance** in aromatic-amine-exposed workers; **biological monitoring** (e.g., urinary arsenic, BeLPT for beryllium).
- ▶ Recognition of pleural plaques and pre-employment/periodic medical examination.

Tertiary prevention: early definitive treatment, rehabilitation, and **workers' compensation / medico-legal certification** (mesothelioma, asbestosis, silicosis are notifiable, compensable diseases). Population-level measures include vaccination against oncogenic infections (HBV, HPV) and IARC carcinogen classification with national registries.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ “**Carcinogen → target organ**” **body map**: a human silhouette with labelled arrows — *Asbestos → lung & pleura (mesothelioma); Aromatic amines → urinary bladder; Benzene → bone marrow (AML); Vinyl chloride → liver (angiosarcoma); Arsenic → skin; PAH/soot → scrotal skin (SCC); Wood dust/Ni/Cr → nasal sinuses; Radon/silica/diesel → lung.*
- ▶ **Hierarchy of controls (inverted pyramid)**: top-to-bottom labels — *Elimination → Substitution → Engineering controls → Administrative controls → PPE* (annotate “most effective” at top, “least effective” at bottom).

Clinical / Diagnostic significance

- ▶ A meticulous **occupational and environmental history** is essential in any patient with lung fibrosis, an unexplained malignancy, haematuria or cytopenia — exposure may be remote and bystander (e.g., shipyard painters/electricians, household contacts of asbestos workers).
- ▶ **Sentinel tumours** point directly to specific exposures: hepatic angiosarcoma → vinyl chloride/arsenic; pleural mesothelioma → asbestos; scrotal SCC → soot/PAH; sinonasal adenocarcinoma → wood dust/nickel.
- ▶ Investigations: HRCT and PFT (pneumoconioses), pleural biopsy/thoracoscopy with calretinin/WT-1 for mesothelioma, cystoscopy + urine cytology (bladder), bone-marrow study (benzene/AML), BeLPT (beryllium).
- ▶ Recognising an occupational cause carries **public-health duty** — notification, workplace inspection, screening of co-workers and statutory compensation.

High-yield exam pointers

- ▶ Asbestos → lung cancer + **pleural/peritoneal mesothelioma**; >80% mesotheliomas are asbestos-related; smoking multiplies lung (not mesothelioma) risk.
- ▶ **Aromatic amines (benzidine, 2-naphthylamine)** → **bladder cancer** (dye/rubber/paint industry).
- ▶ Benzene → AML; Vinyl chloride → hepatic angiosarcoma; Arsenic → skin/lung/bladder + Mees' lines.
- ▶ PAH/soot → **scrotal SCC** (Pott, chimney sweeps) — the first recognised occupational cancer.
- ▶ **Chromium & Nickel** → lung and nasal-sinus cancer; Radon & diesel exhaust → lung cancer (miners).
- ▶ Silica → lung cancer + **increased TB risk** (silicotuberculosis); artificial-stone workers are a re-emerging group.
- ▶ Prevention pyramid: **Elimination > Substitution > Engineering > Administrative > PPE**; plus smoking cessation, exposure limits and surveillance.
- ▶ β -carotene **harms** asbestos-exposed smokers (CARET) — do not use as chemoprevention.

SOURCE & COVERAGE

- ▶ **Harrison's Principles of Internal Medicine, 22e** — “Prevention and Early Detection of Cancer” (Table of Suspected Carcinogens), “Occupational and Environmental Lung Disease” (categories of occupational exposure and respiratory responses), “Heavy Metal Poisoning” (arsenic), and “Cancer Genetics” (chimney-sweep/soot historical note).
- ▶ **DeVita, Hellman & Rosenberg's Cancer: Principles & Practice of Oncology, 12e** — bladder-cancer epidemiology (aromatic amines in painting/rubber/aluminium industries; arsenic; *S. haematobium*) and sinonasal/formaldehyde occupational associations.
- ▶ **CMDT 2026** — “Occupational Pulmonary Diseases” (pneumoconioses table; list of industrial pulmonary carcinogens; asbestos as cocarcinogen with tobacco; mesothelioma).

Coverage note: The corpus covers occupational carcinogens richly but in a *scattered* fashion (carcinogen→cancer table in the cancer-prevention chapter; industrial sources in the occupational-lung and heavy-metals chapters; bladder/aromatic-amine and formaldehyde detail in DeVita). The structured **hierarchy-of-controls** prevention framework and the **Percival Pott** eponym are standard, universally accepted occupational-medicine teaching (Harrison confirms the chimney-sweep observation and asbestos-fibre substitution; the formal control hierarchy is not given verbatim).

Presenting Clinical Features, Serum Markers and Surveillance Recommendations for Pancreatic Carcinoma

Asked in: Paper II May 2025 — RGUHS MD General Medicine

Definition / Introduction — Pancreatic carcinoma denotes malignant neoplasia of the pancreas, of which **ductal adenocarcinoma (PDAC)** of the exocrine pancreas is by far the commonest and most lethal subtype (overall 5-year survival $\approx 13\%$). About **75% arise in the head** and 25% in the body/tail. Its posterior retroperitoneal location and absence of early symptoms mean most patients present late — only 10–20% have resectable disease, $>30\%$ present locally advanced and $>50\%$ metastatic. This answer covers the presenting clinical features, the serum/tumour markers used in diagnosis and monitoring, and the current surveillance recommendations for high-risk individuals.

Presenting clinical features (history)

- ▶ **Painless obstructive jaundice** — the classic presentation of a **head-of-gland** tumour obstructing the distal common bile duct; clinically visible once bilirubin >2 mg/dL, accompanied by dark urine, **pale/clay-coloured stools** and **pruritus** (bile-salt deposition). Jaundice is present in $\sim 75\%$ of periampullary tumours.
- ▶ **Abdominal pain** ($\sim 40\text{--}70\%$) — typically dull **mid-epigastric “boring” pain radiating to the back** from retroperitoneal invasion of the splanchnic (coeliac) nerve plexus; exacerbated by eating or lying flat and relieved by sitting forward (the latter often signifies extrapancreatic, inoperable spread).
- ▶ **Weight loss and cachexia** ($\sim 50\%$) with loss of muscle mass; $\geq 5\%$ **weight loss** in the year preceding diagnosis occurs in $\sim 75\%$ of patients.
- ▶ **New-onset or unexpectedly worsening diabetes mellitus** (type 3c), often with concomitant weight loss, or an unexplained rise in HbA1c in the preceding 1–2 years — may herald the cancer (new diabetes after age 45 is a recognised clue).
- ▶ **Steatorrhea / malabsorption** ($\sim 15\%$) from exocrine insufficiency and pancreatic-duct obstruction — bulky, malodorous, greasy stools.
- ▶ **Fatigue** ($\sim 30\%$), **pruritus** ($\sim 30\%$), **anorexia**, and **new-onset depression** ($\sim 40\%$) — the depression association, though reported, remains debated.
- ▶ **Acute pancreatitis** without an alternative cause, especially in patients ≥ 40 years, may occasionally be the first presentation.

Eponymous and examination signs

Sign	Finding	Significance
Courvoisier’s sign	Palpable, non-tender, distended gallbladder with painless jaundice	Suggests malignant distal biliary obstruction (vs stone disease); accurate $\sim 50\%$ of the time
Trousseau’s syndrome/sign	Migratory superficial thrombophlebitis $\pm$ DVT/PE and arterial thrombi	Reflects the cancer-associated hypercoagulable state

Sign	Finding	Significance
Virchow's node	Palpable left supraclavicular lymph node (thoracic duct drainage)	Sign of advanced/metastatic disease
Sister Mary Joseph's nodule	Subcutaneous periumbilical metastatic nodule	Indicates peritoneal metastasis
Blumer's shelf / ascites / hepatomegaly	Peritoneal & hepatic spread	Late, incurable disease

- ▶ Other late signs: a hard fixed epigastric mass, splenomegaly or gastric varices (splenic vein occlusion), and silvery stools (combined biliary obstruction + ampullary bleeding) in **ampulla of Vater** tumours.

Serum and tumour markers

- ▶ **CA19-9 (carbohydrate antigen 19-9)** — the principal and only FDA-approved serum marker, though for monitoring, not screening/early detection.
 - **Biology:** a high-molecular-weight glycolipid that is a **sialylated derivative of the Lewis (a) blood-group antigen**, shed by tumour mucins. ~8–15% of people are **Lewis-antigen “non-secretors”** and cannot express CA19-9 → falsely normal levels.
 - **Performance:** sensitivity ~70%, specificity ~87%; **false elevations** occur in biliary obstruction/cholestasis, cholangitis, and acute/chronic pancreatitis — so CA19-9 should ideally be measured **after the bilirubin has normalised**.
 - **Prognostic/monitoring role:** higher pre-operative levels correlate with higher stage and unresectability; a **CA19-9 ≥ 500 U/mL (IAP) or ≥ 1000 U/mL (MD Anderson)** defines *biologically borderline* disease; **failure of an elevated level to fall after resection** predicts poor survival (post-operative CA19-9 ≥ 180 U/mL: HR ≈ 3.58 in RTOG 97-04). Falling levels on neoadjuvant therapy indicate response.
- ▶ **CEA (carcinoembryonic antigen)** and **CA125** — drawn as baseline adjuncts; **CA125 is especially useful in the Lewis-negative non-secretors** with undetectable CA19-9. Serial trends of all three guide therapeutic decisions.
- ▶ **Routine bloods:** mild anaemia, cholestatic liver enzyme pattern (raised conjugated bilirubin, ALP), occasionally raised lipase/amylase, raised HbA1c/glucose. **Plasma chromogranin A** is elevated in pancreatic neuroendocrine tumours (a differential), but is falsely raised by PPIs.
- ▶ Emerging “liquid biopsy” markers (ctDNA, cell-free DNA methylation, circulating tumour cells) are investigational and not yet standard.

Diagnostic workup (for completeness)

- ▶ **Multiphase (pancreatic-protocol) contrast-enhanced CT** is the first-line imaging — defines the tumour, vascular (SMA/SMV/portal/coeliac/hepatic) relationships, resectability and metastases; EUS is more sensitive for small tumours and guides biopsy.
- ▶ **MRI/MRCP** is an alternative; **PET-CT** detects occult metastases but is not routine staging.
- ▶ **Tissue diagnosis by EUS-guided FNA/core biopsy** (sensitivity ~90%) — also enables molecular profiling (KRAS, microsatellite/MMR status, BRCA/PALB2).
- ▶ **Staging** uses the AJCC 8th-edition TNM system; disease is grouped as resectable, borderline resectable, locally advanced (unresectable) and metastatic.

Surveillance / screening recommendations

- ▶ **Average-risk (general) population: do NOT screen** — low prevalence makes CA19-9/imaging screening inefficient (unacceptable false-positive rate); the **USPSTF recommends against** population screening.
- ▶ **High-risk individuals warrant surveillance** (per the **International Cancer of the Pancreas Screening — CAPS — Consortium**). Eligible groups:
 - **Hereditary syndromes regardless of family history:** *Peutz-Jeghers syndrome* (STK11/LKB1), *familial atypical multiple-mole melanoma* (p16/CDKN2A), and *hereditary pancreatitis* (PRSS1).
 - **Germline pathogenic-variant carriers** in **ATM, BRCA1, BRCA2, PALB2, MLH1, MSH2, MSH6 or TP53** *plus* at least one affected first- or second-degree relative.
 - **Familial pancreatic cancer** — kindreds with ≥ 1 first-degree and ≥ 1 additional relative with PDAC.
- ▶ **Modality: annual surveillance** alternating/combining **endoscopic ultrasound (EUS) and MRI/MRCP** (low radiation, detect cystic precursors and small solid lesions). Enrolment on a prospective registry with genetic counselling is advised.
- ▶ **Age to start:** generally **age 50, or 10 years before** the youngest affected relative's age at diagnosis; earlier in selected syndromes — **age 40** for *CDKN2A* or *PRSS1* carriers, **age 35** for *Peutz-Jeghers syndrome*, and **within ~20 years of onset** of hereditary pancreatitis.
- ▶ **Risk magnitude (justifies surveillance):** one first-degree relative $\uparrow$ risk ~4.6-fold, two ~6.4-fold, ≥ 3 ~32-fold; syndromic fold-risks — *Peutz-Jeghers* 76–140 $\times$, hereditary pancreatitis ~53 $\times$, FAMMM/p16 15–22 $\times$, Lynch 9–36 $\times$, ATM ~6 $\times$, BRCA2 3.5–10 $\times$.
- ▶ **Cystic-lesion surveillance:** incidental cysts ≤ 2 cm are low-risk — MRI at 1 year then every 2 years; EUS-FNA if a cyst reaches ≥ 2 cm or develops high-risk features. **Main-duct IPMNs** and **mucinous cystic neoplasms** are resected; branch-duct IPMNs with “worrisome features” (cyst ≥ 3 cm, mural nodule, main-duct dilatation, raised CA19-9) need closer EUS evaluation.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Diagram 1 — Pancreas anatomy and tumour spread:** Draw the pancreas (head with uncinate process, neck, body, tail) crossing the L2 vertebra, labelling **common bile duct, ampulla of Vater, duodenal C-loop, superior mesenteric artery (SMA), superior mesenteric vein (SMV)–portal vein confluence, coeliac axis, splenic vessels**; show a head tumour obstructing the CBD (jaundice) and arrows to **Virchow's (left supraclavicular) node** and **Sister Mary Joseph's (periumbilical) nodule**.
- ▶ **Diagram 2 — CA19-9 biology/utility box:** Label “sialylated Lewis(a) antigen,” “Lewis-negative non-secretors (8–15%) → false-normal,” “false-high in cholestasis/pancreatitis,” and the monitoring cut-offs ($\geq 500/\geq 1000$ U/mL = biologically borderline; rising post-op = poor prognosis).

Clinical / Diagnostic significance

- ▶ **Painless jaundice + Courvoisier-positive gallbladder** in an older patient should prompt urgent imaging for periampullary/pancreatic-head cancer.
- ▶ **CA19-9 is a monitoring and prognostic tool, not a screening test** — always interpret against bilirubin and Lewis status; use CEA/CA125 when CA19-9 is uninformative.
- ▶ **New-onset diabetes with weight loss after age 45–50** is a recognised early clue — consider occult PDAC.
- ▶ **Trousseau's syndrome** mandates anticoagulation (LMWH or a DOAC) and should trigger an occult-malignancy search.
- ▶ Identifying a **BRCA1/2 or PALB2** germline variant changes management (PARP inhibitor + platinum sensitivity) and triggers family cascade testing and surveillance.

High-yield exam pointers

- ▶ **PDAC = commonest, most lethal pancreatic cancer; 75% in head; KRAS mutated in 90–95%** (also CDKN2A >90%, TP53 ~75%, SMAD4 ~50%).
- ▶ **Classic triad to write:** painless obstructive jaundice + Courvoisier-positive gallbladder + epigastric pain radiating to back.
- ▶ **Four eponyms:** Courvoisier (gallbladder), Trousseau (migratory thrombophlebitis), Virchow (L supraclavicular node), Sister Mary Joseph (umbilical nodule).
- ▶ **CA19-9 = sialylated Lewis(a) antigen;** ~8–15% Lewis-negative non-secretors give false-normal values; raised by cholestasis/pancreatitis; sensitivity ~70%, specificity ~87%.
- ▶ **No screening in average-risk population (USPSTF against).**
- ▶ **High-risk surveillance = annual EUS + MRI** from age 50 (or 10 years before youngest affected relative); earlier in CDKN2A/PRSS1 (40), Peutz-Jeghers (35).
- ▶ **Diagnosis:** pancreatic-protocol CT + EUS-FNA; **stage by AJCC 8th-edition TNM.**

SOURCE & COVERAGE

- ▶ **Harrison's Principles of Internal Medicine, 22e** — “Pancreatic Cancer” (clinical features, eponymous signs, CA19-9/CEA/CA125 serum markers, germline syndromes and fold-risks, high-risk MRI/EUS screening).
- ▶ **DeVita, Hellman & Rosenberg's Cancer: Principles & Practice of Oncology, 12e** — “Cancer of the Pancreas” (presenting-symptom frequencies, CA19-9 biology and prognostic cut-offs, CAPS Consortium screening eligibility, gene panel and start ages, biological/conditional staging).
- ▶ **CMDT 2026** — “Carcinoma of the Pancreas & Ampulla of Vater” (CA19-9 sensitivity/specificity, current high-risk surveillance schedule and start ages, cystic-lesion surveillance).

Vitamin K-Dependent Coagulation Factors and the Impact of Anticoagulant Drugs

Asked in: Paper I 06 Apr 2026 — RGUHS MD General Medicine

Definition / Introduction — The **vitamin K-dependent factors** are a group of plasma proteins whose biological activity requires post-translational **γ-carboxylation** of glutamic acid residues, a reaction for which **vitamin K** is an obligatory cofactor. They comprise the procoagulant zymogens **factors II** (prothrombin), **VII**, **IX** and **X** and the natural anticoagulants **protein C** and **protein S** (plus protein Z and the non-haemostatic Gla proteins of bone, kidney, lung and placenta). γ-Carboxylation confers the ability to bind **calcium** and assemble on **anionic phospholipid membranes** — without it these proteins are inert. This single biochemical step is the pharmacological target of **vitamin K antagonists** (**warfarin**), and it explains the wider impact of all anticoagulant classes on haemostasis.

The vitamin K-dependent factors and the carboxylation reaction

- ▶ **Procoagulant factors: II** (prothrombin), **VII**, **IX**, **X** — easily recalled by the mnemonic “1972” (factors IX, VII, X, II).
- ▶ **Anticoagulant (regulatory) proteins: Protein C** and its cofactor **Protein S**; also **Protein Z**.
- ▶ **Non-coagulation Gla proteins: osteocalcin** (bone) and **matrix Gla protein** — Harrison notes vitamin K-dependent proteins also occur in bone, lung, kidney and placenta.
- ▶ **Mechanism:** Vitamin K is the cofactor for **γ-glutamyl carboxylase (GGCX)**, which converts **glutamate (Glu)** → **γ-carboxyglutamic acid (Gla)** on these proteins. The Gla residues chelate Ca^{2+} , allowing the factor to dock onto phospholipid surfaces (e.g. activated platelets) and participate in cascade complexes.

- ▶ **The vitamin K cycle:** carboxylation oxidises reduced vitamin K (hydroquinone) to **vitamin K epoxide**; **vitamin K epoxide reductase (VKORC1)** regenerates the reduced form so the cofactor can be reused. Dietary vitamin K is often limiting, making this recycling essential.
- ▶ **Plasma half-lives (clinically pivotal):** **factor VII shortest (~6 h) → PT prolongs first**; factor X ≈ 24 h; **prothrombin ≈ 72 h (longest)**; protein C and protein S are also short-lived.
- ▶ **Genetic disease:** inherited mutations of **GGCX** or **VKORC1** cause combined deficiency of *all* vitamin K-dependent factors (activity 1–30%), a congenital bleeding disorder responsive to vitamin K₁ (5–20 mg) or PCC.

Why this matters: PT/INR, deficiency and the newborn

- ▶ Because PT is sensitive to **II, VII and X**, vitamin K deficiency or warfarin **prolongs the PT/INR before the aPTT**.
- ▶ **Acquired vitamin K deficiency** — causes: poor intake, **broad-spectrum antibiotics** (suppress gut flora), malabsorption/cholestasis (fat-soluble vitamin), chronic liver disease.
- ▶ **Distinguishing from liver failure:** **Factor V is NOT vitamin K-dependent** and is made only in hepatocytes — *low FVII with normal FV = vitamin K deficiency*; *low FV = hepatocellular failure*.
- ▶ **Haemorrhagic disease of the newborn** (vitamin K deficiency bleeding) — prevented by routine neonatal vitamin K; neonates also have physiologically low protein C (relevant to warfarin necrosis).
- ▶ **Treatment of deficiency:** vitamin K₁ (phytonadione) **10 mg parenteral** restores factors in 8–24 h; the SC route is avoided (erratic absorption); for urgent correction give **FFP or 4-factor PCC**.

Impact of anticoagulant medications — overview

Class	Example(s)	Molecular target	Effect on vit-K factors / monitoring
Vitamin K antagonist	Warfarin	Inhibits VKORC1 → ↓ functional II, VII, IX, X, protein C/S	Directly lowers vit-K factors; monitor PT/INR
Unfractionated heparin	Heparin	Activates antithrombin → inhibits IIa & Xa (1:1)	No effect on synthesis; monitor aPTT / anti-Xa
LMWH	Enoxaparin, dalteparin	Antithrombin-mediated, predominantly anti-Xa	Usually no monitoring; anti-Xa if needed
Pentasaccharide	Fondaparinux	Antithrombin-mediated, pure anti-Xa	No routine monitoring
Direct oral – IIa	Dabigatran	Reversible direct thrombin (IIa) inhibitor	Fixed dose; aPTT/dTT qualitative

Class	Example(s)	Molecular target	Effect on vit-K factors / monitoring
Direct oral – Xa	Rivaroxaban, apixaban, edoxaban	Reversible direct factor Xa inhibitor	Fixed dose; anti-Xa if needed

Warfarin — the vitamin-K-antagonist in depth

- ▶ **Mechanism:** a racemic R/S mixture; the **S-enantiomer** is more potent and is metabolised by CYP2C9. By blocking VKOR it prevents regeneration of reduced vitamin K, so the liver secretes under-carboxylated, inactive factors (PIVKA).
- ▶ **Pharmacology:** rapidly/almost completely absorbed, peak ~90 min, **half-life 36–42 h**, >97% albumin-bound.
- ▶ **Delayed onset:** the antithrombotic effect awaits clearance of pre-formed factors and depends on fall in factor X and prothrombin ($t_{1/2}$ 24 and 72 h) — hence **overlap with a parenteral anticoagulant** (heparin/LMWH/fondaparinux) for ≥ 5 days and until INR is therapeutic for ≥ 2 days.
- ▶ **Pharmacogenomics:** **CYP2C9/3 and VKORC1 variants increase sensitivity and bleeding risk; FDA labelling advises lower initiation doses in carriers. Starting dose 5–10 mg*.*
- ▶ **Monitoring:** PT standardised as $INR = (\text{patient PT} / \text{mean normal PT})^{ISI}$; target **INR 2.0–3.0** for most indications, 2.5–3.5 for mechanical (especially mitral) valves. Diet, drugs and disease alter response → frequent monitoring.
- ▶ **Adverse effects:**
 - **Bleeding** (commonest; rises sharply when INR exceeds range).
 - **Warfarin-induced skin necrosis** — 2–5 days after starting, well-demarcated necrotic lesions on thigh/buttock/breast; due to a transient **procoagulant state from rapid fall of short-lived protein C** → microvascular thrombi. **Protein C/S-deficient patients** must be bridged with a parenteral anticoagulant and started low.
 - **Teratogenicity** — crosses the placenta causing **warfarin embryopathy**; contraindicated in pregnancy (but safe in breastfeeding).
- ▶ **Reversal:** asymptomatic high INR → **vitamin K 1 mg PO/IV**; serious bleeding → **vitamin K 5–10 mg slow IV plus 4-factor prothrombin complex concentrate** (contains all four vitamin K-dependent procoagulants; normalises INR faster than FFP).

Impact of the other anticoagulant classes

- ▶ **Heparin (UFH):** binds **antithrombin** (a serpin), accelerating inhibition of **thrombin and factor Xa** equally (anti-Xa:anti-IIa 1:1); also releases TFPI. Parenteral, monitored by aPTT/anti-Xa. Complications: bleeding, **heparin-induced thrombocytopenia (HIT)** — an IgG/PF4 immune

prothrombotic syndrome 5–14 days in, more common than with LMWH — and **osteoporosis**.
Reversed fully by protamine sulfate (≈ 1 mg per 100 U heparin).

- ▶ **LMWH (enoxaparin)**: mean MW ~ 5000 ; chains mostly too short to bridge thrombin $\rightarrow$ **predominant anti-Xa activity**; better bioavailability, less HIT/osteoporosis, renally cleared (caution if CrCl < 30). **Protamine gives only partial ($\sim 60\%$) reversal**.
- ▶ **Fondaparinux**: synthetic pentasaccharide, **pure antithrombin-mediated anti-Xa**, $t_{1/2}$ 17 h, once-daily SC; does **not cause HIT** and is **not reversed by protamine** (contraindicated if CrCl < 30).
- ▶ **DOACs**: **dabigatran** (direct IIa) and **rivaroxaban/apixaban/edoxaban** (direct Xa). Predictable fixed dosing, no routine monitoring, fewer interactions/intracranial bleeds than warfarin (but more GI bleeding at higher doses); cleared partly renally (dabigatran 80%). **Contraindicated in pregnancy**.
- ▶ **DOAC reversal**: vitamin K and FFP are ineffective. Specific antidotes — **idarucizumab** (antibody fragment, 5 g IV) for dabigatran; **andexanet alfa** (decoy Xa) for rivaroxaban/apixaban. If unavailable, 4-factor PCC 25–50 U/kg. Activated charcoal if ingestion < 4 h.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **The vitamin K cycle (Warfarin's site of action)**: draw the closed cycle with labels — *Glutamate (Glu)* $\rightarrow$ (via γ -glutamyl carboxylase + O_2 + CO_2) $\rightarrow$ *γ -Carboxyglutamate (Gla)* on factors II, VII, IX, X, protein C, protein S; *Reduced vitamin K (hydroquinone)* $\rightarrow$ oxidised to *Vitamin K epoxide* $\rightarrow$ regenerated by **VKORC1 (vitamin K epoxide reductase)**; mark Warfarin $\perp$ blocking VKORC1.
- ▶ **Coagulation cascade with anticoagulant targets**: Tissue factor/VIIa $\rightarrow$ IXa $\rightarrow$ Xa $\rightarrow$ prothrombin (II) $\rightarrow$ thrombin (IIa) $\rightarrow$ fibrinogen $\rightarrow$ fibrin; arrows showing warfarin $\downarrow$ synthesis of II/VII/IX/X, heparin–antithrombin on IIa & Xa, LMWH/fondaparinux on Xa, rivaroxaban/apixaban/edoxaban on Xa, dabigatran on IIa.

Clinical / Diagnostic significance

- ▶ PT/INR is the bedside readout of vitamin K–dependent procoagulant function — used to diagnose vitamin K deficiency, monitor warfarin and assess hepatic synthetic capacity.
- ▶ **Mixing study corrects** in vitamin K deficiency (factor deficiency) but not when an inhibitor is present.
- ▶ **FV vs FVII discrimination** separates vitamin K deficiency from liver failure.
- ▶ **Bridging principle**: never start warfarin alone in active/high-risk thrombosis (delayed onset + transient hypercoagulability) — overlap with a parenteral agent.
- ▶ **Procedure planning**: hold DOACs 1–2 days (longer if renal impairment); reverse warfarin with vitamin K + 4F-PCC for emergency surgery.

High-yield exam pointers

- ▶ Vitamin K-dependent factors = II, VII, IX, X (procoagulant) + protein C, protein S (anticoagulant) — mnemonic “1972”.
- ▶ Vitamin K is cofactor for γ -glutamyl carboxylase; recycled by VKORC1 — warfarin blocks VKORC1.
- ▶ Factor VII (shortest $t_{1/2}$) $\rightarrow$ PT/INR rises first; prothrombin ($t_{1/2}$ 72 h) longest.
- ▶ Warfarin skin necrosis = early fall of short-lived protein C (worse in protein C/S deficiency).
- ▶ Warfarin is teratogenic; DOACs and warfarin both contraindicated in pregnancy — LMWH/UFH are the pregnancy anticoagulants.
- ▶ Reversal map: warfarin $\rightarrow$ vitamin K + 4F-PCC; UFH $\rightarrow$ protamine (full); LMWH $\rightarrow$ protamine (partial); dabigatran $\rightarrow$ idarucizumab; rivaroxaban/apixaban $\rightarrow$ andexanet alfa.
- ▶ Low FVII + normal FV = vitamin K deficiency; low FV = liver failure.
- ▶ Target INR 2.0–3.0 (2.5–3.5 for mechanical valves); always overlap warfarin and parenteral anticoagulant ≥ 5 days.

SOURCE & COVERAGE

- ▶ Harrison’s Principles of Internal Medicine, 22e — “Coagulation Disorders” (vitamin K cycle, γ -carboxylation, GGCX/VKORC1, vitamin K deficiency, factor half-lives, FV vs FVII) and “Antiplatelet, Anticoagulant, and Fibrinolytic Drugs” (warfarin mechanism/pharmacology/INR/reversal; heparin, LMWH, fondaparinux; DOACs and their antidotes).
- ▶ CMDT 2026 — “Disorders of Hemostasis, Thrombosis, & Antithrombotic Therapy” (vitamin K deficiency management, phytonadione dosing, protamine neutralisation, DOAC perioperative handling).
- ▶ Coverage note: The spec-listed specialty text *DeVita’s Cancer Principles & Practice* does not substantively cover this coagulation/anticoagulation topic (only a tangential note that progestational agents raise plasma warfarin levels); depth here derives from Harrison and CMDT. Protein Z, osteocalcin/matrix Gla protein, the “1972” mnemonic, PIVKA and protamine 1 mg/100 U are standard textbook haematology included for completeness.

Bipolar disorder

Asked in: Paper IV Nov 2019 — RGUHS MD General Medicine

Definition / Introduction — Bipolar disorder is a chronic, recurrent **mood disorder** characterised by unpredictable swings of mood, energy and activity between **mania (or hypomania)** at one pole and **depression** at the other, separated by periods of relative euthymia. It is a *major affective (mood) disorder* distinguished from major depressive disorder by the presence, current or past, of at least one **manic or hypomanic episode**. It affects ~1.5% of the population, has a strong genetic loading (monozygotic concordance approaching 80%), typically begins between 20–30 years of age, and carries a very high lifetime risk of suicide and psychosocial disability.

Epidemiology and classification (Bipolar spectrum)

- ▶ **Prevalence:** Bipolar I ~1.0–1.5% (lifetime ~3.3% and Bipolar II ~1.1% in the NESARC survey); cross-national bipolar *spectrum* ~2.4%. Cyclothymic disorder ~0.4–2.5%.
- ▶ **Onset:** typically ~20 years (often late adolescence); men tend to have onset ~4–5 years earlier and more **manic** episodes, women more **depressive** episodes and rapid cycling.
- ▶ **Sex ratio:** overall ~1:1 (unlike MDD which is ~2:1 female), but women predominate in Bipolar II, mixed/dysphoric mania and rapid cycling; pure (unipolar) mania is commoner in men.

Subtype	Defining requirement	Key feature
Bipolar I	≥1 lifetime manic episode (≥1 week, or any duration if hospitalised)	Depressive/hypomanic episodes usual but not required
Bipolar II	≥1 hypomanic episode + ≥1 major depressive episode ; <i>never</i> a full manic episode	Depression-predominant; high suicide/comorbidity risk
Cyclothymic disorder	≥2 years (≥1 year in children) of fluctuating hypomanic and depressive symptoms that <i>never</i> meet full episode criteria	Chronic, temperamental; 15–50% convert to Bipolar I/II
Substance/medication-induced & due to another medical condition	Manic/hypomanic symptoms attributable to a drug or organic cause	Secondary mania
Other specified (subthreshold)	Bipolar-like phenomena, e.g. short-duration hypomania	Bipolar spectrum

Clinical features (episode definitions)

- ▶ **Manic episode (Bipolar I):** a distinct period of abnormally **elevated, expansive or irritable mood** *with* persistently increased goal-directed activity/energy, lasting ≥1 week (or any duration if hospitalisation is required), causing **marked functional impairment, hospitalisation, or psychotic features**. DSM-5-TR requires ≥3 (or ≥4 if mood only irritable) of: inflated self-esteem/**grandiosity**; **decreased need for sleep** (rested after 3 h); pressured/over-talkativeness; **flight of ideas/racing thoughts**; distractibility; increased goal-directed activity or **psychomotor**

agitation; and excessive involvement in high-risk pleasurable activities (buying sprees, sexual indiscretions, foolish investments). Severe mania may include **delusions and paranoia indistinguishable from schizophrenia**.

- ▶ **Hypomanic episode (Bipolar II):** same symptom list, lasting ≥ 4 consecutive days, an *unequivocal change in functioning observable by others*, but **NOT severe enough to cause marked impairment or hospitalisation, and no psychotic features** (psychosis automatically makes the episode manic).
- ▶ **Major depressive episode:** depressed mood/anhedonia ≥ 2 weeks with ≥ 5 of 9 symptoms (sleep/appetite/weight change, fatigue, worthlessness/guilt, poor concentration, psychomotor change, suicidal ideation). Depressive phases dominate disability and suicide risk.
- ▶ **Mixed states:** about **one-half** of patients present not with euphoria but with a mixture of **psychomotor agitation/activation plus dysphoria, anxiety and irritability** — difficult to distinguish from agitated depression and carrying high suicide risk.
- ▶ **Rapid cycling:** ≥ 4 mood episodes (mania, hypomania or depression) in one year; occurs in $\sim 15\%$ of patients, mostly women; linked to underlying **thyroid dysfunction** or **iatrogenic antidepressant** exposure.
- ▶ **Course:** untreated episodes last weeks to 8–12 months; $\sim$ half have sustained occupational/psychosocial impairment, depressive phases being more disabling than mania.

Etiology and pathophysiology

- ▶ **Genetic:** strongest of the psychiatric disorders — monozygotic concordance $\sim 80\%$; a first-degree relative raises risk ~ 10 -fold. Replicated risk loci include the L-type **calcium channel α -subunit CACNA1C**, teneurin **ODZ4 (TENM4)**, ankyrin-3 (**ANK3**), neurocan (**NCAN**) and **TRANK1**; common variants individually small but collectively account for $\sim 25\%$ of heritability, with shared loci (pleiotropy) overlapping schizophrenia and autism.
- ▶ **Neurobiology:** evidence for **circadian rhythm dysregulation, calcium dysregulation**, oxidative stress, and mitochondrial/microRNA/endoplasmic-reticulum abnormalities; MRI shows grey-matter thinning in frontal, temporal and parietal cortex.
- ▶ **Precipitants:** stressful life events, sleep deprivation and circadian disruption can trigger episodes; the link to acute stressors weakens as the number of prior episodes increases (kindling). Comorbid **alcohol/substance use** is common.

Differential diagnosis and recognising “hidden” bipolarity

- ▶ **Secondary mania** must be excluded: stimulant/sympathomimetic drugs, **hyperthyroidism**, **AIDS**, **Huntington’s** and **Wilson’s disease**, frontotemporal dementia, and **cerebrovascular accidents**; corticosteroids and antidepressants can also induce mania.
- ▶ Recognising bipolarity in a patient presenting *only* with depression is **essential**, because antidepressants may be contraindicated and can precipitate a **manic switch or accelerate cycling**.

Features predictive of bipolar (vs unipolar) depression (Kaplan/Akiskal): **early age at onset**, psychotic depression before 25 years, postpartum depression (especially with psychotic features), **rapid onset/offset short (<3-month) episodes**, recurrent depression (>5 episodes), marked **psychomotor retardation**, **atypical/reverse vegetative** features (hypersomnia, weight gain), **seasonality**, **bipolar family history**, cyclothymic/hyperthymic temperament, **antidepressant-induced hypomania**, and **repeated loss of antidepressant efficacy** after initial response.

Management

General principles: confirm the diagnosis and stage (acute mania, bipolar depression, or maintenance); ensure safety (suicide/violence risk, hospitalisation for severe mania); withdraw antidepressants/stimulants; treat comorbid thyroid and substance use; **psychoeducation**, **adherence support** and **social-rhythm therapy** are integral.

Acute mania

- ▶ **Lithium carbonate** — mainstay; response **70–80%**, effect in 1–2 weeks. Start 300 mg bid/tid, titrate to a **therapeutic level 0.8–1.2 mEq/L**.
- ▶ **Valproic acid/divalproex** — first-line, *preferred* for **rapid-cycling and mixed/dysphoric mania**; level 50–125 µg/mL.
- ▶ **Carbamazepine** (4–12 µg/mL; 800–1600 mg/day) / **oxcarbazepine** (off-label, safer hepatic profile).
- ▶ **Second-generation antipsychotics** (FDA-approved for acute mania): **aripiprazole**, **asenapine**, **cariprazine**, **olanzapine**, **quetiapine**, **risperidone**, **ziprasidone**; injectable olanzapine/haloperidol for behavioural emergency.
- ▶ **Adjuncts** for agitation/insomnia until mood stabiliser acts: lorazepam 1–2 mg or clonazepam 0.5–1 mg.

Bipolar depression — **quetiapine**, **lurasidone**, **cariprazine**, **lumateperone**, and **olanzapine–fluoxetine** (Symbyax); **lamotrigine** as adjunct/monotherapy. Antidepressant monotherapy is avoided (switch risk).

Maintenance / prophylaxis — required because of the recurrent course. A sustained **lithium level ≥ 0.8 mEq/L** gives optimal prophylaxis and uniquely **reduces suicide risk**. **Quetiapine XR**, **olanzapine**, **risperidone** and **lamotrigine** are approved as maintenance monotherapy (lamotrigine especially prevents depressive relapse but is *not* effective in acute mania). Combinations are often needed; antidepressants are generally avoided in maintenance.

Mood stabiliser	Therapeutic level	Key toxicities / cautions
Lithium	0.8–1.2 mEq/L (acute); 0.6–1.0 maintenance	Fine tremor, polyuria/polydipsia (nephrogenic DI), hypothyroidism/goitre , weight

Mood stabiliser	Therapeutic level	Key toxicities / cautions
		gain, hypercalcaemia, leukocytosis; toxicity >2 mEq/L (ataxia, dysarthria, myoclonus, seizures, coma) → haemodialysis ; levels ↑ by thiazides, NSAIDs, tetracyclines, dehydration
Valproate	50–125 µg/mL	Weight gain, tremor, alopecia; rare hepatotoxicity , pancreatitis ; teratogenic (neural-tube defects)
Carbamazepine	4–12 µg/mL	Sedation, hyponatraemia (SIADH), agranulocytosis, Stevens-Johnson (screen * <i>HLA-B1502*</i> <i>Han Chinese</i> , <i>HLA-A3101</i> N-Europeans); hepatic enzyme inducer
Lamotrigine	(titrate slowly from 25 mg/d)	Stevens-Johnson syndrome/TEN — any rash needs review

Lithium pre-treatment work-up: CBC, T4/TSH, urea/creatinine and electrolytes, urinalysis, and ECG (>45 y or cardiac history); draw levels **12 h post-dose**; monitor thyroid and renal function 4–6 monthly. **Electroconvulsive therapy** is effective for severe, refractory, psychotic, catatonic or pregnant cases.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- **Mood-vs-time (life-chart) graph:** horizontal euthymia baseline; plot peaks above for **Mania (Bipolar I)** and smaller peaks for **Hypomania (Bipolar II)**; troughs below for **Major depression**; small ripples for **Cyclothymia**; mark a **mixed episode** and a **rapid-cycling** segment (≥4 episodes/year). Labels: *Mania*, *Hypomania*, *Euthymia*, *Major depressive episode*, *Mixed state*, *Rapid cycling*, ≥1 week (*mania*), ≥4 days (*hypomania*), ≥2 weeks (*depression*).
- **Treatment-stage box diagram:** three boxes — *Acute mania* (Lithium / Valproate / SGA + benzodiazepine), *Bipolar depression* (Quetiapine / Lurasidone / Lamotrigine / Olanzapine-fluoxetine), *Maintenance* (Lithium ≥0.8 mEq/L — reduces suicide; avoid antidepressants).

Clinical / Diagnostic significance

- **Suicide:** risk is **state-dependent** — highest during severe depressive and **mixed/dysphoric** episodes, very low in euphoric mania; **lithium** is the only mood stabiliser proven to reduce suicide.
- **Misdiagnosis as unipolar depression** delays appropriate treatment and risks antidepressant-induced switching/cycle acceleration — always screen a depressed patient for *past hypomania*.

- ▶ **Organic screen** in new-onset mania: TFTs, drug/toxicology screen, neuroimaging, and consider Wilson's/Huntington's/HIV when atypical or late-onset.
- ▶ **Lithium monitoring is mandatory** — narrow therapeutic index; counsel on hydration, NSAID/diuretic interactions, thyroid and renal surveillance; choose **valproate/lamotrigine alternatives** (with contraception advice) in women of child-bearing potential because of teratogenicity.
- ▶ High **medical comorbidity** (cardiovascular disease, diabetes, substance use) elevates mortality independent of suicide.

High-yield exam pointers

- ▶ **Bipolar I** = ≥ 1 manic episode (≥ 1 week); **Bipolar II** = **hypomania** (≥ 4 days) + **major depression**, never mania.
- ▶ **Mania needs ≥ 3 symptoms** (≥ 4 if irritable) — mnemonic **DIGFAST** (Distractibility, Indiscretion, Grandiosity, Flight of ideas, Activity $\uparrow$, Sleep $\downarrow$, Talkativeness).
- ▶ **Hypomania**: no marked impairment, no psychosis, no hospitalisation; psychosis $\Rightarrow$ episode is *manic* by definition.
- ▶ **Rapid cycling** = ≥ 4 episodes/year ($\sim 15\%$, mostly women) — favour **valproate**; check thyroid; stop antidepressants.
- ▶ **Monozygotic concordance** $\sim 80\%$; risk genes **CACNA1C, ANK3, ODZ4, NCAN, TRANK1**; first-degree relative $\uparrow$ risk $\sim 10\times$.
- ▶ **Lithium** acute level **0.8–1.2 mEq/L** (response 70–80%); toxicity >2 mEq/L $\rightarrow$ haemodialysis; thiazides/NSAIDs raise levels; causes hypothyroidism and nephrogenic DI.
- ▶ **Lamotrigine** prevents depressive relapse but is **ineffective in acute mania** and risks **Stevens-Johnson syndrome**.
- ▶ **Avoid antidepressant monotherapy** — manic switch and cycle acceleration.
- ▶ **Cyclothymia** = ≥ 2 years subthreshold hypomanic + depressive symptoms; 15–50% progress to Bipolar I/II.

SOURCE & COVERAGE

Clinical features, diagnosis and management of delirium tremens

Asked in: Paper IV Oct 2025 — RGUHS MD General Medicine

Definition / Introduction — *Delirium tremens* (DTs) is the most severe and life-threatening expression of the **alcohol withdrawal syndrome**, defined as a **severe, agitated delirium** (mental confusion, fluctuating consciousness and disorientation) accompanied by a coarse tremor and marked **autonomic hyperactivity** (tachycardia, hypertension, hyperthermia, diaphoresis), occurring when blood alcohol falls abruptly in a chronic heavy drinker. It complicates roughly **1% of individuals in withdrawal** (Harrison; <5% in Kaplan; <10% develop “dramatic” withdrawal in DSM-5-TR), typically appears **48–72 h after the last drink**, and is a **medical emergency** with an untreated mortality up to ~5%. By DSM-5-TR it requires the patient to satisfy criteria for **both delirium AND alcohol withdrawal** (alcohol withdrawal delirium, F10.231).

Pathophysiology (brief, to anchor the answer)

- Chronic ethanol is a CNS depressant that **enhances inhibitory GABA-A** tone and **suppresses excitatory NMDA-glutamate** transmission. The brain adapts by **down-regulating GABA-A** and **up-regulating NMDA** receptors.
- Abrupt cessation removes the depressant → unopposed **glutamatergic/adrenergic hyperexcitability** → tremor, seizures, autonomic storm and, at its extreme, delirium.
- Additional drivers: **low thiamine**, hypomagnesaemia, hypokalaemia, dehydration and intercurrent illness, all of which lower the threshold for DTs.

Spectrum and time-course of alcohol withdrawal

Withdrawal is a continuum; DTs sits at the severe end. Knowing the **temporal sequence** is high-yield and is best shown as a timeline.

Syndrome	Typical onset after last drink	Key features
Minor (early) withdrawal / tremulousness	6–12 h (Harrison 5–10 h; CMDT 6–36 h)	Tremor (“shakes”), anxiety, insomnia, nausea/vomiting, tachycardia, sweating; intact sensorium

Syndrome	Typical onset after last drink	Key features
Withdrawal seizures (“rum fits”)	8–48 h, peak ~day 2	Generalised tonic-clonic, brief, usually self-limiting; ~1–3% of patients
Alcoholic hallucinosis	12–48 h	Visual/tactile (± auditory) hallucinations with a clear sensorium and intact orientation — distinguishes it from DTs
Delirium tremens	48–72 h (may appear up to 7–10 days later)	Agitated, fluctuating delirium + autonomic storm; lasts 3–5 days

- ▶ Minor symptoms peak on day 2–3 and improve by day 4–5; a **protracted** abstinence syndrome (anxiety, insomnia, autonomic lability) may linger **3–6 months**.
- ▶ DTs develops in ~50% of patients who have had a withdrawal seizure, but **can occur without a preceding seizure**.

Clinical features of delirium tremens

- ▶ **Delirium (core)**: acute onset over hours-to-days, **fluctuating** course, **inattention**, disorientation to time/place/person, impaired short-term memory, disorganised thinking; typically **hyperactive** form with agitation, but can fluctuate.
- ▶ **Perceptual disturbance**: vivid, frightening **visual hallucinations** (classically crawling insects/snakes — *Lilliputian/zoopsia*), tactile (*formication*), less often auditory; **sensory hyperacuity**.
- ▶ **Coarse tremor** of hands and whole body, psychomotor agitation, picking/restlessness.
- ▶ **Autonomic hyperactivity (hallmark)**: marked **tachycardia**, **hypertension**, **fever**, **profuse diaphoresis**, mydriasis, tachypnoea.
- ▶ **Metabolic/complications**: dehydration, **hypokalaemia**, **hypomagnesaemia**, hypophosphataemia, cardiac **arrhythmias**, rhabdomyolysis, aspiration, seizures and, if untreated, **cardiovascular collapse and death**.
- ▶ Often **unmasked in a hospitalised patient** admitted for an unrelated problem (trauma, surgery, sepsis) on day 2–3 — DTs should be suspected in **any heavy drinker with unexplained delirium**.

Diagnosis

DTs is essentially a **clinical diagnosis** in a chronic drinker with the typical temporal profile; the key task is to **confirm withdrawal AND exclude mimics**.

- ▶ **DSM-5-TR alcohol withdrawal criteria**: (A) cessation/reduction of heavy, prolonged alcohol use; (B) **≥2 of** — autonomic hyperactivity (sweating/pulse >100), increased hand tremor, insomnia, nausea/vomiting, **transient visual/tactile/auditory hallucinations or illusions**,

psychomotor agitation, anxiety, **generalised tonic-clonic seizures**; (C) clinically significant distress/impairment; (D) not due to another condition. *Specifier*: “**with perceptual disturbances**” when hallucinations/illusions occur with intact reality testing.

- ▶ **DSM-5-TR delirium criteria (must also be met for DTs)**: (A) disturbance of **attention and awareness**; (B) develops over hours-days, **fluctuates**; (C) additional cognitive disturbance (memory, orientation, perception); (D) not explained by another neurocognitive disorder/coma; (E) caused by a medical condition or **substance withdrawal**.
- ▶ **Severity scoring — CIWA-Ar** (Clinical Institute Withdrawal Assessment for Alcohol, revised): 10 items — nausea/vomiting, tremor, paroxysmal sweats, anxiety, agitation, tactile, auditory and visual disturbances, headache, and **orientation/clouding of sensorium**; **maximum 67**. Score <8 = minimal; 8–15 mild; 16–20 moderate; >20 severe / impending DTs. Drives **symptom-triggered** dosing.
- ▶ **Risk stratification — PAWSS** (Prediction of Alcohol Withdrawal Severity Scale): score ≥4 predicts complicated withdrawal and the need for inpatient prophylaxis.
- ▶ **Investigations**: CBC, **electrolytes incl. K^+ , Mg^{2+} , Ca^{2+} , phosphate**, glucose (bedside), renal and **liver biochemistry**, amylase/lipase, blood alcohol level, **urine toxicology** (co-ingestants), ECG; **CT head** if focal signs, head trauma, atypical/late or first seizure, or failure to improve — to exclude **subdural haematoma**.
- ▶ **Differential diagnosis**: sedative-hypnotic/benzodiazepine withdrawal, **Wernicke encephalopathy**, hepatic encephalopathy, sepsis/meningoencephalitis, hypoglycaemia, electrolyte derangement, hypoxia, drug intoxication (anticholinergic, stimulant, serotonin syndrome), thyroid storm, non-convulsive status, and **subdural haematoma**. *Alcoholic hallucinosis* (clear sensorium) and *withdrawal seizures* are part of the same spectrum but are distinct entities.

Management

DTs is an emergency best managed in an ICU/high-dependency setting with close monitoring; it tends to run a **3–5 day** course regardless of therapy, so the aim is to **control agitation/autonomic drive, prevent injury and treat reversible contributors**.

- ▶ **General/supportive**: ICU admission, continuous cardiac and **pulse-oximetry** monitoring, quiet well-lit room, reorientation, fall/aspiration precautions, treat the **precipitating illness** (infection, GI bleed, pancreatitis, trauma).
- ▶ **Fluids & electrolytes**: correct dehydration; **replace Mg^{2+} , K^+ , phosphate**; treat hypoglycaemia. (In uncomplicated withdrawal patients are often normo/over-hydrated — give IV fluids only when indicated.)
- ▶ **Thiamine FIRST**: **thiamine 100 mg IV** (high-dose, e.g. 500 mg IV TDS if Wernicke suspected) **before any glucose** to prevent precipitating **Wernicke encephalopathy/Korsakoff**; add

multivitamins and folate. *Caine criteria* (≥ 2 of: dietary deficiency, oculomotor abnormality, cerebellar signs, altered mentation) prompt empirical Wernicke treatment.

- ▶ **Benzodiazepines — mainstay** (only proven agents to prevent/treat DTs; they reduce mortality, seizures and agitation):
 - **Long-acting, self-tapering** agents preferred — **diazepam** or **chlordiazepoxide** (smoother course, fewer breakthrough seizures).
 - **Lorazepam** or **oxazepam** preferred in **significant liver disease/cirrhosis or the elderly** (shorter half-life, no active metabolites, glucuronidated → safer).
 - **Symptom-triggered (CIWA-Ar-guided)** dosing reduces total dose and duration vs fixed-dose; established DTs usually needs aggressive **fixed** + PRN loading.
 - In severe withdrawal/DTs: e.g. **IV lorazepam 1–2 mg every 15 min** titrated until calm-but-rousable; **high doses** are often required (Harrison cites up to **~800 mg/day chlordiazepoxide**; CMDT caps chlordiazepoxide at 600 mg/24 h). Once stable 24 h, taper dose **~20%/day**.
 - **Hold** benzodiazepine if over-sedated or **respiratory rate $< 10/\text{min}$** ; do not bolus lorazepam **> 4 mg IV**; use a **single agent**, titrated.
- ▶ **Refractory DTs (benzodiazepine-resistant)**:
 - Add **phenobarbital** (synergistic at GABA-A) or escalate to **propofol** (usually requires intubation/ventilation for airway protection).
 - **Dexmedetomidine** (α_2 -agonist, 0.2–0.7 $\mu\text{g/kg/h}$) as an **adjunct** to blunt hyperadrenergic output — *not* monotherapy (does not prevent seizures or delirium).
- ▶ **Antipsychotics: not first-line**; benzodiazepines are preferred because **antipsychotics lower the seizure threshold**. Low-dose **haloperidol** may be added **only** as an adjunct for severe agitation/hallucinations not controlled by adequate benzodiazepines.
- ▶ **Withdrawal seizures**: treated with **adequate benzodiazepines**; **phenytoin is ineffective** and routine anticonvulsants are unnecessary unless there is an independent seizure disorder; manage status epilepticus aggressively.
- ▶ **After the acute phase**: screen and treat AUD — **brief intervention/motivational interviewing (FRAMES)**, relapse-prevention CBT, **AA/12-step**, and anti-craving pharmacotherapy (**naltrexone**, **acamprosate**, or supervised **disulfiram**) once withdrawal is complete.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Timeline of alcohol withdrawal** (x-axis = hours/days since last drink; y-axis = severity), labelling each band: *Minor withdrawal/tremulousness 6–12 h*, *Withdrawal seizures 8–48 h (peak 24 h)*, *Alcoholic hallucinosis 12–48 h (clear sensorium)*, *Delirium tremens 48–72 h*, up to 7–10 days.

- ▶ CIWA-Ar “clock” / bar of the 10 domains, labelled: *Nausea/vomiting, Tremor, Paroxysmal sweats, Anxiety, Agitation, Tactile, Auditory, Visual disturbances, Headache, Orientation/clouding of sensorium* — with cut-offs <8 minimal · 8–15 mild · 16–20 moderate · >20 severe (ICU); **max score 67**.

Clinical / Diagnostic significance

- ▶ DTs is a **preventable** cause of death — early identification of at-risk drinkers (PAWSS ≥ 4 , prior DTs/seizures, high intake, intercurrent illness) and **adequate benzodiazepine prophylaxis** sharply reduces progression.
- ▶ **Suspect DTs in any chronic drinker with unexplained delirium**, especially on day 2–3 of an **unrelated admission**; missing it (mistaking it for “ICU agitation”) is a classic exam trap.
- ▶ Always **exclude structural and metabolic mimics** — subdural haematoma, hepatic encephalopathy, Wernicke, sepsis, hypoglycaemia — as several can **coexist** with withdrawal.
- ▶ **Thiamine before glucose and magnesium/potassium correction** are simple, high-impact, often-forgotten steps.

High-yield exam pointers

- ▶ DTs = most severe alcohol withdrawal; ~1% of **withdrawals**, onset **48–72 h** (up to 7–10 days), course **3–5 days**, mortality **up to ~5%**.
- ▶ Triad to write: **agitated fluctuating delirium + coarse tremor + autonomic storm**, with vivid **visual hallucinations** (insects/snakes).
- ▶ **Alcoholic hallucinosis** = **clear sensorium**; DTs = **clouded/fluctuating** sensorium — the key distinguishing point.
- ▶ DSM-5-TR: alcohol withdrawal needs ≥ 2 **features within hours–days**; DTs requires **delirium criteria + withdrawal criteria** together.
- ▶ CIWA-Ar (10 items, **max 67**, treat at ≥ 8 –10) guides symptom-triggered therapy; **PAWSS ≥ 4** flags complicated withdrawal.
- ▶ **Benzodiazepines** are **first-line and the only proven prophylaxis**; long-acting (diazepam/chlordiazepoxide) preferred, **lorazepam/oxazepam in liver disease**.
- ▶ Refractory DTs $\rightarrow$ **phenobarbital / propofol (intubate) / dexmedetomidine adjunct**; **antipsychotics lower seizure threshold** and are adjuncts only.
- ▶ **Thiamine before glucose**; correct $\text{Mg}^{2+}/\text{K}^{+}$; **phenytoin does not work** for withdrawal seizures.

SOURCE & COVERAGE

- ▶ **Harrison’s Principles of Internal Medicine, 22e** — “Alcohol and Alcohol Use Disorders” (withdrawal time-course, DTs ~1% rate and ~5% mortality, benzodiazepine dosing incl.

chlordiazepoxide/diazepam, high-dose/propofol/dexmedetomidine for DTs, cautions on antipsychotics and phenytoin); “Delirium” (clinical/diagnostic framing).

- ▶ **CMDT 2026** — “Substance Use Disorders” (categories/time-course table, CIWA-Ar, PAWSS, symptom-triggered vs fixed dosing, agent choice in liver disease, dexmedetomidine/phenobarbital/propofol, Caine criteria, thiamine-before-glucose).

Depression

Asked in: Paper I Sep 2025 — RGUHS MD General Medicine

Definition / Introduction — Depression is a **mood (affective) disorder** characterised by a sustained disturbance in the regulation of mood, behaviour and affect. A **major depressive episode** is defined as depressed mood and/or loss of interest occurring on a daily basis for a minimum of **2 weeks**, accompanied by neurovegetative and cognitive symptoms causing clinically significant distress or functional impairment. **Major depressive disorder (MDD)** is distinguished from bipolar disorder by the *absence of any manic or hypomanic episode*. In the WHO Global Burden of Disease Study (2019), depression was the **single largest contributor to disability worldwide**, with disability-adjusted life-years (DALYs) having risen 61% since 1990.

Classification of Depressive Disorders (DSM-5-TR)

- ▶ **Major depressive disorder (MDD)** — single or recurrent major depressive episode(s); the core unipolar syndrome.
- ▶ **Persistent depressive disorder (dysthymia)** — chronic (≥ 2 years), low-grade depressive symptoms; less severe but functionally equally disabling; ~2% population prevalence. A superimposed major depressive episode produces “*double depression*”.
- ▶ **Disruptive mood dysregulation disorder** — chronic irritability and temper outbursts in children (onset before age 10).
- ▶ **Premenstrual dysphoric disorder (PMDD)** — affective and somatic symptoms in the late luteal phase.
- ▶ **Substance/medication-induced depressive disorder and depressive disorder due to another medical condition.**

- *Mood disorders broadly* = (1) depressive (unipolar) disorders, (2) bipolar disorders, and (3) depression secondary to medical illness or substance use.

Aetiology and Pathophysiology

- **Genetic** — monozygotic-twin concordance (**46%**) far exceeds dizygotic (**20%**), with little effect of shared family environment. Early-onset depression (before age 25) is *largely genetic*. Large GWAS have identified several hundred risk loci, some overlapping with other psychiatric disorders (pleiotropy); epigenetic change also contributes.
- **Monoamine hypothesis** — the original observation that TCAs **inhibit serotonin/noradrenaline reuptake** and MAOIs are effective antidepressants led to the view that depression reflects a *deficiency of monoamines* (serotonin, noradrenaline, dopamine). This is an over-simplification — therapeutic effects emerge over weeks despite reuptake inhibition within hours, implicating **adaptive changes in second-messenger systems, neurotrophic and transcription factors**.
- **Neuroendocrine (HPA axis)** — increased **cortisol** and **CRH** secretion; **dexamethasone non-suppression**; a **blunted TSH response to TRH**. These normalise with successful treatment.
- **Neurobiological** — altered pro-inflammatory cytokines (raised **IL-6**, **TNF- α**) and neurotrophins, increased oxidative stress, cellular ageing, **telomere shortening**, mitochondrial dysfunction and gut-microbiome change. A subset shows a small reduction in **hippocampal** volume. The limbic circuitry of mood spans the **prefrontal cortex**, **amygdala**, **hippocampus**, **nucleus accumbens** and **hypothalamus**, modulated by monoaminergic projections (noradrenaline from locus coeruleus, serotonin from dorsal raphe, dopamine from VTA).
- **Sleep architecture** — reduced **REM latency**, increased **REM density**, and decreased **stage IV (delta) slow-wave sleep**.
- **Psychosocial** — negative life events (death of a relative, assault, severe relationship problems) precipitate episodes; genes influence sensitivity to these stressors.

Clinical Features and DSM-5-TR Criteria

- **Core**: persistent depressed mood (sad, empty, hopeless) and/or **anhedonia** (loss of interest/pleasure in nearly all activities).
- Diagnosis requires **≥5 of 9 symptoms** over the same 2-week period, at least one being depressed mood OR loss of interest/pleasure — usefully recalled by the mnemonic ***SIG-E-CAPS***:

Letter	Symptom (DSM-5-TR Criterion A)
S — Sleep	Insomnia or hypersomnia nearly every day
I — Interest	Markedly diminished interest/pleasure (anhedonia)
G — Guilt	Feelings of worthlessness or excessive/inappropriate guilt
E — Energy	Fatigue or loss of energy

Letter	Symptom (DSM-5-TR Criterion A)
C — Concentration	Diminished ability to think/concentrate; indecisiveness
A — Appetite	Significant weight/appetite change (>5% body weight/month)
P — Psychomotor	Agitation or retardation (observable by others)
S — Suicidality	Recurrent thoughts of death, suicidal ideation, plan or attempt
(+ depressed mood)	Depressed mood most of the day, nearly every day

- ▶ Criteria B–C: symptoms cause **significant distress/impairment** and are **not attributable to a substance or medical condition**; there has **never been a manic/hypomanic episode** (else bipolar).
- ▶ *Melancholic* features: profound anhedonia, mood worse in the morning (diurnal variation), early-morning awakening, marked guilt, psychomotor change.
- ▶ **Course**: ~15% of the population has a major depressive episode in their lifetime; 6–8% of primary-care outpatients qualify. Onset is usually in early adulthood; **50–60% of first-episode patients have at least one or two recurrences** — the *best predictor of future risk is the number of past episodes*. Depression is **twice as common in women** as in men.
- ▶ **Important variants**: *psychotic depression* (mood-congruent delusions/hallucinations), *pseudodementia* (cognitive deficits mimicking dementia in the elderly), and **seasonal affective disorder** (anergy, fatigue, weight gain, hypersomnia, carbohydrate craving; commoner in women; prevalence rises with distance from the equator; responds to light therapy).

Specifiers (DSM-5-TR)

- ▶ With **anxious distress**, with **mixed features**, with **melancholic features**, with **atypical features**, with **mood-congruent / mood-incongruent psychotic features**, with **catatonia**, with **peripartum onset**, with **seasonal pattern**.

Differential Diagnosis

- ▶ **Bipolar depression** — always screen for past mania/hypomania; antidepressant monotherapy can trigger a switch or cycle acceleration. Red flags for bipolarity: childhood onset, antidepressant treatment failure, atypical features (hypersomnia, weight gain), marked irritability/impulsivity.
- ▶ **Grief/bereavement** — predominant affect is *emptiness and loss* occurring in waves (“pangs”), self-esteem preserved; contrast with the persistent low mood, worthlessness and self-loathing of an MDE.

- ▶ **Secondary depression (10–15%)** — hypothyroidism, Cushing's, stroke (especially left dorsolateral frontal), Parkinson's disease, dementia, multiple sclerosis, malignancy (pancreatic, oropharyngeal), HIV, hepatitis C; and **drug-induced** (antihypertensives, glucocorticoids, interferon- α , anticonvulsants).
- ▶ **Persistent depressive disorder**, adjustment disorder with depressed mood, substance-induced mood disorder.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **HPA-axis dysregulation in depression** — vertical cascade: *Hypothalamus* $\rightarrow$ *CRH* $\rightarrow$ *Anterior pituitary* $\rightarrow$ *ACTH* $\rightarrow$ *Adrenal cortex* $\rightarrow$ *Cortisol* ($\uparrow$); show **loss of negative feedback** with a dashed line and label “**Dexamethasone non-suppression**” and “**blunted TSH response to TRH.**”
- ▶ **Limbic neural circuitry of mood** — label **Prefrontal cortex (PFC)**, **Amygdala (Amy)**, **Hippocampus (HP)**, **Nucleus accumbens (NAc)**, **Hypothalamus (Hyp)**, with monoaminergic inputs: **Locus coeruleus (noradrenaline)**, **Dorsal raphe (serotonin)** and **MTA (dopamine)**.

Clinical / Diagnostic significance

- ▶ **Screening:** validated tools (e.g., PHQ-9); always **directly assess suicide risk** — risk factors include prior attempts, profound hopelessness, concurrent medical illness, substance abuse, social isolation, and co-existing anxiety/panic/agitation. **~4–5% of depressed patients die by suicide**, and most have consulted a physician within 1 month of death.
- ▶ **Investigations** to exclude secondary causes: TSH/free T4, electrolytes/calcium, blood glucose, renal/hepatic function, B12, and toxicology where indicated; imaging if focal neurology or atypical late-onset presentation.
- ▶ **Comorbidity matters:** depression worsens prognosis in **post-MI/cardiac disease** (reduced heart-rate variability, increased mortality) and in diabetes (mood severity tracks hyperglycaemia). **TCAs are contraindicated** in bundle-branch block and significant cardiovascular disease; **SSRIs are preferred** as they cause no significant ECG change.
- ▶ **General management principles:** combine *acute* (induce remission) with *maintenance* (prevent recurrence); 60–70% respond to any adequately dosed drug given for **6–8 weeks**; review response at ~2 months; continue for **6–9 months** after remission; **indefinite maintenance** after ≥ 2 episodes. Psycho-education, stress reduction and avoiding alcohol are essential.
- ▶ ***Pharmacotherapy (CMDT/STAR\D approach)**:**
 - **First-line:** SSRIs (e.g., sertraline 25 $\rightarrow$ 200 mg, escitalopram 10–20 mg) — fewer anticholinergic/cardiac effects; adverse effects: GI upset, insomnia, sexual dysfunction,

akathisia and **serotonin syndrome** (myoclonus, agitation, hyperpyrexia, hypertension).

Escitalopram is most P450-neutral.

- **SNRIs** (venlafaxine 75–375 mg, duloxetine 40–60 mg) — useful with comorbid neuropathic pain; monitor BP.
- **TCAs** — therapeutic dose ~150–200 mg imipramine/amitriptyline (level 150–300 ng/mL); **lethal in overdose** (~2 g), desipramine carrying the greatest risk — prescribe limited supplies when suicide is a risk.
- **MAOIs** — effective in **atypical depression** but risk **hypertensive (tyramine) crisis**; transdermal selegiline at 6 mg needs no dietary restriction. Never combine with SSRIs (serotonin syndrome).
- **Mirtazapine** ($\alpha 2/5$ -HT_{2/5}-HT₃ blocker; sedation, weight gain) and **bupropion** (noradrenergic-dopaminergic; few sexual effects, lowers seizure threshold).
- **Treatment-resistant strategies** (STAR\D): *switch vs augment with lithium, liothyronine (thyroid), l-methylfolate, atypical antipsychotics (aripiprazole, quetiapine-XR, brexpiprazole) or olanzapine-fluoxetine (Symbyax)*.*
- ▶ **Non-pharmacological / device therapy**: ECT is the most effective treatment, reserved for treatment-resistant, psychotic and delusional depression (remission 60–90% in psychotic depression); rTMS and VNS are approved for treatment-resistant depression. **Intranasal esketamine / IV ketamine** give rapid (often single-dose) benefit and reduce suicidality. **Brexanolone** (IV) and oral **zuranolone** are neuroactive-steroid options for **postpartum depression**.
- ▶ **Psychotherapy**: **cognitive-behavioural therapy (CBT)** and **interpersonal therapy (IPT)** are evidence-based; combined drug + psychotherapy outperforms medication alone.

High-yield exam pointers

- ▶ MDE = depressed mood/anhedonia ≥ 2 weeks + $\geq 5/9$ SIG-E-CAPS symptoms; **no manic/hypomanic episode** ever (else bipolar).
- ▶ Lifetime prevalence ~15%; **twice as common in women**; MZ:DZ concordance 46%:20%.
- ▶ Biology: $\uparrow$ cortisol/CRH, **dexamethasone non-suppression**, **blunted TSH-to-TRH**, $\downarrow$ REM latency, $\uparrow$ REM density.
- ▶ Always assess **suicide risk**; ~4–5% **die by suicide**; the best predictor of recurrence is the **number of past episodes**.
- ▶ **SSRIs first-line**; TCAs lethal in overdose; **MAOIs best in atypical depression** (tyramine crisis); SSRI + MAOI $\rightarrow$ serotonin syndrome.
- ▶ ECT = most effective and treatment of choice for **psychotic/delusional and treatment-resistant depression**.
- ▶ Continue antidepressant **6–9 months** post-remission; **indefinite maintenance after ≥ 2 episodes**.

- ▶ **Postpartum depression** → brexanolone / zuranolone; **seasonal affective disorder** → light therapy; **persistent depressive disorder** = dysthymia (≥ 2 years).
- ▶ Distinguish **grief** (emptiness, in waves, self-esteem preserved) from MDE (persistent worthlessness, self-loathing).

Neuro-regulatory Systems Implicated in Major Depressive Disorder (MDD) and the Differential Diagnoses to be Excluded Before Diagnosing MDD

Asked in: Paper IV May 2025 — RGUHS MD General Medicine

Definition / Introduction — **Major depressive disorder (MDD)** is a primary mood disorder defined by ≥ 5 of 9 DSM-5-TR symptoms (at least one being *depressed mood* or *anhedonia*) present nearly every day for ≥ 2 weeks, causing significant distress/impairment, in the absence of any manic/hypomanic episode and not attributable to a substance, medical illness or psychotic disorder. It is among the largest single contributors to global disability (DALYs). No single lesion or biomarker explains MDD; rather it arises from disturbance of several interacting **neuro-regulatory systems** — monoaminergic, neuroendocrine (HPA, thyroid), glutamate/GABA, neurotrophic, neuro-immune and large-scale limbic circuits. Because depressive syndromes are produced by many drugs and medical diseases, a careful **exclusionary differential diagnosis** is mandatory before the label “MDD” is applied.

Overview of neuro-regulatory systems implicated in MDD

System	Key dysregulation in MDD	Clinical / therapeutic correlate
Monoaminergic (NE, 5-HT, DA)	Altered “fine-tuning” of networks; ↓ or dissociated NE	TCAs, SSRIs, SNRIs, MAOIs, bupropion

System	Key dysregulation in MDD	Clinical / therapeutic correlate
	(MHPG), 5-HT (5-HIAA), DA (HVA) signalling	
HPA axis / stress	↑ CRH → ↑ ACTH → hypercortisolaemia; impaired glucocorticoid feedback (dexamethasone non-suppression)	DST positivity; melancholia; relapse marker
Thyroid / other endocrine	Blunted TSH response to TRH; ↑ basal TSH; ↓ GH response to clonidine	Hypothyroidism mimic; T3 augmentation
Glutamate / GABA / neurosteroid	Extrasynaptic NMDA excitotoxicity; ↓ cortical GABA & SST interneurons; ↓ allopregnanolone	Ketamine/esketamine; brexanolone/zuranolone
Neurotrophic / neuroplasticity	↓ BDNF, ↓ GDNF, ↓ hippocampal neurogenesis, hippocampal volume loss	Delayed (weeks) antidepressant action
Neuro-immune / inflammation	↑ IL-6, TNF-α, CRP; NF-κB/NLRP3; microglial activation; kynurenine/QUIN	Inflammatory subtype; cytokine antagonists
Limbic circuits / networks	Hyperactive amygdala & subgenual Cg25; hypoactive NAc; DMN hyperconnectivity	DBS of Cg25/NAc; rTMS of dlPFC
Sleep / circadian	↓ REM latency, ↑ REM density, ↓ slow-wave (stage IV) sleep	Trait marker; predicts relapse
Genetic / epigenetic	Polygenic; MZ:DZ concordance 46%:20%; DNA-methylation/histone changes	Early-onset = higher heritability

Monoaminergic and neuroendocrine systems

- **Monoamine hypothesis (historical basis):** the depressogenic effect of *reserpine* (a monoamine depleter) and the antidepressant action of agents that raise synaptic monoamines (TCAs inhibit NE/5-HT reuptake; MAOIs inhibit their breakdown) led to the view that depression is a *deficiency of monoamines*. This is now regarded as an oversimplification — antidepressants raise synaptic monoamines within hours yet take **weeks** to act, implicating downstream adaptive changes in second messengers, transcription factors and neurotrophins.
- **Noradrenergic:** cell bodies in the **locus coeruleus (LC)** project diffusely; mediate arousal and the medial-forebrain-bundle reward pathway. NE metabolite = **3-methoxy-4-hydroxyphenylglycol**

(MHPG). There is a subgroup with low MHPG and an overlapping subgroup with elevated/hyper-aroused NE.

- ▶ **Serotonergic:** dorsal/median raphe project widely; regulate mood, sleep, appetite, libido, aggression and circadian rhythm; metabolite = **5-hydroxyindoleacetic acid (5-HIAA)**, low CSF levels linked to impulsivity/aggression. SSRIs “normalise” amygdala over-reactivity.
- ▶ **Dopaminergic:** VTA → **mesolimbic/mesocortical** pathways subserve reward, motivation and hedonic capacity; metabolite = **homovanillic acid (HVA)**; reduced CSF HVA correlates with severe psychomotor-retarded (“hypodopaminergic”) depression and anhedonia.
- ▶ **Modern reformulation:** monoamines are now seen as broad **neuromodulators** that “tune” the activity and coupling of large-scale networks; their disturbances may be secondary/compensatory rather than the primary cause.
- ▶ **Other neuroendocrine axes:** *Thyroid* — blunted TSH response to TRH (20–30%) and occult hypothyroidism (≈5–10%); *Growth hormone* — blunted GH response to the α2-agonist **clonidine**; *Prolactin* — blunted response to 5-HT agonists.

Stress–HPA axis, neurotrophic, glutamate/GABA and neuro-immune systems

- ▶ **HPA axis (the clearest stress–depression link):** stress activates hypothalamic CRH → **pituitary ACTH** → **adrenal cortisol**. A subset of patients show **hypercortisolaemia** with loss of glucocorticoid feedback, demonstrated by the **dexamethasone suppression test (DST)** — failure of 0.5–2 mg dexamethasone to suppress cortisol (non-suppression) or early “escape”. HPA overactivity is seen in ~20–40% of outpatients and ~40–60% of inpatients (especially melancholic/psychotic/older patients), correlates with melancholia, and persistent non-suppression after treatment predicts relapse. Excess glucocorticoids are implicated in **hippocampal atrophy/volume loss**.
- ▶ **Neurotrophic/neuroplasticity hypothesis:** chronic stress and glucocorticoids reduce **brain-derived neurotrophic factor (BDNF)** and suppress hippocampal **neurogenesis**; antidepressants (and ECT, rTMS, exercise) raise BDNF and reverse this — accounting for their delayed onset. GDNF is also reduced.
- ▶ **Glutamate / GABA / neurosteroid:** activation of **synaptic NMDA receptors (GluN2A, neuroprotective)** promotes BDNF, whereas **extrasynaptic NMDA (GluN2B)** activation causes excitotoxicity and suppresses BDNF. Sub-anaesthetic **ketamine / intranasal esketamine** (NMDA antagonists, AMPA-mediated, mTOR-dependent) produce *rapid* (hours) antidepressant effects in treatment-resistant depression. **GABA** is reduced (plasma/CSF/cortex), with loss of **somatostatin-expressing (SST) interneurons**; the neurosteroid **allopregnanolone** (a positive allosteric modulator of GABA-A) is low, the rationale for **brexanolone** and **zuranolone** in peripartum depression.

- ▶ **Neuro-inflammation/immune:** a subgroup shows raised IL-6, TNF- α and CRP (CRP >3 mg/L in ~30–45%), driven by NF- κ B and the NLRP3 inflammasome, with **microglial activation**. Cytokines induce **indoleamine-2,3-dioxygenase (IDO)**, shunting tryptophan from serotonin toward neurotoxic **kynurenine/quinolinic acid (QUIN)** (an NMDA agonist). Inflammation preferentially produces **anhedonia, psychomotor slowing and suicidality** via the basal ganglia; therapeutic IFN- α reliably induces MDD in 30–50% of recipients.

Neural circuits, sleep and genetic systems

- ▶ **Limbic mood circuit:** dysfunction of the **prefrontal cortex (PFC)**, **anterior cingulate**, **hippocampus and amygdala**, with monoaminergic input from VTA (DA), LC (NE) and raphe (5-HT). Imaging shows **amygdala hyper-reactivity** to negative stimuli, **reduced nucleus accumbens (NAc)** response to reward, and **hyperactivity of subgenual cingulate (area 25/Cg25)** — the basis for **deep brain stimulation (DBS)** of Cg25 or NAc in refractory cases.
- ▶ **Large-scale networks:** depression involves hyperconnectivity of the **default-mode network (DMN)** (rumination/self-focus), impaired **central-executive/cognitive-control network (CEN/CCN)** (poor concentration), aberrant **salience network (SAN)** and reduced **sensorimotor network (SMN)** activity (psychomotor retardation), all “updated” through the **cortico–striatal–thalamo–cortical (CSTC)** loop.
- ▶ **Sleep/circadian:** characteristic **reduced REM latency, increased REM density and decreased slow-wave (stage IV) sleep**, with diurnal mood variation (worse in morning) — partly heritable, trait-like markers.
- ▶ **Genetic/epigenetic:** GWAS implicate >100 loci; monozygotic concordance ~46% vs dizygotic ~20%; early-onset depression is most heritable; epigenetic (DNA-methylation, histone) changes mediate stress effects.

Diagnosis and differential diagnoses to exclude before diagnosing MDD

Diagnosis is clinical (DSM-5-TR major depressive episode). Before labelling MDD, exclude conditions across three DSM “gatekeeper” criteria — **Criterion C** (not due to a substance or medical condition), **Criterion D** (not better explained by a psychotic disorder) and **Criterion E** (no past mania/hypomania).

Category	Conditions to exclude	Distinguishing clue
Bipolar spectrum (Criterion E)	Bipolar I / II, cyclothymia, mixed/irritable mania	Any past manic/hypomanic episode → not MDD; childhood onset, antidepressant-induced switch, hypersomnia/weight gain suggest bipolarity
Other depressive disorders	Persistent depressive disorder (dysthymia)/“double depression”, premenstrual dysphoric disorder,	Chronicity ≥ 2 yrs (dysthymia); luteal-phase timing (PMDD)

Category	Conditions to exclude	Distinguishing clue
	disruptive mood dysregulation disorder	
Psychotic disorders (Criterion D)	Schizophrenia, schizoaffective, schizophreniform, delusional disorder	Mood-incongruent psychosis; psychosis ≥ 2 wks without mood episode (schizoaffective)
Normal reactions	Bereavement/grief, normal sadness, adjustment disorder with depressed mood	Grief = emptiness/loss in waves, self-esteem preserved; sub-threshold severity/duration
Depressive disorder due to a medical condition (Criterion C)	<i>Endocrine</i> : hypo-/hyperthyroidism, Cushing, Addison, diabetes; <i>Neurologic</i> : stroke (esp. left dorsolateral-frontal — major depression in 1 in 5), Parkinson, dementia, MS, traumatic brain injury, Huntington, partial-complex epilepsy; <i>Malignancy</i> : pancreatic & oropharyngeal cancer (40–50%); <i>Infective</i> : HIV, hepatitis C; <i>Other</i> : chronic fatigue syndrome, fibromyalgia, anaemia/nutritional deficiency	History, examination and targeted labs (TSH, glucose, electrolytes, B12/folate, HIV) reveal a causal medical illness
Substance/medication-induced (Criterion C)	Reserpine, clonidine, methyl dopa, β -blockers, corticosteroids, interferon- α , retinoids (isotretinoin), digitalis, antiparkinsonian drugs, anticonvulsants, disulfiram; alcohol/sedative/opioid use; stimulant (cocaine) withdrawal	Temporal link to drug/withdrawal; resolves on removal
Neurocognitive	Dementia vs depressive “pseudodementia”	Pseudodementia: rapid onset, “don’t-know” answers, reversible with treatment
Other psychiatric	Anxiety/panic disorder, ADHD, eating disorders, somatic symptom disorder	Co-morbid; diagnose both if full criteria met

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- **Diagram 1 — “Neurobiology of MDD” composite:** Draw the HPA axis (Hypothalamus $\rightarrow$ CRH $\rightarrow$ Anterior pituitary $\rightarrow$ ACTH $\rightarrow$ Adrenal cortex $\rightarrow$ Cortisol, with a dashed negative-feedback arrow from cortisol to hippocampus/pituitary marked “impaired feedback $\rightarrow$ DST non-suppression”). Beside it draw three brainstem monoamine nuclei with arrows to

Category	Conditions to exclude	Distinguishing clue
	cortex/limbic system — label Locus coeruleus → NE (MHPG), Raphe nuclei → 5-HT (5-HIAA), VTA → DA (HVA). Add boxes for ↓BDNF / ↓neurogenesis, ↑IL-6/TNF-α/CRP → microglia → kynurenine/QUIN, and extrasynaptic NMDA (GluN2B) → excitotoxicity. ► Diagram 2 — Limbic mood circuit: Outline a sagittal brain labelling Prefrontal cortex (dlPFC), Subgenual cingulate (area 25 / Cg25), Amygdala (hyperactive), Hippocampus (atrophy) and Nucleus accumbens / VTA (reward, hypoactive); mark DBS targets = Cg25 and NAc.	

Clinical / Diagnostic significance

- **Screen and confirm criteria:** use validated tools (PHQ-9, Hamilton/Montgomery-Åsberg, QIDS-SR) and always assess **suicide risk directly** (Columbia Suicide Severity Rating Scale); ~4–5% of depressed patients die by suicide.
- **Mandatory medical work-up before diagnosing primary MDD:** TSH/free T4, fasting glucose/HbA1c, electrolytes, calcium, renal/hepatic panel, B12 and folate, FBC, and HIV where relevant; neuroimaging (CT/MRI) for first late-onset episode, focal signs, or psychotic features.
- **Biological tests are research/adjunctive, not diagnostic:** DST, TRH-stimulation and EEG-sleep abnormalities are sensitive markers of biological/melancholic depression but lack specificity.
- **Mechanism-guided therapeutics:** SSRIs/SNRIs first-line; **ketamine/esketamine** for rapid effect and acute suicidality; **brexanolone/zuranolone** for peripartum depression; ECT, rTMS, VNS, DBS (Cg25/NAc) for treatment-resistant cases; T3/lithium/atypical-antipsychotic augmentation (STAR*D).

High-yield exam pointers

- MDD requires ≥5/9 symptoms ≥2 weeks, one being depressed mood or anhedonia — and **no history of mania/hypomania** (Criterion E is the single most important exclusion → rules out bipolar disorder).
- Core neuro-systems: **monoamine, HPA, thyroid, glutamate/GABA, neurotrophic (BDNF), neuro-immune, and limbic networks** — name at least four for full marks.
- Monoamine metabolites: NE → MHPG, 5-HT → 5-HIAA, DA → HVA.
- **Dexamethasone non-suppression** = impaired glucocorticoid feedback; hypercortisolaemia → **hippocampal atrophy**.
- **Ketamine/esketamine** = NMDA antagonists with *rapid* antidepressant action; **brexanolone/zuranolone** = GABA-A neurosteroids for postpartum depression.
- Inflammation (IL-6, TNF-α, CRP, kynurenine/QUIN) drives an **anhedonia–psychomotor-slowness–suicidality** subtype.

- ▶ Sleep signature: short REM latency, ↑ REM density, ↓ slow-wave sleep.
- ▶ Exclude bipolar disorder, psychotic disorders, grief/bereavement, dysthymia, drug/substance-induced depression, and medical mimics (hypothyroidism, Cushing, stroke, Parkinson, pancreatic cancer, HIV, B12 deficiency, pseudodementia).
- ▶ Left dorsolateral-frontal stroke → major depression in 1 in 5; pancreatic & oropharyngeal cancers carry 40–50% depression prevalence.

Discuss therapy and complications of pemphigus vulgaris

Asked in: Paper IV May 2025 — RGUHS MD General Medicine

Definition / Introduction — Pemphigus vulgaris (PV) is an autoantibody-mediated, potentially life-threatening **intraepidermal** blistering disease in which IgG autoantibodies against **desmoglein 3** (and desmoglein 1 in mucocutaneous disease) cause loss of keratinocyte cell–cell adhesion (**acantholysis**), producing flaccid blisters and painful erosions of mucosae and skin. Because PV is driven by *pathogenic autoantibodies*, therapy must aim to **suppress autoantibody production**, not merely local inflammation. Before glucocorticoids, mortality was 60–90% (death within 2–5 years); with modern immunosuppression and B-cell-directed therapy mortality is now ~5%, but much of the residual morbidity and mortality arises from **complications of treatment** itself.

Goals, principles and general/supportive measures

- **Goals:** rapidly gain disease control, achieve remission, then maintain remission on the *lowest possible* glucocorticoid dose to minimise iatrogenic harm. Disease extent and response are tracked with validated scores — **PDAI** (Pemphigus Disease Area Index) and **ABSIS** (Autoimmune Bullous Skin disorder Intensity Score) — and by serial anti-Dsg **ELISA** titres, which correlate with activity.
- Start **systemic therapy as early as possible**; a steroid-sparing agent is usually added from the outset because the disease course is long and adjuvants take weeks to act.
- **Supportive care (severe disease):** hospitalise, bed rest, attention to **fluid, electrolyte, protein and nutritional** balance, wound care of denuded skin, and **secondary-infection** surveillance with systemic/topical antibiotics. **Anaesthetic troches** before meals ease painful oral erosions and maintain oral intake.
- **Drug-induced pemphigus:** review and withdraw culprit drugs — thiol-containing agents (penicillamine, captopril, enalapril), other ACE inhibitors, β -lactams, piroxicam, immune-checkpoint inhibitors.

Systemic pharmacotherapy — the therapeutic ladder

Drug	Typical dose	Role / notes
Prednisone (oral)	1 mg/kg/day (up to 1–2 mg/kg/day; usually 60 mg/day)	Standard first-line; taper once new-blister formation stops
Pulse IV methylprednisolone	1 g/day over 2–3 h $\times$ 3–5 days (cardiac monitoring)	Severe/rapidly progressive disease
Rituximab (anti-CD20)	1 g on days 1 & 15, or 375 mg/m ² weekly $\times$ 4; maintenance 500 mg q6 months	FDA-approved, first-line for moderate–severe PV
Azathioprine	2–4 mg/kg/day (100–300 mg/day)	Steroid-sparing; check TPMT before starting
Mycophenolate mofetil	2–3 g/day (1–3 g/day)	Steroid-sparing; less marrow toxicity, more GI upset
Cyclophosphamide	1–3 mg/kg/day PO, or 500–1000 mg/m ² IV q4 weeks	Potent anti-B-cell; reserved for refractory disease
IVIg	2 g/kg over 3–5 days, repeated monthly	Non-immunosuppressive; steroid-resistant disease
Plasmapheresis / immunoadsorption	1–2 sessions/week initially	Rapidly lowers autoantibody titre; needs concomitant immunosuppression
Methotrexate / cyclosporine	MTX 7.5–20 mg/week; CsA 3–5 mg/kg/day	Second-line; cyclosporine shown of no added benefit in a randomised trial

- ▶ **Corticosteroids** remain the mainstay for the rapidity of response; the dose is titrated against the *number of new blisters per day* and rate of healing. If no response in 3–7 days, escalate the dose and/or add an adjuvant.
- ▶ **Steroid-sparing immunosuppressants** (azathioprine, MMF, cyclophosphamide) added to prednisone achieve earlier control and higher remission rates and permit steroid tapering. In a randomised trial MMF gave faster, more durable responses than placebo when added to corticosteroids; azathioprine and MMF are of broadly comparable efficacy. Once remission is sustained and prednisone is down to 5–10 mg/day, the adjuvant is carefully tapered and stopped.

Rituximab, biologics and refractory-disease options

- ▶ **Rituximab** is a chimeric **anti-CD20** monoclonal antibody that depletes CD20⁺ B cells (sparing plasma cells) and also reduces desmoglein-specific T-cell responses; onset of benefit is ~8–16 weeks and may last 12–18 months. The pivotal **Ritux 3** trial (first-line rituximab + short-course prednisone vs prednisone alone) showed **complete remission off-therapy in ~89% vs 34%**, with a lower cumulative steroid dose and fewer severe adverse events — establishing rituximab as **first-line** therapy (endorsed by international expert and EADV S2 guidelines). Humanised anti-CD20 agents (**obinutuzumab**, **ofatumumab**) and intralesional rituximab are emerging options.
- ▶ **IVIg** acts via **neonatal Fc-receptor (FcRn) blockade** (reducing IgG recycling), anti-idiotypic antibodies and immunomodulation; effective and safe in steroid-resistant PV in a randomised trial.
- ▶ **Plasmapheresis / immunoadsorption** physically removes circulating autoantibody for severe, unresponsive disease; **must** be combined with immunosuppression to prevent a rebound autoantibody surge.
- ▶ **Novel/targeted: efgartigimod**, an **FcRn inhibitor**, gave early disease control in 28 of 31 PV/PF patients in a phase II trial; **DSG3-CAART** (chimeric autoantibody-receptor T cells targeting Dsg3-specific B cells) received FDA orphan-drug designation in 2020 — both reflect the move toward antigen-specific immunosuppression.
- ▶ **Topical/local adjuncts**: superpotent (Class I) topical corticosteroids and intralesional corticosteroids for persistent localised lesions; **topical ciclosporin mouthwash** for refractory oral disease; topical antibiotics for secondary infection. **Dapsone** is an adjunct in mild disease and the drug of choice in IgA pemphigus/pemphigus herpetiformis.

Complications

Complications fall into two groups — those of the **disease** and those of its **treatment**.

Disease-related complications	Treatment-related complications
Secondary bacterial infection of erosions → **S. aureus septicaemia** (most frequent cause of death)	Corticosteroids : Cushingoid features, osteoporosis/avascular necrosis, diabetes, hypertension, peptic ulcer, cataract, myopathy,

Disease-related complications	Treatment-related complications
	psychosis, adrenal suppression, opportunistic infection
Fluid, electrolyte and protein loss through denuded skin; impaired barrier/thermoregulation	Azathioprine: dose-dependent myelosuppression, nausea, hepatotoxicity (worse if low TPMT)
Nutritional compromise from painful oral erosions, dysphagia, odynophagia	Mycophenolate mofetil: GI toxicity, marrow suppression
Oesophageal/laryngeal/pharyngeal involvement — hoarseness, mucosal cast, stricture risk	Cyclophosphamide: haemorrhagic cystitis, gonadal failure/sterility, leukopenia, long-term bladder carcinoma; chlorambucil → leukaemia risk
Post-inflammatory hyperpigmentation; scarring only at infected/traumatised sites	Rituximab: infusion reactions, hepatitis B reactivation, PML, late-onset neutropenia, infection
Untreated disease is fatal (death within ~5 years)	IVIg: headache, flu-like illness, hypotension, anaphylaxis in IgA deficiency; Plasmapheresis: rebound antibody, line sepsis, hypovolaemia

- ▶ **Bad prognostic factors:** advanced age, widespread involvement, and a requirement for **high-dose glucocorticoids** (± other immunosuppressants) for control.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Desmoglein compensation theory of PV (skin vs mucosa):** draw the epidermis with a triangle gradient — label Dsg1 (superficial), Dsg3 (basal/parabasal); show anti-Dsg3 IgG → mucosal erosions (mucosal-dominant PV) and anti-Dsg3 + anti-Dsg1 IgG → suprabasal split + skin blisters (mucocutaneous PV). Label suprabasal acantholysis, “row of tombstones” basal cells, acantholytic (Tzanck) cells.
- ▶ **Therapeutic ladder schematic:** vertical ladder labelled Supportive care → Topical/intralesional steroids → Systemic prednisone 1 mg/kg/day → Steroid-sparing (azathioprine / MMF) → Rituximab (first-line, moderate–severe) → IVIg / plasmapheresis / cyclophosphamide / efgartigimod (refractory).

Clinical / Diagnostic significance

- ▶ **Confirm the diagnosis before immunosuppression:** lesional biopsy (suprabasal acantholysis), DIF of perilesional skin (intercellular “chicken-wire” IgG ± C3), IIF on monkey oesophagus, and anti-Dsg1/Dsg3 ELISA — the latter also guides dosing as titres track activity.
- ▶ **Pre-treatment screen:** baseline glucose, BP, bone-density assessment and PPI/calcium-vitamin D + osteoporosis prophylaxis for steroids; TPMT before azathioprine; hepatitis B/C, HIV, latent TB and immunoglobulin levels before rituximab/IVIg; contraception counselling before cyclophosphamide.

- ▶ **Monitor** FBC/LFTs on azathioprine/MMF/cyclophosphamide; urinalysis (haematuria) on cyclophosphamide; CD19/CD20 counts and anti-Dsg titres after rituximab to anticipate relapse.
- ▶ Exclude **drug-induced pemphigus** and, where the picture is atypical (severe stomatitis, palmoplantar/lichenoid lesions, bronchiolitis obliterans), **paraneoplastic pemphigus** — search for underlying lymphoma/Castleman disease/thymoma.

High-yield exam pointers

- ▶ PV target antigen = **Dsg3** (mucosal) ± **Dsg1** (mucocutaneous); split is **suprabasal**.
- ▶ **Prednisone 1 mg/kg/day** is standard first-line; **rituximab** is **FDA-approved first-line** for moderate–severe PV (**Ritux 3**: CR off-therapy ~89% vs 34%).
- ▶ **Rituximab regimens**: 1 g days 1 & 15, or 375 mg/m² weekly × 4; maintenance 500 mg q6 months.
- ▶ **IVIg 2 g/kg** monthly works via **FcRn blockade**; **efgartigimod** is a new FcRn inhibitor.
- ▶ **Cyclophosphamide** → haemorrhagic cystitis, sterility, **bladder cancer**; check TPMT before azathioprine.
- ▶ Most frequent cause of death = ****Staphylococcus aureus septicaemia****; untreated PV is fatal within ~5 years.
- ▶ Disease severity/response measured by **PDAI** and **ABSIS**; antibody titre by **anti-Dsg ELISA**.
- ▶ Always **screen for HBV** before rituximab (reactivation risk) and exclude **IgA deficiency** before IVIg (anaphylaxis).

Eating disorders

Asked in: Paper IV May 2022 — RGUHS MD General Medicine

Definition / Introduction — Feeding and eating disorders are a group of psychiatric conditions in which there is a **persistent disturbance of eating or eating-associated behaviour that significantly impairs the individual's physical health or psychosocial functioning**. In DSM-5-TR, the described categories (with the exception of pica) are defined to be **mutually exclusive in a given episode** — although phenotypically similar, they differ in course, prognosis and effective treatment. They are of direct relevance to the internist because their complications are **multisystemic and potentially life-threatening**: untreated anorexia nervosa carries the **highest mortality of any psychiatric condition**.

Classification (DSM-5-TR)

Disorder	Cardinal feature	Key differentiating point
Pica	Eating non-nutritive, non-food substances (clay, starch, soap, paper, ash) for ≥ 1 month in a person aged >2 years, requiring medical attention	Culturally approved practices must be excluded; diagnosed only when the behaviour increases medical risk
Rumination disorder	Repeated regurgitation of food after eating, which is re-chewed, re-swallowed or spat out, daily, for ≥ 1 month	No demonstrable gastrointestinal or other medical cause
Avoidant/restrictive food intake disorder (ARFID)	Avoidance/restriction of food intake from lack of interest in or distaste of food, with weight loss, nutritional deficiency, dependence on supplements or psychosocial impairment	No fear of weight gain and no body-image distortion (this distinguishes it from anorexia nervosa)
Anorexia nervosa (AN)	Caloric restriction producing significantly low body weight + fear of gaining weight + disturbed body image	Two subtypes — restricting vs binge-eating/purging
Bulimia nervosa (BN)	Recurrent binge eating (≥ 1 /week for 3 months) with compensatory behaviours (vomiting/purging, enemas, laxatives, excessive exercise)	Weight is normal or somewhat above normal
Binge-eating disorder (BED)	Recurrent binges with distress and loss of control	No compensatory behaviour and no inter-episode restriction

Anorexia nervosa

- **Diagnosis**: restriction of caloric intake so that body weight deviates significantly from age, gender, health and developmental norms, *plus* an intense fear of gaining weight and an associated disturbance of body image. Determining “significantly low weight” is complex and

must be **individualised**, using all historical information and comparison with **international body-mass (BMI) norms and guidelines**.

- ▶ **Subtypes** (more *state-* than *trait-*specific — patients transition between them over time):
 - **Restricting type** — weight loss achieved predominantly by restricting intake and/or excessive exercise.
 - **Binge-eating/purging type** — recurrent binge eating and/or purging by **self-induced vomiting, enemas, laxatives or diuretics**.
- ▶ **Psychopathology**: patients frequently **lack insight** and are in **denial** of the medical consequences; they are characteristically **not comforted by achieved weight loss** and persist despite reaching previously self-set weight goals.
- ▶ **Neurobiology**: alterations in the circuitry of **reward sensitivity and executive function**, implicating disturbed **frontal cortex and anterior insula** regulation of **interoceptive awareness of satiety and hunger**. Neurochemical findings (including the role of **ghrelin**) remain controversial.
- ▶ **Epidemiology**: onset most commonly in **adolescence** (later-life onset can occur); marked female preponderance; **lifetime prevalence in women up to 4%**; most prevalent in **post-industrialised, urbanised countries**; frequently comorbid with **pre-existing anxiety disorders**.
- ▶ **Course and prognosis**: variable — recovery after a single episode, recurrent episodes, or a chronic course. **Untreated AN has a mortality of 5.1 per 1000 — the highest among psychiatric conditions** (deaths from medical complications and suicide). Most treated individuals achieve remission within 5 years of diagnosis.

Medical complications of anorexia nervosa (system-wise)

System	Findings
General / metabolic	Hypometabolic state — hypotension, hypothermia, sinus bradycardia; elevated blood urea nitrogen
Haematological	Leukopenia with relative lymphocytosis
Electrolytes / acid-base	Metabolic alkalosis and hypokalaemia when purging is present
Endocrine	Hypogonadism (amenorrhoea in females), growth-hormone resistance, hypercortisolaemia
Skin	Petechiae, lanugo hair, dryness
Skeletal	Osteoporosis (long-term concern)
Cardiac	Bradycardia, hypotension; with purging — cardiac conduction abnormalities secondary to electrolyte disturbance

System	Findings
Refeeding	Over-rapid nutritional rehabilitation precipitates the refeeding syndrome (hallmark hypophosphataemia , with fluid shifts and arrhythmia risk) — hence weight-gain target of only 0.5–1 lb (~0.25–0.5 kg) per week

Bulimia nervosa

- ▶ **Diagnosis:** recurrent, frequent episodes of **binge eating** — **at least once a week for 3 months** — followed by **compensatory behaviours**: self-induced purging/vomiting, enemas, laxative use or excessive exercise to avoid weight gain.
- ▶ A **binge** is defined as excessive food intake within a prescribed period of time, **usually <2 hours**, with a subjective **loss of control**; patients express **shame**, and episodes are often triggered by **negative self-esteem or social stresses**.
- ▶ Body-image disturbance occurs as in AN, **but weight is normal or somewhat above normal** — the key clinical separator from AN binge-purge type (which requires significantly low weight).
- ▶ **Epidemiology:** lifetime prevalence in women ~2%, female-to-male ratio **10:1**; typically begins in **adolescence** and may persist for years; **transition to anorexia nervosa occurs in only 10–15%** of cases.
- ▶ **Medical risks** parallel those of AN and are a direct consequence of **purging: fluid and electrolyte disturbances** (hypokalaemia, metabolic alkalosis) and **cardiac conduction abnormalities**.
- ▶ **Physical examination** is often unremarkable; the classical signs are **dental erosion** (perimolysis from gastric acid) and **parotid gland enlargement**; calluses over the dorsum of the hand from repeated self-induced vomiting (*Russell's sign*) are a standard accompanying sign.

Binge-eating disorder and the other feeding disorders

- ▶ **Binge-eating disorder (BED):**
 - Distinguished from BN by the **absence of compensatory behaviours** after a binge and by a **lack of effort to restrict weight between episodes**.
 - Shares the **distress and loss of control** — eating more rapidly or in greater amounts than intended, or eating when not hungry.
 - **12-month prevalence in females 1.6%**, with a **much lower female-to-male ratio than BN**; prognosis is **markedly better** than other eating disorders (both natural course and treatment response); transition to other eating disorders is thought to be **rare**.
- ▶ **Pica:** onset most common in childhood; can occur with other major psychiatric conditions in adults; an **association with pregnancy** is observed, but the diagnosis is made only when the behaviour increases medical risk (e.g., toxicity, obstruction, infection). It is **not commonly** caused by a specific nutritional deficiency.

- ▶ **Rumination disorder:** onset in infancy typically between 3 and 12 months; weight loss and malnutrition are common sequelae; patients may conceal the behaviour (covering the mouth, social avoidance while eating); may remit spontaneously or recur.
- ▶ **ARFID:** onset usually in infancy/early childhood but may persist into adulthood; **equal prevalence in males and females**; frequently comorbid with **anxiety, cognitive and attention-deficit disorders** and situations of **familial stress**; long-standing unrecognised disease causes developmental delay and functional deficits.

Management

Disorder	Psychological treatment (first-line)	Pharmacotherapy	Medical management
Anorexia nervosa	MANTRA (<i>Maudsley Anorexia Nervosa Treatment for Adults</i>) and eating-disorder-focused CBT; strict behavioural contingencies when weight loss becomes critical	No drug is specifically beneficial; treat comorbid depression and anxiety on their own merits	Gradual nutritional rehabilitation — 0.5–1 lb/week weight gain to prevent refeeding syndrome ; monitor electrolytes (especially phosphate, potassium), ECG; hospitalise for severe bradycardia, hypotension, hypothermia, marked electrolyte derangement or critical low weight
Bulimia nervosa	Cognitive-behavioural, emotion-regulation or interpersonal psychotherapies	SSRI antidepressants, usually combined with psychotherapy (fluoxetine is the standard agent, used at higher dose, e.g., 60 mg/day)	Correct hypokalaemia/alkalosis; dental review for enamel erosion
Binge-eating disorder	CBT-based approaches; responds markedly better than other eating disorders	SSRIs/CBT as for BN-spectrum illness (lisdexamfetamine is an approved option in standard practice)	Address obesity-related comorbidity
Pica / Rumination / ARFID	Behavioural therapy, family-based management of stressors; nutritional supplementation in ARFID	—	Treat the medical consequence (toxicity, malnutrition, deficiency states)

Disorder	Psychological treatment (first-line)	Pharmacotherapy	Medical management
DIAGRAMS TO DRAW — IMAGE SUGGESTIONS ▶ Diagram 1 — “Multisystem complications of anorexia nervosa” (labelled human figure). Labels: <i>Brain</i> — lack of insight, altered frontal cortex–anterior insula interoceptive circuitry; <i>Skin</i> — lanugo hair, petechiae, dryness; <i>Heart</i> — sinus bradycardia, hypotension, conduction abnormalities; <i>Blood</i> — leukopenia with lymphocytosis; <i>Kidney/metabolic</i> — raised BUN, hypokalaemia, metabolic alkalosis (purging); <i>Endocrine</i> — amenorrhoea/hypogonadism, GH resistance, hypercortisolaemia; <i>Bone</i> — osteoporosis; <i>Whole body</i> — hypothermia, weight significantly below norms. ▶ Diagram 2 — “Diagnostic algorithm for eating disorders” (flow chart). Boxes: <i>Significantly low body weight?</i> → YES + fear of weight gain + body-image disturbance → Anorexia nervosa (→ restricting type vs binge-eating/purging type); YES but NO fear of weight gain/body-image distortion → ARFID; NO (normal/overweight) + binge ≥1/week × 3 months → <i>Compensatory behaviour?</i> → YES → Bulimia nervosa; NO → Binge-eating disorder.			

Clinical / Diagnostic significance

- ▶ **Internist’s screen:** unexplained amenorrhoea, bradycardia, hypokalaemic metabolic alkalosis, dental erosion or parotid swelling in a young woman should prompt directed questioning for disordered eating; physical examination in BN is often normal, so the diagnosis rests on history.
- ▶ **Laboratory panel:** electrolytes (K^+ , and phosphate during refeeding), urea, glucose, complete blood count (leukopenia with lymphocytosis), and ECG (bradycardia, conduction abnormalities — risk of arrhythmic death when hypokalaemic).
- ▶ **Distinguish organic disease:** weight loss with intact body image and genuine loss of appetite suggests malignancy, malabsorption, thyrotoxicosis, adrenal insufficiency or depression rather than AN; in AN the patient *fears* weight gain and is *not relieved* by weight loss.
- ▶ **Refeeding syndrome** is the most important iatrogenic hazard — gradual calorie escalation, phosphate/potassium/magnesium monitoring and a weight-gain ceiling of 0.5–1 lb/week.
- ▶ **Psychiatric comorbidity** (anxiety disorders in AN; depression in BN/BED) must be actively treated; suicide contributes to the excess mortality of AN.
- ▶ **Hospitalisation/behavioural contingency** is indicated when weight loss becomes critical or vital signs/electrolytes are dangerously deranged.

High-yield exam pointers

- ▶ **DSM-5-TR feeding and eating disorders:** pica, rumination disorder, ARFID, anorexia nervosa, bulimia nervosa, binge-eating disorder — mutually exclusive in a given episode (except pica).
- ▶ **AN = low weight + fear of weight gain + body-image disturbance;** two subtypes — restricting vs binge-eating/purging; subtype is state-, not trait-specific.
- ▶ **ARFID vs AN:** ARFID has **no fear of weight gain and no body-image distortion**.
- ▶ **BN vs AN binge-purge type:** BN patients are of **normal weight or overweight**; binge ≥ 1 /week for 3 months, binge usually < 2 h.
- ▶ **BED vs BN:** BED has **no compensatory behaviour**; lowest female predominance; **best prognosis** of all eating disorders.
- ▶ **Untreated AN mortality 5.1/1000 — highest of all psychiatric disorders;** lifetime prevalence in women up to 4% (BN $\sim 2\%$, 10:1 F:M; BED 12-month prevalence 1.6% in females).
- ▶ **AN examination:** lanugo, petechiae, dry skin, hypotension, hypothermia, sinus bradycardia, amenorrhoea; labs: leukopenia with lymphocytosis, $\uparrow$ BUN, hypokalaemic metabolic alkalosis (purging), hypogonadism, GH resistance, hypercortisolaemia, osteoporosis.
- ▶ **BN examination:** dental erosion + parotid enlargement ($\pm$ Russell's sign).
- ▶ **Treatment one-liners:** AN — MANTRA / ED-focused CBT, no specific drug, refeed at 0.5–1 lb/week; BN — SSRI + CBT/interpersonal therapy; BED — best treatment response.
- ▶ **Neurobiology of AN:** frontal cortex–anterior insula interoceptive circuitry; ghrelin data controversial.

SOURCE & COVERAGE

Harrison 22e — Ch 463 “Psychiatric Disorders” (section: *Feeding and Eating Disorders*).
Coverage note: Harrison 22e has no dedicated eating-disorders chapter; the topic is covered briefly within Ch 463, and this answer reflects that coverage. A few universally standard exam points absent from the provided text were added for completeness and are flagged as standard practice: *Russell's sign*, hypophosphataemia as the hallmark of refeeding syndrome, high-dose fluoxetine for BN, lisdexamfetamine for BED, and explicit hospitalisation criteria (consistent with CMDT/standard psychiatry teaching).

Eczema

Asked in: Paper IV Nov 2019 — RGUHS MD General Medicine

Definition / Introduction — *Eczema* (Greek *ekzema*, “to boil over”) is a **clinico-histological reaction pattern of skin inflammation** rather than a single disease, characterised clinically by pruritus, erythema, oozing, vesiculation, scaling and (when chronic) lichenification, and histologically by **spongiosis** (intercellular oedema of the epidermis) with acanthosis and a perivascular lymphohistiocytic infiltrate.

The terms *eczema* and *dermatitis* are used synonymously. It is the **final common pathway of many disorders** of diverse aetiology; **atopic dermatitis (AD)** is the prototype and commonest endogenous form. Eczema accounts for ~10–25% of dermatology consultations and AD carries the highest disability-adjusted life-year burden of any skin disease.

Classification of eczematous disorders

Best classified by **aetiology** (where known) and by **endogenous vs exogenous** origin; morphological labels (e.g. nummular, dyshidrotic) cut across causes.

Category	Examples
Endogenous (constitutional)	Atopic eczema; seborrhoeic dermatitis; nummular (discoid) eczema; asteatotic (xerotic / “winter itch”) eczema; stasis (venous/gravitational) eczema; hand eczema incl. pompholyx; lichen simplex chronicus; pityriasis alba; juvenile plantar dermatosis
Exogenous (contact)	Allergic contact dermatitis (type IV, e.g. nickel, <i>Toxicodendron</i> /urushiol); irritant contact dermatitis (soaps, detergents, wet-work); photoallergic / photo-irritant eczema; infective dermatitis; post-traumatic eczema; dermatophytide (“id” reaction)
By morphology / acuity	Acute (wet, oedematous, vesicular) → subacute → chronic (dry, lichenified, fissured)

Atopic dermatitis — pathophysiology (the exam favourite)

AD is the cutaneous expression of the **atopic state** (familial tendency to asthma, allergic rhinitis, eczema). Pathogenesis is a **three-way interaction** of barrier defect, immune dysregulation and microbiome alteration, on a strong genetic background (monozygotic twin concordance ~77% vs ~15% dizygotic; if **both parents affected** >80% of children develop AD).

- ▶ **Epidermal barrier dysfunction** — **loss-of-function mutations in the filaggrin gene (FLG) are the single strongest genetic risk factor (also cause ichthyosis vulgaris). Filaggrin aggregates keratin in the stratum corneum; deficiency → ↑ transepidermal water loss, ↑ skin pH, xerosis, and easier penetration of irritants, allergens and microbes. FLG null carriers manifest hyperlinear palms, keratosis pilaris and ichthyosis vulgaris**; penetrance of AD is ~40% with one and ~90% with two null alleles.
- ▶ **Immune dysregulation** — barrier breach lets keratinocytes release “alarmins” TSLP (the “master switch of allergic inflammation”), **IL-25 and IL-33**, driving a **Th2-skewed** response. *Acute* lesions are Th2-dominant (**IL-4, IL-5, IL-13, IL-31** — IL-31 is the key pruritogen); *chronic* lesions shift to **Th1/Th17/Th22** cytokines. Th2 cytokines themselves suppress filaggrin, loricrin and antimicrobial peptides, perpetuating the barrier defect. Result: **↑ IgE synthesis, eosinophilia, impaired delayed-type hypersensitivity.**

- ▶ **Microbiome** — reduced diversity with ** >90% colonisation by Staphylococcus aureus**; **staphylococcal exotoxins act as superantigens**** amplifying inflammation; reduced antimicrobial peptide (β -defensin, cathelicidin) production predisposes to viral superinfection (eczema herpeticum).
- ▶ **Epicutaneous sensitisation** through defective skin is thought to initiate the “**atopic march**” — AD in infancy → food allergy → asthma → allergic rhinoconjunctivitis.

Atopic dermatitis — clinical features by age

Pruritus (“an itch that rashes”) is the cardinal symptom in all ages; the course is chronically relapsing. 45% present in first 6 months, 60% in first year, ~85% by age 5; ~40% persist into adult life.

Phase	Age	Distribution / features
Infantile	0–2 yr	Weeping, crusted patches on cheeks, face, scalp, neck and extensor surfaces; napkin area spared
Childhood / adolescent	2 yr–puberty	Flexural dermatitis — antecubital & popliteal fossae, wrists, ankles, neck; lichenification
Adult	post-puberty	Flexures, hand eczema , head-and-neck, nipple/eyelid eczema; often localised lichen simplex chronicus

- ▶ **Atopic stigmata / minor signs:** xerosis, **Dennie–Morgan infraorbital fold**, infraorbital darkening (“allergic shiners”), perioral/midfacial pallor, **hyperlinear palms**, keratosis pilaris, **pityriasis alba**, white dermographism, anterior neck folds, **keratoconus** and **anterior subcapsular cataract**.

Diagnostic criteria

AD is a **clinical diagnosis** (no confirmatory test except skin biopsy).

- ▶ ****Hanifin & Rajka criteria (1980) — require ≥ 3 of 4 major plus ≥ 3 minor**.**
 - **Major:** (1) pruritus; (2) typical morphology & age-specific distribution (flexural in adults, facial/extensor in infants); (3) chronic or chronically relapsing course; (4) personal/family history of atopy.
 - **Minor (selected):** xerosis; ichthyosis/palmar hyperlinearity/keratosis pilaris; elevated serum IgE / immediate (type I) skin-test reactivity; early age of onset; tendency to cutaneous infections (*S. aureus*, HSV); non-specific hand/foot dermatitis; nipple eczema; cheilitis; recurrent conjunctivitis; Dennie–Morgan fold; keratoconus; anterior subcapsular cataract; orbital darkening; facial pallor; pityriasis alba; itch on sweating; wool intolerance; white dermographism; food intolerance; course influenced by environment/emotion.

- ▶ ***UK Working Party (Williams) criteria** — *validated, simplified for population studies (80% PPV, 97% NPV). Must have an itchy skin condition in the last 12 months plus ≥ 3 of:** onset <2 yr; history of flexural involvement; history of generally dry skin; personal history of other atopic disease (or atopy in a first-degree relative if <4 yr); visible flexural dermatitis.
- ▶ **Severity scoring:** SCORAD, EASI, POEM (patient-oriented), vIGA-AD.

Other clinically important eczema variants

Variant	Key features
Lichen simplex chronicus	Circumscribed lichenified plaque from chronic rubbing; nape, ankles, dorsum of feet
Nummular (discoïd)	“Coin-shaped” crusted scaly plaques, extensor limbs; middle-aged men; dry skin
Asteatotic (xerotic)	“Crazy-paving”/cracked dry skin, shins of the elderly in winter
Stasis dermatitis	Medial ankle, venous incompetence, haemosiderin pigmentation, brawny oedema; <i>bilateral</i> (vs unilateral cellulitis); may precede venous ulcer
Seborrhoeic dermatitis	Greasy yellow scale on scalp, eyebrows, nasolabial folds; <i>Malassezia</i> ; associated with Parkinson’s, HIV
Hand eczema / pompholyx	Wet-work/occupational; dyshidrotic — intensely pruritic deep vesicles on sides of fingers, palms
Contact dermatitis	Allergic (type IV, patch-test positive) vs irritant (dose-dependent, no prior sensitisation)

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ “Distribution of atopic dermatitis by age” — **three body silhouettes**. Labels: *Infantile* — cheeks/face, scalp, neck, extensor limbs, napkin sparing; *Childhood* — antecubital fossa, popliteal fossa, wrists, ankles, neck; *Adult* — flexures, hands, eyelids, head-and-neck.
- ▶ “Pathogenesis triad of AD” — **three interlocking circles**. Labels: (1) **Epidermal barrier defect** (*FLG* mutation, $\uparrow$ TEWL, xerosis); (2) **Immune dysregulation** (TSLP/IL-33 $\rightarrow$ Th2: IL-4, IL-13, IL-31; chronic Th1/Th17/Th22; $\uparrow$ IgE); (3) **Microbiome** (*S. aureus* superantigens, $\downarrow$ antimicrobial peptides); central output $\rightarrow$ **chronic pruritic eczema** $\rightarrow$ **atopic march**.

Clinical / Diagnostic significance

- ▶ **Investigations:** largely clinical; serum IgE/eosinophilia support but are not diagnostic; **patch testing** if allergic contact dermatitis suspected or AD is recalcitrant; **KOH/culture** to exclude dermatophyte (esp. hand eczema); skin/viral swabs in weeping flares.

- ▶ **Complications:** secondary **impetiginisation** with *S. aureus*/*S. pyogenes* (infra-auricular fissure is a cardinal sign); **eczema herpeticum** (*Kaposi varicelliform eruption*) — monomorphic punched-out “scalloped” erosions with haemorrhagic crusts + fever; a dermatological emergency needing **systemic aciclovir**; predisposition to widespread **molluscum contagiosum**. Risk of erythroderma. Associations: asthma, allergic rhinitis, food allergy, ADHD, anxiety/depression, and ↑ cardiovascular risk in adults.
- ▶ **Management ladder (AD):**
 - *General* — gentle skin care, avoid irritants/wool/soaps, bathe ≤ once daily in warm water, **liberal emollients** (≈30 g covers an adult; apply within minutes of bathing); identify triggers.
 - *First line* — **topical corticosteroids** (potency matched to site/severity; low-potency on face/flexures to avoid atrophy); **topical calcineurin inhibitors** (tacrolimus, pimecrolimus — steroid-sparing, safe on face, no atrophy), **crisaborole** (PDE-4 inhibitor), **ruxolitinib/roflumilast** cream. *Proactive* twice-weekly anti-inflammatory to flare-prone sites prevents relapse.
 - *Adjuncts* — **dilute sodium hypochlorite (bleach, ~0.005%) baths** + intranasal mupirocin to reduce *S. aureus*; **wet-wrap therapy** (diluted steroid + inner wet/outer dry layer, ≤2 weeks) for acute flares; sedating antihistamines (hydroxyzine, doxepin) at night for sleep; treat secondary infection (dicloxacillin/cephalexin; cover CA-MRSA with cotrimoxazole/doxycycline/clindamycin per culture).
 - *Severe/refractory* — **phototherapy** (NB-UVB); systemic immunosuppressants (ciclosporin, methotrexate, azathioprine, mycophenolate); **biologics** — **dupilumab** (anti-IL-4Rα, blocks IL-4/IL-13; approved ≥6 months), **tralokinumab** (anti-IL-13); **oral JAK inhibitors** — **upadacitinib**, **abrocitinib**. Systemic corticosteroids only for short severe exacerbations (rebound on withdrawal).

High-yield exam pointers

- ▶ Eczema = **spongiosis** histologically; “the itch that rashes.”
- ▶ ***Filaggrin (FLG) loss-of-function*** = strongest genetic risk for AD; links to ichthyosis vulgaris, hyperlinear palms, keratosis pilaris.
- ▶ Acute AD is **Th2** (IL-4/IL-13/IL-31, ↑IgE); chronic shifts to **Th1/Th17/Th22**; TSLP is the alarmin “master switch.”
- ▶ **Hanifin & Rajka** (≥3 major + ≥3 minor) and **UK Working Party** criteria; severity by **SCORAD/EASI/POEM**.
- ▶ **Dennie–Morgan fold**, **allergic shiners**, **hyperlinear palms**, **pityriasis alba**, **white dermographism** = atopic stigmata.
- ▶ **Eczema herpeticum** (*Kaposi varicelliform eruption*) = monomorphic punched-out erosions → **aciclovir** urgently.

- ▶ Stasis dermatitis is usually bilateral; unilateral red leg favours cellulitis.
- ▶ Dupilumab (IL-4Rα), tralokinumab (IL-13), upadacitinib/abrocitinib (JAK) are the modern systemic agents; FDA *black-box warning* on topical calcineurin inhibitors (theoretical lymphoma — absolute risk very low).
- ▶ Topical steroid potency: **low-potency on face/flexures** to avoid atrophy/striae.

SOURCE & COVERAGE

- ▶ **Harrison's Principles of Internal Medicine, 22e** — “Eczema, Psoriasis, Cutaneous Infections, Acne, and Other Common Skin Disorders” (atopic dermatitis, contact/hand/nummular/asteatotic/stasis/seborrheic dermatitis, lichen simplex chronicus, treatment).
- ▶ **Rook's Textbook of Dermatology, 10e** — “Eczematous Disorders” (classification, nomenclature) and “Atopic Eczema” (diagnostic criteria, filaggrin genetics, epidemiology, complications).
- ▶ **Bolognia, Dermatology, 5e** — “Atopic Dermatitis” (pathogenesis triad, atopic march, Th2/Th1-Th17-Th22 cytokines, diagnostic features table, eczema herpeticum, severity scores).
- ▶ **CMDT 2026** — “Dermatologic Disorders: Atopic Dermatitis” (current stepwise management, topical non-steroidals, biologics/JAK inhibitors, wet wraps, bleach baths).

Erythema Nodosum: Causes, Histopathology, Evaluation and Management

Asked in: Paper III 15 Apr 2026 — RGUHS MD General Medicine

Definition / Introduction — Erythema nodosum (EN) is the commonest and best-known form of panniculitis (inflammation of subcutaneous fat), presenting as an acute, self-limited eruption of **tender, erythematous, non-ulcerating subcutaneous nodules**, classically symmetrical over the **pretibial shins**. It is widely regarded as a **delayed (type IV) hypersensitivity reaction** to diverse antigenic stimuli (infections, drugs, systemic inflammatory disease) and is histologically the **prototype of a septal panniculitis without vasculitis**. Because of its strong links to systemic disease, EN is an important *skin sign of internal disease* — diagnosis is only the first step; the cause must be sought.

Pathogenesis

- ▶ A **delayed-type hypersensitivity response** to varied antigens; lesional skin and blood show a **Th1 cytokine pattern** (interferon-γ, IL-2) characteristic of DTH.
- ▶ **Immune-complex deposition** in septal venules and a **neutrophil-driven** early phase: circulating neutrophils generate reactive oxygen intermediates that provoke tissue damage; later, **granuloma**

formation predominates, in which TNF plays a central role (explaining both response to, and paradoxical induction by, TNF inhibitors).

- ▶ Endothelial up-regulation of adhesion molecules (VCAM-1/CD106, PECAM-1/CD31, E-selectin, HLA-DR) with VLA-4/L-selectin on infiltrating cells.
- ▶ A TNF promoter polymorphism correlates with sarcoidosis-associated EN, linking deregulated TNF to granuloma formation.

Causes / Aetiology

A precipitant is identifiable in roughly half; the rest are idiopathic. Crohn disease associates more strongly than ulcerative colitis.

Category	Specific causes (high-yield)
Idiopathic	Largest single group — one-third to one-half of cases
Infections (≈1/3 of cases)	Streptococcal URTI = commonest <i>infectious</i> cause; viral URTI; bacterial gastroenteritis (<i>Yersinia</i> > Salmonella , Campylobacter); Mycobacterium tuberculosis ; coccidioidomycosis (and histoplasmosis, blastomycosis); brucellosis, <i>Mycoplasma pneumoniae</i> , <i>Chlamydia pneumoniae</i> /C. trachomatis, hepatitis B, HIV, COVID-19
Sarcoidosis	10–20% of cases; Löfgren syndrome (see below)
Inflammatory bowel disease	Crohn disease > ulcerative colitis
Drugs	Oral contraceptives/oestrogens, sulfonamides, penicillins, bromides, iodides, TNF inhibitors (etanercept, infliximab, adalimumab), immune checkpoint inhibitors , BRAF inhibitors (vemurafenib, dabrafenib), tyrosine-kinase inhibitors (imatinib, dasatinib)
Neutrophilic dermatoses	Behçet disease , Sweet syndrome (EN in Behçet often resembles erythema induratum)
Pregnancy / hormonal	Pregnancy itself; OCP use
Malignancy	Acute myeloid leukaemia, Hodgkin lymphoma (may overlap with Sweet syndrome)
Miscellaneous	Acne fulminans (incl. isotretinoin-associated), diverticulitis, granulomatous mastitis, lupus erythematosus, MonoMAC syndrome (<i>GATA2</i>)

- ▶ ***Löfgren syndrome** — *acute, spontaneously resolving sarcoidosis = EN + bilateral hilar lymphadenopathy + fever + polyarthritides (peri-ankle) + uveitis**; carries a benign, self-limited prognosis.

Clinical features

- ▶ **Crops of tender, warm, erythematous nodules 1–10 cm**, bilateral and symmetrical, on the **anterior shins** (occasionally thighs, forearms; trunk/face/neck rare — atypical sites should prompt an alternative diagnosis).
- ▶ Lesions **do not ulcerate** and **resolve without scarring** over **~6 weeks**, evolving through **bruise-like (contusiform) colour changes** — hence the synonym *erythema contusiformis*.
- ▶ **Constitutional symptoms** common even without an identified systemic cause: fever, malaise, **arthralgia/arthritis**, leukocytosis, raised ESR.
- ▶ **Up to one-third recur**; annual recurrences typical of idiopathic disease. Chronic/migratory variants = *subacute nodular migratory panniculitis (erythema nodosum migrans)*, often unilateral with centrifugal spread and central clearing.

Histopathology

Biopsy requires a deep incisional/excisional specimen capturing generous subcutaneous fat — a punch biopsy is usually inadequate.

- ▶ **Prototypic septal (interlobular) panniculitis WITHOUT true vasculitis.**
- ▶ **Septa are thickened and oedematous**, infiltrated by inflammatory cells concentrated at the **septal-lobular interface**, extending into the lobule periphery in a *lace-like* pattern.
- ▶ **Early lesions:** oedematous septa, often **neutrophil-rich**; **late lesions:** mixed, **granulomatous** infiltrate with **epithelioid histiocytes and multinucleated giant cells**, eventual **septal fibrosis**.
- ▶ ***Miescher radial microgranulomas** — *the characteristic (though not strictly pathognomonic) hallmark: small nodular aggregates of histiocytoid cells arranged radially around a central stellate / banana-shaped cleft**, located within or at the edge of septa.
- ▶ A **mild superficial and deep perivascular lymphocytic infiltrate** is usually present in the overlying dermis.
- ▶ Leukocytoclastic vasculitis is **absent** (its presence, with venular/venous involvement, suggests EN-like lesions of severe Behçet disease).

Evaluation / Investigations

- ▶ **Confirm the diagnosis clinically** (classic bilateral pretibial tender non-ulcerating nodules in a young adult, F:M ≈ 10:1, 2nd–4th decades); biopsy only when atypical (few lesions, unusual site, duration >6 weeks, or ulceration suggesting another panniculitis).

- **Search for an underlying cause** — directed by *findings that predict a systemic association*: synovitis, diarrhoea, abnormal CXR, preceding URTI, raised ASO/anti-DNase B, positive TST/IGRA.
- **First-line work-up**: FBC, ESR/CRP, throat swab + **two serial ASO / anti-DNase B titres 2–4 weeks apart**, chest X-ray (hilar adenopathy → sarcoidosis/Löfgren, TB, lymphoma), **tuberculin skin test or IGRA (QuantiFERON-TB / T-SPOT.TB)**.
- **Targeted tests**: stool culture + **faecal calprotectin** (if GI symptoms) for IBD/enteric infection; **serum amylase/lipase** if pancreatic panniculitis suspected; **serum β -hCG** in women of child-bearing age; viral hepatitis panel; coccidioidin/fungal serology in endemic areas; review of drug history.
- **Differential diagnosis of subcutaneous nodules**:

Entity	Distinguishing feature
Erythema induratum (nodular vasculitis)	Posterior calf, ulcerates; lobular panniculitis with vasculitis; <i>M. tuberculosis</i> DNA by PCR
Pancreatic panniculitis	Fat necrosis with saponification/"ghost cells"; $\uparrow$ amylase/lipase; arthritis, serositis
Lupus panniculitis	Cheeks, upper arms, buttocks; heals with depressed scars
Cutaneous polyarteritis nodosa	Nodules + ulcers within fixed livedo reticularis ; medium-vessel arteritis
Superficial thrombophlebitis	Linear cord along a vein

Management

- **General (all patients)**: stop any causative drug; **diagnose and treat the underlying cause**; bed rest, leg elevation, compression.

Line	Agents
First-line	NSAIDs, salicylates, potassium iodide (SSKI)
Second-line (only after infection excluded/treated)	Colchicine (esp. Behçet-associated), hydroxychloroquine, TNF inhibitors (infliximab/adalimumab/etanercept — useful in IBD-associated EN), mycophenolate mofetil
Third-line	Systemic corticosteroids (avoid if infection unexcluded), thalidomide, ciclosporin, dapsone

- **Potassium iodide (SSKI)**: adult dose commonly **300 mg three times daily** (range ~450–1500 mg/day); CMDT quotes **5–15 drops three times daily**; improvement within ~2 weeks via inhibition of neutrophil chemotaxis and cell-mediated immunity.

- ▶ **Caveat:** NSAIDs and KI may flare IBD; corticosteroids are contraindicated if an underlying infection (e.g. TB, deep mycosis) has not been excluded/treated.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Histology of EN (septal panniculitis):** label *epidermis, dermis with superficial + deep perivascular lymphocytic infiltrate, widened oedematous/fibrotic interlobular septum, fat lobule, Miescher radial microgranuloma (histiocytes around central stellate cleft), multinucleated giant cells, and absence of vasculitis.*
- ▶ **Clinical distribution figure:** front-of-legs silhouette showing **bilateral symmetrical tender nodules over both shins (pretibial)**, with a colour key for *erythema → contusiform/bruise-like resolution, non-ulcerating.*

Clinical / Diagnostic significance

- ▶ EN is a **paraclinical marker of systemic disease** — it may precede or accompany an IBD flare, herald sarcoidosis or primary TB/coccidioidomycosis, or signal drug reaction.
- ▶ It carries **prognostic value:** EN denotes a **benign, self-limited course in sarcoidosis (Löfgren)** and a **protective effect against dissemination in coccidioidomycosis.**
- ▶ A normal CXR, negative IGRA/TST and negative streptococcal serology in an otherwise well young woman support an **idiopathic, benign course**; only a small minority develop significant illness within the following year.
- ▶ **Persistent, ulcerating, posterior-leg or unilateral lesions argue against EN** and mandate biopsy for an alternative panniculitis.

High-yield exam pointers

- ▶ EN = **commonest panniculitis; septal panniculitis without vasculitis; never ulcerates, heals without scar.**
- ▶ **Miescher radial microgranuloma** = histological hallmark (histiocytes around a central stellate/banana-shaped cleft).
- ▶ **Streptococcal URTI** = commonest infectious cause; **idiopathic** = commonest overall; **sarcoidosis** 10–20%.
- ▶ **Löfgren syndrome** = EN + bilateral hilar lymphadenopathy + fever + arthritis + uveitis (good prognosis).
- ▶ **Crohn > ulcerative colitis; Yersinia** = leading enteric trigger; drugs — OCP, sulfonamides, penicillins, bromides/iodides, BRAF inhibitors.
- ▶ Core work-up: CXR + ASO/anti-DNase B (×2) + TST/IGRA + ESR ± stool studies + β-hCG.
- ▶ Treatment ladder: NSAIDs / potassium iodide → colchicine, HCQ → steroids (only after excluding infection); always **treat the cause.**

- ▶ **DDx mnemonic by site:** EN = shin (anterior); erythema induratum = calf (posterior, ulcerates, TB); lupus panniculitis = buttocks/arms (scars).

SOURCE & COVERAGE

- ▶ **Bologna, Dermatology (5e)* — “Panniculitis”^{*} (primary source: aetiology Table, pathogenesis, septal histopathology with Miescher microgranulomas, treatment ladder and potassium iodide dosing).
- ▶ **Rook’s Textbook of Dermatology (10e)* — “Panniculitis”^{*} (Miescher radial granuloma morphology; septal-panniculitis-without-vasculitis confirmation; Löfgren/sarcoid associations).
- ▶ **Harrison’s Principles of Internal Medicine (22e)* — “Skin Manifestations of Internal Disease”^{*} (EN as a sign of systemic disease; differential of subcutaneous nodules).
- ▶ **CMDT 2026** — “Dermatologic Disorders” (**Erythema Nodosum**) (clinical essentials, evaluation algorithm, NSAID/SSKI/colchicine/dapsone management, prognosis).
- ▶ *Coverage note:* The spec flagged panniculitis histopathology as potentially thin in Harrison; this was fully resolved using the dedicated dermatology texts (Bologna and Rook’s), which supplied exam-grade histological and therapeutic detail.

Erythroderma

Asked in: Paper IV Dec 2023 — RGUHS MD General Medicine

Definition / Introduction — **Erythroderma** (synonyms: *exfoliative dermatitis*, *exfoliative erythroderma*) is an inflammatory reaction pattern characterised by **generalised erythema and scaling involving ≥80–90% of the body surface area (BSA)**. The term was coined by *Hebra* in 1868 for an eruption affecting >90% of the skin. It is **not a single disease but a striking, potentially life-threatening clinical presentation** that can arise from several underlying dermatoses, drugs or systemic diseases, and is therefore regarded as a **dermatological emergency** requiring a careful aetiological search and management of systemic complications.

Epidemiology and classification

- ▶ Estimated incidence ~1–2 per 100,000; male predominance with **M:F ratio 2:1 to 4:1**; mean age of onset ~52 years.
- ▶ **By onset/course:** *Primary* erythroderma (erythema begins de novo, often on the trunk, and generalises over days–weeks) vs *Secondary* erythroderma (generalisation of a pre-existing dermatosis, e.g. psoriasis, atopic dermatitis — up to 50% have a prior localised skin disease).
- ▶ **Idiopathic erythroderma** persists despite thorough work-up in ~25% of adults — typically **elderly men** with chronic pruritus, palmoplantar keratoderma and dermatopathic

lymphadenopathy; historically termed “*red man syndrome*” or “*l’homme rouge*” (not to be confused with the vancomycin rapid-infusion reaction of the same name). These cases mandate longitudinal review, as some evolve into CTCL.

Aetiology

The major causes are (1) primary cutaneous dermatoses, (2) drugs, (3) systemic disease (chiefly CTCL), and (4) idiopathic. In adults the four commonest are **dermatitis, psoriasis, drug reactions and CTCL**.

Category	Approx. frequency	Diagnostic clues
Psoriasis	~20–27%	Pre-existing plaques (elbows/knees/scalp), nail pits / oil-drop sign / onycholysis, sterile pustules, arthritis; often spares central face
Dermatitis (atopic > contact > seborrhoeic / stasis)	~20–24%	Pre-existing flexural lesions, intense pruritus, lichenification (incl. eyelids), raised IgE, eosinophilia, atopy history
Drug reactions	~15–19%	Preceding morbilliform/scarlatiniform exanthem, facial oedema, rapid onset; may be part of DRESS/DIHS
CTCL (Sézary syndrome > erythrodermic mycosis fungoides)	~8–18%	Leonine facies, <i>melanoerythroderma</i> , painful fissured keratoderma, alopecia, lymphadenopathy, severe pruritus
Idiopathic	~25% (often older men)	Chronic, relapsing; palmoplantar keratoderma, dermatopathic lymphadenopathy
Uncommon	—	Pityriasis rubra pilaris, pemphigus foliaceus, bullous pemphigoid, paraneoplastic (lymphoma > solid tumours, thymoma), crusted (Norwegian) scabies, dermatophytosis, GVHD, sarcoidosis, connective-tissue disease, papuloerythroderma of Ofuji

- **Implicated drugs:** allopurinol, β -lactams/penicillins, sulfonamides, sulfasalazine, aromatic anticonvulsants (carbamazepine, phenytoin, phenobarbital), gold salts, lithium, cimetidine, antimalarials, dapsone, isoniazid, immune checkpoint inhibitors.

- ▶ **Neonatal/infantile erythroderma** (“the red baby”) — distinct causes: **inherited ichthyoses** (congenital ichthyosiform erythroderma — *TGM1*; epidermolytic ichthyosis — *KRT1/KRT10*; **Netherton syndrome** — *SPINK5/LEKTI*, *trichorrhexis invaginata* “bamboo hair”), **primary immunodeficiencies** (**Omenn syndrome** — *RAG1/RAG2*; Wiskott–Aldrich — *WAS*), psoriasis, atopic/seborrhoeic dermatitis (*Leiner phenotype*), and **staphylococcal scalded skin syndrome**.

Pathogenesis

- ▶ A massive, generalised inflammatory response produces a **marked increase in germinative keratinocytes and their mitotic rate** with **shortened epidermal transit time**.
- ▶ Consequently scale (rich in nucleic acids, amino acids and soluble protein) is shed in excess — daily loss rises from a normal **0.5–1 g to 20–30 g**, and protein loss may reach **~9 g/m²/day**, causing **hypoalbuminaemia**.
- ▶ Acquired erythroderma shows a **Th2-skewed cytokine milieu** (IL-4, IL-13) with **raised serum IgE**, and up-regulation of endothelial adhesion molecules (VCAM-1, ICAM-1, E-/P-selectin) facilitating inflammatory cell trafficking.

Clinical features

- ▶ **Cutaneous**: Erythema typically *precedes exfoliation by 2–6 days*; scaling often begins in the flexures. The **character of scale offers clues** — *fine* in atopic dermatitis/dermatophytosis, *bran-like* in seborrhoeic dermatitis, *crusted/cornflake* in pemphigus foliaceus, *exfoliative (peeling)* in drug reactions.
- ▶ **Pruritus** in up to **90%** (most severe in dermatitis and Sézary syndrome); **lichenification** in ~one-third.
- ▶ **Appendages**: nail changes in ~40% (shiny nails, ridging, subungual hyperkeratosis, Beau’s lines, paronychia, shedding); **diffuse non-scarring alopecia** in ~20% of chronic cases; **palmoplantar keratoderma** in ~30% (early sign in PRP; painful/fissured in Sézary; scale-crust in crusted scabies).
- ▶ **Ocular**: bilateral **ectropion** with epiphora and purulent conjunctivitis; secondary *Staphylococcus aureus* colonisation/infection is common.
- ▶ **Systemic complications**: peripheral/pedal oedema (~50%, from hypoalbuminaemia and fluid shift), **tachycardia** (~40%) and **high-output cardiac failure** (markedly increased cutaneous blood flow), **thermoregulatory disturbance** (hypo- or hyperthermia, rigors), **hypermetabolism and cachexia**, anaemia (iron deficiency + chronic disease).
- ▶ **Lymphoreticular**: **peripheral lymphadenopathy** in ~50% — distinguish reactive **dermatopathic lymphadenopathy** from lymphomatous involvement; hepatomegaly ~20%, splenomegaly rare (suggests systemic lymphoma).

Diagnostic evaluation

- ▶ **History:** pre-existing dermatosis, full drug history (including herbal/self-medication), atopy, prior cutaneous lymphoma; examine for residual clues (psoriatic plaques, *nappes claires* of PRP, *deck-chair sign* of Ofuji).
- ▶ **Skin biopsy** (the key test) — take **multiple, serial biopsies**; diagnostic yield up to ~50–66%, but findings are **non-specific in at least one-third** of Sézary syndrome/erythrodermic MF, so repeat sampling is essential.
- ▶ **Bloods:** CBC with differential and **peripheral smear for Sézary cells** (cerebriform lymphocytes), **flow cytometry**, **T-cell receptor gene rearrangement (PCR)** in skin/blood, serum IgE, LFTs, serum albumin, electrolytes, eosinophil count.
- ▶ **Lymph node biopsy** (core/excisional preferred over FNAC) if significant lymphadenopathy — guided by CT or PET-CT to the most FDG-avid node; inform the pathologist that the patient is erythrodermic.
- ▶ **Molecular diagnostics** (NGS / **whole-exome sequencing**) are pivotal in neonatal erythroderma to identify ichthyosis/immunodeficiency mutations.

Sézary syndrome — ISCL/EORTC diagnostic criteria	Requirement
Core triad	Erythroderma + generalised lymphadenopathy + clonal circulating atypical (Sézary) T-cells
Mandatory	Erythroderma plus an identical T-cell clone in blood and skin
Plus one of	(1) ≥ 1000 Sézary cells/mm ³ ; (2) CD4:CD8 ratio $\geq 10:1$; (3) $\geq 40\%$ CD4 ⁺ /CD7 ⁻ or $\geq 30\%$ CD4 ⁺ /CD26 ⁻ cells on flow cytometry (B2 blood tumour burden)

Management

Erythroderma is a **skin emergency**; acute/fulminant cases often need **hospital admission**.

- ▶ **General/supportive (regardless of cause):** correct **fluid and electrolyte balance**, nutritional support (high-protein), **maintain body temperature** (warm blankets, emollients to counter hypothermia), monitor and treat **high-output cardiac failure**, and **detect/treat secondary infection** with anti-staphylococcal antibiotics. **Withdraw all non-essential and suspected drugs**.
- ▶ **Topical:** frequent **bland greasy emollients** to restore barrier; **open wet dressings**; low–mid-potency corticosteroids (high-potency reserved for lichenified sites). **Avoid coal tar and phototherapy** (may aggravate); **avoid salicylic/lactic acid in neonates** (enhanced absorption). Sedating oral antihistamines for pruritus.
- ▶ **Systemic corticosteroids:** useful in **idiopathic and drug-induced** erythroderma — prednisone 1–2 mg/kg/day, maintenance ≤ 0.5 mg/kg/day, tapered cautiously (rebound). **Avoid systemic steroids in psoriatic erythroderma** — withdrawal precipitates a **generalised pustular flare**.

- ▶ **Cause-specific:** *Psoriatic erythroderma* — methotrexate, acitretin, ciclosporin or biologics (anti-TNF, anti-IL-12/23, anti-IL-17, anti-IL-23); *PRP* — acitretin/methotrexate; *Idiopathic/refractory* — ciclosporin 5 mg/kg/day reducing to 1–3 mg/kg/day (± azathioprine, MMF, methotrexate); *DRESS* — drug withdrawal ± systemic steroids/IVIg; *CTCL* — specific topical/systemic therapy.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Diagram 1 — “Whole-body map of erythroderma”:** a body silhouette shaded to show >80–90% confluent erythema with scaling, labelled with: *facial oedema / ectropion, leonine facies (CTCL), diffuse alopecia, generalised lymphadenopathy, shiny dystrophic nails, palmoplantar keratoderma, pedal oedema*, and a flexural arrow marking “*island of sparing — nappes claires (PRP)*” and “*deck-chair sign (Ofuji)*”.
- ▶ **Diagram 2 — Aetiology pie/flow:** a wheel of the major causes with approximate frequencies — Dermatitis ~24%, Psoriasis ~20%, Drugs ~19%, CTCL ~8%, Idiopathic ~25%, feeding into a box: “*Multiple skin biopsies + bloods/flow cytometry/TCR + LN biopsy → underlying diagnosis*”.

Clinical / Diagnostic significance

- ▶ Erythroderma is a **medical emergency**: the principal threats are **high-output cardiac failure, hypothermia, fluid/protein/electrolyte loss, dehydration and sepsis** (cutaneous/respiratory infection — **pneumonia is the commonest cause of death**).
- ▶ **CTCL is the commonest malignancy underlying erythroderma**; any persistent “idiopathic” erythroderma in an elderly man warrants **serial biopsies, repeat flow cytometry and TCR studies** to exclude Sézary syndrome.
- ▶ **Always reconcile drug history** — drug-induced disease has the **best prognosis**, usually resolving 2–6 weeks after withdrawal (exception: DRESS/DIHS).
- ▶ Mortality historically quoted at **18–64%**; modern outcomes are better, and **deaths are rare in the absence of CTCL**, but relapse rates reach **20–30% at one year**.

High-yield exam pointers

- ▶ **Definition:** generalised erythema + scaling over ≥80–90% BSA; term coined by *Hebra* (1868); = exfoliative dermatitis.
- ▶ **Commonest causes (adults):** dermatitis, psoriasis, drugs, CTCL; **idiopathic in ~25%** (elderly men = “red man syndrome / l’homme rouge”).
- ▶ **Scale clues:** fine (eczema), bran-like (seborrhoeic), crusted (pemphigus foliaceus), peeling (drugs); **nappes claires** = PRP; **deck-chair sign** = papuloerythroderma of Ofuji.
- ▶ **Systemic effects:** high-output cardiac failure, hypothermia, hypoalbuminaemia (scale protein loss up to ~9 g/m²/day), peripheral oedema, dermatopathic lymphadenopathy.

- ▶ **Sézary syndrome** = erythroderma + lymphadenopathy + clonal blood Sézary cells; *ISCL/EORTC*: ≥ 1000 Sézary cells/mm³, CD4:CD8 $\geq 10:1$, or CD4⁺/CD7⁻ $\geq 40\%$ / CD4⁺/CD26⁻ $\geq 30\%$.
- ▶ **Investigation**: multiple skin biopsies (non-specific in $\geq 1/3$ of Sézary), TCR gene rearrangement, flow cytometry; **NGS in neonates**.
- ▶ **Treatment cardinal rule**: supportive care + stop offending drug; **systemic steroids help idiopathic/drug-induced but are CONTRAINDICATED in psoriatic erythroderma** (pustular rebound) — use MTX/acitretin/ciclosporin/biologics instead.
- ▶ **Neonatal mnemonics**: Netherton (*SPINK5*, bamboo hair), Omenn (*RAG1/RAG2*), epidermolytic ichthyosis (*KRT1/10*), SSSS.

SOURCE & COVERAGE

- ▶ **Bologna Dermatology 5e* — “Erythroderma” (*Chapter 10, Sean Whittaker*)* — primary source for definition, epidemiology, aetiology tables (adult + neonatal), pathogenesis, clinical/systemic features, Sézary *ISCL/EORTC* criteria, and treatment.
- ▶ **Rook’s Textbook of Dermatology 10e* — “Erythroderma” (*in Eczematous Disorders*)* — causes/prevalence, complications, mortality, treatment ladder, Sézary cell thresholds.

- ▶ **CMDT 2026** — “Exfoliative Dermatitis (Exfoliative Erythroderma),” **Dermatologic Disorders** — current diagnostic essentials, frequencies, and management.

Neuroleptic malignant syndrome

Asked in: Paper III Dec 2023 — RGUHS MD General Medicine

Definition / Introduction — Neuroleptic malignant syndrome (NMS) is a rare, potentially fatal, idiosyncratic hyperthermic syndrome caused by dopamine receptor blockade, classically after antipsychotic exposure, or by abrupt withdrawal of dopaminergic therapy in Parkinson disease. It is defined clinically by the tetrad of **hyperthermia, severe generalized rigidity, altered mental status, and autonomic instability**, with laboratory evidence of muscle injury. It is a medical emergency because death results from hyperpyrexia, aspiration pneumonia, rhabdomyolysis with acute kidney injury, hepatic failure, respiratory arrest, or cardiovascular collapse.

Epidemiology and etiopathogenesis

- ▶ **Incidence**: DSM-5-TR database studies suggest **0.01-0.02%** among antipsychotic-treated patients; one Hong Kong population study reported **0.11%**.

- ▶ **Mechanism:** central **hypodopaminergic state** due to dopamine D2 receptor blockade or sudden reduction of dopaminergic stimulation.
- ▶ **Striatum:** dopamine blockade in the corpus striatum causes sustained muscle contraction and **lead-pipe rigidity**, generating heat and rhabdomyolysis.
- ▶ **Hypothalamus:** impaired central thermoregulation causes hyperthermia; spinal/autonomic dopaminergic dysfunction contributes to tachycardia, labile BP, diaphoresis, pallor, and incontinence.
- ▶ **Muscle injury:** sustained contraction causes raised **creatinine kinase (CK)**, myoglobinemia/myoglobinuria, metabolic acidosis, hyperkalemia, and AKI.
- ▶ **Overlap:** NMS is considered by many authors to overlap with malignant catatonia and parkinsonian hyperthermia syndrome, but the drug exposure/withdrawal history is decisive.

Precipitating drugs and risk factors

- ▶ **Dopamine receptor blockers:** all antipsychotics may cause NMS; risk is greater with **high-potency first-generation antipsychotics** such as haloperidol and fluphenazine, especially high dose, rapid titration, or parenteral use.
- ▶ **Atypical antipsychotics:** NMS is reported with olanzapine, risperidone, clozapine, quetiapine, and other SGAs; presentation may be milder or partial, so diagnosis may be delayed.
- ▶ **Nonpsychiatric dopamine blockers:** antiemetics and prokinetics such as **metoclopramide** and **prochlorperazine** can precipitate NMS.
- ▶ **Dopaminergic withdrawal:** abrupt withdrawal of levodopa or dopamine agonists in Parkinson disease can precipitate an NMS-like parkinsonian hyperthermia syndrome.
- ▶ **Patient and illness risks:** dehydration, exhaustion, psychomotor agitation, low serum iron/iron deficiency, affective illness, pre-existing catatonia, neurologic disease, prior NMS, and history of malignant hyperthermia.
- ▶ **Treatment-related risks:** high total antipsychotic dose, rapid escalation, intermittent nonadherence followed by re-exposure, long-acting injectable/depot preparations, and **lithium plus antipsychotic** combination.
- ▶ **Demographic risks:** Kaplan notes higher risk in **men** and younger patients, but DSM emphasizes that NMS can occur in any patient receiving dopamine antagonists, even at therapeutic doses.

Clinical features and diagnostic criteria

- ▶ **Timing:** onset ranges from hours to days after drug initiation or dose increase; some develop within **24 hours**, most within the **first week**, and virtually all within **30 days**. CMDT notes most cases develop within the first **2 weeks** of antipsychotic treatment.
- ▶ **Hyperthermia:** DSM-5-TR describes oral temperature **>100.4 F (>38.0 C)** **on at least two occasions**, often with profuse diaphoresis; extreme temperature supports the diagnosis.

- ▶ **Rigidity:** severe generalized **lead-pipe rigidity**, usually unresponsive to routine antiparkinsonian agents; associated tremor, akinesia, dystonia, trismus, sialorrhea, dysarthria, dysphagia, and rhabdomyolysis may occur.
- ▶ **Mental status:** delirium or altered consciousness is often early; spectrum includes alert but dazed state, mutism, catatonic stupor, stupor, and coma.
- ▶ **Autonomic instability:** tachycardia **>25% above baseline**, tachypnea **>50% above baseline**, diaphoresis, pallor, urinary incontinence, BP elevation **≥25% above baseline**, or BP fluctuation of **≥20 mmHg diastolic** or **≥25 mmHg systolic** within 24 hours.
- ▶ **Respiratory compromise:** chest wall restriction, aspiration pneumonia, pulmonary embolism, hypermetabolism, and metabolic acidosis may cause respiratory distress or sudden respiratory arrest.
- ▶ **Diagnostic frame:** NMS is a **clinical diagnosis of exclusion** in a patient exposed to dopamine blockade or dopaminergic withdrawal, with hyperthermia, rigidity, mental change, autonomic instability, and muscle enzyme elevation.

Investigations and monitoring

Investigation	Expected / useful finding
CBC	Leukocytosis common; Kaplan notes WBC often 10,000-40,000/mm ³
CK serially	Usually >1000 IU/L or ≥4 times upper limit of normal; may be modest/normal early or before rigidity develops
Renal profile	Rising urea/creatinine from rhabdomyolysis, dehydration, or myoglobinuric AKI
Electrolytes, ABG/VBG	Hyperkalemia, metabolic acidosis, hypoxia; guide ICU care
Urinalysis	Myoglobinuria; assess renal complications and exclude urinary infection
LFTs	Transaminase elevation may occur; hepatic failure is a fatal complication
Blood/urine cultures, CXR	Fever workup; do not miss sepsis, aspiration pneumonia, or CNS infection
ECG and hemodynamics	Tachyarrhythmia, QT issues from antipsychotics, BP lability
CSF/neuroimaging/EEG	CSF and imaging generally normal in NMS; EEG may show generalized slowing if encephalopathic

- ▶ **Interpretation pearl:** isolated CK elevation after IM injections, restraint, agitation, or dystonia is not NMS unless accompanied by hyperthermia and rigidity.

- **Monitoring:** chart temperature, pulse, BP, respiratory rate, SpO₂, urine output, hydration status, CK, creatinine, potassium, bicarbonate, and complications at least daily; severe cases need ICU-level monitoring.

Differential diagnosis

Disorder	Clues favouring it over NMS
Serotonin syndrome	Onset within hours of serotonergic drug/MAOI interaction; clonus, hyperreflexia, myoclonus , tremor, GI symptoms; treat with drug withdrawal, benzodiazepine, and cyproheptadine
Malignant hyperthermia	Occurs during/after volatile anesthetic or succinylcholine exposure; severe rigidity and hypercapnia; dantrolene is central therapy
Malignant catatonia	Catatonic prodrome with psychiatric illness before dopamine blocker exposure; may be clinically indistinguishable
Heat stroke / exertional hyperthermia	Environmental heat/exertion, anhidrosis or exertional collapse; antipsychotics may impair heat loss but dopamine-blocker chronology absent
Anticholinergic toxicity	Hot dry skin, mydriasis, ileus, urinary retention, delirium; usually no lead-pipe rigidity or marked CK pattern
CNS infection/autoimmune encephalitis/status epilepticus	Headache, meningism, seizures, focal signs, abnormal CSF/EEG/imaging; always exclude in first presentation
Tetanus, strychnine, thyrotoxicosis, pheochromocytoma	Exposure/history and characteristic spasms or endocrine crisis; not linked to recent dopamine blockade

- **Serotonin syndrome vs NMS:** the exam contrast is **clonus/hyperreflexia/myoclonus** in serotonin syndrome versus **lead-pipe rigidity, hypodopaminergic exposure, and slower days-weeks evolution** in NMS.

Management

- **Immediate actions:** stop the offending antipsychotic/dopamine blocker and avoid all dopamine antagonists; if due to Parkinson drug withdrawal, promptly reinstitute dopaminergic therapy.
- **Site of care:** admit to HDU/ICU for severe hyperthermia, altered consciousness, rigidity, dysphagia, aspiration risk, AKI, metabolic acidosis, arrhythmia, or labile BP.
- **Supportive care:** airway protection, oxygen, aspiration precautions, IV fluids, correction of electrolytes/acidosis, urine output monitoring, prevention/treatment of rhabdomyolysis and AKI, DVT/pressure sore prevention, and nutrition.

- ▶ **Temperature control:** active cooling with cooling blankets, tepid spraying/fanning, ice packs, or more aggressive external cooling for severe hyperthermia; do not rely on antipyretics because NMS is hyperthermia rather than cytokine-mediated fever.
- ▶ **Benzodiazepines:** useful for agitation, rigidity with catatonic features, and when serotonin syndrome cannot be confidently excluded; lorazepam is commonly used.
- ▶ **Dopamine agonists:** **bromocriptine 2.5 mg orally twice or thrice daily**, titrating up to **45 mg/day**, or CMT dose **2.5-10 mg orally three times daily**; watch for hypotension, vomiting, psychosis, and possible worsening of serotonin syndrome if the diagnosis is wrong.
- ▶ **Amantadine:** **100-200 mg orally twice daily** or **200-400 mg/day in divided doses** when bromocriptine is unsuitable or as adjunctive dopaminergic therapy.
- ▶ **Dantrolene:** for severe rigidity/hyperthermia; CMT gives **50 mg IV as needed**, not exceeding **10 mg/kg/day** because of hepatotoxicity; other Kaplan dosing uses IV weight-based regimens up to the same daily ceiling.
- ▶ **Severe hyperthermia with rigidity:** toxicology guidance supports rapid nondepolarizing neuromuscular paralysis, intubation, mechanical ventilation, and sedation when cooling fails or rigidity is extreme.
- ▶ **ECT:** consider for refractory NMS, prominent malignant catatonia, or when psychosis/catatonia needs treatment while antipsychotics are stopped.
- ▶ **Evidence caveat:** no drug is specifically approved for NMS; dantrolene, bromocriptine, amantadine, benzodiazepines, levodopa, and ECT are supported mainly by clinical experience and case-based evidence, so early recognition and supportive care remain the core treatment.

Prevention, rechallenge and prognosis

- ▶ **Prevention:** use the lowest effective antipsychotic dose, avoid rapid escalation, correct dehydration, avoid unnecessary parenteral high-potency agents, monitor early fever/rigidity in catatonic or agitated patients, and avoid abrupt withdrawal of Parkinson medications.
- ▶ **Course after stopping drug:** mean recovery is **7-10 days**; most recover within **1 week** and nearly all within **30 days**, but depot/long-acting injectable exposure can prolong illness.
- ▶ **Mortality:** DSM-5-TR reports **10-20%** fatality when unrecognized; older Kaplan descriptions report **20-30%** in well-developed cases, higher with depot drugs, but mortality falls with early recognition.
- ▶ **Residual sequelae:** weeks of residual neurologic signs, cognitive deficits, renal injury, or complications of prolonged ICU stay may occur.
- ▶ **Rechallenge:** if antipsychotic therapy is essential, wait at least **2 weeks after full clinical resolution**, correct dehydration/iron deficiency and other risks, avoid lithium, choose an alternate lower-risk agent, start low, titrate slowly, and monitor temperature, rigidity, autonomic signs, CK, and renal function.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Pathogenesis flow diagram:** dopamine antagonist / dopaminergic withdrawal -> D2 blockade in striatum, hypothalamus, spinal autonomic pathways -> rigidity + impaired thermoregulation + autonomic instability -> hyperthermia, rhabdomyolysis, AKI, respiratory/cardiovascular collapse.
- ▶ **NMS bedside diagnostic tetrad:** four labelled boxes: hyperthermia; lead-pipe rigidity; altered mental status; autonomic instability; central label: recent dopamine blocker or dopaminergic withdrawal; side labels: high CK, leukocytosis, myoglobinuria.

Clinical / Diagnostic significance

- ▶ Any patient on antipsychotics who develops **fever plus rigidity or altered mental status** should be treated as possible NMS until proven otherwise.
- ▶ NMS may present to medicine, emergency, ICU, neurology, or psychiatry; it is not restricted to psychiatric patients because antiemetics such as metoclopramide and prochlorperazine are common triggers.
- ▶ Early differentiation from serotonin syndrome matters: bromocriptine may worsen serotonin syndrome, whereas cyproheptadine is used for serotonin toxicity.
- ▶ Normal early CK does not exclude NMS; serial examination and CK trend are more useful than one value.
- ▶ In a clozapine patient with fever, tachycardia, and dyspnea, also evaluate for **clozapine myocarditis** with ECG, troponin, and echocardiography where clinically indicated.
- ▶ Do not label every antipsychotic fever as NMS: rule out infection, aspiration pneumonia, heat illness, toxic ingestion, CNS infection/encephalitis, status epilepticus, and endocrine crisis.

High-yield exam pointers

- ▶ Write the tetrad: **hyperthermia + lead-pipe rigidity + altered sensorium + autonomic instability**.
- ▶ Key trigger: recent **dopamine antagonist** exposure or abrupt **dopaminergic withdrawal**.
- ▶ DSM thresholds: temperature **>38 C twice**, CK often **>=4 times ULN**, tachycardia **>25% baseline**, tachypnea **>50% baseline**.
- ▶ Best differentiator from serotonin syndrome: **NMS = rigidity; serotonin syndrome = clonus/hyperreflexia/myoclonus**.
- ▶ Common labs: **CK rise, leukocytosis, metabolic acidosis, low serum iron, myoglobinuria, raised creatinine, raised transaminases**.
- ▶ First treatment step: **stop antipsychotic immediately** and start aggressive supportive care.

- ▶ Drug options: **bromocriptine**, **amantadine**, **dantrolene**, benzodiazepines; ECT for refractory/catatonic cases.
- ▶ Severe cases die from **hyperpyrexia**, **aspiration**, **AKI**, **hepatic failure**, **respiratory arrest**, **cardiovascular collapse**.
- ▶ Rechallenge only after full recovery, preferably after **>=2 weeks**, using low dose, slow titration, alternate agent, and close monitoring.

Obsessive Compulsive Disorder

Asked in: Paper IV Jul 2021 · Paper IV Nov 2020 (2×) — RGUHS MD General Medicine

Definition / Introduction — Obsessive-compulsive disorder (OCD) is a chronic, often disabling neuropsychiatric condition characterised by **obsessions** (recurrent, intrusive, unwanted thoughts, images or urges that cause marked anxiety) and/or **compulsions** (repetitive behaviours or mental acts performed to neutralise that anxiety), which are time-consuming (typically >1 hour per day) or cause clinically significant distress and functional impairment. In DSM-5-TR it heads its own category — *Obsessive-Compulsive and Related Disorders* — separated from the anxiety disorders, and the patient generally recognises the symptoms as excessive or senseless yet feels driven to perform them. Lifetime prevalence is ~2–3% worldwide.

Clinical features — obsessions, compulsions and symptom dimensions

- ▶ **Obsessions** are intrusive and *not pleasurable*: fears of contamination/germs, pathological doubt, aggressive or sexual/blasphemous (taboo) thoughts, and need for symmetry. They are resisted but provoke anxiety or disgust.
- ▶ **Compulsions (rituals)** are repetitive behaviours (handwashing, ordering, checking) or covert mental acts (counting, praying, repeating words) performed rigidly to reduce distress or prevent a dreaded event — yet are *not realistically connected* to it, or are clearly excessive.
- ▶ Four recurring **symptom dimensions** (DSM-5-TR): **cleaning** (contamination/washing); **symmetry** (ordering, counting, repeating); **forbidden/taboo thoughts** (aggressive, sexual,

religious); and **harm** (fear of harm → checking). Most patients have symptoms in more than one dimension.

- **Sensory phenomena** (“just-right”, incompleteness, premonitory urges) precede compulsions in up to 60%.
- Patients commonly **conceal** symptoms out of embarrassment — the physician must ask directly. Physical clues: *chafed, reddened hands* (washing) or *patchy hair loss* (trichotillomania).
- **Insight** varies and defines a specifier — good/fair, poor, or absent/delusional ($\leq 4\%$); poorer insight predicts worse outcome. **Accommodation** (family participating in rituals) maintains symptoms.

Diagnostic criteria (DSM-5-TR) and specifiers

Component	Requirement
A	Presence of obsessions, compulsions, or both (each defined by intrusive nature + neutralising attempt)
B	Time-consuming (>1 h/day) or clinically significant distress/impairment
C	Not attributable to a substance or another medical condition
D	Not better explained by another mental disorder (GAD, BDD, hoarding, trichotillomania, eating disorder, etc.)
Insight specifier	With good/fair insight · With poor insight · With absent insight/delusional beliefs
Tic specifier	“Tic-related” — current or past tic disorder (up to 30% of OCD)

- Severity and treatment response are graded with the ***Yale-Brown Obsessive-Compulsive Scale (Y-BOCS)***, scored out of 40; the children’s version is the CY-BOCS.

Epidemiology, etiology and neurobiology

- **Prevalence:** 12-month prevalence $\sim 1.2\%$ (US); lifetime $\sim 2\text{--}3\%$. **Mean age of onset 19.5 years**, with 25% of cases beginning by age 14; onset after 35 is unusual. Males have earlier (childhood) onset and more tic comorbidity; among adults it is slightly more common in women.
- **Genetics:** Strong familial aggregation — first-degree relative risk $\sim 2\times$ (adult-onset proband) and $\sim 10\times$ for childhood-onset probands; twin concordance 0.57 (MZ) vs 0.22 (DZ); additive genetic effects explain $\sim 40\%$ of variance. No single susceptibility gene is established. Familial co-aggregation with **Tourette’s disorder**.
- **Neuroanatomy:** Dysfunction of the **cortico-striato-thalamo-cortical (CSTC) circuit** — *orbitofrontal cortex, anterior cingulate cortex, caudate nucleus and globus pallidus*. The caudate

mediates habit/skill learning; effective treatment reduces caudate metabolic activity.

Serotonergic dysregulation underpins the selective efficacy of serotonin-reuptake-blocking drugs.

- **Environmental:** Adverse perinatal events, prematurity, maternal smoking, childhood abuse, and post-infectious autoimmune mechanisms (**PANDAS** — Pediatric Autoimmune Neuropsychiatric Disorders Associated with Streptococcal infection) in some abrupt-onset paediatric cases.

Differential diagnosis and comorbidity

- **Differential diagnosis:** generalised anxiety disorder (real-life worries, no rituals); major depressive disorder (mood-congruent ruminations, not linked to compulsions); specific/social phobia; body dysmorphic disorder; trichotillomania and excoriation disorder; hoarding disorder; tics/stereotypies (preceded by premonitory urge, not by an obsession); psychotic disorders (in delusional-insight OCD, obsessions/compulsions persist and other psychotic features are absent); and crucially **obsessive-compulsive personality disorder** (pervasive perfectionism/rigidity *without* true obsessions or compulsions).
- **OCD-spectrum (related) disorders:** body dysmorphic disorder, hoarding, trichotillomania (hair-pulling), excoriation (skin-picking), and tics.
- **Comorbidity (high):** anxiety disorder ~76%, depressive/bipolar disorder ~63% (MDD ~41% — develops in roughly two-thirds over a lifetime), impulse-control disorder ~56%, substance use ~39%, and lifetime tic disorder up to 30%.
- **Suicide risk is significant** — mean lifetime suicidal ideation ~44% and lifetime attempts ~14%; registry data show markedly elevated odds of suicide death and attempt, especially with the taboo-thoughts dimension and comorbid depression.

Treatment / Management

- **General principles:** OCD responds more slowly than depression — an adequate SSRI trial needs **8–12 weeks at higher doses** than for depression. Only **50–60%** improve with pharmacotherapy alone; **combining medication with exposure and response prevention (ERP)** is superior to either alone. Achieved responders need long-term maintenance.

Modality	Agents / technique	Notes
First-line drugs (SSRIs)	Fluoxetine 5–60 (up to 80) mg/d · Fluvoxamine 25–300 mg/d · Paroxetine 40–60 mg/d · Sertraline 50–150 mg/d	FDA-approved for OCD; high-dose, prolonged trials
TCA	Clomipramine 25–250 mg/d	Potent serotonergic TCA; efficacy <i>independent</i> of antidepressant action; anticholinergic/sedative limits use; keep plasma

Modality	Agents / technique	Notes
		clomipramine + metabolite <500 ng/mL
Other (off-label)	Venlafaxine, duloxetine	Efficacious but not FDA-approved
Augmentation (resistant)	Antipsychotic (neuroleptic), buspirone, benzodiazepine; CMTD adds topiramate, memantine, riluzole, N-acetylcysteine, lamotrigine, ondansetron, anti-inflammatories (minocycline, celecoxib)	For partial/non-responders
Psychotherapy	Exposure and response prevention (ERP) — first-line; cognitive-behavioural therapy; acceptance and commitment therapy	Graded exposure + ritual prevention; family psychoeducation/de-accommodation
Neuromodulation	rTMS (high-dose theta-burst) — FDA-approved for treatment-resistant OCD	Non-invasive
Refractory/severe	Deep-brain stimulation (ventral capsule/ventral striatum, VC/VS) — FDA humanitarian device exemption; ablative psychosurgery	<1% of patients qualify; Y-BOCS typically ≥26–30

- Ablative psychosurgery (bilateral, stereotactic) for intractable OCD after exhausting drugs + ERP: **anterior cingulotomy** (target ACC, Brodmann areas 24/32 at the cingulum margin), **anterior/gamma ventral capsulotomy** (anterior limb of the internal capsule), and **subcaudate tractotomy** (substantia innominata) — ~40–60% respond.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- **Cortico-striato-thalamo-cortical (CSTC) loop in OCD.** Draw and label: **Orbitofrontal cortex (OFC)** and **Anterior cingulate cortex (ACC)** → **Striatum (Caudate nucleus)** → **Globus pallidus / Substantia nigra** → **Thalamus** → back to **Cortex**; mark the hyperactive OFC–caudate–thalamus circuit and indicate **SSRI / ERP** reducing caudate metabolic activity, plus **DBS at VC/VS** as the surgical target.
- **Stepwise management ladder.** Boxes: (1) High-dose SSRI + ERP → (2) Switch SSRI / Clomipramine → (3) Augmentation (antipsychotic / others) → (4) rTMS → (5) DBS / ablative surgery; side label “Y-BOCS to monitor severity & response.”

Clinical / Diagnostic significance

- ▶ A general physician must **actively screen** for concealed OCD when faced with unexplained dermatitis of the hands, trichotillomania-related alopecia, or refractory anxiety — early recognition prevents years of disability.
- ▶ **Y-BOCS** quantifies severity, guides escalation, and defines surgical candidacy (≥ 26 –30/40).
- ▶ OCD carries **substantial suicide risk** and heavy psychiatric comorbidity (depression, tics, substance use) — these must be screened and treated concurrently.
- ▶ Distinguishing OCD from **OCPD** and from psychotic rumination changes management entirely; abrupt paediatric onset warrants evaluation for **PANDAS**.

High-yield exam pointers

- ▶ OCD = obsessions $\pm$ compulsions, **>1 h/day**; lifetime prevalence 2–3%; mean onset **~19.5 yr**, 25% by 14.
- ▶ DSM-5-TR places it in **Obsessive-Compulsive and Related Disorders**, not anxiety disorders; specifiers = **insight** (good-fair/poor/absent-delusional) and **tic-related**.
- ▶ Four symptom dimensions: **cleaning, symmetry, forbidden thoughts, harm**.
- ▶ Neurobiology = **CSTC loop** (OFC–ACC–caudate–globus pallidus–thalamus) + **serotonin** dysregulation; co-aggregates with **Tourette's**.
- ▶ **SSRIs first-line** (higher doses, 8–12 week trials); **clomipramine** second-line (keep level <500 ng/mL); only **50–60%** respond to drugs alone.
- ▶ **ERP** is the core psychotherapy; **drug + ERP** beats either alone.
- ▶ Refractory ladder: augmentation $\rightarrow$ **rTMS (FDA-approved)** $\rightarrow$ **DBS (VC/VS, HDE)** / ablative psychosurgery (cingulotomy, capsulotomy).
- ▶ Up to **30%** have a comorbid tic disorder; MDD develops in **~two-thirds**; significant **suicide risk**.

SOURCE & COVERAGE

- ▶ **Harrison's Principles of Internal Medicine, 22e** — “Psychiatric Disorders” (OCD clinical features, neuroanatomy, drug doses, treatment-resistance and neuromodulation).
- ▶ **DSM-5-TR (American Psychiatric Association)** — “Obsessive-Compulsive Disorder” (diagnostic criteria, specifiers, symptom dimensions, epidemiology, course, risk factors, suicide, comorbidity, differential diagnosis).
- ▶ **Kaplan & Sadock's Comprehensive Psychiatry, 2024** — psychiatric neurosurgery for intractable OCD (Y-BOCS thresholds, anterior cingulotomy, anterior/gamma ventral capsulotomy, subcaudate tractotomy, DBS at VC/VS) and PANDAS.
- ▶ **CMDT 2026** — “Psychiatric Disorders” (current pharmacologic/behavioural management, augmentation agents, rTMS, DBS, prognosis).

Coverage note: Harrison 22e covers OCD only briefly; depth here (DSM-5-TR criteria/specifiers, surgical targets, augmentation regimens) is drawn from the dedicated psychiatric texts and CMDT as directed by the grounding hierarchy.

Personality disorders

Asked in: Paper IV 17 Apr 2026 — RGUHS MD General Medicine

Definition / Introduction — Personality disorders (PDs) are **characteristic patterns of thinking, feeling and interpersonal behaviour that are relatively inflexible**, deviate markedly from the expectations of the individual's culture, and cause **significant functional impairment or subjective distress**. The behaviours are not secondary to another mental disorder, substance use or a general medical condition — an important distinction, because *personality change may be the first sign of serious neurologic, endocrine or other medical illness* (e.g., frontal-lobe tumour). PDs occur in **10–20% of the general population and in about half of psychiatric in-/out-patients**, where they constitute the prototypical “difficult patient”.

General diagnostic criteria (DSM-5-TR)

- ▶ **Criterion A** — an *enduring pattern* of inner experience and behaviour deviating markedly from cultural expectations, manifest in **two or more of: cognition, affectivity, interpersonal functioning, impulse control**.
- ▶ **Criterion B** — the pattern is **inflexible and pervasive** across a broad range of personal and social situations.
- ▶ **Criterion C** — leads to **clinically significant distress or impairment** (social, occupational or other functioning).
- ▶ **Criterion D** — **stable and of long duration**; onset traceable at least to **adolescence or early adulthood**.
- ▶ **Criteria E and F** — not better explained by another mental disorder, a substance or another medical condition (e.g., head trauma).
- ▶ **Diagnosis before age 18 years** requires the features to be present for **at least 1 year**; the single exception is **antisocial PD, which cannot be diagnosed below 18 years**.
- ▶ Traits are typically **egosyntonic** (perceived as appropriate by the patient) and **alloplastic** (blame is externalised); avoidant and dependent PD are relatively egodystonic. Collateral information and cultural/gender context are essential.

Classification — DSM-5-TR clusters and dimensional models

Cluster	Disorders	Shared descriptor	Temperament correlate (Cloninger)
A — odd, eccentric, aloof	Paranoid, Schizoid, Schizotypal	Emotional distance, restricted affect, social isolation	Low reward dependence (detachment)
B — dramatic, erratic, impulsive	Antisocial, Borderline, Histrionic, Narcissistic	Impulsive, excessively emotional behaviour	High novelty seeking (impulsivity)
C — anxious, fearful	Avoidant, Dependent, Obsessive-compulsive	Enduring anxiety and fear	High harm avoidance (OCPD: high persistence)

- Cluster boundaries are **overlapping and partly artificial**; many patients meet criteria for more than one PD, and comorbid major mental disorder risk is increased. All PDs share **low self-directedness and low cooperativeness**.
- DSM-5-TR also recognises **personality change due to another medical condition** (labile, disinhibited, aggressive, apathetic, paranoid, combined subtypes) and **other specified / unspecified PD** (mixed, passive-aggressive, depressive presentations).
- Alternative DSM-5 model (Section III) — hybrid dimensional–categorical**: **Criterion A** = moderate or greater impairment on the **Level of Personality Functioning Scale** (self = *identity, self-direction*; interpersonal = *empathy, intimacy*; levels 0–4); **Criterion B** = pathological traits in **five domains — Negative Affectivity, Detachment, Antagonism, Disinhibition, Psychoticism** (25 facets). It retains six disorders (antisocial, avoidant, borderline, narcissistic, obsessive-compulsive, schizotypal) plus **PD–trait specified**.
- ICD-11 (WHO, 2019) — abolishes categorical subtypes**: PD is rated first by **severity (mild / moderate / severe)** based on self and interpersonal dysfunction (with a *late-onset* qualifier when no manifestations exist before age 25), then qualified by **five trait domains — negative affectivity, detachment, dissociality, disinhibition, anankastia — plus a “borderline pattern” specifier**.

Aetiology and pathophysiology

- Genetic contribution**: one study of 106,000 subjects identified **nine loci** significantly linked to aspects of neuroticism (Harrison); genetics explains roughly **half of the variance** in temperament traits.
- Cluster A disorders** aggregate in families of probands with **schizophrenia and delusional disorder** (schizotypal PD shows smooth-pursuit eye-movement abnormalities, a putative schizophrenia-vulnerability marker).

- ▶ **Antisocial PD:** adoption studies show genetic + environmental contributions; **conduct disorder before age 10 plus ADHD**, erratic parenting and neglect increase adult risk; familial co-transmission with substance use and somatisation disorder.
- ▶ **Borderline PD:** a *tripartite model* — **childhood trauma** (physical/sexual abuse, neglect, early parental loss), **vulnerable temperament**, **triggering events**; **five times more common among first-degree relatives of probands**.
- ▶ Antisocial–narcissistic–histrionic form a familial “**spectrum**” of increasing severity (manipulation → exploitation → violent/property crime) driven by impulsive-aggressive traits.

Clinical features of the individual disorders

Disorder	Hallmark (key criteria)	Epidemiology / pearls
Paranoid	Pervasive distrust and suspiciousness — bears grudges, doubts loyalty/fidelity, reads hidden demeaning meanings (≥ 4 features)	0.5–4.4%; more in males; may precede delusional disorder; brief reactive psychosis under stress
Schizoid	Social detachment + restricted affect — “loner”, anhedonia, indifferent to praise or criticism, no desire for relationships (≥ 4)	3.1–4.9%; more in males; solitary work may suit them
Schizotypal	Ideas of reference, magical thinking , unusual perceptions, odd speech/affect, social anxiety that does not diminish with familiarity (≥ 5)	3.9–4.6%; transient psychotic episodes; >50% have lifetime major depression; familial link to schizophrenia
Antisocial	Disregard for/violation of others’ rights since age 15 — deceit, impulsivity, aggression, recklessness, irresponsibility, lack of remorse (≥ 3); requires age ≥ 18 + conduct disorder before 15	3% men, 1% women (3:1); flagrant behaviour “burns out” after age 30; <i>psychopathy</i> variant = low anxiety + bold dominance
Borderline	Instability of affect, self-image and relationships + marked impulsivity — frantic avoidance of abandonment, idealisation–devaluation , identity disturbance, self-damaging impulsivity, recurrent suicidal/self-mutilating behaviour , chronic emptiness, intense anger, stress-related paranoid/dissociative symptoms (≥ 5 of 9)	~2% general, 10% of outpatients, 20% of inpatients; 75% female; defence = splitting ; up to 80% of hospitalised patients attempt suicide; completed suicide up to 5% (CMDT)

Disorder	Hallmark (key criteria)	Epidemiology / pearls
Histrionic	Excessive emotionality and attention seeking — seductiveness, shallow rapidly shifting emotions, suggestibility, impressionistic speech , theatricality (≥ 5)	~2%; suicidal <i>gestures</i> to coerce caregiving; comorbid somatisation/conversion
Narcissistic	Grandiosity, need for admiration, lack of empathy — entitlement, exploitativeness, chronic envy, arrogance (≥ 5)	<1% general, 2–16% clinical; 50–75% male; fragile self-esteem with rage/depression after criticism
Avoidant	Hypersensitivity to negative evaluation, social inhibition, feelings of inadequacy — but craves relationships (vs schizoid) (≥ 4)	0.5–2%; overlaps with generalised social phobia
Dependent	Excessive need to be taken care of — clinging, submissive, cannot decide alone, fears separation, urgently seeks replacement relationships (≥ 5)	0.5–0.6%; predisposed by chronic physical illness, separation anxiety
Obsessive-compulsive (anankastic)	Preoccupation with orderliness, perfectionism and control — rules/lists, workaholism, hypermorality, inability to discard objects, stinginess, rigidity (≥ 4)	2–8%; twice as common in males ; <i>no true obsessions/compulsions</i> (unlike OCD); type-A features

Differential diagnosis and assessment

- ▶ Exclude **another medical condition** (frontal-lobe tumour, temporal-lobe epilepsy, head trauma, hyperthyroidism), **substance use** and episodes of another mental disorder; *new personality change in middle/late life mandates organic work-up*.
- ▶ **Cluster A vs psychotic disorders** — PDs lack sustained delusions/hallucinations; schizophrenia preceded by schizotypal/schizoid traits is coded “premorbid”.
- ▶ **Borderline vs mood disorders** — abandonment fears, identity disturbance, emptiness and idealisation–devaluation favour borderline; bipolar/cyclothymia are episodic.
- ▶ Classic differentials: **avoidant vs social phobia**, **OCPD vs OCD**, **antisocial vs adult antisocial behaviour** (no enduring personality pathology).
- ▶ Patients commonly present with **anxiety, depression or psychotic decompensation when coping fails** (CMDT) — the underlying PD is easily missed.

Management

- ▶ **Hospitalisation** only for serious suicidal or homicidal danger; otherwise day-hospital, halfway-house or therapeutic-community settings (CMDT).
- ▶ **Psychotherapy is the mainstay**, proceeding in stages: crisis management and stabilisation → positive perspective/therapeutic alliance → growth in self-awareness and integration (Kaplan).
- ▶ **Dialectical behaviour therapy (DBT)** — individual + group programme blending **mindfulness with a cognitive-behavioural model**, designed for **chronic suicidality / borderline PD**; efficacy shown in several **randomised trials** (Harrison, CMDT).
- ▶ Other modalities: **mentalization-based treatment**, **transference-focused psychotherapy**, **schema-focused therapy**, psychodynamic, CBT and group therapy; the therapist must manage **negative countertransference** and maintain boundaries.
- ▶ **Pharmacotherapy is adjunctive, symptom-domain-targeted** (evidence limited; use temporarily and taper):

Target symptom domain	First-line drugs	Notes
Mood dysregulation / anxiety	SSRIs/SNRIs; lithium, lamotrigine or valproate for emotional lability; MAOIs for atypical depression/rejection hypersensitivity	TCAs risky in overdose and may worsen atypical depression; avoid long-term benzodiazepines (dependence)
Impulsive (affective) aggression	Lithium (multiple double-blind trials), SSRIs (fluoxetine 20–60 mg/day; sertraline 50–200 mg/day), anticonvulsants — carbamazepine 400–800 mg/day, valproate 500–2000 mg/day, lamotrigine 50–200 mg/day	No effective drug for predatory (planned) aggression ; benzodiazepines disinhibit violence
Social–emotional detachment (cluster A)	Low-dose second-generation antipsychotics ; antidepressants if underlying depression	May reduce social withdrawal in “aloof” PDs
Cognitive–perceptual distortions / brief psychosis	Low-dose atypical antipsychotics (e.g., risperidone 0.5–2 mg/day, olanzapine 2.5–10 mg/day, quetiapine) only for symptom duration	Schizotypal patients often improve with antipsychotics

- ▶ Cluster-wise rule of thumb (Harrison): **cluster A** — antidepressants ± low-dose antipsychotics; **cluster B** — anticonvulsant mood stabilisers and MAOIs for mood reactivity, behavioural dyscontrol and rejection hypersensitivity; **cluster C** — drugs used for anxiety disorders (SSRIs).
- ▶ **Neuromodulation** — growing evidence for **transcranial magnetic stimulation** for borderline mood dysregulation and impulsivity (CMDT 2026).

- ▶ **Prognosis** — borderline and antisocial PD attenuate with age (borderline stabilises in the 4th–5th decades); obsessive-compulsive and schizotypal PD persist; **antisocial and narcissistic PD have a guarded prognosis** (limited engagement in therapy).

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Diagram 1 — DSM-5-TR cluster wheel:** three sectors around a central circle labelled “General criteria: enduring, pervasive, inflexible, early-onset pattern → distress/impairment”. Sector labels: **Cluster A (odd–eccentric): Paranoid, Schizoid, Schizotypal — low reward dependence; Cluster B (dramatic–erratic): Antisocial, Borderline, Histrionic, Narcissistic — high novelty seeking; Cluster C (anxious–fearful): Avoidant, Dependent, Obsessive-compulsive — high harm avoidance.**
- ▶ **Diagram 2 — ICD-11 two-step dimensional model:** horizontal severity arrow labelled *Mild PD* → *Moderate PD* → *Severe PD* (axis caption: “self + interpersonal dysfunction; harm to self/others”); below it five trait-qualifier boxes labelled **Negative affectivity, Detachment, Dissociality, Disinhibition, Anankastia**, plus flags **Borderline-pattern specifier** and “Late onset: no manifestations before age 25”.

Clinical / Diagnostic significance

- ▶ PD patients are demanding, non-adherent and boundary-testing; recognising the pattern prevents counter-therapeutic reactions (firm limits for borderline, non-confrontational clarity for paranoid patients).
- ▶ **Always exclude organic disease** in apparent personality change: frontal-lobe tumour, temporal-lobe epilepsy, head injury, thyroid disease and substance use can all masquerade as PD.
- ▶ **Borderline PD is a medical emergency risk** — recurrent self-harm, overdose risk (avoid TCAs), suicide in up to 5%; document risk assessment and use DBT-based crisis planning.
- ▶ Comorbidity is the rule: depression, anxiety, substance use, eating disorders (bulimia with borderline), somatisation (histrionic) — treat comorbid syndromes actively.
- ▶ PD predicts poorer outcomes of comorbid illness and heavy use of health, welfare and prison resources; OCPD traits correlate with type-A behaviour and myocardial infarction risk.

High-yield exam pointers

- ▶ **Three clusters:** A = odd/eccentric (paranoid, schizoid, schizotypal); B = dramatic/erratic (antisocial, borderline, histrionic, narcissistic); C = anxious/fearful (avoidant, dependent, obsessive-compulsive).
- ▶ General criteria: enduring, pervasive, inflexible pattern from adolescence/early adulthood causing distress/impairment; ≥2 of cognition, affectivity, interpersonal functioning, impulse control.

- ▶ **Antisocial PD:** only PD that cannot be diagnosed <18 years; requires conduct disorder before 15; M:F = 3:1; “burns out” after 30.
- ▶ **Borderline PD:** ≥5 of 9 criteria; splitting; 75% female; suicide up to 5%; **DBT is the best-evidenced treatment.**
- ▶ **Schizotypal vs schizoid:** schizotypal has magical thinking/perceptual distortions; schizoid is merely detached. **Avoidant vs schizoid:** avoidant *wants* relationships but fears rejection.
- ▶ **OCPD ≠ OCD** — no true obsessions/compulsions; egosyntonic; twice as common in males.
- ▶ Pharmacotherapy is symptom-targeted: SSRIs for mood/impulsivity, lithium/anticonvulsants for affective aggression, low-dose atypical antipsychotics for cognitive-perceptual symptoms; **benzodiazepines are generally avoided** (dependence, disinhibition).
- ▶ **ICD-11** has replaced categories with a severity rating (mild/moderate/severe) + five trait qualifiers + borderline-pattern specifier; the **DSM-5** alternative model uses the Level of Personality Functioning Scale + five trait domains.

SOURCE & COVERAGE

Harrison’s Principles of Internal Medicine, 22e — “Psychiatric Disorders” (Personality Disorders section); Kaplan & Sadock’s Comprehensive Textbook of Psychiatry — “Personality Disorders” chapter (Cloninger & Lester) and “The Classification of Mental Disorders in the International Classification of Diseases (ICD-11)”; DSM-5-TR — “Personality Disorders” and “Alternative DSM-5 Model for Personality Disorders”; CMDT 2026 — “Psychiatric Disorders” (Personality Disorders: classification, DBT, pharmacotherapy doses, TMS). *Coverage note:* Harrison 22e itself covers personality disorders only briefly (clusters, genetics, one treatment paragraph); the criteria-level detail, epidemiology and dimensional models above are drawn from Kaplan & Sadock and DSM-5-TR, with current management from CMDT 2026.

Post-traumatic stress disorder

Asked in: Paper IV Nov 2021 — RGUHS MD General Medicine

Definition / Introduction — Post-traumatic stress disorder (PTSD) is a chronic, often recurrent trauma- and stressor-related disorder that develops after exposure to an extreme traumatic event such as the threat of personal death or injury or the death of a loved one. It is characterised by intrusive re-experiencing of the trauma, persistent avoidance of reminders, negative alterations in cognition and mood, and heightened arousal, persisting for more than 1 month and causing significant distress or functional impairment. It lies on a continuum with **acute stress disorder** (a self-limited reaction occurring shortly after the trauma); when the reaction is delayed or recurrent it is termed PTSD.

Between **5 and 10%** of the population will satisfy criteria for PTSD at some point in life, with women affected more often than men.

Etiology, risk factors and epidemiology

- ▶ **Inciting event:** exposure to actual or threatened death, serious injury or sexual violence — directly experienced, witnessed, learned to have happened to a close relative/friend, or through repeated/extreme exposure to aversive details (e.g., first responders, police investigating child abuse).
- ▶ **Lifetime prevalence:** 5–10% of Americans; **women > men**.
- ▶ **Risk factors:** a past psychiatric history; personality traits of **high neuroticism and extroversion**; presence of peritraumatic dissociative symptoms and development of an acute stress disorder at the time of trauma (strongly predict later PTSD).
- ▶ **Genetics:** twin studies show a **substantial genetic influence** on all PTSD symptoms, with comparatively less evidence for an environmental effect.
- ▶ **Comorbidity:** patients are at high risk of other disorders related to **anxiety, mood, and substance abuse** (especially alcohol).

Clinical features

- ▶ **Re-experiencing / intrusion:** the trauma is typically re-experienced through intrusive thoughts, distressing dreams, or **flashbacks**, particularly when cues of the original event are present.
- ▶ **Avoidance:** patients actively avoid stimuli that precipitate recollections of the trauma.
- ▶ **Hyperarousal:** a resulting increase in **vigilance, arousal and exaggerated startle response**.
- ▶ **Emotional numbing / dissociation:** associated **detachment and loss of emotional responsivity**; the patient may feel *depersonalised* and may be unable to recall specific aspects of the trauma.
- ▶ **Temporal pattern:** reaction may be acute (acute stress disorder) or delayed and recurrent (PTSD).
- ▶ **Screening:** a validated four-item screen, the **PC-PTSD** (Primary Care PTSD screen), is available for case-finding in primary care.

DSM-5-TR diagnostic criteria (Table 463-6) — symptom clusters

PTSD is diagnosed using the DSM-5-TR. Criteria A–H must be satisfied (criteria for adults and children >6 years summarised below).

Criterion	Requirement	Representative features
A — Stressor	Exposure to actual/threatened death, serious injury or sexual violence	Direct experience; witnessing in person; learning it occurred to a close relative/friend (violent or accidental); repeated/extreme

Criterion	Requirement	Representative features
		exposure to aversive details (work-related)
B — Intrusion (≥ 1)	Re-experiencing	Intrusive distressing memories; recurrent distressing dreams; dissociative flashbacks ; intense distress at cues; marked physiological reactions to cues
C — Avoidance (one or both)	Persistent avoidance	Avoidance of distressing memories/thoughts/feelings; avoidance of external reminders (people, places, conversations, objects, situations)
D — Negative cognition/mood (≥ 2)	Worsening after trauma	Inability to recall an important aspect (dissociative amnesia); exaggerated negative beliefs about self/others/world; distorted self-blame; persistent negative emotional state (fear, horror, anger, guilt, shame); diminished interest; detachment/estrangement; inability to feel positive emotions
E — Arousal/reactivity (≥ 2)	Worsening after trauma	Irritability/angry outbursts; reckless or self-destructive behaviour; hypervigilance ; exaggerated startle; impaired concentration; sleep disturbance
F — Duration	> 1 month (criteria B, C, D and E)	—
G — Distress	Clinically significant distress or impairment	Social, occupational or other important domains
H — Exclusion	Not due to a substance or another medical condition	—

- Specify “With dissociative symptoms”: persistent/recurrent **depersonalisation** (detachment, as an outside observer of oneself) and/or **derealisation** (unreality of surroundings), not attributable to a substance or condition such as complex partial seizures.
- Specify “With delayed expression”: full criteria not met until ≥ 6 months after the event (some symptoms may begin immediately).
- In children ≤ 6 years, modified criteria apply — intrusion may manifest as **trauma-specific reenactment in play**, dreams may lack recognisable content, and avoidance/negative-mood items are combined into a single cluster.

Pathophysiology

- ▶ It is hypothesised that PTSD involves **excessive release of norepinephrine** from the **locus coeruleus** in response to stress, with **increased noradrenergic activity** at **projection sites** in the **hippocampus and amygdala** — theoretically facilitating the **encoding of fear-based memories**.
- ▶ **Greater sympathetic responses** occur to trauma-associated cues, whereas **pituitary-adrenal responses are blunted**.
- ▶ Beyond fear learning, documented changes include altered **threat detection (insula overactivity)**, executive dysfunction, impaired **emotional regulation**, and disturbed **contextual learning**.
- ▶ Candidate **predictive biomarkers**: increased heart rate and serum lactate, decreased coagulation, insulin resistance, and alterations in glycolysis and fatty-acid uptake.

Treatment / Management

General principles: acute stress reactions are usually self-limited; chronic, recurrent PTSD requires a combined drug-plus-behavioural approach. **Benzodiazepines and SSRIs should NOT be given in the early aftermath of trauma**, and routine **debriefing does not prevent PTSD and may exacerbate symptoms**. Attempts to prevent/ameliorate PTSD in the acute period (escitalopram, hydrocortisone, intranasal oxytocin) have proven **equivocal**.

Modality	Agents / methods	Notes
Acute stress reaction	Short-term benzodiazepines + supportive/expressive psychotherapy	Self-limited; benzodiazepines avoided in early post-trauma period for PTSD prevention
First-line drugs (PTSD)	SSRIs — paroxetine and sertraline (FDA-approved for PTSD)	Reduce anxiety, intrusion and avoidance
Other useful drugs	Venlafaxine , fluoxetine , topiramate	Reduce anxiety, intrusion symptoms and avoidance behaviours
For insomnia	Low-dose trazodone , mirtazapine (sedating antidepressants)	Given at night
Emerging adjuncts	MDMA as adjunct to intensive psychotherapy; stellate ganglion block	MDMA demonstrated efficacy as a psychotherapy adjunct
Psychotherapy (most effective)	Trauma-focused cognitive-behavioural therapy ; eye-movement desensitisation and reprocessing (EMDR) ; prolonged exposure therapy (augmented / virtual reality)	Dismantle avoidance via stepwise focusing on the traumatic experience; help master fear of recurrence

Modality	Agents / methods	Notes
DIAGRAMS TO DRAW — IMAGE SUGGESTIONS		
▶ PTSD symptom-cluster wheel / box diagram — a central box labelled “<i>Traumatic event (Criterion A)</i>” with four radiating clusters labelled: (1) Intrusion / re-experiencing (B) — flashbacks, nightmares, intrusive memories; (2) Avoidance (C) — of thoughts and external reminders; (3) Negative cognition & mood (D) — guilt, detachment, negative beliefs, amnesia; (4) Hyperarousal/reactivity (E) — hypervigilance, startle, irritability, insomnia. Annotate “Duration >1 month (F)”. ▶ Neurobiology schematic — label: <i>Locus coeruleus</i> → <i>excess norepinephrine</i>; <i>Amygdala</i> (<i>fear encoding, ↑</i>); <i>Hippocampus</i> (<i>memory</i>); <i>Insula</i> (<i>threat detection, overactive</i>); <i>Prefrontal cortex</i> (<i>impaired emotional regulation</i>); <i>Blunted HPA / pituitary-adrenal axis</i>.		

Clinical / Diagnostic significance

- ▶ **Recognise referral triggers:** PTSD symptoms, like psychosis, mania, severe depression and suicidal/homicidal preoccupation, warrant psychiatric consultation or transfer of care.
- ▶ **Screen in primary care** using the four-item PC-PTSD, especially after trauma, assault, disaster, combat or serious illness.
- ▶ **Differentiate from acute stress disorder** (same symptoms but earlier onset and self-limited; PTSD requires duration >1 month) and from **adjustment, panic, phobic and depressive disorders**.
- ▶ **Co-manage comorbidities** — alcohol/substance misuse, depression and other anxiety disorders are frequent and worsen prognosis.
- ▶ **Avoid harm:** do not start SSRIs/benzodiazepines in the immediate post-trauma window, and avoid single-session debriefing.
- ▶ **Set expectations:** medication relapse rates are high if used alone — combine pharmacotherapy with trauma-focused psychotherapy for durable response.

High-yield exam pointers

- ▶ PTSD = trauma-related disorder with **four symptom clusters (B–E)** persisting **>1 month**; <1 month with prominent dissociation = acute stress disorder.
- ▶ **Lifetime prevalence 5–10%; women > men**; validated PC-PTSD four-item screen.
- ▶ **Risk factors:** prior psychiatric history, high neuroticism/extroversion, peritraumatic dissociation; **strong genetic (twin-study) contribution**.
- ▶ **Core neurobiology:** ↑ norepinephrine from **locus coeruleus**, ↑ noradrenergic drive to **amygdala & hippocampus** → fear-memory encoding; **blunted HPA axis**; insula overactivity.

- ▶ **FDA-approved drugs:** paroxetine and sertraline (SSRIs). Also venlafaxine, fluoxetine, topiramate.
- ▶ **Most effective psychotherapies:** trauma-focused CBT, EMDR, prolonged exposure therapy.
- ▶ **Pitfalls:** do NOT give benzodiazepines/SSRIs in the early aftermath; **debriefing does not prevent PTSD and may worsen it.**
- ▶ **Specifiers:** *with dissociative symptoms* (depersonalisation/derealisation); *with delayed expression* (criteria met ≥ 6 months later).
- ▶ Emerging adjuncts: **MDMA-assisted psychotherapy** and **stellate ganglion block**; trazodone/mirtazapine for insomnia.

SOURCE & COVERAGE

Harrison's Principles of Internal Medicine, 22e — Ch 463 "Psychiatric Disorders" (Stress Disorders section, Table 463-6 DSM-5-TR criteria, Etiology/Pathophysiology and Treatment of Stress Disorders). Coverage note: the chapter covers PTSD comprehensively for an MD-level answer; DSM-5-TR criteria are reproduced from Table 463-6. The PC-PTSD acronym expansion ("Primary Care PTSD screen") and the standard cluster-count phrasing are universally accepted additions; all drug names, doses-where-stated, FDA approvals, and neurobiological mechanisms are faithful to the source text.

Psoriasis and its complications

Asked in: Paper IV Jun 2024 — RGUHS MD General Medicine

Definition / Introduction — Psoriasis is a common, chronic, immune-mediated, genetically determined inflammatory skin disease characterised by sharply demarcated, erythematous plaques surmounted by silvery (*micaceous*) scale, affecting up to ~2% of the world population. It is best understood as a **systemic inflammatory disorder**: the IL-23/IL-17 (Th17) axis drives keratinocyte hyperproliferation in skin while the same inflammation underpins articular, metabolic and cardiovascular *complications* — most importantly **psoriatic arthritis (PsA)** and **metabolic syndrome**. There is a fundamental division into **plaque (non-pustular)** and **pustular** forms.

Epidemiology, aetiopathogenesis and genetics

- ▶ **Bimodal onset (Type I / Type II):** Type I — early onset (peak 16–22 yr), strong family history, **HLA-C*06:02*-associated, more severe*; Type II — late onset (peak 57–62 yr), *sporadic, HLA-C*06:02-unrelated*, generally milder.
- ▶ **Genetics:** lifetime risk 4% / 28% / 65% with neither / one / both parents affected; monozygotic twin concordance gives heritability ~60–90%. Polygenic/multifactorial with >65 susceptibility loci.

- **PSORS1** (chromosome 6p, MHC class I) — the major determinant; consensus risk allele *HLA-C*06:02**.
- **PSORS2 = CARD14** — gain-of-function mutations enhance NF-κB signalling in keratinocytes.
- **IL36RN** loss-of-function (deficiency of IL-36 receptor antagonist) and **AP1S3** — drive **generalised pustular psoriasis**.
- ▶ **Pathogenesis:** plasmacytoid dendritic cells/neutrophils release **NETs** and the cathelicidin peptide **LL37**, which (with self-DNA) triggers IFN-α; myeloid dendritic cells secrete **IL-12 (→Th1)** and **IL-23 (→Th17)**; **IL-17A/IL-17F**, **TNF-α**, **IL-22** drive keratinocyte hyperproliferation and self-amplifying loops via **JAK-STAT** and **NF-κB** — the rationale for all modern targeted therapy.
- ▶ **Triggers / exacerbating factors:** streptococcal pharyngitis (guttate), HIV, **Koebner (isomorphic) phenomenon** (cutaneous trauma, *Heinrich Köbner 1877*), drugs (**lithium**, antimalarials, beta-blockers, **TNF-α inhibitors** [paradoxical], **interferon-α**, **NSAIDs**, **ACE inhibitors**), withdrawal of systemic/potent topical corticosteroids, smoking, alcohol, obesity, psychological stress.

Clinical variants and diagnostic signs

Variant	Key features
Chronic plaque (vulgaris)	Commonest (~80–90%); symmetric well-demarcated plaques on elbows, knees, scalp, sacrum, extensors
Guttate (eruptive)	Shower of 2–10 mm “drop-like” papules in children/young adults, ~2 weeks after group A streptococcal pharyngitis
Inverse (flexural)	Glazed, scale-poor plaques in axillae, groin, submammary, natal cleft, umbilicus; obesity-associated
Erythrodermic	>90% body surface; <i>complication</i> — skin failure (see below)
Pustular	Localised palmoplantar pustulosis, or generalised (von Zumbusch)
Nail	Pitting (~1 mm), subungual “ oil-drop ”/ salmon patch (highly specific), subungual hyperkeratosis, splinter haemorrhages, distal onycholysis
Scalp / seborrheic dermatitis	Often first site; pityriasis amiantacea

- ▶ **Diagnostic signs:** *Auspitz sign* (pinpoint bleeding on scale removal from thin suprapapillary epidermis), *ring/halo of Woronoff* (pale rim around resolving plaque), *Koebner phenomenon*; geographic & fissured tongue associations.

Histopathology

- ▶ **Confluent parakeratosis** with focal orthokeratosis and near-absence of the granular layer.
- ▶ **Regular epidermal hyperplasia** with elongated, clubbed/fused rete ridges and **suprapapillary thinning**.
- ▶ **Munro microabscesses** — neutrophils in the (para)keratotic stratum corneum.
- ▶ **Spongiform pustule of Kogoj** — neutrophils within the stratum spinosum (prominent in pustular forms).
- ▶ Dilated, tortuous papillary capillaries (correlate of the Auspitz sign).

Complications and co-morbidities

Psoriasis (especially severe disease) carries excess morbidity and mortality across most organ systems; **severe disease shortens life expectancy by ~4–6 years**, chiefly from cardiovascular death.

A. Psoriatic arthritis (PsA) — the principal articular complication, a **seronegative spondyloarthritis** occurring in up to ~30–40% of patients; skin precedes joints in ~70%. **Five patterns (Moll & Wright)**: asymmetric mono-/oligoarthritis (classically regarded as commonest), symmetric “rheumatoid-like” polyarthritis (~50% in Harrison), **distal interphalangeal-predominant** (distinguishes from RA), **arthritis mutilans** (rare, deforming “telescoping” digits), and **axial disease/spondylitis** (HLA-B27-linked). Hallmarks: **dactylitis** (“sausage digit”), **enthesitis** (Achilles, plantar fascia), nail disease (~80%). Diagnosis by **CASPAR criteria** (≥ 3 points; sensitivity 99%, specificity 91%):

CASPAR category	Points
Current psoriasis (2) / personal history (1) / family history 1st–2nd degree relative (1)	2 / 1 / 1
Typical psoriatic nail involvement	1
Negative rheumatoid factor	1
Current or past dactylitis	1
Radiographic juxta-articular new bone formation (hands/feet)	1

B. Acute dermatological emergencies (skin failure):

- ▶ **Erythrodermic psoriasis** (1–2% of patients; underlies ~25% of all erythroderma) — sepsis, hypothermia/hyperthermia, hypoalbuminaemia, anaemia, dehydration, high-output cardiac failure.
- ▶ **Generalised pustular psoriasis (von Zumbusch)** — fever, sheets of sterile pustules (“lakes of pus”), leucocytosis; complications: **acute kidney injury**, hypoalbuminaemia with hypocalcaemia, neutrophilic cholangitis / cholestatic jaundice, ARDS (aseptic pneumonitis),

telogen effluvium, amyloidosis; mortality 2–16%. GPP confined to pregnancy = **impetigo herpetiformis** (last trimester; placental insufficiency, stillbirth).

C. Systemic co-morbidities (Box 35.2):

- ▶ **Metabolic syndrome** (prevalence ~34% vs 26%) — obesity (strongest, often predates psoriasis), hypertension, hyperlipidaemia, type 2 diabetes.
- ▶ **Cardiovascular disease** — myocardial infarction, stroke, peripheral vascular disease, atrial fibrillation, venous thromboembolism (risk greatest in young, severe disease/PsA).
- ▶ **Other immune-mediated disease** — Crohn's disease, ulcerative colitis, coeliac disease, **uveitis**.
- ▶ **Hepatobiliary** — **non-alcoholic fatty liver disease (up to 50%)**, alcoholic liver disease.
- ▶ **Malignancy** — non-melanoma skin cancer (esp. post-PUVA), Hodgkin lymphoma.
- ▶ **Psychiatric** — depression, anxiety, increased suicidality; alcohol misuse.
- ▶ **Miscellaneous** — hyperuricaemia/gout, secondary (AA) amyloidosis, IgA nephropathy (rare).

Management

- ▶ **Assess severity** with the **PASI (Psoriasis Area and Severity Index, 0–72)** grading erythema, scaling and induration over four regions, $\pm$ **BSA** and **DLQI**; “candidate for systemic therapy” $\approx$ **BSA $\geq 10\%$** , high-impact sites, or topical failure. Screen at every visit for **PsA, metabolic syndrome and depression**.
- ▶ **Topical (limited disease)**: mid-/high-potency corticosteroids; **vitamin D analogues** (calcipotriene 0.005% [max 100 g/wk], calcitriol 0.003% [max 200 g/wk] — hypercalcaemia risk); tazarotene; coal tar, salicylic acid, dithranol; **calcineurin inhibitors** (tacrolimus/pimecrolimus) for face/flexures; newer **roflumilast (PDE-4)** and **tapinarof (AhR agonist)** creams.
- ▶ **Phototherapy (moderate/widespread)**: **narrowband UVB** (first-line, 3 $\times$ /week) and **PUVA**; avoid with ciclosporin and in the immunosuppressed (skin-cancer risk).
- ▶ **Conventional systemics**: **methotrexate** (≤ 25 mg weekly + folic acid 1–2 mg/day; cumulative 3.5–4 g $\rightarrow$ hepatology); **acitretin** (0.5–0.75 mg/kg/day; teratogen — avoid pregnancy 3 yr; best for pustular); **ciclosporin** (≤ 5 mg/kg/day; rebound on stopping); **apremilast (PDE-4)**; **deucravacitinib (oral TYK2 inhibitor)**.
- ▶ **Biologics**: anti-TNF- α (etanercept, adalimumab, infliximab, certolizumab, golimumab); **anti-IL-12/23 ustekinumab**; **anti-IL-23p19** (guselkumab, risankizumab, tildrakizumab); **anti-IL-17** (secukinumab, ixekizumab, brodalumab, bimekizumab); **anti-IL-36R spesolimab** for GPP. Screen for TB, HIV, hepatitis B/C before starting; TNF inhibitors with caution in CHF.
- ▶ **Avoid systemic (oral) corticosteroids** — withdrawal precipitates life-threatening pustular/erythrodermic flares. Weight loss improves both disease and response.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Labelled cross-section of a psoriatic plaque (histology):** label *parakeratosis*, *Munro microabscess* (*neutrophils in stratum corneum*), *Kogoj spongiform pustule* (*stratum spinosum*), *absent/diminished granular layer*, *acanthosis with elongated regular rete ridges*, *suprapapillary thinning*, *dilated tortuous papillary capillary*, *dermal lymphocytic infiltrate*.
- ▶ **IL-23/IL-17 immunopathogenesis schematic:** label *plasmacytoid DC* → *IFN- α* , *myeloid DC* → *IL-12 (Th1)* and *IL-23 (Th17)*, *Th17* → *IL-17A/IL-17F*, *IL-22*, *TNF- α* , *keratinocyte hyperproliferation* — with arrows showing biologic drug targets (*anti-TNF*, *anti-IL-12/23*, *anti-IL-23*, *anti-IL-17*, *TYK2/JAK*).

Clinical / Diagnostic significance

- ▶ Diagnosis is **clinical**; biopsy reserved for atypical cases. No constant laboratory abnormality; **hs-CRP/ESR** rise in PsA and GPP. KOH/fungal culture distinguishes nail/flexural psoriasis from onychomycosis and candidiasis.
- ▶ **Differential diagnosis:** seborrheic dermatitis, eczema, lichen planus, pityriasis rosea, pityriasis rubra pilaris, secondary syphilis, mycosis fungoides, tinea, discoid lupus; severe/atypical/treatment-resistant psoriasis should prompt **HIV testing**.
- ▶ Recognise **erythrodermic and von Zumbusch GPP as emergencies** needing fluid/electrolyte support, temperature control and rapid systemic therapy (infliximab for severe flares; spesolimab for GPP).
- ▶ Treat psoriasis as a **systemic disease** — proactively screen and manage cardiometabolic risk, PsA (early referral prevents irreversible joint destruction) and mood disorder.

High-yield exam pointers

- ▶ **IL-23/IL-17 (Th17) axis** is central; **HLA-C*06:02 / PSORS1* is the **major genetic determinant**; *CARD14* and *IL36RN*** drive familial/pustular disease.
- ▶ **Auspitz sign**, **Woronoff ring**, **Koebner phenomenon** — classic triad of signs; nail “**oil-drop**” sign is highly specific.
- ▶ Histology: **Munro microabscess** (stratum corneum) vs **Kogoj spongiform pustule** (stratum spinosum); parakeratosis + suprapapillary thinning.
- ▶ **Guttate** follows streptococcal pharyngitis; **inverse** is scale-poor and flexural; **von Zumbusch** is febrile generalised pustular psoriasis.
- ▶ **PsA** = seronegative spondyloarthritis; **5 Moll & Wright patterns**; diagnose by **CASPAR** (≥ 3 points); DIP involvement, dactylitis and enthesitis distinguish from RA.
- ▶ **Complications:** PsA, metabolic syndrome, MI/stroke, NAFLD, lymphoma/NMSC, depression, amyloidosis; severe disease shortens life by ~4–6 years.

- ▶ **Never give systemic steroids** (rebound pustular psoriasis); first-line widespread therapy = **NB-UVB**; **methotrexate** is the workhorse systemic, especially with PsA.
- ▶ Screen for **TB/HIV/hepatitis B & C** before biologics; **TNF inhibitors** can paradoxically induce psoriasis and worsen CHF.

SOURCE & COVERAGE

- ▶ **Harrison's Principles of Internal Medicine, 22e** — “Eczema, Psoriasis, Cutaneous Infections, Acne, and Other Common Skin Disorders” (clinical types, FDA-approved systemic and biologic therapy tables, PsA subtypes).
- ▶ **Rook's Textbook of Dermatology, 10e** — “Psoriasis and Related Disorders” (epidemiology, Type I/II, genetics PSORS1/HLA-C*06:02/CARD14/IL36RN, IL-23/IL-17 pathogenesis, histopathology, clinical variants, PASI, Box 35.2 co-morbidities, von Zumbusch GPP, impetigo herpetiformis, PsA with Moll & Wright and CASPAR criteria).
- ▶ **CMDT 2026** — “Dermatologic Disorders: Psoriasis” (current management, drug doses: calcipotriene/calcitriol ceilings, methotrexate, acitretin, etanercept, deucravacitinib, spesolimab).

Psoriasis cutaneous and extra cutaneous manifestations

Asked in: Paper IV Nov 2022 — RGUHS MD General Medicine

Definition / Introduction — Psoriasis is one of the commonest dermatologic diseases, affecting up to **2% of the world's population**. It is a chronic, **immune-mediated** disorder clinically characterised by **erythematous, sharply demarcated papules and rounded plaques covered by silvery micaceous scale**, which are variably pruritic. It is now best regarded as a **systemic “psoriatic disease”**: beyond the skin and nails it carries musculoskeletal (psoriatic arthritis), ocular, gastrointestinal, cardiometabolic and psychiatric burden. Skin lesions contain infiltrates of **activated T cells** that elaborate cytokines driving **keratinocyte hyperproliferation**, with a strong genetic predisposition (positive family history in **30–50%**).

Pathogenesis (in brief)

- ▶ T-cell-mediated disorder; activated T cells release proinflammatory cytokines → keratinocyte hyperproliferation → characteristic plaques and scale.
- ▶ The **IL-23/IL-17 axis** is central — explaining why agents targeting IL-23, IL-12/23, IL-17 and TNF-α are highly effective.
- ▶ **Strong genetic component**: 30–50% report a positive family history; the spondyloarthritis literature links psoriatic disease to ***HLA-B27*** (positive in ~20% of all PsA and ~50% of axial PsA).

- ▶ **Koebner (isomorphic) phenomenon** — traumatised skin develops new lesions.
- ▶ **Exacerbating factors:** infections (streptococcal), psychological stress, and drugs — **lithium, beta blockers, antimalarials**; systemic glucocorticoid withdrawal can precipitate pustular flares.

Cutaneous manifestations — morphology

- ▶ **Primary lesion:** sharply demarcated, erythematous plaque with a loosely adherent **silvery (micaceous) scale**; predominantly over **extensor surfaces** — **elbows, knees, gluteal cleft and scalp**, with a tendency to **symmetry**.
- ▶ Course is typically **indolent and chronic**; plaque psoriasis develops slowly and **rarely remits spontaneously**.
- ▶ **Auspitz sign** (pinpoint bleeding on removal of scale, reflecting dermal vascular proliferation) and **Munro microabscesses** on histology are classic features (standard textbook; see Coverage note).
- ▶ **Histology** (Table 60-2): **acanthosis with dermal vascular proliferation**.

Clinical variants of cutaneous psoriasis

Variant	Typical patient / trigger	Distinguishing features
Plaque-type (psoriasis vulgaris)	Commonest variety; adults	Stable, slowly enlarging plaques; elbows, knees, gluteal cleft, scalp; symmetric; indolent
Inverse (flexural) psoriasis	Intertriginous skin	Affects axillae, groin, submammary region, navel ; also scalp, palms, soles; sharply demarcated plaques that may be moist and without scale due to location
Guttate (eruptive) psoriasis	Children and young adults; often after URTI with β -hemolytic streptococci	Acute onset of many small erythematous, scaling papules ; DDX — pityriasis rosea, secondary syphilis
Pustular psoriasis	Localised (palms/soles) or generalised; triggers — local irritants, pregnancy, drugs, infection, systemic glucocorticoid withdrawal	Erythema studded with sterile pustules ; generalised form has fever (39–40°C) for several days , recurrent episodes; may become erythrodermic . Oral retinoids are treatment of choice (non-pregnant). Localised form mimics dyshidrotic eczema

Nail involvement

- ▶ **Fingernail involvement** may be the only clue when the skin presentation is atypical.

- ▶ **Nail matrix disease:** pitting (punctate), leukonychia, crumbling, and red spots in the lunula.
- ▶ **Nail bed disease:** onycholysis, subungual hyperkeratosis, oil-drop (salmon patch) change, and splinter haemorrhages; nail thickening.
- ▶ Nail disease is intimately linked to **DIP-joint** psoriatic arthritis (the nail bed is closely related to the DIP joint).
- ▶ Frequency: ~40% of psoriasis patients *without* arthritis have nail lesions, rising to ~90% in those with PsA — i.e., nail change is a strong marker of arthritis.

Extra-cutaneous manifestations

1. Psoriatic arthritis (PsA) — the major extra-cutaneous manifestation

- ▶ Affects **up to 30%** of psoriasis patients (range 6–42%); incidence ~3 per 100 patient-years, rising with severity of skin disease; onset usually 30–50 years.
- ▶ **Moll & Wright (1973)** definition: inflammatory arthritis (peripheral and/or sacroiliitis/spondylitis) **with cutaneous psoriasis** and **absence of RF**; described **five phenotypes** (below); enthesitis and dactylitis added later.
- ▶ Temporal pattern: **psoriasis precedes arthritis** in ~80%, simultaneous in ~10%, and **arthritis precedes skin disease** in ~10% (“psoriatic arthritis sine psoriasis”).
- ▶ Cardinal musculoskeletal features: **peripheral arthritis** (early oligoarticular/asymmetric → later polyarticular/symmetric), **DIP-joint involvement** (typical, linked to nail disease), **axial arthritis/spondylitis** (5% early, ~50% after 20 years), **dactylitis** (“sausage digit” — inflammatory swelling of an entire digit; marker of severity), **enthesitis** (commonest at plantar fascia and Achilles insertion on calcaneum), and **tenosynovitis**.

2. **Ocular** — **uveitis** in ~5% (commonly **unilateral acute anterior uveitis**; posterior/bilateral also reported); conjunctivitis rare.

3. **Gastrointestinal** — **inflammatory bowel disease** (Crohn’s disease, rarely ulcerative colitis) may coexist; mucous-membrane inflammation with painful mouth ulcers, rarely urethritis.

4. **Cardiometabolic / systemic** — increased risk of **metabolic syndrome** with raised cardiovascular morbidity and mortality. Patients with psoriasis + PsA have CV risk as **high as in diabetes mellitus**, independent of conventional risk factors, with more severe subclinical atherosclerosis; higher prevalence of **hypertension, type 2 diabetes, obesity, fatty liver, angina and MI**. Obesity worsens disease activity and treatment response. Malignancy is **not** increased.

5. **Psychiatric** — increased rates of **depression and suicidality**.

Psoriatic arthritis — phenotypes, criteria & imaging

Five clinical phenotypes (Moll & Wright)	Notes
Symmetric polyarticular (~50%)	Resembles rheumatoid arthritis

Five clinical phenotypes (Moll & Wright)	Notes
Asymmetric oligoarticular (~35%)	Any joint; “sausage digits”; early-stage pattern
Distal (DIP) arthritis (~5%)	Classic form; dystrophic nails, pitting
Spondylitis (axial) (~5%)	Inflammatory back/neck pain; sacroiliitis often unilateral
Arthritis mutilans (<5%)	Severe, deforming; small joints of hands/feet; end-stage with osteolysis

- ▶ **CASPAR criteria** (Table 374-6): in a patient with **inflammatory articular disease** (joint, spine or enthesal), need **≥3 points** from — current psoriasis (2) / personal or family history of psoriasis (1), typical **nail dystrophy** (1), **RF negative** (1), **dactylitis** (1), **juxta-articular new bone formation** on X-ray (1). **Specificity 98.7%, sensitivity 91.4%.**
- ▶ **Radiology:** marginal erosions with adjacent “fluffy” new bone formation (characteristic), “pencil-in-cup” deformity, bony ankylosis in a “ray” distribution, **acro-osteolysis**; **chunky nonmarginal syndesmophytes** and (usually unilateral) sacroiliitis. MRI/ultrasound detect synovitis, enthesitis and erosions earlier than X-ray.
- ▶ **Labs:** ESR/CRP raised in ~50%; **RF negative** (low-titre RF or anti-CCP in <10%); **HLA-B27** positive in ~20% (≈50% of axial PsA).

Management (overview)

- ▶ **Cutaneous, localised:** skin hydration; **mid-potency topical glucocorticoids** (limited by tachyphylaxis and atrophy); **vitamin D analogue** (calcipotriene) and **retinoid** (tazarotene) — have largely replaced coal tar, salicylic acid and anthralin.
- ▶ **Phototherapy** for widespread disease: **UV-B, narrowband UV-B, and PUVA** (UV-A + psoralens); mutagenic (skin-cancer risk); **contraindicated with cyclosporine** and in the immunocompromised.
- ▶ **Systemic agents** (Table 60-3): **methotrexate** (weekly; especially with PsA), **acitretin** (teratogenic), **cyclosporine**, **apremilast** (PDE-4 inhibitor; for psoriasis and PsA), **deucravacitinib** (TYK2 inhibitor — blocks IL-23/IL-12/type-1-IFN; plaque psoriasis). **Oral glucocorticoids must NOT be used** — withdrawal can trigger **life-threatening generalised pustular psoriasis**.
- ▶ **Biologics** (Table 60-4): **Anti-TNF-α** (etanercept, adalimumab, certolizumab, infliximab, golimumab); **Anti-IL-12/23** (ustekinumab); **Anti-IL-23** (risankizumab, tildrakizumab, guselkumab); **Anti-IL-17** (secukinumab, ixekizumab, brodalumab). Screen for **TB, HIV, hepatitis B/C** before starting; TNF-α inhibitors may worsen **CHF** and cause **paradoxical psoriasiform lesions**.
- ▶ **PsA-specific** (Table 374-7): “**treat-to-target**” (minimal disease activity/remission); **NSAIDs** short-term; **local glucocorticoid injections** (avoid weight-bearing lower-limb entheses — rupture risk); **avoid systemic steroids**; **csDMARDs** (methotrexate preferred if relevant skin disease,

sulfasalazine, leflunomide); **bDMARDs** (TNF/IL-12-23/IL-17/IL-23 inhibitors), **PDE-4/TYK2 inhibitors**; **JAKi after TNFi failure** (CV black-box warning). For predominant **skin + joint** disease prefer IL-12/23, IL-17 or IL-23 inhibitors over TNF; **avoid IL-17i in active IBD**; prefer **TNF mAbs** for uveitis.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Labelled cutaneous psoriasis plaque (cross-section/surface)** — labels: *silvery micaceous scale, sharply demarcated erythematous plaque, Auspitz sign (pinpoint bleeding), Koebner phenomenon at trauma site, extensor distribution (elbows, knees, scalp, gluteal cleft).*
- ▶ **Psoriatic nail + DIP joint schematic** — labels: *nail pitting, onycholysis, oil-drop sign, subungual hyperkeratosis, splinter haemorrhage, DIP arthritis, dactylitis (“sausage digit”), “pencil-in-cup” deformity.*

Clinical / Diagnostic significance

- ▶ Recognise the **clinical variants** — guttate (post-streptococcal, young), inverse (flexural), pustular (febrile, can be erythrodermic) — as each alters prognosis and therapy.
- ▶ **Nail disease and dactylitis** are red flags for psoriatic arthritis; examine **hidden sites** (scalp, umbilicus, natal cleft, nails) when arthritis precedes obvious skin disease.
- ▶ **Screen every patient** for cardiometabolic risk (BP, lipids, glucose, weight), IBD, uveitis and **depression/suicidality** — psoriasis is a systemic disease.
- ▶ Biopsy (acanthosis, dermal vascular proliferation, Munro microabscesses) helps when the presentation is atypical; **CASPAR criteria** confirm PsA.
- ▶ A **multidisciplinary team** (dermatology, rheumatology, ophthalmology, gastroenterology, psychiatry, cardiology) optimises outcomes.

High-yield exam pointers

- ▶ Prevalence ~2%; **immune-mediated**, T-cell driven via the **IL-23/IL-17 axis**; family history in 30–50%.
- ▶ **Koebner phenomenon**; drug triggers — **lithium, beta blockers, antimalarials**; never use systemic steroids (rebound **pustular flare**).
- ▶ **Auspitz sign, silvery micaceous scale, extensor/scalp distribution**; **Munro microabscess** on histology.
- ▶ Variants: **plaque (commonest)**, guttate (post-streptococcal), inverse, pustular/erythrodermic.
- ▶ **PsA in up to 30%**; five Moll–Wright phenotypes; **psoriasis precedes arthritis in ~80%**; nail change in ~90% of PsA.
- ▶ **CASPAR criteria** (≥ 3 points; specificity 98.7%); radiology — “**pencil-in-cup**”, fluffy new bone, **acro-osteolysis**, asymmetric (often unilateral) sacroiliitis.

- ▶ Extra-cutaneous: **anterior uveitis**, **IBD**, **metabolic syndrome**, **CV disease** (risk like diabetes), **depression**.
- ▶ Therapeutic ladder — topical steroids/calcipotriene/tazarotene → phototherapy (NB-UVB/PUVA) → MTX/acitretin/cyclosporine/apremilast/deucravacitinib → **biologics** (TNF, IL-12/23, IL-17, IL-23 inhibitors).

SOURCE & COVERAGE

Harrison's Principles of Internal Medicine, 22e — **Ch 60 “Eczema, Psoriasis, Cutaneous Infections, Acne, and Other Common Skin Disorders”** (cutaneous variants, nail disease, treatment) and **Ch 374 “Spondyloarthritis”** (psoriatic arthritis, extra-cutaneous/systemic manifestations, CASPAR criteria, PsA management).

Coverage note: **Auspitz sign** and **Munro microabscess** are not stated verbatim in the provided chapters but are included as universally-accepted standard dermatology; histology in Table 60-2 explicitly supports **acanthosis with dermal vascular proliferation**. The pithy ranges for PsA phenotype proportions and subtype names are drawn from Ch 60 (symmetric ~50%, asymmetric ~35%, distal ~5%, spondylitis ~5%, arthritis mutilans <5%); Ch 374 frames the same as the five Moll–Wright phenotypes. All drug names, criteria, and numerical figures are taken directly from the two chapters.

Schizophrenia

Asked in: Paper IV Jun 2024 · Paper IV Dec 2023 (2×) — RGUHS MD General Medicine

Definition / Introduction — Schizophrenia is a chronic, heterogeneous psychotic syndrome characterised by perturbations of perception, thinking, language, affect, social activity and volition, in which the patient progressively loses contact with reality. There is **no pathognomonic feature and no confirmatory laboratory test**; diagnosis is clinical and one of exclusion. It typically begins in late adolescence/early adulthood, has an insidious (less often acute) onset and a frequently poor outcome, and is best conceptualised as a **neurodevelopmental disorder** of multifactorial (genetic, environmental and neurotransmitter) origin. Lifetime prevalence is ~0.3–1.5% (Harrison quotes 0.85% worldwide; CMDT ~1%), and ~10% of patients die by suicide.

Epidemiology and risk factors

- ▶ **Prevalence:** ~0.85% worldwide; lifetime ~1–1.5% (Harrison). DSM-5-TR lifetime estimate 0.3–0.7%. ~300,000 acute episodes/year in the USA.
- ▶ **Age/sex at onset:** late teens to mid-30s; peak in early–mid 20s in **men** (~18 yr) and late 20s in **women** (~25 yr), with a second mid-life peak in women. Onset before adolescence is rare.

- ▶ **Genetic susceptibility** (strongest risk factor): present in ~6.6% of first-degree relatives; risk ~40% if both parents affected; monozygotic twin concordance 50% vs 10% for dizygotic. Sibling of a proband → ~10-fold risk. Most affected individuals nonetheless have no family history.
- ▶ **Environmental/developmental**: early developmental insults, winter/early-spring birth, advancing paternal age, obstetric complications with hypoxia, prenatal infection/malnutrition/maternal diabetes, urban upbringing, migration/refugee status, childhood trauma and social adversity.

Clinical features

- ▶ **Positive symptoms** (added experiences) — *delusions* (often persecutory/somatic), *auditory hallucinations* (characteristically third-person/derogatory; visual hallucinations suggest an organic state), *conceptual disorganisation*, *disorganised (formal thought-disordered) speech* with derailment, neologisms, echolalia and verbigeration, and *grossly disorganised or catatonic behaviour*.
- ▶ **Negative symptoms** (lost function) — *affective flattening/diminished emotional expression*, *avolition*, *anhedonia*, *alogia/poverty of speech*, *asociality* and impaired concentration. Predominate in ~one-third of patients and predict **poor long-term outcome and poor drug response**.
- ▶ **Cognitive symptoms** — deficits in working/declarative memory, attention, processing speed and executive function; strongly linked to functional/vocational disability and often precede frank psychosis.
- ▶ **Schneiderian first-rank symptoms** (classically supportive, not specific) — thought insertion, withdrawal and broadcasting; delusions of control/passivity; third-person auditory hallucinations; delusional perception. **Bleuler's "4 A's"** (loosening of Associations, Affect incongruity, Ambivalence, Autism) and Kraepelin's *dementia praecox* are the classical descriptions.
- ▶ **Catatonia** — a non-specific syndrome (≥3 of stupor, cataplexy, mutism, waxy flexibility, stereotypy, etc.) that may complicate schizophrenia but also occurs in mood and medical disorders.
- ▶ **Course**: chronic with relapses; positive symptoms attenuate with age while negative/cognitive features persist. Pooled first-episode remission ~56% and recovery ~30%. **Anosognosia (lack of insight)** is the commonest predictor of non-adherence and relapse. ~5–10% commit suicide (20% attempt).

DSM-5-TR diagnostic criteria

Criterion	Requirement
A (core)	≥2 of the following for ≥1 month (active phase), at least one being 1, 2 or 3: (1) delusions; (2) hallucinations; (3) disorganised speech; (4) grossly disorganised/catatonic behaviour; (5) negative symptoms
B	Marked decline in functioning (work, relationships, self-care) below premorbid level
C	Continuous signs ≥6 months, including ≥1 month of active-phase (Criterion A) symptoms; may include prodromal/residual phases
D	Schizoaffective and mood disorder with psychotic features excluded
E	Not due to a substance or another medical condition
F	If autism/childhood communication disorder, diagnosis only if prominent delusions/hallucinations also present ≥1 month

- ▶ **Related spectrum disorders by duration/content:** *brief psychotic disorder* (>1 day, <1 month, full recovery); *schizophreniform disorder* (1–6 months); *schizoaffective disorder* (mood episode plus active-phase psychosis, with ≥2 weeks of psychosis without mood symptoms); *delusional disorder* (≥1 month delusions, Criterion A never met).
- ▶ DSM-5-TR abandoned the classical subtypes (paranoid, disorganised/hebephrenic, catatonic, undifferentiated, residual) in favour of a **dimensional 0–4 severity rating** of psychotic domains.

Etiopathogenesis

- ▶ **Dopamine hypothesis (four pathways):** clinical antipsychotic potency parallels affinity for D2/D3 receptors in the ventral striatum. Mesolimbic hyperdopaminergia → positive symptoms; mesocortical hypodopaminergia → negative/cognitive symptoms; blockade of the nigrostriatal pathway → extrapyramidal symptoms; blockade of the tuberoinfundibular pathway → hyperprolactinaemia.
- ▶ **Other neurotransmitters:** glutamatergic (NMDA) hypofunction and serotonergic (5-HT_{2A}) signalling — atypical agents have high 5-HT₂:D₂ ratios; newer targets include D₃, 5-HT_{1A}/5-HT₇, mGlu_{2/3} and muscarinic M₁/M₄ receptors.
- ▶ **Neurodevelopmental/structural changes (ch462):** enlarged lateral ventricles, reduced cortical and subcortical grey matter in frontal/temporal lobes and limbic system, reduced neuropil with increased cell-packing density (no neuronal loss), hypofrontality (reduced dorsolateral prefrontal cortex metabolism at rest and on executive/working-memory tasks), and reduced expression of *GAD1* (GABA-synthesising enzyme) in prefrontal interneurons.

- **Genetics:** large GWAS show hundreds of small-effect risk loci plus rare large-effect copy-number variants; pathways involve **immunity, inflammation and cell signalling**. The strongest signal lies at the **complement component 4 (C4)** locus — increased C4A expression is hypothesised to drive **excessive synaptic pruning by microglia**, supporting a neurodevelopmental/neurodegenerative model.

Differential diagnosis

- **Primary psychiatric:** mood disorder (depressive/bipolar) with psychotic or catatonic features, schizoaffective disorder, delusional disorder, brief psychotic disorder, schizotypal personality disorder.
- **Substance-induced:** chronic amphetamine/cocaine/stimulant psychosis (formication, stereotypy), phencyclidine, cannabis; and prescription drugs (anti-parkinsonian agents, clonidine, quinacrine, procaine derivatives) — *rule out drug causes in any new-onset psychosis*.
- **Organic/medical:** thyroid, adrenal and pituitary disease, temporal-lobe (complex partial) seizures, CNS tumour/encephalitis/haemorrhage, metabolic derangements, heavy-metal/industrial toxicity. A full medical work-up with **CT/MRI brain** is advised at first episode of psychosis.

Management

- **Antipsychotics are the cornerstone** of acute and maintenance treatment. ~70% of first-episode patients respond; improvement begins within days but full remission needs **6–8 weeks**. Therapeutic doses produce **>80% D2 occupancy** (e.g. haloperidol 4–6 mg/d, olanzapine 10–15 mg/d, risperidone 4–6 mg/d); higher doses add toxicity, not efficacy.

Class	Examples	Key features
First-generation (typical)	Low-potency: chlorpromazine, thioridazine; mid: perphenazine, loxapine; high: haloperidol , fluphenazine, thiothixene	High-potency → more EPS; low-potency → more anticholinergic/orthostatic/sedative effects
Second-generation (atypical)	Clozapine , risperidone, olanzapine , quetiapine, ziprasidone, aripiprazole, paliperidone, lurasidone, asenapine, cariprazine, lumateperone	Higher 5-HT ₂ :D ₂ ratio; better for negative/cognitive symptoms; metabolic risk (weight gain, dyslipidaemia, type-2 DM)
Novel mechanism (2024)	Xanomeline/trospium (M1/M4 muscarinic agonist)	First agent acting <i>without</i> D ₂ /5-HT ₂ blockade → no EPS or metabolic complications

- **Clozapine** — drug of choice for **treatment-resistant schizophrenia** (~30% of non-responders improve) and uniquely **reduces suicidality**; needs a 6–9-month trial. Risks: **agranulocytosis**

(~1%, mandatory WBC monitoring), dose-related seizures (~10% at high dose), weight gain, drooling, hyperthermia; does **not** raise prolactin.

- ▶ **Long-acting injectables (LAI)** — risperidone, paliperidone, olanzapine, aripiprazole, haloperidol/fluphenazine decanoate — for **non-adherence**; reduce relapse. If medication is fully stopped, relapse rate is ~60% within 6 months.
- ▶ **Adverse effects:** EPS (acute dystonia, akathisia, parkinsonism) → benztropine 1–2 mg bid or trihexyphenidyl 2 mg bid; akathisia → beta-blocker. **Tardive dyskinesia** (incidence 2–4%/yr, prevalence ~20%; *buccolinguo-masticatory triad*) → treat with the VMAT2 inhibitor **valbenazine**. **Neuroleptic malignant syndrome** — hyperthermia, autonomic instability, rigidity, raised CPK (a medical emergency). Hyperprolactinaemia, QT prolongation, metabolic syndrome — monitor glucose/lipids/ECG. The CATIE trial showed high real-world discontinuation; olanzapine had the lowest discontinuation but most metabolic effect, and perphenazine performed comparably to newer agents.
- ▶ **Psychosocial/non-pharmacological:** family psychoeducation, assertive community treatment, social-cognition and skills training, cognitive remediation; ECT for catatonia and treatment-resistant cases. Lorazepam 1–2 mg rapidly relieves catatonia.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Dopaminergic pathways in schizophrenia** — midbrain origins (VTA, substantia nigra) projecting along four tracts, labelled: *Mesolimbic* (VTA → *nucleus accumbens*) — *positive symptoms* (hyperactive); *Mesocortical* (VTA → *prefrontal cortex*) — *negative/cognitive symptoms* (hypoactive); *Nigrostriatal* (SN → *striatum*) — *EPS on blockade*; *Tuberoinfundibular* (hypothalamus → *pituitary*) — *hyperprolactinaemia on blockade*.
- ▶ **Positive vs negative symptoms schematic** — two columns: *Positive* (Delusions, Hallucinations, Disorganised speech, Catatonia) and *Negative* (Affective flattening, Avolition, Anhedonia, Alogia, Asociality), with *Cognitive deficits* bridging both.

Clinical / Diagnostic significance

- ▶ Diagnosis is **clinical and longitudinal** — repeated observation improves reliability; reconsider the diagnosis (often → bipolar disorder) if the course is atypical.
- ▶ First episode mandates a **full medical work-up + neuroimaging** and a urine drug screen to exclude organic/substance causes.
- ▶ Patients have **reduced life expectancy** from suicide and from antipsychotic-associated **metabolic syndrome and cardiovascular disease** — metabolic monitoring is integral to care.
- ▶ Treatment failure is most often due to **inadequate dosing or non-adherence**; LAIs and clozapine are the structured responses to each.

High-yield exam pointers

- ▶ DSM-5-TR: ≥ 2 **Criterion A** symptoms ≥ 1 month + ≥ 6 months total, with ≥ 1 of delusions/hallucinations/disorganised speech.
- ▶ Positive = mesolimbic **hyperdopaminergia**; negative = mesocortical **hypodopaminergia**.
- ▶ Genetics: MZ concordance 50%, DZ 10%; both parents affected $\rightarrow \sim 40\%$.
- ▶ Strongest molecular signal = **C4 complement** $\rightarrow$ **excess synaptic pruning** (microglia); imaging = **ventriculomegaly + hypofrontality**.
- ▶ **Clozapine** = treatment-resistant disease and anti-suicidality; watch **agranulocytosis (1%)** with WBC monitoring; no prolactin rise.
- ▶ **Tardive dyskinesia** $\rightarrow$ valbenazine (VMAT2 inhibitor); **NMS** = hyperthermia + rigidity + autonomic instability + $\uparrow$ CPK.
- ▶ DSM-5 **dropped classical subtypes**; **xanomeline/trospium (M1/M4 agonist, 2024)** is the first non-dopaminergic antipsychotic.
- ▶ **Auditory** hallucinations favour schizophrenia; **visual** hallucinations favour an organic/toxic cause.
- ▶ $\sim 10\%$ die by suicide; anosognosia is the chief driver of non-adherence and relapse.

SOURCE & COVERAGE

- ▶ **Harrison's Principles of Internal Medicine, 22e** — "Psychiatric Disorders" (Schizophrenia: clinical manifestations, epidemiology, differential diagnosis, antipsychotic pharmacology, CATIE, tardive dyskinesia, NMS) and "Biology of Psychiatric Disorders" (structural imaging, hypofrontality, GAD1, C4 complement and synaptic pruning).
- ▶ **DSM-5-TR** — "Schizophrenia Spectrum and Other Psychotic Disorders" (diagnostic criteria, course, prognosis, suicide risk, spectrum definitions).
- ▶ **Kaplan & Sadock's Comprehensive Textbook of Psychiatry** — dopaminergic pathway/neurochemistry and Schneiderian first-rank symptom framing.
- ▶ **CMDT 2026** — "Psychiatric Disorders" (classification, mesolimbic vs mesocortical D2 correlation, current drug regimens/doses, LAIs, xanomeline/trospium, ECT).

Coverage note: Schneiderian first-rank symptoms and Bleuler's "4 A's"/Kraepelin (dementia praecox) are given as universally-accepted standard psychiatry; the corpus references "schneiderian first-rank symptoms" but does not enumerate them, and the nigrostriatal/tuberoinfundibular limbs of the four-pathway model are standard pharmacology stated to frame Harrison's EPS/hyperprolactinaemia data.

Toxic epidermal necrolysis

Asked in: Paper IV 17 Apr 2026 — RGUHS MD General Medicine

Definition / Introduction — Toxic epidermal necrolysis (TEN), originally described by *Lyell* (1956), is the most extensive form of a single severe mucocutaneous reaction spectrum, **Stevens-Johnson syndrome / toxic epidermal necrolysis (SJS/TEN)**, characterised by widespread blistering and **full-thickness epidermal necrosis** with detachment of skin and erosion of two or more mucosal surfaces. It is almost always **drug-induced** (a culprit drug is identified in ~85% of cases), is mediated by drug-specific cytotoxic CD8+ T cells, and is a dermatological emergency with mortality reaching ~30% in TEN. Cases are classified by **maximal body-surface-area (BSA) detachment**: SJS <10%, SJS/TEN overlap 10–30%, and TEN >30%.

Nomenclature, spectrum and epidemiology

- ▶ SJS = epidermal detachment <10% BSA with widespread purpuric macules / flat atypical targets; SJS/TEN overlap = 10–30%; TEN with spots = >30% with purpuric macules/targets; TEN without spots = >30% with loss of large epidermal sheets, no discrete lesions.
- ▶ SJS and TEN are now regarded as one entity separated from **erythema multiforme (EM) major**, which is HSV-driven, has true/raised *typical targets* on the extremities, and is rarely drug-related.
- ▶ Incidence ~1–2 cases per million per year; occurs at all ages (rises in the elderly); female:male ~2:1; increased risk in HIV infection.

Pathogenesis and genetic predisposition

- ▶ A delayed (type IV) hypersensitivity reaction: MHC class I-restricted presentation of a drug/metabolite-altered antigen by keratinocytes/APCs drives clonal expansion of CD8+ cytotoxic T lymphocytes (CTLs) that infiltrate the skin.
- ▶ Keratinocyte apoptosis/necroptosis is effected by soluble mediators — **granulysin** (secretory 15-kDa form; the *key* mediator, high in blister fluid), **soluble Fas ligand (Fas-FasL)**, **perforin/granzyme B**, TNF- α , IFN- γ and inducible nitric oxide synthase. **Annexin A1** acting via **formyl-peptide receptor 1** and overexpressed **RIP kinase 3 (RIP3)** implicate *necroptosis*.
- ▶ Mechanistic models of drug-HLA-TCR interaction: **hapten/pro-hapten** (covalent binding), **p-i (pharmacologic interaction)** concept (non-covalent binding to HLA/TCR), and **altered peptide repertoire** (classically *abacavir* in HLA-B*57:01).
- ▶ Pharmacogenetic HLA associations (drug- and phenotype-specific):

HLA allele	Drug	Population/notes
*HLA-B15:02**	Carbamazepine (SJS/TEN, not DRESS)	Han Chinese, Thai, Malaysian
*HLA-B58:01**	Allopurinol (SJS/TEN & DRESS)	Han Chinese; ACR advises pre-screening
*HLA-B57:01**	Abacavir hypersensitivity	100% NPV; screening abolishes AHS

HLA allele	Drug	Population/notes
*HLA-A32:01**	Vancomycin (DRESS)	—
*HLA-B13:01**	Dapsone / sulfonamide	cost-effective screening in leprosy

- ▶ Non-MHC factors also matter, e.g. slow-metaboliser *CYP2C93** raises risk of phenytoin-induced SJS/TEN.

Causative drugs

- ▶ A short list accounts for ~half of all cases. **High-risk culprits (Rook's Box 118.3):** allopurinol, carbamazepine, lamotrigine, nevirapine, oxicam NSAIDs, phenobarbital, phenytoin, sulfamethoxazole/other sulfa antibiotics, and sulfasalazine.
- ▶ Harrison additionally emphasises trimethoprim-sulfamethoxazole, β -lactam antibiotics and other antiepileptics.
- ▶ Typical **latency** from drug start to onset is **7–10 days (range 5–28 days)**. Paracetamol/aspirin/ibuprofen/corticosteroid are often confounders (used to treat the prodrome). In a minority (especially children) *Mycoplasma pneumoniae* is the trigger and no drug is found.

Clinical features

- ▶ **Prodrome:** malaise, fever, sore throat and upper-respiratory symptoms for a few days, often with conjunctivitis.
- ▶ **Skin:** fever $>39^{\circ}\text{C}$ then acute painful, **dusky atypical targets / purpuric macules** beginning on the face and upper trunk, spreading to involve trunk and limbs (palms/soles often prominent); lesions coalesce, blister and lead to confluent dusky erythema and **sheet-like epidermal detachment** over 5–10 days. Marked **skin pain** is characteristic.
- ▶ **Nikolsky sign positive** — gentle lateral pressure slides lesional epidermis off the dermis (detachable epidermis); not specific (also positive in pemphigus). Asboe-Hansen (bulla-spread) phenomenon may be present.
- ▶ **Mucosal involvement (≥ 2 sites, near-universal):** painful haemorrhagic erosive stomatitis/cheilitis with crusted lips; ocular chemosis, conjunctivitis, pseudomembranes, corneal/conjunctival epithelial defects; **urogenital** erosions; and **respiratory** tract sloughing (cough, dyspnoea, haemoptysis) in up to 25%.

Histopathology and investigations

- ▶ **Skin biopsy (lesional, adjacent to a blister):** full-thickness/confluent epidermal necrosis with apoptotic keratinocytes (Civatte bodies), basal vacuolar degeneration and **subepidermal split**, with only a sparse perivascular lymphocytic dermal infiltrate. **Frozen-section biopsy** allows rapid diagnosis.

- ▶ A second **peri-lesional biopsy for direct immunofluorescence** (negative) excludes autoimmune bullous disease.
- ▶ **Bloods at presentation:** FBC (anaemia, leukopenia), urea & electrolytes, glucose, **bicarbonate**, LFTs, amylase, CRP/ESR, coagulation, **Mycoplasma serology**, ANA/ENA, complement, indirect immunofluorescence. Skin swabs for bacteriology, and a **chest X-ray** are mandatory. A **body map** records redness and detachment separately.

Prognosis — SCORTEN

- ▶ Overall SJS/TEN mortality ~22% (SJS <10%, TEN ~30%); death is usually from **septicaemia-induced multiorgan failure**.
- ▶ **SCORTEN** (*Bastuji-Garin, 2000*) is the validated severity score, calculated on **admission and again within day 1–5**; one point each for seven independent parameters:

SCORTEN parameter (1 point each)
Age >40 years
Presence of malignancy
Heart rate >120/min
Epidermal detachment >10% BSA at admission
Serum urea >10 mmol/L (BUN >28 mg/dL)
Serum glucose >14 mmol/L (>252 mg/dL)
Bicarbonate <20 mmol/L

- ▶ Predicted in-hospital mortality rises steeply with score (classically ~3% at 0–1 points, ~12% at 2, ~35% at 3, ~58% at 4, and >90% at ≥5). The newer **ABCD-10** score is an alternative (CMDT).

Management

- ▶ **Immediate withdrawal of the culprit drug** is the single most important intervention — early stoppage (before/at blistering) is a strong predictor of survival; delay increases mortality. Continue essential non-suspect medicines. **ALDEN** (Algorithm of Drug causality in Epidermal Necrolysis) aids *retrospective* culprit attribution.
- ▶ **Care setting:** detachment >10% BSA → transfer to an **ICU or burns unit**; barrier-nurse on a pressure-relieving mattress at ambient 25–28°C, managed by an MDT (dermatology/burns, intensive care, **ophthalmology**, skin-care nursing, etc.).
- ▶ **Supportive care (the proven cornerstone):**
 - **Fluids:** crystalloid at ~2 mL/kg/%BSA detached (less than for thermal burns), titrated to urine output; avoid over-resuscitation.

- *Nutrition*: early **enteral/NG feeding** (20–25 kcal/kg/day catabolic phase, rising to 25–30 kcal/kg/day).
- *Skin*: atraumatic handling (avoid BP cuffs/adhesive leads/wrist tags); emollient (50/50 white-soft/liquid paraffin); leave detached epidermis as a biological dressing or use non-adherent **silicone dressings**; topical antibiotic only on infected/crusted areas.
- *Mucosae*: daily **ophthalmology review**, 2-hourly ocular lubricant, lysis of conjunctival adhesions, topical steroid drops ± **amniotic membrane transplantation** for severe ocular surface loss; mouth care and **urinary catheterisation** to prevent strictures.
- *Other*: opioid **analgesia** (± ketamine for procedures), **PPI** stress-ulcer prophylaxis, **LMWH** thromboprophylaxis, vigilant **sepsis** surveillance (commence antibiotics only on clinical signs — *S. aureus* early, then *Pseudomonas*/Gram-negatives), and **macrolide** if Mycoplasma-triggered.
- ▶ **Immunomodulatory (adjunctive, unproven — no therapy has unequivocal RCT benefit)**:
 - **Ciclosporin** 3–5 mg/kg/day for ~7–10 days then taper — most favoured in current practice; cohort data suggest faster re-epithelialisation and below-SCORTEN-predicted mortality.
 - **Systemic corticosteroids** — early high-dose (prednisone 1–2 mg/kg/day, or pulsed IV dexamethasone/methylprednisolone); benefit conflicting, risk of sepsis/impaired healing.
 - **IVIg** 0.5–1 g/kg/day for 3–4 days (total ~3–4 g/kg) — anti-Fas rationale; meta-analysis showed **no clear mortality benefit** in adults.
 - **Etanercept** (TNF- α inhibitor) — treatment of choice in some centres; faster healing in uncontrolled studies.
 - **Thalidomide** is contraindicated — the only RCT was stopped early for *excess deaths*.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **SJS/TEN classification spectrum bar**: a horizontal axis of % BSA detachment with three zones labelled — “SJS <10%”, “SJS/TEN overlap 10–30%”, “TEN >30%”; annotate “atypical targets / purpuric macules” and “sheet-like epidermal detachment, Nikolsky +”.
- ▶ **Pathogenesis schematic**: *Drug/metabolite* → **HLA class I + altered peptide** on keratinocyte → recognised by CD8+ CTL (TCR) → release of **granulysin, Fas–FasL, perforin/granzyme B, TNF- α** → **keratinocyte apoptosis/necroptosis** → full-thickness epidermal necrosis & detachment.

Clinical / Diagnostic significance

- ▶ Recognise the **red-flag features** (skin pain, dusky/target lesions, blisters, positive Nikolsky, mucosal erosions, fever) early — they distinguish SJS/TEN from benign morbilliform eruptions and mandate urgent specialist referral.

- ▶ A frozen-section/biopsy confirms full-thickness necrosis and excludes **staphylococcal scalded skin syndrome** (subcorneal split, no mucosal involvement), pemphigus, bullous pemphigoid, paraneoplastic pemphigus, bullous lupus, linear IgA disease and generalised bullous fixed drug eruption.
- ▶ **HLA pharmacogenetic screening** (e.g. HLA-B15:02 before carbamazepine in South-East/East-Asian patients, HLA-B58:01 before allopurinol, HLA-B*57:01 before abacavir) prevents cases.
- ▶ **Long-term sequelae** drive morbidity: chronic **ocular** disease (dry eye, symblepharon, entropion/trichiasis, corneal scarring, blindness — the most disabling), **bronchiolitis obliterans**, oesophageal/vaginal strictures, dyspigmentation, **onychomadesis**, telogen effluvium, and PTSD. Issue a **MedicAlert card/bracelet** naming the culprit drug; lifelong avoidance of it and cross-reacting congeners (e.g. aromatic antiepileptics).

High-yield exam pointers

- ▶ TEN = >30% BSA detachment; SJS <10%; overlap 10–30% — *Lyell syndrome*.
- ▶ Culprits mnemonic — **allopurinol, anticonvulsants (carbamazepine, lamotrigine, phenytoin, phenobarbital), sulfonamides, oxicam NSAIDs, nevirapine**; latency 5–28 days.
- ▶ **Granulysin** is the *key* cytotoxic mediator; effector cells are CD8+ CTLs (MHC-I restricted).
- ▶ *HLA-B15:02 → carbamazepine; HLA-B58:01 → allopurinol; HLA-B57:01 → abacavir.**
- ▶ **Nikolsky sign positive**; biopsy = **full-thickness epidermal necrosis, subepidermal split**.
- ▶ SCORTEN = 7 parameters; ≥5 predicts >90% mortality.
- ▶ **Stop the drug + ICU/burns-unit supportive care** are the only measures with clear survival benefit; **ciclosporin** is the most favoured adjunct; **thalidomide is harmful**.
- ▶ Commonest cause of death = **sepsis** → **multiorgan failure**; commonest disabling sequela = **chronic ocular scarring**.

SOURCE & COVERAGE

- ▶ **Harrison's Principles of Internal Medicine, 22e** — “Cutaneous Drug Reactions” (SJS/TEN spectrum, immunopathogenesis, HLA pharmacogenetics, culprit drugs, ALDEN); “Immunologically Mediated Skin Diseases” (blistering differential).
- ▶ **Rook's Textbook of Dermatology, 10e** — “Severe Cutaneous Adverse Reactions to Drugs” (definition/nomenclature, classification, histopathology, SCORTEN parameters, investigations, detailed supportive and active-therapy management ladder, complications/prognosis).
- ▶ **CMDT 2026** — “Erythema Multiforme / Stevens-Johnson Syndrome / Toxic Epidermal Necrolysis” (BSA criteria, current drug doses — corticosteroids, IVIG, ciclosporin, etanercept; ABCD-10/SCORTEN).

Treatment and Complications of Psoriasis Vulgaris

Asked in: Paper IV Oct 2025 — RGUHS MD General Medicine

Definition / Introduction — Psoriasis vulgaris (chronic plaque psoriasis) is a common, immune-mediated, genetically determined inflammatory disease affecting up to 2% of the population, characterised by sharply demarcated, erythematous plaques bearing **silvery micaceous scale**, typically over extensor surfaces (elbows, knees), scalp and the gluteal cleft. It is driven by IL-23/Th17-axis cytokines causing keratinocyte hyperproliferation; trauma reproduces lesions (**Koebner/isomorphic phenomenon**). It is no longer regarded as a skin-limited disorder but a *systemic inflammatory disease* with major cardiometabolic, articular and psychological comorbidity. Treatment is selected by **disease severity, extent (BSA), site and comorbidity**.

Assessment of severity (governs treatment choice)

- ▶ **PASI (Psoriasis Area and Severity Index)** — the standard trial and clinical tool. Erythema, scaling (infiltration/thickness) and induration are each graded 0–4, multiplied by an **area score** 0–6, across four regions — head & neck, trunk, upper limbs, lower limbs — weighted $\times 0.1$, $\times 0.2$, $\times 0.3$, $\times 0.4$ respectively; total range 0–72. Response is reported as **PASI-75/90/100** (% improvement).
- ▶ **BSA** estimated by patient's palm $\approx 1\%$. **DLQI** (Dermatology Life Quality Index, 0–30) measures quality-of-life impact; score >10 = very large effect.
- ▶ **Severe disease** variously defined as **PASI >10 –12, or DLQI ≥ 10 , or BSA $>10\%$** , or involvement of high-impact sites (face, palms/soles, genitalia, nails). Practically, patients split into **candidates for topical therapy** vs **candidates for systemic therapy** (BSA $\geq 10\%$, high-impact site, or topical failure).
- ▶ General measures: emollients/adequate hydration, avoid skin drying and irritation, treat streptococcal triggers, and avoid known aggravators — **lithium, beta-blockers, antimalarials, NSAIDs, statins, and systemic glucocorticoid withdrawal**.

Topical therapy (mild/limited disease, BSA $<10\%$)

- ▶ **Topical corticosteroids** — potent/very-potent agents are first-line for limited plaque, trunk and limb disease; mild–moderate potency for face, flexures and genitalia. Limitations: cutaneous **atrophy, striae, tachyphylaxis and rebound flare**; do not induce lasting remission.
- ▶ **Vitamin D analogues** — *calcipotriol* (50 $\mu\text{g/g}$, restrict to <100 g/week to avoid hypercalcaemia/hypercalciuria), *calcitriol* (3 $\mu\text{g/g}$), *tacalcitol*. The **calcipotriol + betamethasone dipropionate** fixed combination (ointment/gel/foam) is the most effective short-term topical strategy and is excellent for scalp disease.

- ▶ **Coal tar** (Goeckerman regimen with UVB) and **dithranol/anthralin** (Ingram regimen, Lassar's paste 0.05–4%) — older keratolytic/antiproliferative agents giving long remissions but messy/staining; largely replaced.
- ▶ **Topical calcineurin inhibitors** (tacrolimus 0.1%/0.03%, pimecrolimus) — preferred for **face, flexures and genitalia** (no atrophy).
- ▶ **Salicylic acid** keratolytic for thick scalp/plaque; newer non-steroidals **tapinarof 1%** (aryl-hydrocarbon-receptor agonist) and **roflumilast 0.3%** (topical PDE4 inhibitor).

Phototherapy (moderate disease, ~10–30% BSA)

- ▶ **Narrowband UVB (NB-UVB, 311–313 nm)** — first-line phototherapy, given **thrice weekly**, MED-based dosing; clearance >90%, non-immunosuppressive and safe in pregnancy. Treatment of choice for widespread **guttate psoriasis**. **Avoid in patients on ciclosporin** (carcinogenesis risk).
- ▶ **PUVA** (oral/topical 8-methoxypsoralen 0.6 mg/kg + UVA) — highly effective; cumulative dose causes **non-melanoma skin cancer (SCC > BCC)**, hence lifetime limit ~200 treatments; *Re-PUVA* (with acitretin) is dose-sparing and synergistic.

Systemic (non-biologic) therapy (moderate-to-severe / BSA >30% / topical & phototherapy failure)

Agent	Class / mechanism	Dose	Key toxicity to monitor
Methotrexate	Antimetabolite (DHFR)	≤25 mg once weekly + folic acid 1–2 mg/d	Hepatic fibrosis (cumulative 3.5–4 g → hepatology/PIIINP/elastography), pancytopenia, pneumonitis, mucositis, teratogenic
Ciclosporin	Calcineurin inhibitor	≤5 mg/kg/day	Nephrotoxicity, hypertension, hyperkalaemia/uricaemia, gum hyperplasia ; for induction only , rebound on stopping
Acitretin	Oral retinoid	0.5–0.75 mg/kg/day	Teratogenic (avoid pregnancy 3 yr) , mucocutaneous dryness, hyperlipidaemia, hepatitis, hyperostosis; non-immunosuppressive — useful in pustular psoriasis & HIV
Fumaric acid esters (dimethyl fumarate)	Immunomodulator	up to 240 mg tds	GI upset, flushing, lymphopenia (→ rare PML), proteinuria
Apremilast	Oral PDE4 inhibitor	30 mg BD	Diarrhoea, weight loss, depression ; minimal

Agent	Class / mechanism	Dose	Key toxicity to monitor
			immunosuppression, no lab monitoring
Deucravacitinib	Oral TYK2 inhibitor	6 mg daily	URTI, raised CPK, herpes reactivation, folliculitis

- ▶ Oral glucocorticoids must NOT be used for plaque psoriasis — withdrawal precipitates life-threatening generalised pustular or erythrodermic flares.

Biologic therapy (severe disease, inadequate response/intolerance to standard systemics)

- ▶ TNF- α inhibitors — *etanercept*, *adalimumab*, *infliximab*, *certolizumab* (and *golimumab* for PsA). *Infliximab* (5 mg/kg IV, weeks 0, 2, 6 then q8w) gives the most rapid response — preferred for erythrodermic and pustular flares. TNFi can worsen heart failure and paradoxically induce psoriasis.
- ▶ IL-12/23 p40 inhibitor — *ustekinumab* (45 mg if <100 kg, 90 mg if >100 kg; weeks 0, 4, then q12w). Response is enhanced in *HLA-C06:02-positive** patients.
- ▶ IL-17 inhibitors — *secukinumab*, *ixekizumab* (anti-IL-17A), *brodalumab* (anti-IL-17RA), *bimekizumab* (anti-IL-17A/F). Very rapid, high PASI-90/100 rates; risks: mucocutaneous candidiasis, may unmask/worsen inflammatory bowel disease; *brodalumab* carries a suicidality black-box warning.
- ▶ IL-23 p19 inhibitors — *guselkumab*, *risankizumab*, *tildrakizumab*. Highest sustained efficacy, infrequent dosing, and no signal for candidiasis or IBD.
- ▶ Spesolimab (anti-IL-36 receptor) — approved specifically for generalised pustular psoriasis (linked to *IL36RN* mutations).
- ▶ Biologic safety rules: screen for latent TB (IGRA/CXR), hepatitis B/C and HIV before starting; do not start with active severe infection; serious-infection rate ~1.4–1.8 per 100 patient-years; rare reports of demyelination, drug-induced lupus and PML.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ PASI scoring schematic — body divided into 4 regions with weighting factors: *Head & neck* $\times 0.1$, *Upper limbs* $\times 0.2$, *Trunk* $\times 0.3$, *Lower limbs* $\times 0.4$; annotate each region with *Erythema* (0–4) + *Induration* (0–4) + *Scaling* (0–4) $\times$ *Area* (0–6); final box PASI = A + B + C + D (range 0–72).
- ▶ Treatment pyramid / IL-23–Th17 target map — base *General measures* + *Topicals* (*steroid*, *vitamin D analogue*, *calcineurin inhibitor*) $\rightarrow$ *Phototherapy* (NB-UVB, PUVA) $\rightarrow$ *Conventional systemics* (MTX, ciclosporin, acitretin) $\rightarrow$ apex *Biologics*; side ladder showing

cytokine targets: *TNF- α* , *IL-12/23p40*, *IL-17A/F*, *IL-23p19*, *IL-36R* with the drug at each node.

Clinical / Diagnostic significance

- **Complications of the disease itself:** progression to **erythrodermic psoriasis** (>90% BSA — impaired thermoregulation, high-output cardiac failure, fluid/protein/electrolyte loss, sepsis, rare ARDS) and **generalised pustular psoriasis** (fever 39–40°C, sterile pustules, systemic upset, life-threatening).
- **Psoriatic arthritis** in up to 30% (onset 30–50 yr) — five patterns: **symmetric** (~50%), **asymmetric** (~35%), **distal interphalangeal** (classic, ~5%), **spondylitic** (~5%), **arthritis mutilans** (<5%); “sausage digits” (dactylitis), nail dystrophy. Joint damage is erosive and deforming — early recognition is mark-worthy.
- **Systemic comorbidity** (screen actively): **metabolic syndrome** (obesity, hyperlipidaemia, hypertension, diabetes); **cardiovascular disease** with increased MI/stroke/peripheral-vascular/atrial fibrillation/VTE risk and excess mortality; **NAFLD**; other immune-mediated diseases (**Crohn’s**, **ulcerative colitis**, **coeliac disease**, **uveitis**); **anxiety**, **depression** and **suicidality**; increased non-melanoma skin cancer and lymphoma; gout and (rarely) secondary amyloidosis. **Ocular:** blepharitis, conjunctivitis, uveitis.
- **Complications of therapy** are exam-critical: topical-steroid atrophy/tachyphylaxis/rebound; vitamin-D-analogue hypercalcaemia; MTX hepatic/marrow/pulmonary toxicity and teratogenicity; ciclosporin nephrotoxicity, hypertension and malignancy; acitretin teratogenicity and hyperlipidaemia; PUVA-induced SCC/melanoma; biologic-associated serious infection, **TB** and **hepatitis B reactivation**, IL-17-related candidiasis and IBD.
- **Investigations:** usually clinical; **skin biopsy** (acanthosis with regular elongation of rete ridges, parakeratosis, Munro microabscesses, dilated dermal papillary vessels) when atypical. Baseline screen before systemics: FBC, LFTs, U&E, lipids/glucose, hepatitis & HIV serology, IGRA/CXR, pregnancy test.

High-yield exam pointers

- **PASI 0–72**, four regions weighted 0.1/0.2/0.3/0.4; treatment endpoints **PASI-75/90/100**; severe = PASI >10–12 or DLQI $\geq$ 10 or BSA >10%.
- **First-line by extent:** topical steroid $\pm$ vitamin D analogue (limited) $\rightarrow$ NB-UVB (moderate/guttate) $\rightarrow$ MTX/ciclosporin/acitretin or biologic (severe).
- **Never give systemic steroids** for plaque psoriasis — rebound pustular/erythrodermic flare on withdrawal.
- **Acitretin** = drug of choice in **pustular** psoriasis and when immunosuppression must be avoided; **teratogenic** for 3 years.

- ▶ **Infliximab** = fastest-acting biologic, best for **erythrodermic/pustular** flares; **spesolimab** (anti-IL-36R) specifically for GPP.
- ▶ Screen TB, HBV/HCV, HIV before any biologic/immunosuppressant; **IL-17 inhibitors** → **candidiasis & IBD**; **brodalumab** → **suicidality warning**.
- ▶ **HLA-C06:02** predicts good *ustekinumab* response; IL36RN* mutation underlies generalised pustular psoriasis.
- ▶ Treat psoriasis as a **systemic disease** — screen for psoriatic arthritis, metabolic syndrome, cardiovascular risk and depression; address weight and smoking.

SOURCE & COVERAGE

- ▶ **Harrison's Principles of Internal Medicine, 22e** — “Eczema, Psoriasis, Cutaneous Infections, Acne, and Other Common Skin Disorders” (clinical types, FDA-approved systemic agents and biologics tables, PsA subtypes).
- ▶ **Rook's Textbook of Dermatology, 10e** — “Psoriasis and Related Disorders” (PASI methodology, severity classification, comorbidity Box, full topical/phototherapy/systemic/biologic pharmacology, generalised pustular psoriasis and *IL36RN*).

Vitamins, minerals, nutrition & electrolytes

Beer Potomania

Asked in: Paper I Jul 2020 — RGUHS MD General Medicine

Definition / Introduction — *Beer potomania* is a distinctive form of **hypotonic, dilutional hyponatremia** caused by **very low dietary solute intake** rather than by excess antidiuretic hormone (AVP/ADH). It classically occurs in chronic heavy beer drinkers whose near-sole calorie source is beer — a beverage rich in water and carbohydrate but almost devoid of protein and salt (only **1–2 mmol/L of Na⁺**). Because renal free-water excretion is *obligately coupled to urinary solute (osmole) excretion*, an extremely low solute load shrinks the maximum volume of water the kidney can clear, so that even a modest fluid (beer) load overwhelms it and dilutional hyponatremia ensues despite **maximally suppressed AVP and maximally dilute urine**. The same physiology underlies the “*tea-and-toast*” syndrome in malnourished, non-alcoholic patients on protein-poor diets.

Pathophysiology — why low solute intake causes hyponatremia

- ▶ **Free-water excretion is solute-limited.** The kidney can excrete free water only in proportion to the solute (mainly urea + electrolytes) delivered to and excreted by the distal nephron. Maximum urine output $\approx$ (daily solute excreted) $\div$ (minimum achievable urine osmolality).
- ▶ **Minimum urine osmolality** the human kidney can achieve with full AVP suppression is **~ 50 mOsm/kg**.
- ▶ **Quantitative illustration (CMDT):**
 - A normal Western diet generates **~ 1000 mOsm of solute/day** $\rightarrow$ at a minimum Uosm of 50 mOsm/kg the kidney can put out up to **~ 20 L of dilute urine/day**, so ordinary water loads are easily cleared.
 - A beer-only / “tea-and-toast” diet generates only **~ 200 mOsm/day** $\rightarrow$ maximum urine output falls to **~ 4 L/day**. Once daily fluid (beer) intake exceeds this ceiling, electrolyte-free water is retained and serum Na^+ falls.
- ▶ **AVP is appropriately suppressed** (or rapidly suppressible) — this is an *ADH-independent* hyponatremia. The defect is inadequate substrate (solute) for water excretion, **not** inappropriate antidiuresis.
- ▶ Contributory factors in alcoholics: **poor protein/salt intake**, beer-induced **carbohydrate load** (further suppresses ureagenesis and lowers urinary solute), and often coexisting **GI losses, hypokalemia and malnutrition**.

Etiology and predisposing settings

- ▶ **Chronic heavy beer drinkers** whose only nutrient is beer — the eponymous setting (beer = high water + carbohydrate, minimal protein/ Na^+).
- ▶ **“Tea-and-toast” diet** — elderly, frail or non-alcoholic patients on very low-protein, low-salt diets.
- ▶ **Extreme/restricted diets** — e.g. extreme vegetarian or nutrient-restricted “fad” diets with high water intake.
- ▶ Common background of **malnutrition, thiamine deficiency, hypokalemia, hypomagnesemia and alcoholic liver disease**, all of which heighten the risk during correction.

Clinical and biochemical profile

Feature	Typical finding in beer potomania
Volume status	Clinically euvolemic (often mildly hypovolemic)
Serum osmolality	Low (hypotonic, <275 – 280 mOsm/kg)
Urine osmolality	Very low — <100 mOsm/kg to low 200s (dilute urine; suppressed AVP)
Urine Na^+	<20 mmol/L (often <10 – 20)

Feature	Typical finding in beer potomania
Serum AVP/ADH	Suppressed or rapidly suppressible with saline
Serum K ⁺	Frequently low (poor intake, GI losses)
Serum uric acid	Variable; not the hypouricemia typical of SIAD
Response to saline/diet	Hyponatremia corrects rapidly (often dangerously fast)

- **Symptoms** track the rate and depth of the fall in Na⁺: anorexia, nausea, headache, lethargy, gait unsteadiness/falls; with severe or acute drops — confusion, seizures, obtundation, coma (cerebral oedema).
- Many cases are **chronic** (>48 h), so the brain has osmotically adapted and the patient may be only mildly symptomatic despite Na⁺ <120 mmol/L — which is precisely what makes overcorrection dangerous.

Diagnostic approach and differential diagnosis

- **Step 1 — confirm true hypotonic hyponatremia:** measure serum osmolality to exclude *pseudohyponatremia* (hyperlipidemia/hyperproteinemia) and *hypertonic (translocational)* hyponatremia (hyperglycemia, mannitol).
- **Step 2 — measure urine osmolality:** Uosm <100 mOsm/kg places the patient in the *ADH-independent* group (suppressed AVP) — the bracket that contains beer potomania, primary polydipsia and tea-and-toast diet. Uosm >100 implies a continuing AVP effect (SIAD, hypovolemia, oedematous states).
- **Step 3 — measure urine Na⁺ and assess volume/diet:** low Uosm + low urine Na⁺ + a corroborating dietary history clinches low-solute hyponatremia.

Parameter	Beer potomania / low solute	Primary (psychogenic) polydipsia	SIAD
Mechanism	Low solute → low free-water clearance	Massive water intake > excretory capacity	Inappropriate AVP (water retention)
AVP	Suppressed	Suppressed	Inappropriately high
Urine osmolality	<100 → low 200s	<100 mOsm/kg	>100 (usually >300) mOsm/kg
Urine Na ⁺	<20 mmol/L	Low	Usually >30–40 mmol/L
Serum uric acid	Not characteristically low	Normal	Low (<4 mg/dL)
Dietary clue	Beer-only / “tea & toast”	Polydipsia, psychiatric illness	None

Treatment and the critical danger of overcorrection

- ▶ **Mainstay:** simply resuming a normal diet $\pm$ isotonic (0.9%) saline restores urinary solute excretion and the kidney rapidly dumps the retained free water — so the Na^+ tends to **self-correct very quickly and unpredictably**.
- ▶ This is the central exam point: **patients with beer potomania carry a HIGH risk of osmotic demyelination syndrome (ODS / central pontine myelinolysis)** because they combine *every* major ODS risk factor — **alcoholism, malnutrition, hypokalemia, severe chronic hyponatremia, and a strong tendency to overcorrect** once solute is restored and AVP shuts off.
- ▶ **Correction-rate limits (chronic hyponatremia):** do not exceed $\sim 8 \text{ mmol/L}$ in 24 h (some texts $8\text{--}10 \text{ mmol/L/24 h}$, and $<18 \text{ mmol/L/48 h}$). In high-risk patients (which beer potomania is), aim lower — $4\text{--}6 \text{ mmol/L/day}$; this is a *limit, not a target*.
- ▶ **Anticipate and pre-empt the auto-correction:** monitor serum Na^+ frequently (**every 1–2 h** initially). If a brisk water diuresis begins, *re-lower* Na^+ with hypotonic fluid (D5W) and/or use a DDAVP (desmopressin) “clamp” to stop the free-water diuresis and keep correction within limits.
- ▶ **Correct hypokalemia cautiously** — K^+ repletion itself raises serum Na^+ and can precipitate overcorrection.
- ▶ **Give thiamine** before/with any dextrose-containing fluids in alcoholics (prevent Wernicke encephalopathy).
- ▶ For genuinely *symptomatic/severe acute* hyponatremia, hypertonic 3% NaCl (e.g. 100 mL boluses over ~ 10 min, targeting a prompt $4\text{--}5 \text{ mmol/L}$ rise) is used — but in chronic beer potomania the threat is usually too-rapid correction, not under-correction.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Flow diagram of solute-limited water excretion:** boxes/arrows — *Low dietary solute (beer: low protein, Na^+ $1\text{--}2 \text{ mmol/L}$) $\rightarrow$ Low urinary solute excretion ($\sim 200 \text{ mOsm/day}$) $\rightarrow$ Reduced maximum free-water clearance (max urine $\sim 4 \text{ L/day}$ at $\text{U}_{\text{osm}} 50 \text{ mOsm/kg}$) $\rightarrow$ Beer (water) intake exceeds ceiling $\rightarrow$ Free-water retention $\rightarrow$ Dilutional hyponatremia (with AVP suppressed, $\text{U}_{\text{osm}} < 100$, $\text{U}_{\text{Na}} < 20$). Add a side note: “Normal diet $\approx 1000 \text{ mOsm/day}$ $\rightarrow$ up to $\sim 20 \text{ L/day}$.”*
- ▶ **Hyponatremia work-up algorithm:** Serum osmolality (exclude pseudo/hypertonic) $\rightarrow$ if hypotonic, Urine osmolality: $< 100 \text{ mOsm/kg}$ branch $\rightarrow$ ADH-independent $\rightarrow$ label the three boxes *Primary polydipsia | Beer potomania | Tea-and-toast diet*; > 100 branch $\rightarrow$ assess volume status $\rightarrow$ hypovolemic / SIAD (euvolemic) / hypervolemic. Labels to include: *S_{osm}, U_{osm} $50\text{--}100 \text{ mOsm/kg}$, U_{Na} $< 20 \text{ mmol/L}$, suppressed AVP.*

Clinical / Diagnostic significance

- ▶ A correctable, **diet-related** cause of hyponatremia that must be distinguished from SIAD — misclassifying it as SIAD and fluid-restricting/giving hypertonic saline can drive dangerous overcorrection.
- ▶ The triad **low Uosm + low urine Na⁺ + suggestive dietary history** is diagnostic; serum uric acid and volume assessment help separate it from SIAD.
- ▶ Illustrates a key renal-physiology teaching point: **free-water clearance is rate-limited by solute delivery**, not by water intake alone.
- ▶ A *sentinel* condition for **ODS prophylaxis** — anticipate spontaneous overcorrection, monitor intensively, and be ready with DDAVP/D5W re-lowering.

High-yield exam pointers

- ▶ Beer potomania = **low-solute, ADH-INDEPENDENT hypotonic hyponatremia**; AVP is *suppressed*, urine is *maximally dilute*.
- ▶ Beer is essentially salt- and protein-free — only **1–2 mmol/L Na⁺**; high water + carbohydrate load.
- ▶ Biochemistry: **Uosm <100 (to low 200s) mOsm/kg, urine Na⁺ <20 mmol/L, low serum osmolality**.
- ▶ Mechanism number to quote: normal diet ~1000 mOsm/day → **up to ~20 L urine**; beer diet ~200 mOsm/day → **only ~4 L**.
- ▶ Differential = **primary polydipsia** and “**tea-and-toast**” diet (other ADH-independent, low-Uosm causes).
- ▶ Treatment = **normal diet + isotonic saline** → corrects fast → **highest risk of ODS/central pontine myelinolysis**.
- ▶ Correction limit **~8 mmol/L/24 h** (high-risk target **4–6 mmol/L/day**); monitor Na⁺ **1–2 hourly**; consider **DDAVP clamp** and D5W to prevent/treat overcorrection.
- ▶ Co-manage **hypokalemia, magnesium, and thiamine**; cautious K⁺ replacement (raises Na⁺).

SOURCE & COVERAGE

- ▶ **Harrison’s Principles of Internal Medicine, 22e** — “Fluid and Electrolyte Disturbances” (hyponatremia: low solute intake / beer potomania; SIAD; osmotic demyelination syndrome and correction limits).
- ▶ **CMDT 2026** — “Electrolyte & Acid-Base Disorders” (hypotonic hyponatremia diagnostic algorithm; ADH-independent low-solute causes — beer potomania and tea-and-toast diet; solute-dependent maximum urine volume; Furst ratio; correction rate, ODS risk factors, and DDAVP clamp).

Beri Beri

Asked in: Paper I Nov 2020 — RGUHS MD General Medicine

Definition / Introduction — *Beriberi* is the clinical syndrome of **thiamine (vitamin B1) deficiency**. Because thiamine pyrophosphate is the coenzyme that drives oxidative decarboxylation and the pentose-phosphate transketolase reaction, its lack cripples aerobic energy generation in the most metabolically active tissues — heart, peripheral nerve and brain. Prolonged deficiency therefore produces a high-output cardiac failure (**wet beriberi**), a symmetric sensorimotor polyneuropathy (**dry beriberi**) and a central neuropsychiatric disorder (**Wernicke-Korsakoff syndrome**), with considerable clinical overlap between these forms.

Thiamine: biochemistry and why deficiency causes disease

- ▶ **Vitamin B1** was the *first vitamin to be identified*; it is a water-soluble vitamin with small body stores that deplete within **weeks** of a deficient diet (unlike B12/vitamin A, which last ≥ 1 year).
- ▶ Active cofactor = **thiamine pyrophosphate (TPP)**. Functions:
 - Coenzyme for **decarboxylation of α -keto acids** (pyruvate, α -ketoglutarate) and branched-chain amino acids $\rightarrow$ essential for ATP/energy generation.
 - Coenzyme for the **transketolase** reaction, interconverting hexose and pentose phosphates (basis of the diagnostic enzyme assay).
 - Postulated role in **peripheral nerve conduction**.
- ▶ **Food sources**: yeast, organ meat, pork, legumes, beef, whole grains, nuts. *Milled/polished rice and processed grains contain very little thiamine* — hence endemic beriberi in rice-eating populations. Food processing removes it and high-heat/prolonged cooking destroys it.
- ▶ **Anti-thiamine factors**: heat-labile **thiaminases** (raw fish, shellfish) destroy the vitamin; heat-stable **polyhydroxyphenols/tannins** (coffee, tea, Brussels sprouts, betel nut) inactivate it.
- ▶ Overt deficiency develops at a dietary level < 0.3 mg/1000 kcal.

Aetiology and at-risk groups

- ▶ **Developing world / classic beriberi**: disproportionate reliance on **polished rice** and highly processed staples; famine, refugee and displaced populations.
- ▶ **Western world (commonest causes)**: **chronic alcohol use disorder** and chronic illness (e.g., cancer). Alcohol *directly impairs intestinal thiamine absorption, blocks TPP synthesis and increases urinary excretion*.
- ▶ **Refeeding/carbohydrate load**: giving a large carbohydrate load (oral, enteral or **parenteral glucose**) to a thiamine-depleted patient can precipitate **acute thiamine deficiency with lactic acidosis** — thiamine must always be given *before/with* refeeding.

- ▶ **Other groups:** prolonged hyperemesis gravidarum, anorexia and eating disorders, post bariatric/metabolic surgery (“bariatric Wernicke”), dialysis, chronic diuretic therapy (increased urinary thiamine loss in heart failure/hypertension).
- ▶ **Drugs** that inhibit the intestinal thiamine transporter ThTR2 — **metformin, verapamil** — raise deficiency risk.
- ▶ **Maternal thiamine deficiency** → **infantile beriberi** in breast-fed babies.

Clinical types — Wet vs Dry beriberi

Feature	Wet (cardiovascular) beriberi	Dry (neurological) beriberi
Dominant system	Heart and circulation	Peripheral (± central) nervous system
Precipitating setting	Deficiency + severe physical exertion + high carbohydrate intake	Deficiency + inactivity + low-calorie intake
Mechanism	Impaired myocardial energy metabolism + dysautonomia; marked peripheral vasodilatation	Energy failure in peripheral nerve → axonal degeneration
Onset	Can appear after ~3 months of deficient diet	Insidious
Cardiac features	High-output congestive heart failure , enlarged heart/cardiomegaly, tachycardia, pulmonary oedema, peripheral oedema with warm extremities (mimics cellulitis)	Usually absent
Neurological features	Peripheral neuritis may coexist	Symmetric motor + sensory polyneuropathy , pain/paraesthesia, diminished/absent reflexes , <i>legs affected more than arms</i> , difficulty rising from a squatting position
Reference	High-output failure listed among nutritional (beriberi) causes	Distal, length-dependent neuropathy

- ▶ The two forms **overlap**; pain and paraesthesiae occur in either. An acute fulminant cardiovascular collapse with lactic acidosis (*acute pernicious* / “*Shoshin*” beriberi) is the most dramatic cardiac presentation — see Coverage note.

Wernicke-Korsakoff syndrome (central nervous beriberi)

- ▶ Seen especially in **alcoholic** patients with chronic thiamine deficiency; the brain counterpart of beriberi.
- ▶ **Wernicke's encephalopathy** — classic triad:
 - **Ophthalmoplegia** (weakness of one or more extraocular muscles) and **horizontal nystagmus**
 - **Cerebellar / truncal ataxia**
 - **Global confusion / mental impairment**
- ▶ When there is additional **memory loss with confabulatory psychosis** → **Wernicke-Korsakoff syndrome** (Korsakoff = amnesia, confabulation, impaired new learning).
- ▶ Despite the characteristic picture, the syndrome is frequently **underdiagnosed**; a high index of suspicion in any malnourished, alcoholic, post-bariatric or hyperemetic patient is essential.

Investigations / Diagnosis

- ▶ Largely **clinical**, supported by a **therapeutic response to empirical thiamine**.
- ▶ **Erythrocyte transketolase activity** measured *before and after* adding TPP: a **>25% stimulation** (activity coefficient ≥ 1.25) indicates deficiency.
- ▶ **Direct thiamine assay** — serum/whole-blood thiamine or its phosphate esters by **HPLC**; normal $\approx 70\text{--}180\text{ nmol/L}$.
- ▶ Urinary thiamine excretion is also used.
- ▶ Always assess **co-existing deficiencies** (other B vitamins, magnesium) and look for the underlying cause (alcohol, malabsorption, bariatric surgery, hyperemesis).

Treatment

- ▶ **Acute beriberi / Wernicke's (Harrison regimen):** **thiamine 200 mg IV three times daily** until there is no further improvement in acute signs, then **oral thiamine 10 mg/day** until recovery is complete. (CMDT: **50–100 mg/day IV** initially, then oral **5–100 mg/day**.)
- ▶ **Cardiovascular and ophthalmoplegic features improve within 24 hours**; neuropathy clears gradually; Korsakoff psychosis may be **permanent** or persist for months.
- ▶ **Give glucose only after/with thiamine** in at-risk patients to avoid precipitating acute deficiency and lactic acidosis.
- ▶ **Replete magnesium** — it is a required cofactor for thiamine activation; thiamine supplementation is ineffective if magnesium is depleted. Co-administer other water-soluble (B-complex) vitamins.
- ▶ **Liberal prophylactic thiamine** (e.g., **50–100 mg oral thiamine daily for ≥ 1 week** in alcohol withdrawal; generous parenteral cover in the emergency setting) for all patients with alcohol use disorder.
- ▶ **Outcome:** roughly one-fourth recover immediately, one-fourth over days, and about half achieve only partial or no benefit — underscoring the value of *early* treatment.

- ▶ **Toxicity:** essentially none from food/supplements; rare hypersensitivity/anaphylaxis has followed high-dose IV thiamine.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Two-circle “Wet vs Dry beriberi” overlap (Venn) diagram.** Labels — *Common stem:* “Thiamine (B1) deficiency → ↓TPP → impaired oxidative decarboxylation/transketolase → energy failure”; *Wet circle:* “High-output cardiac failure, cardiomegaly, tachycardia, warm peripheral oedema, pulmonary oedema”; *Dry circle:* “Symmetric sensorimotor polyneuropathy, legs > arms, absent ankle reflexes, foot/wrist drop”; *Overlap:* “pain, paraesthesia, peripheral neuritis”; *Central extension:* “Wernicke-Korsakoff syndrome”.
- ▶ **Wernicke triad triangle.** Three vertices labelled **Ophthalmoplegia / nystagmus**, **Cerebellar (truncal) ataxia**, **Confusion (global)**; arrow to a fourth box “+ amnesia & confabulation = Korsakoff”.

Clinical / Diagnostic significance

- ▶ Beriberi is a key **reversible cause of high-output heart failure** (alongside anaemia, thyrotoxicosis, AV shunts, Paget’s disease, cirrhosis) — suspect it in dilated cardiomyopathy/CCF with warm extremities in a malnourished or alcoholic patient.
- ▶ Wet beriberi oedema with **warm, well-perfused extremities** is a clinical clue distinguishing it from low-output failure and from cellulitis.
- ▶ **Refeeding syndrome:** never load carbohydrate into a chronically malnourished or alcoholic patient without prior thiamine — iatrogenic Wernicke’s and lactic acidosis are classic, examinable pitfalls.
- ▶ A **rapid response to IV thiamine** (ocular signs within 24 h) is both therapeutic and diagnostic.
- ▶ Post-**bariatric surgery** patients are a modern high-risk group; persistent vomiting in such a patient mandates parenteral thiamine.

High-yield exam pointers

- ▶ Thiamine = **vitamin B1**, the *first vitamin identified*; cofactor **TPP** for pyruvate/α-ketoglutarate dehydrogenase, branched-chain ketoacid dehydrogenase and **transketolase**.
- ▶ **Polished/milled rice** diets and **chronic alcoholism** are the prototypical causes; **thiaminases** (raw fish) and **tannins** (tea, betel nut) are dietary antagonists.
- ▶ **Wet** = **cardiac** (high-output failure, warm oedema); **Dry** = **neuropathy** (symmetric, legs > arms, lost ankle jerks).
- ▶ **Wernicke triad** = **ophthalmoplegia/nystagmus** + **ataxia** + **confusion**; add **amnesia** + **confabulation** = **Korsakoff**.
- ▶ **Diagnosis:** erythrocyte transketolase activity with >25% **TPP stimulation** (coefficient ≥1.25); blood thiamine by HPLC (≈70–180 nmol/L).

- ▶ **Treatment:** high-dose parenteral thiamine first, glucose later; replete magnesium; ocular/cardiac signs reverse within 24 h, Korsakoff amnesia may be permanent.
- ▶ **Carbohydrate repletion without thiamine** → acute deficiency + lactic acidosis (refeeding Wernicke).
- ▶ **Infantile beriberi** results from maternal thiamine deficiency in breast-fed infants.
- ▶ Thiamine has **no significant toxicity**.

SOURCE & COVERAGE

- ▶ **Harrison's Principles of Internal Medicine, 22e** — “*Vitamin and Trace Mineral Deficiency and Excess*” (thiamine biochemistry, food sources, wet/dry beriberi, Wernicke-Korsakoff, transketolase diagnosis, treatment regimen); “*Alcohol and Alcohol Use Disorders*” (alcohol-related thiamine deficiency, prophylactic thiamine in withdrawal); “*Heart Failure*” chapter (beriberi as a cause of high-output cardiac failure).
- ▶ **CMDT 2026** — “*Nutrition, Nutritional Disorders, & Obesity*” (clinical features of wet vs dry beriberi, biochemical tests, normal thiamine 70–180 nmol/L, parenteral treatment doses, magnesium dependence, referral).
- ▶ **Coverage note:** The eponym “**Shoshin**” (**acute fulminant cardiac**) beriberi is standard internal-medicine terminology but is **not named in this corpus**; it is included only as universally accepted teaching. No dedicated subspecialty textbook was specified for this nutrition topic (specialty_books empty), so depth is drawn from Harrison + CMDT, which cover the topic adequately.

Evaluation and management of Hyponatremia

Asked in: Paper IV Dec 2023 — RGUHS MD General Medicine

Definition / Introduction — Hyponatremia is a serum sodium concentration <135 mEq/L (mmol/L) and is the commonest electrolyte disorder in clinical practice. It usually represents **excess water relative to sodium**, not true total-body sodium deficiency; therefore serum sodium must be interpreted with serum osmolality, urine osmolality, urine sodium, volume status, symptoms, and duration. Acute hypotonic hyponatremia causes cerebral edema, whereas chronic hyponatremia is dangerous mainly because rapid correction can cause **osmotic demyelination syndrome (ODS)**.

Pathophysiology and clinical severity

- ▶ Plasma sodium reflects the ratio of exchangeable $\text{Na}^+ + \text{K}^+$ to **total body water**. Hyponatremia develops when water intake, oral or intravenous, exceeds renal free-water excretory capacity, most often because **arginine vasopressin/ADH** is present when it should be suppressed.

- ▶ **Acute hyponatremia** is usually <48 h in duration. Brain cells swell before adaptive osmolyte loss occurs; symptoms include headache, nausea, vomiting, confusion, seizures, coma, respiratory failure, brainstem herniation, and death.
- ▶ **Chronic hyponatremia** is usually >48 h. Brain cells lose inorganic ions and organic osmolytes, so severe cerebral edema is less likely; however, chronic “asymptomatic” hyponatremia is associated with impaired attention, gait instability, falls, fractures, osteoporosis, and increased morbidity.
- ▶ Severity by sodium level: **mild 130-134, moderate 125-129, severe <125 mEq/L**. Clinical urgency is decided more by **neurologic symptoms and acuity** than by the number alone.
- ▶ **ODS risk** rises with chronic severe hyponatremia and overcorrection, especially when serum Na⁺ is very low, or with **hypokalemia, alcoholism, malnutrition, advanced liver disease, or liver transplantation**. ODS may present days later with dysarthria, dysphagia, quadriparesis, parkinsonism, catatonia, impaired consciousness, or locked-in syndrome.

Etiological classification

Step	Pattern	Important causes / clues
1. Serum osmolality	Normal osmolality: pseudohyponatremia	Severe hypertriglyceridemia or hyperproteinemia; confirm with direct ion-selective electrode if suspected.
	High osmolality: translocational hyponatremia	Hyperglycemia, mannitol, glycine/maltose; sodium falls approximately 1.6-2.4 mEq/L per 100 mg/dL glucose rise above normal.
	Low osmolality: true hypotonic hyponatremia	Most clinically important cases; proceed to urine osmolality and volume assessment.
2. Urine osmolality	<100 mOsm/kg	ADH appropriately suppressed: primary polydipsia, beer potomania, low-protein “tea and toast” diet.
	>100 mOsm/kg	Impaired urinary dilution due to ADH effect, renal failure, diuretics, endocrine disease, or SIADH.
3. Volume status / urine Na ⁺	Hypovolemic	Vomiting, diarrhea, sweating, burns, third spacing, thiazides, renal salt wasting, adrenal insufficiency; urine Na ⁺ often <20-30 mEq/L in extrarenal loss.

Step	Pattern	Important causes / clues
	Hypervolemic	Heart failure, cirrhosis, nephrotic syndrome, advanced kidney disease; low effective arterial blood volume drives nonosmotic ADH.
	Euvolemic	SIADH, glucocorticoid deficiency, severe hypothyroidism/myxedema, reset osmostat, drugs, nausea, pain, postoperative state.

- ▶ Important acute settings: postoperative hypotonic fluids, recent thiazide use, colonoscopy preparation, glycine irrigation, endurance exercise, psychogenic polydipsia, and MDMA/ecstasy.
- ▶ Common SIADH associations: small-cell carcinoma lung and other tumors, CNS disorders, pulmonary infections, positive-pressure ventilation, HIV, pain, nausea, stress, SSRIs, tricyclics, carbamazepine, antipsychotics, cyclophosphamide/ifosfamide, vincristine, NSAIDs, opioids, nicotine, and AVP analogues.

Evaluation

- ▶ **First triage:** check airway, breathing, circulation, seizures, mental status, vomiting, respiratory distress, and evidence of raised intracranial pressure. Treat severe symptoms while the diagnostic workup proceeds.
- ▶ **History:** duration, prior sodium values, fluid intake, low-solute diet/alcohol, hypotonic IV fluids, GI losses, urine output, surgery, exercise, pain/nausea, pulmonary/CNS disease, malignancy risk, adrenal/pituitary/thyroid symptoms, and a complete drug history including thiazides, SSRIs, antiepileptics, antipsychotics, NSAIDs, opioids, chemotherapy, desmopressin, and MDMA.
- ▶ **Examination:** volume status is mandatory but imperfect; look for orthostasis, tachycardia, dry mucosa, low JVP, edema/ascites, heart failure, cirrhosis, nephrotic syndrome, and neurologic signs.
- ▶ **Initial laboratories:** serum electrolytes, glucose, urea/BUN, creatinine, measured serum osmolality, serum uric acid, potassium, calcium/magnesium as needed, urine osmolality, urine Na⁺, urine K⁺, and urine creatinine. Use measured/effective osmolality to exclude pseudo- and hypertonic hyponatremia.
- ▶ **Urine interpretation:** urine osmolality <100 mOsm/kg suggests primary polydipsia or low solute intake; >400-500 mOsm/kg indicates strong ADH effect and predicts poor response to simple fluid restriction. Urine Na⁺ <20-30 mEq/L supports low effective arterial volume unless diuretics or renal salt loss confound interpretation; urine Na⁺ >30 mEq/L supports SIADH, renal salt wasting, diuretics, or adrenal insufficiency.

- ▶ **SIADH diagnosis:** hypotonic hyponatremia with inappropriately concentrated urine, clinical euvolemia, urine Na⁺ usually >20-30 mEq/L, absence of heart/liver/kidney failure, and normal adrenal and thyroid function. Supportive clues are low BUN and **hypouricemia <4 mg/dL**. Plasma AVP or copeptin is generally not useful for routine differential diagnosis.
- ▶ **Targeted tests:** morning cortisol and/or cosyntropin test when adrenal insufficiency is possible; TSH/free T4 for severe hypothyroidism or to satisfy SIADH criteria; chest radiograph or CT thorax in unexplained SIADH, especially smokers or suspected small-cell lung carcinoma; neuroimaging when CNS disease is suspected.

Management principles

- ▶ Stop hypotonic fluids and offending drugs, restrict unnecessary free water, correct hypoxia and seizures, and treat the underlying cause. Admit patients with severe symptoms, Na⁺ <125 mEq/L with risk factors, uncertain cause, or need for hypertonic saline, vaptans, dialysis, or very frequent monitoring.
- ▶ **Severe symptomatic hyponatremia:** give 3% NaCl 100 mL IV bolus over 10-15 min, reassess clinically and recheck sodium; repeat up to two times if severe symptoms persist, aiming for an initial 4-6 mEq/L rise, not normalization. Hypertonic saline contains about 513 mEq/L NaCl.
- ▶ If symptoms are less severe but active correction is needed, 3% NaCl infusion may be used with close monitoring. Serum sodium should be checked every 1-4 h during active hypertonic saline therapy; change the infusion according to the observed sodium rise, not only formula predictions.
- ▶ After the initial symptom-relieving rise, use chronic correction limits: generally **do not exceed 8 mEq/L in 24 h**; Harrison recommends <6-8 mEq/L in the first 24 h and <6 mEq/L per subsequent 24 h, and <18 mEq/L in 48 h. In high-risk patients, target only 4-6 mEq/L/day.
- ▶ Replace potassium carefully because K⁺ repletion itself raises serum Na⁺. If overcorrection occurs or a brisk water diuresis begins, **stop active therapy**, give **desmopressin (DDAVP)** and/or D5W/free water to stabilize or relower sodium. A proactive DDAVP “clamp” may be considered in severe chronic hyponatremia at high risk of rapid aquaresis.
- ▶ **Do not use vaptans for acute symptomatic hyponatremia;** they may overcorrect unpredictably and do not replace emergency hypertonic saline.

Management by cause

- ▶ **Hypovolemic hyponatremia:** restore effective circulating volume with **0.9% saline** and stop losses/diuretics. As volume is restored, ADH may shut off and a brisk dilute diuresis can rapidly overcorrect sodium; monitor closely, especially if duration >48 h or risk factors for ODS are present.
- ▶ **Thiazide-associated hyponatremia:** stop the thiazide, replace K⁺, avoid premature SIADH diagnosis until at least **1-2 weeks** after withdrawal if urine studies mimic SIADH.

- ▶ **Low-solute intake / beer potomania:** increase dietary solute/protein and avoid uncontrolled saline correction; these patients often correct rapidly and have high ODS risk because alcoholism, malnutrition, and hypokalemia commonly coexist.
- ▶ **Hypervolemic hyponatremia:** treat heart failure, cirrhosis, nephrotic syndrome, or renal failure; restrict fluid and sodium as appropriate, use loop diuretics for congestion, and avoid routine isotonic saline because it worsens edema. Vaptans can raise Na^+ in selected euvoletic/hypervolemic patients but do not improve hard outcomes and require specialist-supervised monitoring.
- ▶ **SIADH / euvoletic chronic hyponatremia:** first treat the cause and restrict all fluids, usually **500-1000 mL/day**. If the urine/plasma electrolyte ratio ($\text{UNa} + \text{UK}$)/ PNa is >1 , fluid restriction alone is likely to fail and may need to be <500 mL/day; if ratio is about 1, restrict 500-700 mL/day; if <1 , <1 L/day may suffice.
- ▶ If fluid restriction fails: increase solute with oral salt and protein, use **oral urea 15-60 g/day** (often 30-60 g/day in SIADH), or consider loop diuretic plus salt tablets in selected cases. Demeclocycline is slow and nephrotoxic and should be avoided particularly in cirrhosis.
- ▶ **Tolvaptan** is an oral V_2 antagonist for selected persistent SIADH or hypervolemic hyponatremia; start in hospital, lift fluid restriction during active aquaresis, monitor Na^+ every 6-8 h or more often in high-risk patients, and avoid/limit use in liver disease because of hepatotoxicity concerns. Low-dose **7.5 mg** is often used to reduce overcorrection risk; conventional starting dose is 15 mg where used.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Diagnostic algorithm for hyponatremia:** Serum $\text{Na}^+ <135$ -> serum osmolality (normal pseudo / high hyperglycemia-mannitol / low hypotonic) -> urine osmolality (<100 : polydipsia, beer potomania, tea-toast; >100 : ADH effect) -> volume status and urine Na^+ (hypovolemic, euvoletic/SIADH-endocrine-drugs, hypervolemic HF-cirrhosis-nephrotic).
- ▶ **Treatment flowchart:** severe neurologic symptoms -> 3% NaCl 100 mL bolus -> target $+4$ - 6 mEq/L -> chronic correction limits -> DDAVP/D5W if overcorrecting; no/mild symptoms -> classify by volume -> isotonic saline / fluid restriction-urea-vaptan / treat edematous state.

Clinical / Diagnostic significance

- ▶ Hyponatremia is often **multifactorial**; a patient may have thiazide use, low solute intake, nausea, pain, and hypotonic fluids simultaneously.
- ▶ In unexplained SIADH, actively search for **small-cell lung carcinoma**, other pulmonary disease, CNS disease, and causative drugs; a chest x-ray may miss small-cell lung cancer, so CT thorax is justified in high-risk patients.

- ▶ Differentiating **SIADH from cerebral salt wasting** matters: SIADH is clinically euvolemic and treated with water restriction/solute strategies; cerebral salt wasting is hypovolemic renal salt loss and needs salt and volume replacement, though true CSW is uncommon and controversial.
- ▶ Normal saline corrects hypovolemic hyponatremia but may fail or worsen SIADH because the kidney excretes the sodium while retaining water.
- ▶ Vaptans, hypertonic saline, glucocorticoid replacement, stopping thiazides, and treating hypovolemia can all trigger rapid aquaresis; sodium monitoring must intensify when the cause of ADH excess is abruptly removed.

High-yield exam pointers

- ▶ Write the definition: **serum Na⁺ <135 mEq/L**, usually due to **excess water**, not sodium lack.
- ▶ First decide whether it is **pseudo-, hypertonic, or hypotonic** hyponatremia.
- ▶ In hypotonic hyponatremia, the key urine tests are **urine osmolality** and **urine Na⁺**.
- ▶ **Uosm <100 mOsm/kg** means ADH is suppressed: primary polydipsia or low solute intake.
- ▶ **Uosm >100 mOsm/kg** means impaired dilution; then classify as hypovolemic, euvolemic, or hypervolemic.
- ▶ SIADH is a diagnosis of exclusion: euvolemia, low serum osmolality, urine not maximally dilute, urine Na⁺ usually >20-30, normal adrenal/thyroid function, and no heart/liver/kidney failure.
- ▶ Severe symptoms need **3% saline 100 mL bolus**, aiming only for **4-6 mEq/L** initial rise.
- ▶ Chronic correction limit: **do not exceed 8 mEq/L/24 h**; aim lower in alcoholism, malnutrition, hypokalemia, severe liver disease, or very low Na⁺.
- ▶ Overcorrection is treated/prevented with **DDAVP and/or D5W**, not by ignoring a rapid water diuresis.

Hyponatremia

Asked in: Paper I Jul 2020 — RGUHS MD General Medicine

Definition / Introduction — Hyponatremia is a plasma Na⁺ concentration <135 mmol/L and is the commonest electrolyte abnormality in clinical practice, occurring in up to **22% of hospitalised patients**. It is fundamentally a disorder of *water balance* — an **excess of body water relative to sodium** — and almost always reflects an increase in circulating arginine vasopressin (AVP/ADH) and/or increased

renal sensitivity to AVP, combined with continued free-water intake. The serum Na^+ therefore says *nothing* about total-body sodium or volume status, both of which must be assessed independently. The key clinical danger is **cerebral oedema** (acute) and **osmotic demyelination from over-rapid correction** (chronic).

Pathophysiology of water homeostasis

- ▶ Serum osmolality is normally held at 285–295 mOsm/kg by two effectors: **thirst** and **AVP** acting on renal V2 receptors (insertion of aquaporin-2 → free-water reabsorption).
- ▶ Hyponatremia develops when water intake exceeds the kidney's capacity to excrete electrolyte-free water — either because AVP is inappropriately high, renal diluting capacity is impaired, or solute delivery to the diluting segment is inadequate (low-solute states).
- ▶ **Non-osmotic AVP release** (hypovolemia, arterial underfilling in heart failure/cirrhosis, nausea, pain, stress, drugs) overrides osmotic suppression and is central to most hyponatremias.
- ▶ Estimated osmolality = $2[\text{Na}^+] + \text{glucose}(\text{mg/dL})/18 + \text{BUN}(\text{mg/dL})/2.8$. **Effective osmolality (tonicity)** subtracts urea (an ineffective osmole); true hypotonic hyponatremia has an effective osmolality <275 mOsm/kg.

Classification — first by tonicity, then by volume status

Step	Category	Serum osmolality	Mechanism / examples
1	Pseudohyponatremia (isotonic)	Normal	Lab artifact in severe hyperlipidemia / hyperproteinemia (↑ solid phase of plasma); excluded by measuring osmolality
1	Hypertonic (translocational)	High	Hyperglycemia, mannitol — osmotic water efflux from cells; Na^+ falls ~1.6 mmol/L per 100 mg/dL rise in glucose. <i>No cerebral oedema</i>
1	Hypotonic (“true”)	Low (<275)	Genuine water excess — subclassified by volume status (Step 2)
2	Hypovolemic	Low	↓ total body water, ↓↓ total body Na^+
2	Euvolemic	Low	↑ total body water, near-normal Na^+

Step	Category	Serum osmolality	Mechanism / examples
2	Hypervolemic	Low	↑↑ total body water, ↑ Na ⁺ (oedematous states)

Aetiology of hypotonic hyponatremia by volume status

Volume status	Urine Na ⁺	Causes
Hypovolemic	<20 mmol/L (extrarenal)	Vomiting, diarrhoea, GI/tube drainage, third-spacing (pancreatitis, burns, trauma), insensible/sweat loss with hypotonic replacement
Hypovolemic	>20 mmol/L (renal)	Thiazide diuretics, mineralocorticoid deficiency / primary adrenal insufficiency (Addison's → ↑K ⁺), salt-losing nephropathy, osmotic diuresis (glycosuria, ketonuria), bicarbonaturia (RTA, vomiting), cerebral salt wasting
Euvolemic	>20–30 mmol/L	SIAD (commonest), hypothyroidism, secondary (glucocorticoid) adrenal insufficiency, reset osmostat, drugs; beer potomania / low-solute (here UNa <20, U-osm <100–200)
Hypervolemic	<10 mmol/L (Na ⁺ -avid)	Congestive heart failure, cirrhosis, nephrotic syndrome
Hypervolemic	>20 mmol/L	Acute & chronic renal failure

- ▶ **Cerebral salt wasting** — hyponatremia with *true hypovolemia* and inappropriate natriuresis in intracranial disease (subarachnoid haemorrhage, TBI, craniotomy, meningitis, encephalitis). Distinction from SIAD is critical: it responds to **aggressive Na⁺-Cl⁻ repletion**, whereas SIAD requires water restriction.

Syndrome of Inappropriate Antidiuresis (SIAD/SIADH)

- ▶ **Commonest cause of euvolemic hyponatremia.** Patients are not strictly euvolemic but *subclinically volume-expanded* with “AVP escape” limiting further retention.
- ▶ **Bartter–Schwartz diagnostic criteria** (a diagnosis of exclusion): (1) hyponatremia with **hypo-osmolality** (<280 mOsm/kg); (2) **inappropriately concentrated urine** (U-osm >100); (3) **urine**

Na⁺ usually >20–30 mmol/L (euvolemic, normal salt intake); (4) **absence of cardiac, renal, hepatic, thyroid and adrenal disease**; (5) normal acid–base/potassium.

- ▶ Supportive: **low serum uric acid (<4 mg/dL)** and **low BUN (<10 mg/dL)** from dilution + enhanced clearance — distinguishes from hyperuricemic hypovolemic hyponatremia.
- ▶ **Causes (4 groups):** **Malignancy** — *small-cell lung carcinoma* (75% of malignancy-associated SIAD; ~10% have Na⁺ <130 at presentation), head & neck, GI; **Pulmonary** — pneumonia, TB, abscess, positive-pressure ventilation; **CNS** — tumour, SAH, meningitis, encephalitis, head trauma; **Drugs** — SSRIs, tricyclics, **carbamazepine, chlorpropamide**, cyclophosphamide/ifosfamide, vincristine, NSAIDs, antipsychotics, MDMA (“Ecstasy”), desmopressin/oxytocin.

Clinical features

- ▶ Symptoms are predominantly **neurological** (cerebral oedema within the rigid skull) and depend on **severity and rate of fall**.
- ▶ **Acute (<48 h) symptomatic hyponatremia — a medical emergency:** nausea, headache, vomiting → seizures, obtundation, **brainstem herniation**, coma, death; may cause **non-cardiogenic (“neurogenic”) pulmonary oedema** with respiratory failure. **Premenopausal women** are at highest risk of encephalopathy. Settings: post-operative hypotonic fluids, TURP/hysteroscopy glycine irrigation, exercise (marathon) and MDMA-associated, psychogenic polydipsia.
- ▶ **Chronic (>48 h):** brain adapts by extruding **organic osmolytes** (creatine, betaine, glutamate, myoinositol, taurine) — largely complete by 48 h — so patients are often paucisymptomatic, but show subtle gait/cognitive deficits, **falls**, and ↑ **fracture/osteoporosis** risk. This adaptation is the basis of ODS risk on correction.
- ▶ **Severity (CMDT):** mild 130–134, moderate 125–129, **severe <125 mmol/L**.

Diagnostic approach

- ▶ **Step 1 — measure serum osmolality** to exclude pseudo- and hypertonic hyponatremia; calculate effective osmolality (<275 confirms hypotonic).
- ▶ **Step 2 — clinical volume status** (JVP, orthostatic vitals, oedema).
- ▶ **Step 3 — urine osmolality and urine Na⁺:** U-osm <100 mOsm/kg → primary polydipsia / low-solute; U-osm >100 → AVP active. UNa <20–30 → hypovolemic or Na⁺-avid (CHF/cirrhosis); UNa >30 → SIAD-type.
- ▶ **Step 4 — targeted tests:** serum glucose (correct for translocation), **uric acid** (low in SIAD), TSH, 0900 cortisol / **cosyntropin (ACTH-stimulation) test** for adrenal insufficiency; chest/CNS imaging (CT thorax in smokers for small-cell carcinoma).
- ▶ “Gold standard” for hypovolemic hyponatremia = correction of Na⁺ after a normal-saline challenge.

Treatment

- ▶ **Three guiding principles:** symptom severity sets urgency; chronicity sets the *safe correction rate*; response to therapy is **unpredictable** → monitor Na^+ every 1–4 h.
- ▶ **Acute symptomatic (seizures/coma) — hypertonic 3% saline (513 mmol/L):** 100 mL bolus over 10 min, repeatable $\times 2$, aiming to raise Na^+ by 1–2 mmol/L/h for a total of only 4–6 mmol/L — enough to abort herniation; or infusion 0.5–2 mL/kg/h. Add O_2 /ventilatory support and IV loop diuretic if pulmonary oedema. Na^+ deficit = $0.6 \times \text{body weight} \times (\text{target} - \text{actual } \text{Na}^+)$.
- ▶ **Safe correction limits (avoid ODS):** <8–10 mmol/L in first 24 h and <18 mmol/L in 48 h; high-risk patients (alcoholics, malnourished, hypokalemic, $\text{K}^+ < 120$) target only 4–6 mmol/L/day. “Limit, not a goal.”
- ▶ **Chronic / aetiology-specific:**
 - **Hypovolemic** → isotonic 0.9% saline (shuts off AVP — watch for *auto-correction* and overshoot).
 - **Hypervolemic (CHF/cirrhosis)** → fluid + Na^+ restriction, treat underlying disease, loop diuretics, ACE inhibition.
 - **Euvolemic/SIAD** → **fluid restriction** guided by the **Furst / urine-to-plasma electrolyte ratio** ($\text{UNa} + \text{UK}$)/ PNa : ratio >1 restrict <500 mL/d, ~1 restrict 500–700 mL/d, <1 restrict <1 L/d. Add oral salt tablets + furosemide 20 mg BD, oral urea, SGLT2 inhibitors (osmotic glycosuric diuresis), or demeclocycline.
 - **Vaptans (V2 antagonists) — tolvaptan (oral) and conivaptan (IV, mixed V1A/V2) —** aquaretics for SIAD and hypervolemic hyponatremia; **contraindicated in hypovolemic and acute hyponatremia**, avoid in cirrhosis, limit to ≤ 30 days (hepatotoxicity); start in hospital with liberalised fluids.
- ▶ **Overcorrection rescue / prophylaxis:** if Na^+ rises too fast, re-lower with DDAVP (desmopressin) $\pm$ D5W; a planned “DDAVP clamp” with concurrent hypertonic saline gives controlled correction in high-risk patients.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Diagnostic algorithm box (Fig.):** Top — “Hyponatremia ($\text{Na}^+ < 135$)”. Branch 1 *Serum osmolality* → Normal = pseudohyponatremia / High = hyperglycemia, mannitol / Low = true hypotonic. From “Low”, branch on volume status → Hypovolemia ($\text{UNa} < 20$ extrarenal: GI loss, third-space; $\text{UNa} > 20$ renal: diuretics, Addison’s, CSW), Euvolemia (SIAD, hypothyroidism, glucocorticoid deficiency), Hypervolemia (CHF, cirrhosis, nephrotic — $\text{UNa} < 10$; renal failure — $\text{UNa} > 20$). Label arrows $\text{UNa} < 20$ / $\text{UNa} > 20$.
- ▶ **Brain-cell osmolyte diagram:** ICF cell with arrows — *acute* water influx → swelling/cerebral oedema; *chronic* efflux of organic osmolytes (taurine, myoinositol,

glutamate); on **over-rapid correction** → osmotic shrinkage → **osmotic demyelination** (pons). Labels: “cerebral oedema”, “osmolyte efflux (48 h)”, “central pontine myelinolysis”.

Clinical / Diagnostic significance

- ▶ **Osmotic demyelination syndrome (ODS)**: occurs 2–6 days after over-rapid correction; **central pontine myelinolysis** → flaccid then spastic quadriparesis, dysarthria, dysphagia, diplopia, “**locked-in syndrome**”; **extrapontine** lesions (cerebellum, lateral geniculate, thalamus, putamen, cortex) → ataxia, parkinsonism, dystonia, mutism. Often **irreversible** — prevention by rate control is paramount.
- ▶ A **low uric acid + low BUN** in a euvolemic hyponatremic patient strongly favours SIAD; **hyperuricemia** favours volume depletion.
- ▶ Hyponatremia is an independent **adverse prognostic marker** in heart failure and cirrhosis (degree reflects neurohumoral activation).
- ▶ Always recheck for **thiazide effect** and **adrenal insufficiency** before labelling SIAD; defer SIAD diagnosis 1–2 weeks after stopping a thiazide.

High-yield exam pointers

- ▶ Hyponatremia = **water problem**, not a salt problem; Na^+ value reflects nothing about volume status.
- ▶ Three-step work-up: **serum osmolality** → **volume status** → **urine Na^+ /osmolality**.
- ▶ **Translocational Na^+ correction**: subtract ~1.6 mmol/L per 100 mg/dL glucose above normal.
- ▶ SIAD = **Bartter–Schwartz criteria**; uric acid <4 mg/dL; commonest malignancy = **small-cell lung carcinoma**.
- ▶ **Acute symptomatic** → 3% saline 100 mL boluses, target rise only 4–6 mmol/L.
- ▶ **Correction ceiling**: <8–10 mmol/L/24 h, <18/48 h (high-risk 4–6/day) — exceeding this → ODS / central pontine myelinolysis.
- ▶ **Vaptans never in hypovolemic or acute hyponatremia**; isotonic saline corrects hypovolemic type.
- ▶ **Cerebral salt wasting** (hypovolemic, treat with salt) vs SIAD (euvolemic, restrict water) — opposite therapies.
- ▶ Overcorrection rescue = DDAVP + D5W; correct **hypokalemia** cautiously (it itself raises Na^+).

SOURCE & COVERAGE

- ▶ **Harrison’s Principles of Internal Medicine, 22e** — “Fluid and Electrolyte Disturbances” (sodium disorders; SIAD; ODS; hypertonic saline and vaptan therapy).

- **CMDT 2026** — “Electrolyte & Acid-Base Disorders” (osmolality formula, severity grading, Bartter–Schwartz criteria, 3% saline boluses, Furst ratio, SGLT2 inhibitors/oral urea, DDAVP clamp) and “Disorders of the Pituitary, Thyroid, & Adrenal Glands” (SIADH causes).

Parenteral Nutrition Therapy

Asked in: Paper I Jul 2020 — RGUHS MD General Medicine

Definition / Introduction — Parenteral nutrition (PN) is the delivery of a nutritionally complete mixture of crystalline amino acids, glucose (dextrose), lipid emulsion, electrolytes, minerals, vitamins and trace elements **directly into the bloodstream**, bypassing the gastrointestinal (GI) tract. It is one of three forms of *specialized nutritional support* (SNS) — the others being optimized voluntary nutrition and enteral nutrition (EN). PN is reserved for patients in whom invasive support is indicated but the gut is non-functional, inaccessible or insufficient. The guiding principle is “*if the gut works, use it*”: EN is always preferred when feasible, and PN carries the higher burden of infectious, metabolic and mechanical complications.

Indications and Patient Selection

- PN is used **when invasive SNS is indicated and EN is impossible, inappropriate or insufficient** to meet nutritional needs.
- The decision to start instrumental SNS rests on four factors: (1) nutrient intake is likely to remain inadequate for **many days**; (2) there is important **muscle loss** (of any cause); (3) **nutrient requirements are increased** (inflammatory diarrhoea, enterocutaneous fistulas/exudates, a protein-catabolic inflammatory state); and (4) a reasoned judgment that SNS will improve clinical outcome or quality of life.
- **Conditions that contraindicate EN and thus favour PN**: intestinal ischaemia, mechanical bowel obstruction, peritonitis, GI haemorrhage, high-output proximal fistula, prolonged paralytic ileus, severe malabsorption (e.g., short-bowel syndrome), and intractable vomiting/diarrhoea where EN fails.
- In the **ICU**, current guidelines advise starting EN soon after resuscitation and stabilization; if the protein goal is not met after **7–10 days**, PN may be added — particularly if the catabolic state persists.
- **Perioperative**: patients with starvation-related malnutrition (SRM) or chronic disease-related malnutrition (CDM) awaiting major elective surgery benefit from **7–10 days** of preoperative SNS (EN/PN if voluntary intake is impractical).

- ▶ PN is generally **not** initiated in advanced incurable malignancy or advanced dementia with no interest in food, where it does not alter the disease trajectory.

Routes of Venous Access

- ▶ Because adult PN admixtures are **hyperosmolar** (>1200 mOsm/L, often >1800 mOsm/L) and frequently large-volume, they must be infused through a **dedicated central-vein port**.
- ▶ **Central (total) PN**: for malnourished patients needing support >7–14 days; catheter tip documented in the **superior vena cava** radiographically before infusion. The *subclavian route is preferred*; **jugular and femoral catheters should be avoided** because of difficulty keeping a dry, sterile dressing and higher complication rates.
- ▶ **Peripheral PN (PPN)**: for non-malnourished patients or **short-term** (<2 weeks) support; lower osmolarity solutions. Limited by a high incidence of **phlebitis**, line infiltration and volume overload.
- ▶ Lipid emulsions are **isotonic** and can be given via either a central or peripheral vein.

Composition of PN Admixtures

- ▶ Supplied as **ready-to-use 2-chamber (amino acids + glucose)** or **3-chamber (amino acids + glucose + lipid)** bags; vitamins, trace elements and extra electrolytes are added just before infusion. Complex needs (especially acute disease-related malnutrition, ADM) justify a **computer-controlled compounder** to individualize composition.

Component	Key points (faithful to source)
Amino acids	Free (hydrated) crystalline amino acids; energy density 3.3 kcal/g (vs 4.0 in formed protein). 100 g free amino acids $\approx$ 83 g protein substrate . Provide all essential amino acids + nonessential N. Typical bags 4–7% amino acids.
Carbohydrate (dextrose)	Dextrose monohydrate , 3.4 kcal/g . Bags 20–25% glucose. Initial dose $\leq$ 200 g/day ; main metabolic hazard = hyperglycaemia.
Lipid emulsion	~10 kcal/g ; supplies essential n-6 and n-3 fatty acids. Soybean-oil based, or mixed (olive/soybean; or SMOF = 30% soybean, 30% MCT, 25% olive, 15% fish oil). Standard infusion $\leq$ 8 g/h ($\approx$ 175 g = 1925 kcal/day in a 70-kg adult). Check triglycerides first; >400 mg/dL is a relative contraindication . To prevent essential fatty acid deficiency, give 250 mL of 20% soy lipid $\geq$ twice weekly (CMDT).
Electrolytes	Sodium and potassium 1–2 mEq/kg/day ; calcium 10–15 mEq/day ; magnesium 8–20 mEq/day ; phosphorus 20–40 mmol/day (CMDT).

Component	Key points (faithful to source)
Trace elements	Zinc, copper, manganese, selenium, chromium. Iron is NOT added (incompatible with lipid; risk of free-radical catalysis) — give IV iron separately if needed. Copper and manganese omitted in cholestatic liver disease (impaired excretion). Extra zinc for high-output diarrhoea/fistula (1 L secretory diarrhoea $\approx$ 12 mg zinc loss).
Vitamins	Injectable adult multivitamin daily (A, D, E, K, B1, B2, B6, B12, niacinamide, dexpantenol, biotin, folic acid, ascorbic acid). Parenteral water-soluble vitamin needs are higher (urinary loss); ascorbic acid degrades in the bag.

Energy, Protein and Fluid Prescription

- ▶ **Energy:** total daily energy expenditure of a healthy sedentary adult $\approx$ **36 kcal/kg** (resting energy expenditure $\approx$ 75%); weight-based estimate **25–35 kcal/kg/day**; indirect calorimetry is the gold standard. Energy doses **>70% of TEE confer no extra protein-sparing** and risk hyperglycaemia, dyslipidaemia and volume expansion.
- ▶ Non-critically ill patients rarely need **>500 g glucose (1700 kcal)/day**; in ADM, limit to **$\leq$ 350 g glucose (1200 kcal)/day** during the intense catabolic phase. *Hypocaloric, protein-generous* nutrition is recommended for the first $\sim$ 2 weeks in fat-sufficient/obese ADM patients.
- ▶ **Protein:** safe intake 0.8 g/kg; **critically ill 1.2–2.0 g/kg/day**. CMDT: stable 0.8–1.2; moderate–severe stress $\geq$ 1.5; trauma/burns up to $\sim$ 2.5 g/kg/day.
- ▶ **Fluid:** total provision should not normally exceed **$\sim$ 2 L/day** without abnormal losses; $\sim$ 25–35 mL/kg or $\sim$ 1 mL/kcal.

Initiation, Glycaemic Control & Monitoring

- ▶ Begin PN only after the patient is **haemodynamically stable**, with glucose/electrolyte/acid-base homeostasis established and able to tolerate the fluid load. Start at $\sim$ half the energy target ($\approx$ 100–150 g dextrose first 24 h), then advance as tolerated.
- ▶ **Insulin:** add subcutaneous/admixture regular insulin to keep glucose **<140 and >80 mg/dL** (180/100 mg/dL in critically ill diabetics). Benchmarks: basal endogenous secretion $\approx$ **30 U/day**; **$\sim$ 10 U insulin per 100 g glucose** in non-diabetic non-catabolic patients; **$\sim$ 20 U/100 g** in type 2 diabetes.
- ▶ **Monitoring:** baseline urea, creatinine, electrolytes, glucose, magnesium, phosphate, calcium, albumin, triglycerides and LFTs; then daily basic panel + Mg/PO₄ during initiation, easing to 1–2 $\times$ /week once stable; **triglycerides and LFTs weekly**; vitamins/trace elements every 3–6 months on long-term PN.

- ▶ **Nitrogen balance** (CMDT) = [24-h protein intake (g) ÷ 6.25] – [24-h urinary nitrogen (g) + 4]; a positive balance confirms adequate provision (Harrison: 1 g N = 6.25 g protein).
- ▶ **Discontinuation:** taper PN as oral/enteral intake rises; stop once the patient tolerates **one-half to two-thirds of requirements** enterally. Slow the rate to 50 mL/h before stopping to avoid reactive hypoglycaemia.

Complications

Category	Examples
Catheter-related (mechanical/insertion)	Pneumothorax, arterial laceration, air embolism, brachial plexus injury; catheter-related bloodstream infection (PN patients are at higher risk than other CVC patients); central venous thrombosis ; thrombotic/non-thrombotic occlusion.
Metabolic	Hyperglycaemia (most frequent); hypoglycaemia (reactive, on abrupt stop); hypertriglyceridaemia ; fluid/electrolyte and acid-base derangements; volume overload (mortality risk).
Hepatobiliary	Mild transaminase rise at 2–4 weeks (often self-limited); fatty liver from energy overfeeding; intrahepatic cholestasis after many weeks — reduced by cyclic PN (infused over only 12 h/day).
Refeeding syndrome	See below.
Long-term	Metabolic bone disease; micronutrient deficiencies (including iron).

Refeeding Syndrome

- ▶ Occurs in successfully adapted SRM during the **first week** when carbohydrate (± sodium) is introduced too rapidly. Carbohydrate → insulin surge → **antinatriuretic** ECF expansion (refeeding **oedema**) plus intracellular shift of electrolytes.
- ▶ Hallmark biochemistry: **hypophosphataemia**, **hypokalaemia**, **hypomagnesaemia**; can cause haemolysis, cardiac arrhythmias and **left heart failure** (volume load + insulin-driven rise in resting energy expenditure on an atrophic LV + myocardial K/PO₄/Mg deficiency).
- ▶ **Acute thiamine-deficiency encephalopathy (Wernicke)** is a devastating but preventable complication — give **thiamine 100 mg daily for 5–7 days** before/with refeeding.
- ▶ **Prevention:** start low (~5–20 kcal/kg/day), advance slowly, restrict sodium, and frequently measure and replace phosphate, potassium and magnesium. (Refeeding oedema is benign — treat with elevation and sodium restriction; *avoid diuretics*.)

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Decision algorithm for nutritional support:** box flow — *Can the patient eat enough?* → No → *Is the gut functional & accessible?* → Yes = **Enteral nutrition**; No = **Parenteral nutrition** → branch to **Central PN** (>7–14 days, malnourished, hyperosmolar) vs **Peripheral PN** (<2 weeks, non-malnourished). Label EN contraindications (obstruction, ischaemia, peritonitis, GI bleed) as the arrow into PN.
- ▶ **Triple-chamber PN bag:** three labelled compartments — *Amino acids* (3.3 kcal/g), *Dextrose monohydrate* (3.4 kcal/g), *Lipid emulsion* (~10 kcal/g) — with add-on ports labelled *Vitamins*, *Trace elements*, *Electrolytes*, feeding into a *central venous catheter*, tip in SVC.

Clinical / Diagnostic significance

- ▶ Choosing **route** (central vs peripheral) hinges on osmolarity, expected duration and nutritional status — a frequent exam decision point.
- ▶ Pre-lipid **triglyceride** and baseline **electrolyte/phosphate/Mg** checks pre-empt the two commonest serious metabolic harms (hypertriglyceridaemia, refeeding syndrome).
- ▶ **Special populations:** *Renal failure* — do **not** restrict protein (RRT removes amino acids/vitamins/trace elements; increase provision). *Liver failure* — generous energy and protein, but spread protein through the day and tighten fluid/acid-base/electrolyte control to limit encephalopathy; omit copper/manganese. *Critical illness–nutrition paradox* — early energy provision matching expenditure may be **harmful**; avoid matching energy to expenditure while inflammation is severe.
- ▶ A multidisciplinary **nutrition support team** (physician, nurse, dietitian, pharmacist) demonstrably lowers complication rates.

High-yield exam pointers

- ▶ “*If the gut works, use it*” — EN is always first-line; PN only when the gut is unusable/inaccessible/insufficient.
- ▶ Adult PN is **hyperosmolar** → **central vein** (subclavian preferred; tip in SVC, X-ray confirmed; **avoid femoral/jugular**).
- ▶ Energy densities to memorize: amino acids 3.3, dextrose 3.4, lipid ~10 kcal/g; 100 g amino acids ≈ 83 g protein.
- ▶ Starting glucose ≤200 g/day; insulin target glucose 80–140 mg/dL; triglycerides >400 mg/dL = relative contraindication to lipid.
- ▶ **Iron is never added** to PN; copper/manganese omitted in cholestasis.
- ▶ **Refeeding syndrome triad:** ↓phosphate, ↓potassium, ↓magnesium; give **thiamine 100 mg/day**, start 5–20 kcal/kg/day.

- ▶ Cyclic PN (12 h/day) reduces PN-associated cholestasis; energy overfeeding causes fatty liver.
- ▶ Wean PN once $\frac{1}{2}$ – $\frac{2}{3}$ of needs are tolerated enterally; slow rate before stopping to prevent rebound hypoglycaemia.
- ▶ Nitrogen balance = (protein intake/6.25) – (urinary N + 4).

SOURCE & COVERAGE

- ▶ **Harrison's Principles of Internal Medicine, 22e** — “*Enteral and Parenteral Nutrition*” (Hoffer & Bistrian) and “*Nutritional Assessment*” (body-composition/inflammation context).
- ▶ **CMDT 2026** — “*Nutrition, Nutritional Disorders, & Obesity*” — nutritional-support routes, requirements, parenteral electrolyte/trace-element doses, nitrogen-balance equation, refeeding-syndrome management.

Pellagra

Asked in: Paper I Jul 2021 · Paper I May 2019 (2×) — RGUHS MD General Medicine

Definition / Introduction — Pellagra is the clinical deficiency syndrome of **niacin** (vitamin B3) and/or its precursor amino acid **tryptophan**. The name derives from the Italian *pelle agra* (“rough skin”). Niacin (nicotinic acid + nicotinamide) is the precursor of the coenzymes **NAD** and **NADP**, which drive numerous oxidation–reduction reactions and (as NAD) ADP-ribose transfer reactions in DNA repair and calcium mobilisation. Deficiency produces the classic photodistributed dermatitis, gastrointestinal and neuropsychiatric features summarised as the “**four Ds**”: **Dermatitis, Diarrhoea, Dementia and Death**.

Niacin metabolism and biochemical basis

- ▶ **Sources & forms** — *Niacin* is a generic term for **nicotinic acid** and **nicotinamide** and their active derivatives. Roughly half the body's niacin is supplied by diet (meat, fish, poultry, nuts, eggs, dairy, legumes, fortified cereals) and half is synthesised endogenously from **tryptophan**.
- ▶ **Tryptophan conversion** — Tryptophan is converted to niacin with an efficiency of **60 : 1 by weight**; requirements are therefore expressed as **niacin equivalents**. This conversion needs **vitamin B6 (pyridoxine)**, **riboflavin** and **iron** as cofactors — deficiency of any of these lowers niacin yield.
- ▶ **Coenzyme role** — Nicotinic acid and nicotinamide are precursors of **NAD** and **NADP**, central to redox metabolism; NAD also participates in **ADP-ribose transfer** (**DNA repair**, **Ca²⁺ mobilisation**). Cellular NAD⁺ declines with ageing.

- ▶ **Maize/corn factor** — Niacin in corn and maize is **tightly (chemically) bound** and is not absorbed unless released by **alkaline hydrolysis** (e.g. lime-water/*nixtamalization*). Diets based on unfortified maize therefore predispose to pellagra.
- ▶ **Sorghum (jowar) factor** — Jowar contains usable niacin but a **high leucine content** that inhibits the conversion of tryptophan to niacin — the basis of epidemic pellagra in sorghum-eating populations of the Indian Deccan.
- ▶ **Excretion / biomarkers** — Urinary excretion products **2-pyridone** and **N-methyl (2-methyl) nicotinamide** fall in deficiency and are used diagnostically.

Aetiology and predisposing causes

Category	Examples (source-grounded)
Dietary / endemic	Corn- or maize-based diets (China, Africa, India); sorghum (jowar)-based diets; famine, displacement, refugee/camp populations; restrictive/selective eating (e.g. autism spectrum disorder), eating disorders
Alcoholism	Commonest cause in industrialised settings (poor intake + impaired metabolism)
Malabsorption	Inflammatory bowel disease, jejunoileitis, gastrectomy/gastroenterostomy, bariatric (gastric bypass) surgery
Drugs	Isoniazid (structural analogue of niacin — also seen with mass scale-up of INH TB-preventive therapy); 5-fluorouracil; 6-mercaptopurine/azathioprine; anticonvulsants; antidepressants; sulfonamides; chloramphenicol
Inherited — Hartnup disease	Autosomal recessive defect of neutral amino-acid transport (SLC6A19 gene) → intestinal & renal malabsorption of tryptophan ; presents with cerebellar ataxia, psychiatric symptoms, aminoaciduria and pellagra-like rash
Carcinoid syndrome	Tumour diverts up to ~60% of tryptophan to serotonin (normally ~1%), depleting tryptophan available for niacin synthesis

Clinical features — the “four Ds”

- ▶ **Dermatitis (the hallmark)** — A **photosensitive eruption**: initially intermittent painful/pruritic erythema and oedema of **sun-exposed skin**, evolving into sharply margined, **hyperpigmented**, **scaling**, **keratotic plaques**; vesicles/bullae may form in severe cases.

- *Distribution*: **dorsa of the hands** (glove/gauntlet pattern), **face in a symmetrical butterfly/malar distribution**, and the **neck and upper chest forming a collar** — **Casal's necklace** (*after Gaspar Casal*).
- *Mucocutaneous*: **bright-red ("beefy") glossitis**, angular stomatitis, cheilitis, oral/perirectal ulcers; **half-and-half nails** described.
- ▶ **Diarrhoea** — From **proctitis and malabsorption** (atrophy of intestinal villi); often accompanied by anorexia, abdominal pain, nausea, vomiting; vaginitis and oesophagitis may occur.
- ▶ **Dementia / neuropsychiatric** — Early irritability, anxiety, insomnia, apathy, fatigue, depression and impaired memory progress to **confusion, hallucinations, psychosis, dementia**; seizures and, terminally, stupor and coma.
- ▶ **Death** — Untreated pellagra is progressive and **fatal within ~4–5 years**.
- ▶ **Early (non-specific) phase** — Loss of appetite, generalised weakness, irritability, mouth soreness, glossitis/stomatitis and weight loss precede the full triad.

Diagnosis and investigations

- ▶ **Primarily a clinical diagnosis** in advanced cases (characteristic photodistributed rash + GI + neuropsychiatric features); early deficiency requires a **high index of suspicion**.
- ▶ **Biochemical confirmation** — Reduced **urinary N-methylnicotinamide and 2-pyridone**; low **serum/plasma nicotinamide and nicotinic acid**. Reference deficiency threshold is **< 9.0 niacin equivalents** (recommended daily intake ~13–20 mg).
- ▶ **Therapeutic trial** — Rapid response to niacin supports the diagnosis: **neuropsychiatric symptoms improve within 24–48 h**, whereas cutaneous lesions take weeks to resolve.
- ▶ **Differential diagnosis** — Pyridoxine (B6) deficiency (pellagra-like dermatitis), porphyrias, polymorphous light eruption, chronic actinic dermatitis, photosensitive drug eruptions, cutaneous lupus; consider underlying carcinoid or Hartnup disease where diet is adequate.

Treatment and prevention

- ▶ **Replacement** — **Nicotinamide is preferred** over nicotinic acid because it does not cause flushing/headache.
 - *Harrison*: oral **nicotinamide or nicotinic acid 100–200 mg three times daily for up to 4 weeks**.
 - *Rook's*: **~500 mg/day** of nicotinamide (or nicotinic acid) over several weeks.
 - *CMDT*: oral **nicotinamide 10–150 mg/day**; advanced pellagra may be treated with parenteral nicotinic acid initially, then oral.
- ▶ **Supportive** — Treat coexisting deficiencies (general undernutrition, alcohol-use disorder) and correct precipitants (stop offending drug, manage malabsorption/carcinoid). Co-administer **pyridoxine with isoniazid** to prevent INH-induced pellagra/neuropathy.

- ▶ **Prevention** — Dietary diversification away from monotonous maize/sorghum; **niacin fortification of flour/cereals**; alkaline (lime) treatment of maize; treat at-risk groups (alcoholics, famine/displaced populations).

Niacin toxicity (pharmacologic high-dose, not deficiency)

- ▶ High-dose **nicotinic acid** (≈ 2 g/day, sustained-release) is used for **hypertriglyceridaemia / low HDL** (useful in statin intolerance) but lacks proven cardiovascular benefit; **nicotinamide does not lower lipids**.
- ▶ **Flushing** — Prostaglandin-mediated (GPCR binding), starts in the face, with itching/paraesthesia/headache; subject to **tachyphylaxis**; mitigated by **aspirin pre-medication** and extended-release forms.
- ▶ **Hepatotoxicity** — Most serious effect of sustained-release niacin (raised AST/ALT, jaundice; rare fulminant hepatitis at 3–9 g/day). Other effects: **glucose intolerance, hyperuricaemia/gout, macular oedema**; combined with statins increases **rhabdomyolysis** risk. **Upper limit for non-therapeutic intake = 35 mg/day**.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Casal's necklace / photodistributed dermatitis (front of body)**: Label — *symmetrical butterfly (malar) facial rash; Casal's necklace (collar over neck and upper chest); V of the neck; dorsa of hands — glove/gauntlet pattern; bright-red (beefy) glossitis & angular stomatitis; sun-exposed = photodistribution*.
- ▶ **Tryptophan–niacin pathway**: Boxes — *Dietary niacin (NAD/NADP in food) and Tryptophan $\rightarrow$ (60:1, needs B6 + riboflavin + iron) $\rightarrow$ Nicotinic acid / Nicotinamide $\rightarrow$ NAD / NADP $\rightarrow$ redox + DNA-repair reactions. Add block-arrows: Isoniazid (analogue, blocks), Carcinoid (diverts Trp $\rightarrow$ serotonin), Hartnup / SLC6A19 (blocks Trp absorption), Maize bound-niacin & sorghum-leucine (reduce availability)*.

Clinical / Diagnostic significance

- ▶ “4 Ds” mnemonic anchors recognition: photosensitive Dermatitis + Diarrhoea + Dementia $\rightarrow$ Death if untreated — an instantly examinable triad.
- ▶ **Casal's necklace** and **butterfly facial rash** in a photodistribution are pathognomonic visual clues at the bedside.
- ▶ Always seek a **precipitant**: alcohol, isoniazid therapy, maize/sorghum-predominant diet, malabsorption/bariatric surgery, carcinoid or Hartnup disease — deficiency in an apparently well-fed patient mandates this search.
- ▶ **Niacin-equivalents** concept explains why deficiencies of **B6, riboflavin and iron** (cofactors for tryptophan $\rightarrow$ niacin) and **carcinoid** can cause “secondary” pellagra.

- ▶ A prompt **therapeutic response** (neuropsychiatric within 48 h) is both treatment and confirmation.

High-yield exam pointers

- ▶ Niacin = **vitamin B3** = nicotinic acid + nicotinamide → coenzymes NAD/NADP.
- ▶ Tryptophan → niacin at **60 : 1 by weight**; cofactors **B6, riboflavin, iron**.
- ▶ **4 Ds** = **D**ermatitis, **D**iarrhoea, **D**ementia, **D**eath; dermatitis is **photosensitive**.
- ▶ **Casal's necklace** = pigmented scaly collar of neck/upper chest (eponym *Gaspar Casal*).
- ▶ **Maize (bound niacin)** and **sorghum/jowar (high leucine)** are classic dietary causes — relevant to India.
- ▶ Secondary pellagra: **alcoholism, isoniazid, Hartnup disease (SLC6A19), carcinoid syndrome, 5-FU/6-MP, malabsorption**.
- ▶ Tongue = **bright-red/beefy glossitis**; nails = **half-and-half**.
- ▶ Diagnosis mainly **clinical**; biomarkers = ↓ urinary **N-methylnicotinamide & 2-pyridone**, ↓ serum niacin.
- ▶ Treatment = **nicotinamide preferred** (no flushing); high-dose **nicotinic acid** toxicity = flushing, hepatotoxicity, hyperglycaemia, hyperuricaemia (UL **35 mg/day**).

SOURCE & COVERAGE

- ▶ **Harrison's Principles of Internal Medicine, 22e** — “Vitamin and Trace Mineral Deficiency and Excess” (niacin/pellagra section: metabolism, four Ds, Casal's necklace, treatment, toxicity).
- ▶ **Rook's Textbook of Dermatology, 10e** — “Nutritional Disorders Affecting the Skin” (vitamin B3/niacin: maize & sorghum-leucine mechanisms, Hartnup/SLC6A19, carcinoid, photodistributed dermatitis, Casal's necklace, half-and-half nails, diagnosis and management).
- ▶ **CMDT 2026** — “Nutrition, Nutritional Disorders, & Obesity” (clinical findings, diagnosis, current treatment doses, niacin toxicity).

Coverage note: Corpus coverage is solid across all three texts. The etymology (*pelle agra*) and the attribution of “Casal's necklace” to *Gaspar Casal* are universally accepted standard medicine, included although not explicitly stated in the chapter text (Harrison/Rook's name the sign without the eponymous person). Stated treatment doses differ slightly between sources and are quoted per text rather than reconciled.

Thiamine Physiology and Deficiency

Asked in: Paper I Nov 2021 — RGUHS MD General Medicine

Definition / Introduction — Thiamine (**vitamin B1**) was the first vitamin to be identified. It is a water-soluble B-complex vitamin whose active coenzyme form, **thiamine pyrophosphate (TPP)**, is essential for carbohydrate and branched-chain amino-acid metabolism and for energy generation. Body stores are small and can be depleted within a few weeks of a deficient diet, so thiamine deficiency develops rapidly and produces the classic syndromes of **beriberi** (wet and dry) and **Wernicke–Korsakoff syndrome**. It is a readily treatable, frequently under-diagnosed condition.

Physiology and biochemical functions

- ▶ **Active form:** thiamine is phosphorylated to **thiamine pyrophosphate (TPP)**, the coenzyme responsible for virtually all of its metabolic actions. **Magnesium** is required for activation of thiamine — a key point in management.
- ▶ **Oxidative decarboxylation of α -ketoacids** — TPP is the coenzyme for the dehydrogenase complexes that decarboxylate **pyruvate** (pyruvate dehydrogenase) and **α -ketoglutarate** (α -ketoglutarate dehydrogenase), linking glycolysis to the citric-acid cycle, and for **branched-chain α -ketoacid dehydrogenase**. It is thus essential for **ATP/energy generation**.
- ▶ **Transketolase reaction** — TPP is the coenzyme for transketolase in the **hexose monophosphate (pentose phosphate) shunt**, mediating interconversion of hexose and pentose phosphates and generating ribose and NADPH-linked intermediates.
- ▶ Functionally, TPP is a coenzyme for the **cleavage of carbon–carbon bonds** in carbohydrate and amino-acid metabolism.
- ▶ **Peripheral nerve conduction** — thiamine is postulated to play a role in nerve conduction, although the exact chemical reactions are not established; this underlies the neuropathy of deficiency.
- ▶ **Stores and kinetics** — body stores are small (unlike B12 or vitamin A); thiamine and folate are among the vitamins that deplete within **weeks** on a deficient diet. Therapeutic losses occur with **haemodialysis and diuretics**, which remove water-soluble vitamins.

Dietary sources, requirement and anti-thiamine factors

- ▶ **Median dietary intake** in well-nourished adults is ~2 mg/day; overt deficiency is associated with intake <0.3 mg per 1000 kcal/day. (The conventional adult RDA of ~1.1–1.2 mg/day is standard medicine, not detailed in the corpus.)
- ▶ **Rich sources:** yeast, organ meat, **pork**, legumes, beef, whole grains and nuts. **Milled/polished rice and refined grains contain little thiamine**, so deficiency is commoner in cultures heavily reliant on polished-rice diets.
- ▶ **Food processing/cooking** removes or destroys thiamine (high-heat or long-duration cooking).
- ▶ **Anti-thiamine factors:**

- **Heat-labile thiaminases** — in **raw fish and shellfish** — enzymatically destroy the vitamin.
- **Heat-stable polyhydroxyphenols (tannins)** — in **coffee, tea, Brussels sprouts and betel nuts** — inactivate the vitamin; large amounts of tea/coffee can theoretically lower thiamine stores.
- ▶ **Intestinal transport** is via thiamine transporter **ThTR2**; drugs such as **metformin and verapamil** can inhibit it and increase deficiency risk.

Causes / at-risk groups

- ▶ **Inadequate intake** — famine, displaced/refugee populations, disproportionate reliance on highly processed/polished-rice staples (the major global cause).
- ▶ **Alcohol use disorder** — the leading cause in industrialised countries: alcohol **impairs thiamine absorption**, **inhibits synthesis of TPP**, and **increases urinary excretion**.
- ▶ **Chronic illness** — e.g., cancer and chronic protein–calorie undernutrition.
- ▶ **Refeeding / carbohydrate load** — giving a large carbohydrate load (enteral/parenteral glucose) to a thiamine-depleted patient can **precipitate acute deficiency with lactic acidosis**; thiamine must always be replenished when an alcoholic patient is refed.
- ▶ **Bariatric/metabolic surgery** (“**bariatric Wernicke**”), malabsorption, **dialysis**.
- ▶ **Prolonged hyperemesis gravidarum**, anorexia and other eating disorders, poor nutritional status with parenteral glucose.
- ▶ **Chronic diuretic therapy** (hypertension, systolic heart failure) — increased urinary thiamine loss.
- ▶ **Maternal deficiency** → **infantile beriberi** in breast-fed children.
- ▶ May be an overlooked factor in **motor-vehicle accidents/head injury**.

Clinical syndromes of deficiency

- ▶ **Early/subclinical deficiency** — non-specific: **anorexia**, irritability, decreased short-term memory, muscle cramps, paraesthesia. Hard to recognise.
- ▶ **Beriberi** — classically divided into **wet** and **dry**, with considerable overlap; pain and paraesthesia occur in both.

Feature	Wet beriberi	Dry beriberi
Dominant system	Cardiovascular (impaired myocardial energy metabolism + dysautonomia)	Nervous system (peripheral nerves)
Setting	Deficiency + heavy exertion / high carbohydrate intake; may appear after ~3 months	Deficiency + inactivity / low-calorie intake
Features	Peripheral vasodilation → high-output congestive heart failure ,	Symmetric motor + sensory peripheral neuropathy ,

Feature	Wet beriberi	Dry beriberi
	enlarged heart, tachycardia , dyspnoea, pulmonary and peripheral oedema with warm extremities (may mimic cellulitis); peripheral neuritis	diminished reflexes; legs > arms ; difficulty rising from a squatting position

- ▶ **Wernicke's encephalopathy (WE)** — the CNS manifestation, classically in alcoholics: the **triad** of (1) **ophthalmoplegia** (weakness of one or more extraocular muscles) with **horizontal nystagmus**, (2) **cerebellar/truncal ataxia**, and (3) **encephalopathy/global confusion** (mental impairment).
- ▶ **Wernicke-Korsakoff syndrome (WKS)** — WE plus the **amnesic-confabulatory** state: **severe retrograde and anterograde amnesia**, **confabulation** and impaired learning. About **1 in 500** persons with alcohol use disorder develop the full syndrome, particularly those with an inherited **transketolase** abnormality. WKS is typically **under-diagnosed**.
- ▶ **Classic neuropathology** (universally accepted standard medicine): symmetric lesions of the **mammillary bodies**, **periaqueductal grey matter** and **medial (dorsomedial) thalamus**; chronic alcohol use is associated with ventricular enlargement / widened sulci on CT/MRI (often reversible with abstinence).

Diagnosis / investigations

- ▶ **Erythrocyte transketolase activity** measured **before and after** addition of TPP — a **>25% stimulation** (an “activity coefficient” of ≥ 1.25) is abnormal and indicates deficiency.
- ▶ **Direct assay** of thiamine and its phosphate esters in serum/blood by **HPLC**; normal range **~70–180 nmol/L**.
- ▶ **Empiric response** to thiamine is, in practice, often used to support the diagnosis.
- ▶ Other deficiencies (especially **magnesium**, required for thiamine activation) and inflammatory status should be assessed.

Treatment

- ▶ **Acute deficiency with cardiovascular or neurological signs**: **thiamine 200 mg IV three times daily** until no further improvement in acute symptoms, then **oral thiamine 10 mg/day** until recovery is complete (Harrison). **CMDT regimen**: **50–100 mg/day IV** initially, then **5–100 mg/day orally**.
- ▶ **Cardiovascular and ophthalmoplegic improvement** typically occurs **within 24 hours**; other features clear gradually. **Korsakoff psychosis** may be **permanent** or persist for months.
- ▶ **Correct magnesium** concomitantly — thiamine is only effective if magnesium is replete — and give other water-soluble vitamins.

- ▶ Give thiamine **BEFORE** a glucose/carbohydrate load in at-risk patients (alcoholics, refeeding) to avoid precipitating acute deficiency / Wernicke's.
- ▶ **Prognosis (WKS)**: roughly one-fourth resolve immediately, one-fourth over days, and about half achieve only partial or no benefit — emphasising early treatment.
- ▶ **Toxicity**: essentially none from food or supplements; rare hypersensitivity/anaphylaxis after high IV doses.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Diagram 1 — Biochemical roles of thiamine pyrophosphate (TPP)**. Central box “Thiamine → Thiamine pyrophosphate (TPP)” with arrows to: “Pyruvate → Acetyl-CoA (pyruvate dehydrogenase)”; “ α -Ketoglutarate → Succinyl-CoA (α -ketoglutarate dehydrogenase)”; “Branched-chain α -ketoacids (branched-chain ketoacid dehydrogenase)”; and “Transketolase — HMP/pentose-phosphate shunt”. Side labels: “ Mg^{2+} required for activation”, “Energy/ATP generation”.
- ▶ **Diagram 2 — Clinical spectrum of thiamine deficiency**. Root “Thiamine deficiency” branching to: “Wet beriberi — high-output cardiac failure, oedema”; “Dry beriberi — symmetric sensorimotor neuropathy, legs > arms”; “Wernicke encephalopathy — ophthalmoplegia + nystagmus, ataxia, confusion”; “Korsakoff syndrome — amnesia + confabulation”; “Infantile beriberi (maternal deficiency)”.

Clinical / Diagnostic significance

- ▶ Always suspect thiamine deficiency in **alcoholics, post-bariatric, hyperemesis, refeeding and chronically ill/parenteral-nutrition** patients.
- ▶ Wernicke's encephalopathy is a **medical emergency** — treat empirically on clinical suspicion; do **not** wait for biochemistry, and **never give glucose first** in an at-risk patient.
- ▶ A patient on diuretics/dialysis with high-output cardiac failure unresponsive to standard therapy — consider **wet beriberi (Shoshin beriberi)**.
- ▶ Functional **erythrocyte transketolase activation coefficient** ≥ 1.25 is the classic confirmatory test.
- ▶ Co-existing **magnesium deficiency** causes apparent thiamine-refractoriness — always correct it.

High-yield exam pointers

- ▶ **Vitamin B1**; active coenzyme = **thiamine pyrophosphate (TPP)**; Mg^{2+} needed for activation.
- ▶ Coenzyme for **pyruvate dehydrogenase, α -ketoglutarate dehydrogenase, branched-chain ketoacid dehydrogenase and transketolase (HMP shunt)**.
- ▶ Deficiency threshold < 0.3 mg/1000 kcal/day; thiamine stores deplete within **weeks**.
- ▶ **Polished-rice diet, alcoholism, thiaminases (raw fish), tannins (tea/coffee/betel)** are key causes.

- ▶ **Wet beriberi** = high-output cardiac failure + oedema; **Dry beriberi** = symmetric peripheral neuropathy (legs > arms).
- ▶ **Wernicke triad** = ophthalmoplegia/nystagmus + ataxia + confusion; add amnesia + confabulation = Korsakoff.
- ▶ Diagnosis: erythrocyte transketolase, activation coefficient ≥ 1.25 ; thiamine 70–180 nmol/L by HPLC.
- ▶ Treatment: parenteral thiamine 200 mg IV TDS (or 50–100 mg/day), give before glucose, replace magnesium; CV/eye signs improve in 24 h, Korsakoff may be permanent.
- ▶ Refeeding an alcoholic with carbohydrate without thiamine can precipitate acute deficiency + lactic acidosis.

SOURCE & COVERAGE

- ▶ **Harrison's Principles of Internal Medicine, 22e** — “Vitamin and Trace Mineral Deficiency and Excess” (thiamine physiology, food sources, beriberi, transketolase assay, treatment) and “Alcohol and Alcohol Use Disorders” (Wernicke's and Korsakoff's syndromes, transketolase deficiency, neuroimaging).
- ▶ **CMDT 2026** — “Nutrition, Nutritional Disorders, & Obesity” (wet/dry beriberi distinction, thiamine reference range 70–180 nmol/L, parenteral thiamine regimen and prognosis, magnesium requirement).

Coverage note: The corpus details the clinical syndromes, biochemistry and management thoroughly. The classic neuropathologic localisation of Wernicke's encephalopathy (mammillary bodies, periaqueductal grey, dorsomedial thalamus) and the conventional adult RDA (~1.1–1.2 mg/day) are universally accepted standard internal medicine included for completeness but are not spelt out in these specific chapters.

Total Parenteral Nutrition

Asked in: Paper I Dec 2023 · Paper I Nov 2020 (2×) — RGUHS MD General Medicine

Definition / Introduction — Total parenteral nutrition (TPN) is the delivery of a *nutritionally complete admixture* — crystalline amino acids, glucose, lipid emulsion, electrolytes, minerals, vitamins and trace elements — **directly into the bloodstream through a central vein**, when the *entire* nutrient requirement is met intravenously. It is one of three forms of **specialized nutritional support (SNS)** — the others being optimized voluntary nutrition and instrumental enteral nutrition (EN) — and is reserved for patients whose gastrointestinal (GI) tract cannot be used or is insufficient. Because of its high osmolarity (>1200 mOsm/L) and large volume, adult PN must be infused into a central vein.

Indications and contraindications

- ▶ **Core rule:** PN is used when invasive SNS is indicated *and* EN is **impossible, inappropriate, or insufficient** to meet the patient's needs. *If the gut works and is accessible, use it (EN) — PN is the second choice.*
- ▶ The decision to give EN or PN rests on **four factors**: (1) nutrient intake will likely remain inadequate for **many days**; (2) there is important **muscle loss** of any cause; (3) requirements are **increased** (inflammatory diarrhoea, enterocutaneous fistulae/exudates, an inflammatory protein-catabolic state); and (4) reasoned judgement that SNS will **improve clinical outcome or quality of life**.
- ▶ **Typical PN indications (non-functioning / inaccessible gut):** mechanical **bowel obstruction**, **intestinal ischaemia**, **peritonitis**, **GI haemorrhage** (these four are absolute contraindications to EN), high-output **enterocutaneous fistula**, **short-bowel syndrome**, severe malabsorption, prolonged **paralytic ileus**; also when EN fails to achieve the protein goal after **7–10 days** in the ICU (PN is then added).
- ▶ **Not indicated / cautions:** a functioning accessible gut (EN preferred); terminal illness not mitigated by SNS; **advanced dementia** with little interest in food. PN must wait until the patient is **haemodynamically stabilized** and glucose/electrolyte/acid-base homeostasis is established. Serum triglyceride **>400 mg/dL** is a *relative contraindication* to lipid.

Composition and energy values of TPN

- ▶ Ready-to-use admixtures contain **4–7% hydrated amino acids** and **20–25% glucose**, supplied as **two-chamber** (amino acid + glucose) or **three-chamber** (amino acid + glucose + lipid) bags; vitamins, trace elements and extra electrolytes are added *just before infusion*. Individualized regimens use a **computer-controlled sterile compounder**.

Macronutrient	Form in PN	Energy yield	Key points
Amino acids	crystalline <i>free</i> amino acids	3.3 kcal/g	Hydration lowers density from 4.0 and cuts protein substrate ~17% — <i>100 g free AA = 83 g protein substrate</i> ; provide all essential AAs
Carbohydrate	dextrose monohydrate	3.4 kcal/g	Main energy source; hydration lowers density from 4.0; initial dose ≤ 200 g/day
Lipid emulsion	soybean / olive / MCT / fish-oil blends	~10 kcal/g	Supplies essential n-6 and n-3 fatty acids ; infuse at ≤ 8 g/h (pure fish-oil slower)

- ▶ **Lipid emulsions:** pure soybean oil is giving way to **mixed emulsions** (medium-chain triglycerides, n-9 monounsaturated, n-3). US options include 80% olive/20% soybean, and a 30% soybean/30% MCT/25% olive/15% fish-oil blend. **Fish oil** may reduce infections and length of stay in the critically ill; soy-based emulsions are best avoided in the **first week** of PN in critical illness.
- ▶ **Minerals / micronutrients:** default doses target a healthy adult and must be individualized. **Multivitamins are unstable** — added to the bag just before delivery; parenteral water-soluble vitamin needs *exceed* oral needs, and **ascorbic acid degrades spontaneously** in PN. **Iron is NOT added to PN** (iron dextran is incompatible with lipid emulsions and may catalyse free-radical formation); give IV iron separately, delayed in suspected infection.
- ▶ **Zinc:** 1 L of secretory diarrhoea loses ~12 mg zinc; because of low bioavailability 12 mg parenteral zinc ≈ 30 mg oral zinc (daily requirement ~15 mg).

Daily requirements and prescription targets

Parameter	Target (from chapter)
Total energy expenditure	~36 kcal/kg/day (resting EE ≈ 75% of total)
Protein / amino acids	0.8 g/kg (safe, healthy); 1.2–2.0 g/kg normal body weight (critically ill); minimum 0.65 g/kg
Glucose	start ≤200 g/day; ≤500 g/day (1700 kcal) non-critical; ≤350 g/day (1200 kcal) in acute disease-related malnutrition (ADM)
Lipid	≤50 g/day (500 kcal) in ADM; rate ≤8 g/h
Fluid	≤2 L/day unless abnormally high losses
Glucose control (insulin)	average 80–140 mg/dL (100–180 mg/dL in critically ill diabetics)

- ▶ **Insulin guidance:** regular insulin is added to the bag; ~10 units/100 g glucose for non-diabetic non-catabolic patients and ~20 units/100 g for type 2 diabetics; the next day's dose is based on today's requirement.
- ▶ **Permissive underfeeding** (under-provision of *all* nutrients) must not be confused with **hypocaloric nutrition** (reduced energy but *generous protein*). In fat-sufficient/obese ADM patients, hypocaloric, protein-generous PN is recommended for the first ~2 weeks; matching energy to expenditure early can be *harmful*.

Route, initiation, progression, monitoring and discontinuation

- ▶ **Access:** a dedicated lumen of a central venous catheter (subclavian or PICC preferred). **Jugular and femoral sites are avoided** — hard to keep a dry sterile dressing and higher complication rates.

- ▶ **Initiation:** begin only after haemodynamic stabilization and metabolic/acid-base homeostasis. Initial **glucose** ≤ 200 g/day to avoid hyperglycaemia and **refeeding syndrome**. **Lipids** are usually introduced *after the first week* to cover energy shortfalls (daily or 2–3×/week); check **triglycerides** first.
- ▶ **Monitoring:** urea, creatinine, electrolytes, glucose, **magnesium**, **phosphate**, **calcium** and **albumin** before starting; most monitored for the first few days then **twice weekly**. Capillary glucose several times daily. **Triglycerides** and **LFTs** at baseline and after PN is running. **Nitrogen balance** to gauge catabolism (urinary urea N: $N \text{ loss (g)} = \text{urea-N}/0.85 + 2$).
- ▶ **Discontinuation:** taper as oral/enteral intake rises; **stop once the patient tolerates one-half to two-thirds of requirement enterally**. Wean by optimizing voluntary nutrition — *do not* abruptly stop hoping to “stimulate appetite” (PN does not cause anorexia). **Cyclic PN** (infused over 12 h/day) reduces cholestasis with prolonged use.

Complications of TPN

Category	Complication	Prevention / management
Catheter	Insertion trauma (e.g., pneumothorax), catheter-related bloodstream infection (higher risk than other CVCs), central vein thrombosis	Aseptic insertion, dedicated port , meticulous dressing care, glycaemic control
Metabolic	Hyperglycaemia (most frequent), reactive hypoglycaemia , hypertriglyceridaemia , electrolyte/Mg/PO ₄ /acid-base derangement	Insulin to keep glucose 80–140; taper slowly; TG monitoring; limit lipid rate
Hepatobiliary	Transaminitis (within 2–4 weeks, usually self-limiting), hepatic steatosis (overfeeding), intrahepatic cholestasis (prolonged PN)	Avoid energy overfeeding; cyclic PN
Fluid	Volume overload (raises morbidity/mortality)	Limit fluid to ≤ 2 L/day; use a compounder; lowest appropriate glucose rate
Other	Toxic overfeeding (PN especially prone); artefactual hyperglycaemia/hyperkalaemia from sampling	Careful prescribing; clean blood draws from a dual-port CVC

- ▶ **Reactive hypoglycaemia** can follow abrupt stoppage of high-glucose, non-insulin PN — prevent by slowing the infusion to **50 mL/h for 1–2 h**, then 10% glucose or an oral snack.

- ▶ **Hypertriglyceridaemia** occurs when lipid infusion outpaces clearance (sepsis, renal failure, diabetes, glucocorticoids, multi-organ failure reduce clearance); risks include pancreatitis and impaired immunity — keep lipid ≤ 50 g/day in ADM.

Refeeding syndrome

- ▶ Occurs in patients with **successfully adapted starvation-related malnutrition (SRM)** during the first week of repletion when **carbohydrate and sodium** are reintroduced too rapidly.
- ▶ **Mechanism:** carbohydrate $\rightarrow$ **insulin surge** $\rightarrow$ (a) antinatriuretic effect $\rightarrow$ ECF expansion / **refeeding oedema**; (b) intracellular shift driving glucose-6-phosphate/glycogen synthesis $\rightarrow$ falling serum **phosphate, potassium and magnesium**, impairing skeletal/cardiac muscle and triggering **haemolysis**.
- ▶ **Left heart failure** has three causes: abrupt intravascular volume rise (insulin-mediated Na^+ retention); increased demand on an **atrophic left ventricle** from a higher resting EE; and myocardial $\text{K}^+/\text{PO}_4/\text{Mg}^{2+}$ deficiency. **Arrhythmias** may occur.
- ▶ **Acute thiamine-deficiency encephalopathy (Wernicke's)** is a devastating but **preventable** complication — can be precipitated even by simple glucose infusion.
- ▶ **Prevention:** restrict sodium, **advance carbohydrate slowly**, start glucose ≤ 200 g/day, and measure and replace phosphate, potassium, magnesium and thiamine frequently.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Labelled algorithm** — “Choosing the route of nutritional support”: boxes/arrows reading *Can patient eat enough?* $\rightarrow$ *Yes: Optimized voluntary nutrition* | *No* $\rightarrow$ *Is the gut functional and accessible?* $\rightarrow$ *Yes: Enteral nutrition (EN)* $\rightarrow$ *No (obstruction / ischaemia / peritonitis / GI haemorrhage / high-output fistula / failed EN)* $\rightarrow$ *Parenteral nutrition (PN/TPN)***. Label the four EN contraindications and the four-factor decision rule.
- ▶ **Labelled diagram** — “Central venous access for TPN”: label subclavian vein, SVC tip, **dedicated PN lumen**, sterile dressing; annotate “high osmolarity >1200 mOsm/L $\rightarrow$ central vein,” “avoid jugular/femoral.”

Clinical / Diagnostic significance

- ▶ TPN is **life-saving but high-risk** — EN and PN carry equivalent overall complication rates *except* that PN adds catheter and bloodstream-infection risk and is far more prone to **toxic overfeeding**; hence “*if the gut works, use it.*”
- ▶ **Glycaemic control** (80–140 mg/dL) and **strict catheter asepsis with a dedicated port** are the two interventions that most reduce TPN morbidity.
- ▶ **Baseline electrolytes, Mg, PO_4 , Ca, triglycerides and transferrin saturation** identify patients at risk of refeeding syndrome and functional iron deficiency before starting.

- ▶ In critical illness (ADM), early energy provision near/above expenditure is **not beneficial** and may be harmful; favour hypocaloric, protein-generous regimens while inflammation is severe.

High-yield exam pointers

- ▶ TPN = complete IV nutrition via a **central vein**; osmolality >1200 mOsm/L.
- ▶ Energy values: AA 3.3, dextrose monohydrate 3.4, lipid ~10 kcal/g; 100 g AA = 83 g protein substrate.
- ▶ **Initial glucose** ≤200 g/day; ADM ≤350 g; non-critical ≤500 g; **lipid** ≤8 g/h (≤50 g/day in ADM); **fluid** ≤2 L/day.
- ▶ Protein: 0.8 g/kg healthy, 1.2–2.0 g/kg critically ill.
- ▶ **Iron is never added** to PN; multivitamins added just before infusion; **ascorbic acid degrades** in the bag.
- ▶ Most frequent metabolic complication = **hyperglycaemia**; most feared early complication = **refeeding syndrome** (low PO₄/K⁺/Mg²⁺ + thiamine deficiency).
- ▶ **Triglyceride** >400 mg/dL = relative contraindication to lipid; transaminitis appears within 2–4 weeks; cyclic PN (12 h/day) for cholestasis.
- ▶ Stop PN once ½–⅔ of **requirement** is tolerated enterally; wean by optimizing voluntary intake, never abruptly.

SOURCE & COVERAGE

Harrison's Principles of Internal Medicine, 22e — Ch 346 "Enteral and Parenteral Nutrition" (Hoffer & Bistrian).

Coverage note: All doses, energy values, osmolality, insulin ratios and complication data are taken verbatim from Ch 346. The chapter uses the term "PN"; "Total PN" (entire requirement given IV) is the universally accepted clinical term and is used here. A few standard-textbook specifics not stated explicitly in Ch 346 are flagged as universally accepted: the *subclavian/PICC* preference (the chapter states only that jugular/femoral are avoided), *short-bowel syndrome* as a classic PN indication (chapter lists fistulae/malabsorption), the *pneumothorax* example of insertion trauma, and naming acute thiamine-deficiency encephalopathy *Wernicke's*. Peripheral PN is implied by the chapter (high osmolality mandates a central vein) but not detailed.

Re-feeding Syndrome: Definition, Patients at Risk, Electrolyte Pathogenesis, Prevention and Treatment

Asked in: Paper I 06 Apr 2026 — RGUHS MD General Medicine

Definition / Introduction — *Re-feeding syndrome (RFS)* is a constellation of potentially fatal **fluid and electrolyte shifts** that occur when nutrition (oral, enteral or parenteral) is reintroduced too rapidly to a previously **starved or severely malnourished** patient. The hallmark biochemical lesion is **hypophosphataemia** developing in the first week of re-feeding, accompanied by **hypokalaemia, hypomagnesaemia, thiamine depletion, sodium-water retention and hyperglycaemia**. The clinical consequences—cardiac arrhythmia, heart failure, respiratory failure, neuromuscular and haematological dysfunction—are largely **preventable**, making early recognition of the at-risk patient the single most important step.

Pathophysiology — the metabolic switch and the electrolytes/minerals involved

- ▶ **Starvation (adaptation phase):** prolonged semi-starvation lowers insulin, raises glucagon, and switches metabolism from carbohydrate to **fat and protein (ketone/free-fatty-acid)** fuel. The body downregulates resting energy expenditure and conserves visceral mass at the cost of muscle. Crucially, **total-body phosphate, potassium and magnesium are progressively depleted**, yet *serum* levels are often maintained because these ions leave the shrinking intracellular compartment — masking the deficit.
- ▶ **Re-feeding (anabolic switch):** an abrupt carbohydrate (glucose) load **stimulates insulin secretion**. Insulin drives **glucose, phosphate, potassium and magnesium into cells** for glycogen and protein synthesis, and reactivates the depleted Na^+/K^+ -ATPase pump — unmasking the profound deficits as plasma levels crash.
- ▶ **Phosphate (the cardinal disturbance):** carbohydrate refeeding stimulates **intracellular glucose-6-phosphate and glycogen synthesis**, consuming phosphate to form phosphorylated intermediates and ATP/2,3-DPG, producing severe **redistributive hypophosphataemia** (movement of phosphate from ECF into cells/bone). This compromises every ATP-dependent process — skeletal and cardiac muscle function and red-cell integrity (haemolysis).
- ▶ **Potassium & magnesium:** insulin-driven cellular uptake produces **hypokalaemia and hypomagnesaemia**; hypomagnesaemia further impairs PTH function and renal K^+/PO_4 handling and is itself arrhythmogenic.
- ▶ **Thiamine (vitamin B₁):** re-introduced carbohydrate sharply increases demand for thiamine as the cofactor of pyruvate dehydrogenase/transketolase; in an already depleted patient this precipitates **acute thiamine-deficiency encephalopathy (Wernicke)** — *a devastating, preventable complication of refeeding, occurring even with simple glucose infusion* (Harrison).
- ▶ **Sodium, water and glucose:** carbohydrate-stimulated insulin has an **antinatriuretic effect**, expanding ECF volume, especially if sodium is given liberally → **refeeding oedema** and, in predisposed patients, **left heart failure**. Excess glucose provision also causes **hyperglycaemia**.

Mineral / factor	Direction in RFS	Mechanism	Main danger
Phosphate	↓↓ (hypophosphataemia)	Insulin-driven cellular uptake + consumption in glucose-6-P/ATP synthesis	ATP depletion → cardiac/respiratory/neuromuscular failure, haemolysis
Potassium	↓ (hypokalaemia)	Insulin shifts K ⁺ intracellularly via Na ⁺ /K ⁺ -ATPase	Arrhythmia, weakness, ileus
Magnesium	↓ (hypomagnesaemia)	Cellular uptake; total-body depletion	Arrhythmia, refractory hypo-K/hypo-Ca, tetany
Thiamine (B ₁)	depleted	Carbohydrate load increases coenzyme demand	Wernicke encephalopathy, lactic acidosis
Sodium / water	retained	Insulin antinatriuresis → ECF expansion	Refeeding oedema, congestive heart failure
Glucose	↑ (hyperglycaemia)	Excess CHO load + insulin resistance	Osmotic diuresis, hyperosmolar state, infection

Who is at risk

- ▶ **Core principle:** risk reflects the **degree of antecedent depletion** — the more malnourished/starved the patient, the greater the risk, and (in anorexia data) the degree of refeeding hypophosphataemia correlates with severity of malnutrition on admission more than with the calories prescribed.
- ▶ **Clinical high-risk groups (textbook):**
 - **Anorexia nervosa** and other eating disorders — *particularly high risk*; especially those <70–75% of expected body weight (Sleisenger).
 - **Starvation-related malnutrition (SRM) and chronic disease-related malnutrition / cachexia (CDM)** — malignancy, chronic infection (e.g. TB), inflammatory/autoimmune disease, advanced cardiac/renal/hepatic/pulmonary disease.
 - **Chronic alcohol use disorder** (combined phosphate/thiamine/Mg depletion).
 - **Prolonged fasting / starvation, hunger strikes, prolonged unfed ICU stay**, post-operative patients fed after long catabolic periods.
 - **Malabsorption / high GI losses** — short bowel, fistulae, chronic diarrhoea/vomiting, after bariatric surgery.
 - **Elderly with sarcopenia and comorbidities**; uncontrolled diabetes (insulin therapy causes redistributive hypophosphataemia, as in DKA treatment).

- ▶ ***NICE high-risk criteria** (*standard screening framework — see Coverage note*). A patient is high risk with one of: BMI <16 kg/m²; unintentional weight loss >15% in 3–6 months; little/no intake >10 days; low baseline K⁺, PO₄³⁻ or Mg²⁺. Or two* of: BMI <18.5 kg/m²; weight loss >10% in 3–6 months; little/no intake >5 days; history of alcohol misuse or drugs (insulin, chemotherapy, antacids, diuretics).

Clinical features / manifestations

- ▶ **Cardiac:** arrhythmias (atrial/ventricular), and **left heart failure** from three mechanisms — abrupt rise in intravascular volume (fluid + insulin-mediated Na⁺ retention), increased cardiac demand on an **atrophic left ventricle** from raised resting energy expenditure, and myocardial K⁺/PO₄/Mg deficiency; sudden cardiac death.
- ▶ **Neuromuscular (hypophosphataemia):** weakness, lethargy, confusion, dysarthria, dysphagia, ophthalmoplegia, nystagmus, ataxia, paraesthesiae, a **Guillain–Barré-like ascending paralysis**, seizures and coma; serious sequelae (paralysis, seizures) typically at phosphate <0.25 mmol/L (<0.8 mg/dL). **Rhabdomyolysis** may occur.
- ▶ **Respiratory:** diaphragmatic weakness and reversible respiratory failure at phosphate 0.5–0.8 mmol/L (1.5–2.5 mg/dL) — may impede ventilator weaning.
- ▶ **Haematological:** erythrocyte microspherocytosis and **haemolysis**, impaired oxyhaemoglobin dissociation (low 2,3-DPG), and defective leucocyte/platelet function.
- ▶ **Neurological (thiamine):** acute **Wernicke encephalopathy** — confusion, ophthalmoplegia, ataxia.
- ▶ **Fluid:** benign **refeeding oedema** (dependent, from renal Na⁺ reabsorption and poor vessel integrity) — must be distinguished from heart failure; **diuretics should not be used**.

Prevention

- ▶ **Identify the at-risk patient before feeding** and check baseline K⁺, PO₄³⁻, Mg²⁺, Na⁺, glucose and renal function.
- ▶ **Start low, go slow:** begin at only 5–20 kcal/kg/day for the first few days (depending on severity), advancing calories cautiously over ~7 days; once past the refeeding window, build to 30–35 kcal/kg/day and ~1.5 g protein/kg/day (CMDT). In enteral feeding, at-risk patients warrant conservative initiation/advancement; parenteral nutrition is begun at **about half the estimated energy requirement** (~100–150 g dextrose) for the first 24 h and increased daily as tolerated.
- ▶ **Give thiamine before/with the first feed:** thiamine 100 mg daily for at least 5–7 days (and other B vitamins) to prevent Wernicke encephalopathy.
- ▶ **Correct/replace electrolytes proactively** — supplement phosphate, potassium and magnesium and replete deficits, ideally before or alongside calories rather than withholding feed.
- ▶ **Restrict sodium and fluid** to minimise refeeding oedema and cardiac overload; increase carbohydrate provision slowly.

- ▶ **Monitor intensively:** serum phosphate and magnesium every 6–12 h (every 6–8 h after feeds begin) during at least the first week; daily weights, fluid balance, heart rate, respiratory rate and signs of failure; **cardiac telemetry** in severely malnourished patients.

Treatment

- ▶ **Slow or temporarily reduce the calorie load** if electrolytes fall, and aggressively replace phosphate, potassium and magnesium while continuing thiamine.
- ▶ **IV phosphate replacement** (Harrison) for severe hypophosphataemia <0.75 mmol/L (<2 mg/dL) — neutral sodium/potassium phosphate, initial **0.2–0.8 mmol/kg elemental phosphorus** over 6 h (e.g. 10–50 mmol/6 h); measure serum Ca^{2+} and PO_4^{3-} every 6–12 h; **reduce dose 50% if creatinine >2.5 mg/dL**, correct hypocalcaemia first:

Serum phosphorus	Infusion rate	Duration	Total administered
<0.8 mmol/L (<2.5 mg/dL)	2 mmol/h	6 h	12 mmol
<0.5 mmol/L (<1.5 mg/dL)	4 mmol/h	6 h	24 mmol
<0.3 mmol/L (<1 mg/dL)	8 mmol/h	6 h	48 mmol

- ▶ **Hypokalaemia / hypomagnesaemia:** replace with IV/oral KCl and magnesium; **correct magnesium** as it is required for sustained K^+ and PO_4 repletion and for PTH action.
- ▶ **Refeeding oedema:** elevate the area and **restrict sodium** — *do not give diuretics*; distinguish from true heart failure.
- ▶ **Heart failure / arrhythmia:** supportive management, telemetry, treat the underlying electrolyte deficits.
- ▶ **Glycaemic control:** keep glucose <140 – 180 mg/dL using hypocaloric glucose $\pm$ lipid and minimal-dose insulin.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **“Metabolic switch” flow diagram:** Starvation (low insulin, fat/ketone fuel, depleted total-body $\text{PO}_4/\text{K}^+/\text{Mg}^{2+}$) $\rightarrow$ **Carbohydrate re-feed** $\rightarrow$ $\uparrow$ **Insulin** $\rightarrow$ branches to: (1) cellular uptake of PO_4^{3-} $\rightarrow$ **hypophosphataemia** $\rightarrow$ $\downarrow$ ATP/2,3-DPG, (2) cellular uptake of K^+ $\rightarrow$ **hypokalaemia**, (3) cellular uptake of Mg^{2+} $\rightarrow$ **hypomagnesaemia**, (4) **thiamine consumption** $\rightarrow$ **Wernicke**, (5) **renal Na^+ /water retention** $\rightarrow$ **oedema/heart failure**. End-organ boxes labelled: *Cardiac arrhythmia/HF, Respiratory failure, Neuromuscular weakness/seizures, Haemolysis*.

- ▶ **Timeline bar:** Day 0 (start feed) → Days 1–3 (nadir phosphate, highest risk) → Day 7 (refeeding window closes); annotate “monitor $\text{PO}_4/\text{K}^+/\text{Mg}^{2+}$ every 6–12 h” and “thiamine 100 mg/day ×5–7 days”.

Clinical / Diagnostic significance

- ▶ **Diagnosis is biochemical + temporal:** a falling phosphate ($\pm \text{K}^+, \text{Mg}^{2+}$) within the **first week** of re-instituted nutrition in an at-risk patient. Serum phosphate at presentation can be normal (masked by prerenal azotaemia/depletion) and falls *hours* after feeding/insulin — so **serial** measurement, not a single baseline, is required.
- ▶ **Investigations:** daily basic metabolic panel, **phosphate and magnesium**, glucose; ECG/telemetry for arrhythmia and QTc; CK if rhabdomyolysis suspected (CK may peak 1–2 days after the phosphate nadir).
- ▶ **Management pearls:** the safe-feeding rule is *prevention beats rescue*; never withhold thiamine waiting for confirmation; replace electrolytes **before** escalating calories; refeeding can occur by **any route** including oral.

High-yield exam pointers

- ▶ **Cardinal lab abnormality = hypophosphataemia;** the triad $\text{PO}_4^{3-} \downarrow, \text{K}^+ \downarrow, \text{Mg}^{2+} \downarrow$ plus thiamine deficiency and fluid overload.
- ▶ **Trigger = carbohydrate/glucose load → insulin surge** driving intracellular shift of phosphate/potassium/magnesium.
- ▶ **Highest-risk group = anorexia nervosa, especially <70–75% expected body weight;** also chronic alcoholism, prolonged starvation, malabsorption, cancer cachexia, elderly.
- ▶ **NICE one-major criterion:** BMI <16, weight loss >15%/3–6 mo, intake >10 days, or low baseline $\text{K}/\text{PO}_4/\text{Mg}$.
- ▶ **Prevent:** start 5–20 kcal/kg/day, advance over 7 days; **thiamine 100 mg/day ×5–7 days;** restrict sodium; monitor PO_4/Mg 6–12 hourly.
- ▶ **Treat severe hypophosphataemia IV:** 0.2–0.8 mmol/kg elemental P over 6 h; replace K and Mg concurrently.
- ▶ **Refeeding oedema is benign — never treat with diuretics;** distinguish from heart failure.
- ▶ **Acute thiamine-deficiency (Wernicke) encephalopathy can follow plain glucose infusion —** always give thiamine first.
- ▶ Serious paralysis/seizures occur at phosphate <0.25 mmol/L (<0.8 mg/dL); respiratory/cardiac failure at 0.5–0.8 mmol/L.

SOURCE & COVERAGE

- ▶ **Harrison's Principles of Internal Medicine, 22e** — “Enteral and Parenteral Nutrition” (refeeding syndrome: carbohydrate–insulin mechanism, phosphate/potassium/magnesium deficiencies, left heart failure, thiamine encephalopathy) and “Malnutrition and Nutritional Assessment” (SRM/CDM/ADM and at-risk groups); “Disorders of Bone and Mineral Metabolism / Fluid and Electrolyte Disturbances” (redistributive hypophosphataemia, clinical thresholds, and IV phosphate therapy table).
- ▶ **Sleisenger & Fordtran's Gastrointestinal and Liver Disease** — “Feeding and Eating Disorders” (anorexia nervosa <70–75% expected body weight as highest-risk group; refeeding hypophosphataemia; 6–8-hourly electrolyte monitoring, telemetry).
- ▶ **CMDT 2026** — “Nutrition, Nutritional Disorders & Obesity” (definition, 5–20 kcal/kg/day initiation advancing to 30–35 kcal/kg/day and 1.5 g protein/kg/day, thiamine 100 mg/day ×5–7 days, refeeding oedema — avoid diuretics).
- ▶ *Coverage note:* The exact numerical **NICE 2006 (CG32) high-risk thresholds** (BMI/weight-loss/days-without-intake cut-offs) are not stated verbatim in this corpus; they are included as universally accepted standard internal-medicine screening criteria. All other figures (calorie ranges, thiamine dose, phosphate thresholds and IV phosphate dosing) are taken directly from Harrison/CMDT/Sleisenger as cited.

Miscellaneous

Anatomy of spinal cord

Asked in: Paper I Jul 2020 — RGUHS MD General Medicine

Definition / Introduction — The spinal cord is the thin, tubular caudal extension of the central nervous system housed within the bony vertebral canal, carrying — within a small cross-sectional area — almost the entire motor output and sensory input of the trunk and limbs. It originates at the medulla, ends caudally as the **conus medullaris**, and is continued by the fibrous **filum terminale** to the coccyx. Because of this dense packing of ascending and descending tracts, focal cord lesions produce devastating, anatomically predictable syndromes, making cord anatomy the key to bedside lesion localisation.

Gross anatomy and vertebro-segmental relationships

- ▶ **Length & shape:** ~45 cm in the adult male and 42–43 cm in the adult female (Harrison quotes ~46 cm); the vertebral column is ~70 cm, so the cord fills only the upper two-thirds of the canal. It is oval/cylindrical, flattened dorsoventrally.
- ▶ **Enlargements:** the **cervical enlargement (C5–T1)** supplies the upper limbs (brachial plexus) and the **lumbosacral enlargement (L3–S2)** supplies the lower limbs (lumbosacral plexus).

- ▶ **Segments:** 31 segments — 8 cervical, 12 thoracic, 5 lumbar, 5 sacral, 1 coccygeal — each defined by an exiting ventral (motor) root and an entering dorsal (sensory) root.
- ▶ **Conus & cauda equina:** because the cord grows more slowly than the vertebral column, the adult cord ends at ~L1–L2. *Descent of the conus:* L4–L5 at 20 weeks' gestation → L3 at term → adult L1–L2 by ~2 months of age. Below this, the lumbosacral roots travel a long intrathecal course as the **cauda equina** around the filum terminale — the safe target for lumbar puncture (below L2).
- ▶ **Cord-segment vs vertebral-body mismatch (localisation rule):** the first 7 cervical nerves exit **above** the same-numbered vertebra (8 cervical segments but 7 cervical vertebrae); all lower nerves exit **below** the same-numbered vertebra. Cord segments therefore lie progressively higher than their vertebral spinous processes — upper cervical ≈ same level, lower cervical ≈ 1 higher, upper thoracic ≈ 2 higher, lower thoracic ≈ 2–3 higher, lumbar cord ≈ T10–T12, sacral cord ≈ T12–L1.
- ▶ **External surface landmarks:** ventral (anterior) median fissure, dorsal (posterior) median sulcus (with dorsal median septum), dorsolateral sulcus (dorsal rootlet entry), and a less distinct ventrolateral sulcus (ventral rootlet exit). These divide each half into dorsal, lateral and ventral funiculi.
- ▶ **Coverings:** pia, arachnoid and dura — continuous with cerebral meninges; CSF lies in the subarachnoid space; the cord is anchored to dura by the **dentate (denticulate) ligaments**.

Cross-sectional anatomy — grey matter, Rexed laminae and white funiculi

- ▶ **Grey matter** is centrally placed, **butterfly / H-shaped**, comprising a **dorsal (posterior) horn**, a **ventral (anterior) horn**, and a **lateral horn**, joined across the midline by the grey commissure around the **central canal** (an extension of the fourth ventricle).
- ▶ **Lateral horn / intermediolateral column:** T1–L2 = preganglionic **sympathetic** neurons; S2–S4 intermediolateral zone = preganglionic **parasympathetic** (sacral) outflow.
- ▶ **Anterior horn motor neurons:** large **alpha** motor neurons (extrafusal skeletal muscle) and small **gamma** motor neurons (intrafusal muscle-spindle fibres); somatotopy — flexor neurons dorsal to extensor neurons, limb-girdle laterally, axial muscles medially.
- ▶ **Rexed cytoarchitectonic laminae (I–IX, plus X):**

Lamina	Named nucleus / zone
I	Nucleus posteromarginalis (posterior marginal nucleus)
II	Substantia gelatinosa of Rolando (pain/temperature)
III–IV	Nucleus proprius (nucleus proprius dorsalis)
V	Nucleus reticularis (zone anterior to lamina IV)

Lamina	Named nucleus / zone
VI	Base of dorsal horn
VII	Intermediate zone — contains nucleus dorsalis of Clarke + intermediolateral column
VIII	Ventral horn interneuronal zone
IX	Anterior horn cell columns (alpha/gamma motor neurons)
X	Dorsal & ventral grey commissure (peri-central canal)

- ▶ The **zone (tract) of Lissauer** (posterolateral tract) caps the dorsal horn, carrying short ascending/descending pain fibres.

Ascending (sensory) tracts

- ▶ General rule: **dorsal columns and spinocerebellar/pyramidal tracts lie ipsilateral**; the **spinothalamic tracts ascend contralateral** to the body half they serve (decussating in the cord).

Ascending tract	Modality	Decussation & key features
Dorsal columns — <i>fasciculus gracilis</i> (Goll) medial = lower limb; <i>fasciculus cuneatus</i> (Burdach) lateral = upper limb	Joint position, vibration, fine/discriminative touch, two-point discrimination	1st-order fibres ascend uncrossed → synapse in gracile/cuneate nuclei (medulla) → 2nd-order internal arcuate fibres cross → medial lemniscus → VPL thalamus
Lateral spinothalamic (neospinothalamic)	Sharp, localised pain and temperature	2nd-order neuron decussates via ventral white commissure , ascends 1–2 segments higher; lamination — cervical fibres dorsomedial , sacral fibres ventrolateral (basis of <i>sacral sparing</i>)
Ventral (anterior) spinothalamic	Light (crude) touch & pressure	Crosses in ventral white commissure → VPL
Spinoreticulothalamic (paleospinothalamic)	Poorly localised, dull/aching pain	Short axons synapse in brainstem reticular formation → intralaminar thalamic nuclei
Dorsal & ventral spinocerebellar	Unconscious proprioception, lower half of body	To cerebellum (dorsal via Clarke's column)
Cuneocerebellar & rostromerebellar	Unconscious proprioception, upper half of body	To cerebellum

Descending (motor) tracts

Descending tract	Origin	Course / location in cord	Function
Lateral corticospinal (pyramidal)	Brodmann area 4 (MI, precentral), area 6 (premotor/SMA), areas 3,1,2 (postcentral), 5 & 7 (sup. parietal), cingulate	~90% of ~1 million pyramidal fibres decussate at the medullary pyramids → lateral funiculus; terminate laminae IV–IX	Skilled distal-limb movement; inhibits antigravity (antagonist) muscles
Ventral (anterior) corticospinal	Same cortical areas	~10% uncrossed , ventral funiculus (cross in cord, lamina VIII)	Axial/proximal control
Rubrospinal (corticorubrospinal)	Red nucleus (input from cortical areas 4, 6, 1–3)	Crosses, descends in lateral funiculus	Distal flexor tone
Vestibulospinal	Lateral & medial vestibular nuclei	Lateral/ventral funiculus (uncrossed)	Facilitates antigravity (extensor) tone , posture
Lateral & medial reticulospinal	Medullary & pontine reticular formation	Ventrolateral/ventral funiculus	Modulate axial/proximal tone (medial facilitates, lateral inhibits)
Tectospinal	Superior colliculus	Ventral funiculus	Reflex head/neck orientation to visual/auditory stimuli

Blood supply and venous drainage

- ▶ **Single anterior spinal artery** (from paired vertebral branches) runs in the ventral median fissure and supplies the **anterior two-thirds** of the cord (anterior + lateral horns, central grey, corticospinal & spinothalamic tracts) via **sulcal (sulco-commissural) arteries**.
- ▶ **Paired posterior spinal arteries** (from vertebral or PICA) supply the **posterior one-third** — the dorsal columns and dorsal horns.
- ▶ **Radiculomedullary (radicular) feeders** from the aorta reinforce the cord segmentally. The dominant lumbar feeder is the **great anterior radicular artery of Adamkiewicz** (*artery of the lumbar enlargement*), most often entering on the **left between T9 and T12** (≈75%).
- ▶ **Three longitudinal vascular regions**: upper/cervicothoracic (richly supplied), the **intermediate/mid-thoracic region** (~T4–T8) — the **relatively poorly perfused “watershed” zone**, and the richly supplied lower thoracolumbosacral region. The watershed and the anterior territory (high metabolic demand of anterior horn cells) are most vulnerable to ischaemia.

- **Veins** mirror the arteries (anteromedial/anterolateral and posterior trunks) and drain into the valveless **internal vertebral venous plexus (Batson's plexus)** — a route for haematogenous spread of pelvic/prostatic tumours and infection to the spine.

Clinically important cord syndromes (localisation pay-off)

Syndrome	Tracts involved	Hallmark signs
Complete transection (transverse myelopathy)	All tracts at one level	Loss of all modalities + UMN paraplegia/quadruplegia below; autonomic loss; initial spinal shock (flaccid areflexia)
Brown-Séquard (hemicord)	Hemisection	Ipsilateral UMN weakness + dorsal-column loss; contralateral pain/temperature loss (1–2 levels below); typically extramedullary
Central cord	Decussating spinothalamic ± anterior horns	“ Cape/suspended ” dissociated loss of pain/temperature with preserved touch/position; arms > legs weakness; syringomyelia, hyperextension injury
Anterior cord / anterior spinal artery occlusion	Anterior two-thirds	Para/quadruplegia + dissociated pain/temperature loss with preserved vibration & position (dorsal columns spared)
Posterolateral column (subacute combined degeneration)	Dorsal + lateral columns	Sensory ataxia, +Romberg, vibration/position loss + UMN signs — B12, copper, HIV, nitrous oxide, HTLV-1 (HAM/TSP)
Posterior column (tabes dorsalis)	Dorsal columns/roots	Sensory ataxia, lightning pains, Argyll Robertson pupils, Charcot joints
Foramen magnum	Decussating pyramidal fibres	“Around-the-clock” limb involvement, crural paresis, suboccipital pain

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- **Spinal cord cross-section (composite “tract map”)**: draw the H-shaped grey matter and label — dorsal (posterior) horn, ventral (anterior) horn, lateral horn (intermediolateral column), central canal, ventral median fissure, dorsal median sulcus, dorsal root + ganglion, ventral root. On the white matter label ascending tracts (left): fasciculus gracilis, fasciculus cuneatus, dorsal & ventral spinocerebellar tracts, lateral spinothalamic, ventral spinothalamic (show somatotopy C→T→L→S with sacral

Syndrome	Tracts involved	Hallmark signs
	outermost in spinothalamic, lateral in dorsal columns); and descending tracts (right): lateral corticospinal, ventral corticospinal, rubrospinal, vestibulospinal, reticulospinal, tectospinal.	
	► Vascular supply diagram: label anterior spinal artery (anterior 2/3), paired posterior spinal arteries (posterior 1/3), anterior sulcal artery, circumflex (perimedullary) arteries, radiculomedullary feeders / artery of Adamkiewicz.	

Clinical / Diagnostic significance

- **Lesion localisation:** a sharply demarcated **sensory level** plus a band of segmental signs marks the upper border of a cord lesion; remember sensory level is set ~1–2 segments below a unilateral spinothalamic lesion (crossing fibres). Useful landmarks: **nipple = T4**, **umbilicus = T10**, **Bevor's sign = T9–T10 lesion**.
- **Conus medullaris vs cauda equina:** conus → early/symmetric **saddle anaesthesia (S3–S5)**, prominent bladder/bowel/sexual dysfunction, lax anal tone, absent bulbocavernosus (S2–S4) and anal (S4–S5) reflexes, relatively preserved power; cauda equina → asymmetric radicular pain, leg weakness/areflexia, later sphincter involvement.
- **Intramedullary vs extramedullary:** intramedullary lesions give **poorly localised burning pain and sacral sparing**, late corticospinal signs; extramedullary lesions give early **radicular pain**, early sacral sensory loss and spastic paraparesis.
- **Investigation of choice:** MRI with **gadolinium** of the whole spine excludes treatable **compressive myelopathy** (metastasis, epidural abscess/haematoma, disc, spondylosis) before intrinsic causes. **Horner's syndrome** signals a cervicothoracic (T1) lesion; autonomic dysreflexia complicates lesions above T6.

High-yield exam pointers

- 31 segments: 8C, 12T, 5L, 5S, 1Co; cervical enlargement C5–T1, lumbosacral L3–S2.
- Adult cord ends at L1–L2; LP done **below L2** through the cauda equina.
- 8 cervical segments but 7 cervical vertebrae — explains the exit rule and cord-vertebra mismatch.
- **Gracilis (Goll) = medial/leg; cuneatus (Burdach) = lateral/arm**; dorsal columns cross in the medulla.
- **Spinothalamic decussates in the cord** (ventral white commissure), ascends 1–2 levels above entry; sacral fibres lie **outermost** → *sacral sparing* in intramedullary lesions.
- ~90% of corticospinal fibres **decussate at the pyramids** → lateral corticospinal tract.

- ▶ Anterior spinal artery = anterior 2/3; posterior spinal arteries = posterior 1/3; artery of Adamkiewicz (left, T9–T12) feeds the lumbar enlargement; T4–T8 = watershed zone.
- ▶ Batson's (internal vertebral venous) plexus — valveless route for pelvic/prostate metastasis.
- ▶ Lateral horn: sympathetic T1–L2, parasympathetic S2–S4.
- ▶ Classic syndromes: Brown-Séquard, central cord (dissociated/cape), anterior cord (ASA), SACS, tabes dorsalis — know the tract pattern for each.

SOURCE & COVERAGE

- ▶ Harrison's Principles of Internal Medicine, 22e — "Diseases of the Spinal Cord" (S.L. Hauser): cord anatomy relevant to clinical signs, segment–vertebra relationships, tract map (Fig. 453-1), and cord syndromes.
- ▶ *Brazis, Masdeu & Biller — Localization in Clinical Neurology, Chapter 5 "Spinal Cord": gross & cross-sectional anatomy, Rexed laminae, detailed ascending/descending tract tables, arterial supply (anterior/posterior spinal arteries, artery of Adamkiewicz, vascular regions), venous drainage (Batson plexus), and the spinal cord syndromes.
- ▶ Coverage note: the spec flags Harrison's anatomy as brief — the depth (laminae, tract tables, blood supply, named nuclei) is drawn from Brazis Ch. 5, which covers this purely-anatomical topic comprehensively; no fabrication required.

Autophagy mechanism in health and disease

Asked in: Paper I Nov 2019 — RGUHS MD General Medicine

Definition / Introduction — **Autophagy** ("self-eating") is an evolutionarily conserved, lysosome-dependent **catabolic process** by which cytoplasmic constituents — long-lived and misfolded proteins, protein aggregates, damaged organelles, lipid droplets and even intracellular microbes — are sequestered, delivered to the lysosome and degraded, with recycling of the resulting amino acids, fatty acids and nucleotides. Together with the **ubiquitin–proteasome system (UPS)** it forms the two major degradative arms of the cellular **proteostasis network**. At basal levels it provides continuous **quality control**; it is sharply upregulated by starvation, hypoxia, oxidative stress and infection to liberate nutrients and remove damage. Its discovery earned *Yoshinori Ohsumi* the 2016 Nobel Prize in Physiology or Medicine.

Types of autophagy

Type	How cargo reaches the lysosome	Key features
Macroautophagy	Cargo enclosed by a <i>de novo</i> double-membrane phagophore → autophagosome → fuses with lysosome (autolysosome)	The major, best-studied form; “autophagy” usually denotes this; can be bulk or selective
Microautophagy	Direct invagination/engulfment of cytosol by the lysosomal membrane	Constitutive, bulk turnover; no autophagosome
Chaperone-mediated autophagy (CMA)	<i>Hsc70</i> recognises a KFERQ motif and translocates the protein across the lysosomal membrane via LAMP-2A	Highly selective, single-protein, no vesicle; degrades α-synuclein (along with macroautophagy)

Molecular machinery and regulation

- ▶ **Stages of macroautophagy** (sequential): induction → **nucleation** (phagophore/isolation-membrane formation) → **elongation** (autophagosome engulfs cargo) → **fusion** with lysosome (autolysosome) → **degradation** by acid hydrolases → recycling of building blocks.
- ▶ **Core ATG (autophagy-related) machinery**: the *ULK1* kinase complex initiates; the **Beclin-1** / class III PI3-kinase (*VPS34*) complex nucleates the membrane; two ubiquitin-like conjugation systems — the *ATG12-ATG5-ATG16L1* complex and lipidation of **LC3 (ATG8)** to **membrane-bound LC3-II** — drive elongation and closure (LC3-II is the standard autophagosome marker).
- ▶ **Nutrient sensing — the master switches** (Harrison, *Biology of Aging*):
 - **mTORC1** (activated by amino acids, insulin/IGF-1 and growth factors in the fed state) **inhibits** autophagy; its inactivation by dietary restriction or **rapamycin/sirolimus** reduces protein synthesis and **increases autophagy**.
 - **AMP-activated protein kinase (AMPK)**, activated by a low energy charge (high AMP), exercise and **metformin**, **promotes** autophagy.
 - **Sirtuins** (*SIRT1*/NAD-dependent), *FGF21*, **spermidine** and **resveratrol** also induce autophagy and extend lifespan.
- ▶ **Selective autophagy** (cargo-specific): **mitophagy** (removal of damaged mitochondria, governed by *PINK1/Parkin*); **xenophagy** (capture and lysosomal killing of intracellular bacteria, with cargo tagged by ubiquitin and **galectins**); **aggrephagy** (clearance of ubiquitinated protein aggregates); ER-phagy; ferritinophagy.

Physiological roles in health

- ▶ **Proteostasis / quality control**: recognises and degrades misfolded proteins, large aggregates and condensates that escape or overwhelm the UPS (the autophagy–lysosomal pathway is “highly responsive to nutrient deprivation and damage”).

- ▶ **Energy and nutrient homeostasis:** during fasting/starvation it recycles macromolecules to maintain the amino-acid and ATP supply.
- ▶ **Organelle turnover:** mitophagy replenishes the mitochondrial pool and limits ROS generation; also clears damaged ER and peroxisomes.
- ▶ **Innate immunity:** xenophagy is a *cell-autonomous* defence — bacterial invasion triggers sequestration of the pathogen in an autophagosome and its destruction on lysosomal fusion; NOD2 sensing of bacteria activates autophagy.
- ▶ **Neuronal survival:** particularly important to neurons, which cannot dilute aggregates by division.
- ▶ **Longevity, development, antigen presentation and tissue remodelling.**

Autophagy in disease

System / disease	Link to autophagy
Neurodegeneration (AD, PD, FTD, HD)	Autophagy is impaired , so toxic aggregates accumulate — $A\beta/\tau$, α -synuclein (Lewy bodies), polyglutamine <i>mutant huntingtin</i> , <i>SOD1</i> , <i>TDP-43</i> ; in HD there is a failure of cargo recognition ; <i>PINK1/Parkin</i> mitophagy defects in autosomal-recessive PD; <i>GBA</i> (glucocerebrosidase) mutations impair lysosomal clearance of α -synuclein
Cancer	Double-edged: early, it is <i>tumour-suppressive</i> (a form of programmed cell death/"type II", limiting genomic instability and ROS); in established tumours it is <i>pro-survival</i> , enabling cells to withstand hypoxia and nutrient stress and conferring chemoresistance ; cytotoxic agents can induce autophagy
Crohn's disease / IBD	Susceptibility loci impair autophagy and bacterial handling: <i>ATG16L1</i> , <i>IRGM</i> (immunity-related GTPase M), <i>NOD2</i> , <i>LRRK2</i>
Aging	"Disabled macroautophagy" and loss of proteostasis are hallmarks of aging ; pro-longevity interventions (rapamycin, metformin, spermidine, resveratrol, caloric restriction) converge on the autophagic machinery
Storage / metabolic myopathy & cardiomyopathy	Danon disease — X-linked <i>LAMP2</i> deficiency → defective autophagosome-lysosome fusion → autophagic-vacuole accumulation → HCM + ventricular pre-excitation/WPW + skeletal myopathy ; Pompe disease (GSD II) — autosomal-recessive deficiency of lysosomal acid α -glucosidase

System / disease	Link to autophagy
	(acid maltase) → lysosomal glycogen and autophagic build-up
Drug-induced autophagic vacuolar myopathy/neuropathy	Amphiphilic cationic drugs — chloroquine , hydroxychloroquine , amiodarone — and colchicine cause painless proximal weakness with autophagic vacuoles on muscle (and nerve) biopsy
Infection	Pathogens (e.g., intracellular bacteria, HIV) subvert or are targeted by autophagy; xenophagy is a key host defence
Heart failure / cardiometabolic	Enhanced autophagy is among the proposed cardiorenal-protective mechanisms of SGLT2 inhibitors

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Macroautophagy pathway (flow diagram).** Labels: *Cargo* (damaged mitochondrion / protein aggregate / intracellular bacterium) → *Phagophore* (isolation membrane) → *Autophagosome* (double membrane, LC3-II on membrane) → *Lysosome* → *Autolysosome* → *Acid hydrolases* → *Recycled amino acids / fatty acids*. Add regulators: *mTORC1* — *inhibits* (active when fed); *AMPK / starvation / rapamycin* — *activate*; *ULK1 complex*; *Beclin-1 / VPS34 (PI3K-III)*; *ATG12-ATG5-ATG16L1*.
- ▶ **Health-vs-disease balance.** A central “Autophagy” box; left arm *Health* (proteostasis, organelle quality control, innate immunity/xenophagy, longevity) and right arm *Disease* with an “impaired/dysregulated autophagy” arrow to *neurodegeneration*, *cancer*, *Crohn’s disease*, *Danon/Pompe myopathy*.

Clinical / Diagnostic significance

- ▶ Muscle biopsy showing autophagic vacuoles → think Danon, Pompe, or chloroquine/hydroxychloroquine/amiodarone/colchicine toxicity (a treatable, reversible cause).
- ▶ A young male with hypertrophic cardiomyopathy plus a WPW/pre-excitation ECG pattern strongly suggests **Danon disease** (LAMP2) — pre-excitation is ~5× commoner than in idiopathic/familial HCM; gene therapy delivering functional LAMP2 is in trials.
- ▶ **mTOR inhibitors** (sirolimus, everolimus) used in transplantation and oncology act in part by inducing autophagy.
- ▶ **Chloroquine/hydroxychloroquine inhibit autophagic flux** (block lysosomal acidification) — the rationale for combining them with chemotherapy in trials.
- ▶ **Pharmacologic autophagy induction** (rapamycin, metformin, spermidine, caloric restriction) is being explored for aging and neurodegeneration.

- ▶ Enzyme replacement (Pompe) and emerging gene therapy (Danon) directly target the lysosomal/autophagy defect.

High-yield exam pointers

- ▶ Autophagy = lysosomal degradation; UPS = proteasomal — together they constitute the proteostasis network.
- ▶ Three types: macroautophagy, microautophagy, chaperone-mediated autophagy (*Hsc70* / *KFERQ* / *LAMP-2A*).
- ▶ mTORC1 inhibits; AMPK and starvation activate — both converge on the *ULK1* complex.
- ▶ Stages: phagophore → autophagosome → autolysosome; LC3-II = autophagosome marker.
- ▶ Yoshinori Ohsumi — 2016 Nobel Prize for autophagy mechanisms.
- ▶ Danon = LAMP2 (defective autophagosome–lysosome fusion); Pompe = acid maltase deficiency (GSD II).
- ▶ Crohn's disease autophagy genes: *ATG16L1*, *IRGM*, *NOD2*, *LRRK2*.
- ▶ Cancer = a double-edged sword (tumour-suppressive early, pro-survival/chemoresistant later).
- ▶ Chloroquine/HCQ, amiodarone, colchicine → autophagic vacuolar myopathy; chloroquine/HCQ are autophagy inhibitors.
- ▶ Impaired autophagy underlies aggregate accumulation in AD, PD, FTD, HD; *PINK1*/*Parkin* defects impair mitophagy.

SOURCE & COVERAGE

- ▶ **Harrison's Principles of Internal Medicine, 22e** — “Protein Quality Control and Cellular Stress Responses” (proteostasis network, autophagy–lysosomal pathway vs UPS); “Cancer Cell Biology” and “Principles of Cancer Treatment” (autophagy as programmed cell death and drug-induced autophagy); “Biology of Aging” (loss of proteostasis, mTOR/AMPK/SIRT1, rapamycin/metformin/spermidine); “Molecular Mechanisms of Microbial Pathogenesis” (xenophagy/innate immunity, phagophore–autophagosome stages); “Inflammatory Bowel Disease” (*ATG16L1*, *IRGM*, *NOD2*, *LRRK2*); “Glycogen Storage Diseases and Other Inherited Disorders of Carbohydrate Metabolism” (Pompe/GSD II, Danon/LAMP2); “The Cardiomyopathies” (Danon, LAMP2 HCM); “Disorders of the Autonomic Nervous System... / Peripheral Neuropathy” and “Muscular Dystrophies and Other Muscle Diseases” (chloroquine/hydroxychloroquine/amiodarone/colchicine autophagic vacuolar neuropathy and myopathy); “Heart Failure: Pathophysiology and Diagnosis” (SGLT2-inhibitor effects); “Neurodegenerative Disorders” (impaired autophagy in AD/PD/FTD/HD, mitophagy, α-synuclein/GBA).
- ▶ **Coverage note:** The spec flags this topic as a gap — Harrison 22e has **no dedicated autophagy chapter**, so the answer is synthesised across the chapters above. Harrison

explicitly supports the named disease links and the macroautophagy/chaperone-mediated terminology, the phagophore→autophagosome→autolysosome stages, mTOR/AMPK regulation, and ATG16L1/IRGM/NOD2/LRRK2. A few standard cell-biology specifics not spelled out in this corpus — *microautophagy*, *ULK1*, *Beclin-1/VPS34*, *LC3/ATG8 (LC3-II)* and *ATG12-ATG5 conjugation systems*, and the *Ohsumi 2016 Nobel Prize* — are included as universally accepted textbook biology and are accurate.

Autosomal Inherited Diseases

Asked in: Paper I Nov 2019 — RGUHS MD General Medicine

Definition / Introduction — *Autosomal inherited diseases* are monogenic (single-gene, *Mendelian*) disorders caused by a pathogenic variant in a gene residing on one of the 22 **autosomes** (chromosomes 1–22), as distinct from genes on the X or Y sex chromosomes. Because autosomes are present in two homologous copies and segregate randomly at meiosis, both sexes are affected with equal frequency. Depending on whether one or both alleles must be mutated to express the phenotype, transmission is **autosomal dominant (AD)** or **autosomal recessive (AR)**. Of all human monogenic disorders, ~65% are AD, ~25% are AR, and ~5% are X-linked.

Basic genetic terminology

- ▶ **Allele** — an alternative form of a gene at a given locus; the normal/common allele is *wild type*. Each person carries two alleles per autosomal locus (one maternal, one paternal).
- ▶ **Homozygous** — identical alleles at a locus; **heterozygous** — different alleles; **compound heterozygote** — two *different* mutant alleles at the same locus (common in AR disease, e.g. CFTR).
- ▶ **Genotype vs phenotype** — the genetic constitution vs the observed trait.
- ▶ **Mendelian transmission** follows the principles of allelic segregation; the mode of inheritance is established by **pedigree analysis** using standard symbols.

Autosomal dominant (AD) disorders

- ▶ **Definition** — a pathogenic variant in a *single* allele is sufficient to cause disease; the affected individual is usually heterozygous (Aa).
- ▶ **Pedigree characteristics:**
 - Disease appears in *successive generations* (*vertical transmission*); it does **not** appear in the offspring of unaffected individuals (no generation-skipping, unless reduced penetrance).
 - **Males and females affected equally**; *male-to-male* (father→son) transmission is possible (distinguishes from X-linked).

- Each child of an affected (heterozygous) parent has a **50% risk** of being affected (alleles segregate randomly at meiosis).
- Unless a new germline mutation has occurred, an affected child has an affected parent; children with a normal genotype do not transmit the disease.
- ▶ **Molecular mechanisms** (varied, unlike the uniform loss-of-function of AR):
 - **Gain of function** — constitutive activation (e.g. *RET* in MEN 2).
 - **Dominant-negative effect** — mutant protein interferes with the wild-type product within a multimeric complex (e.g. type I collagen *COL1A1/COL1A2* in osteogenesis imperfecta; mutant thyroid hormone receptor β).
 - **Haploinsufficiency** — one normal allele cannot maintain a normal phenotype (common with transcription-factor and rate-limiting enzyme genes, e.g. heme-synthesis enzymes in porphyria).
- ▶ **Examples:** Huntington's disease, myotonic dystrophy, Marfan's syndrome, neurofibromatosis types 1 and 2, von Hippel–Lindau disease, MEN 1 and MEN 2, hypertrophic cardiomyopathy, autosomal dominant polycystic kidney disease (*PKD1/PKD2*), Holt-Oram syndrome (*TBX5*), achondroplasia, familial hypercholesterolaemia, osteogenesis imperfecta.

Autosomal recessive (AR) disorders

- ▶ **Definition** — the disease is expressed only when *both* alleles are mutated; the affected individual (of either sex) is a **homozygote** or a **compound heterozygote**. Mutated alleles typically cause complete or partial **loss of function** and frequently involve metabolic enzymes, receptors, or signalling proteins.
- ▶ **Pedigree characteristics:**
 - Disease typically appears in a *single sibship* without affected ancestors (*horizontal* pattern).
 - Usually both parents are unaffected **heterozygous carriers**; for a carrier $\times$ carrier mating, offspring risk = **25% affected : 50% carrier : 25% unaffected** (Punnett 1:2:1).
 - **Consanguinity** raises the risk because relatives share alleles (identity by descent); AR disorders are also commoner in geographically/genetically isolated populations (restricted gene pool).
 - **Pseudodominance** — when an affected homozygote mates with a heterozygous carrier, 50% of children are affected, mimicking dominant (vertical) transmission.
 - New mutations rarely manifest in AR disease because they usually produce an asymptomatic carrier state.
- ▶ **Heterozygote (carrier) state** — usually clinically silent, but may show subtle phenotypes under stress (e.g. sickle crises in sickle trait during dehydration/hypoxia). A **selective heterozygote advantage** explains the high frequency of some AR alleles — sickle-cell heterozygotes are

relatively protected from *Plasmodium* (malaria), maintaining the mutant allele in malaria-endemic regions.

- **Examples:** cystic fibrosis (*CFTR*, $\Delta F508$), sickle-cell anaemia (β -globin Glu6Val/E6V), β -thalassaemia, phenylketonuria, Friedreich's ataxia, Wilson's disease, haemochromatosis (*HFE*), congenital adrenal hyperplasia (21-hydroxylase deficiency), autosomal recessive polycystic kidney disease (*PKHD1*, fibrocystin).

AD vs AR — comparison

Feature	Autosomal dominant	Autosomal recessive
Alleles needed	One mutant allele (heterozygous)	Both alleles mutant (homozygote/compound het)
Pedigree pattern	Vertical, successive generations	Horizontal, single sibship
Sex distribution	Equal	Equal
Risk to offspring	50% (affected $\times$ normal)	25% (carrier $\times$ carrier)
Parental consanguinity	Not characteristic	Often increased
Typical mechanism	Gain of function / dominant-negative / haploinsufficiency	Loss of function (enzymes, receptors)
Common confounder	Reduced penetrance, variable expressivity, new mutation	Pseudodominance, carrier state
Examples	Huntington's, Marfan's, NF1, ADPKD, HCM	CF, sickle-cell, thalassaemia, PKU, Wilson's

Trinucleotide (nucleotide) repeat expansion disorders

Several autosomal diseases arise from **dynamic mutations** — expansion of a tandem nucleotide repeat above a critical threshold. The expanded DNA is unstable and tends to lengthen further at each cell division; longer repeats correlate with greater severity and earlier onset (**anticipation**). A *premutation* is a small intermediate increase.

Disease	Locus	Repeat	Normal/Disease length	Inheritance	Gene product
Huntington's disease	4p16.3	CAG	6–34 / 37–180	AD	Huntingtin
Myotonic dystrophy (DM1)	19q13.32	CTG	5–30 / 200–1000	AD (variable penetrance)	Myotonin protein kinase (DMPK)
Spinocerebellar ataxias (SCA1, 2, 3, 6, 7, 12)	various	CAG	e.g. SCA1 6–39 / 40–88	AD	Ataxins, etc.

Disease	Locus	Repeat	Normal/Disease length	Inheritance	Gene product
Dentatorubral-pallidoluysian atrophy (DRPLA)	12p13.31	CAG	7–23 / 49–75	AD	Atrophin 1
Friedreich's ataxia	9q21.11	GAA	7–22 / 200–900	AR	Frataxin

(Fragile X and spinobulbar muscular atrophy are X-linked and are not autosomal.)

Factors modifying autosomal inheritance

- ▶ **Incomplete (reduced) penetrance** — proportion of mutation carriers expressing the phenotype is <100%; dominant pedigrees may *skip generations* via unaffected transmitting carriers (e.g. HCM from myosin-binding protein C variants). Penetrance is often *age-dependent* (Huntington's, familial ALS).
- ▶ **Variable expressivity** — same variant produces a different severity/organ pattern in different individuals (e.g. MEN 1, cystic fibrosis, neurofibromatosis), influenced by **modifier genes** and environment.
- ▶ **Allelic heterogeneity** — many different variants in one gene cause the same phenotype (β -thalassaemia; ~2000 *CFTR* variants).
- ▶ **Locus (non-allelic) heterogeneity** — similar phenotype from variants at *different* loci (osteogenesis imperfecta from *COL1A1* or *COL1A2*; familial HCM from many sarcomeric genes).
- ▶ **Phenotypic heterogeneity / pleiotropy** — different phenotypes from variants in one gene (laminopathies from *LMNA*; *FGFR2* → Crouzon's or Pfeiffer's syndrome).
- ▶ **Phenocopy** — a non-genetic condition mimicking the inherited disorder (toxin-induced chorea resembling Huntington's).
- ▶ **New (de novo) mutations & paternal age** — many AD cases are new germline mutations; rates rise with advanced **paternal age** (achondroplasia, Marfan's, neurofibromatosis). **Gonadal (germline) mosaicism** can cause recurrence in siblings despite unaffected parents.
- ▶ **Knudson "two-hit" mechanism** — in dominantly inherited cancer-predisposition syndromes (retinoblastoma, MEN 1, NF1/NF2), an inherited germline loss of one tumour-suppressor allele is followed by somatic inactivation (loss of heterozygosity) of the second — dominant at the pedigree level but biallelic loss in the tumour.
- ▶ **Genomic imprinting / uniparental disomy** — parent-of-origin-dependent expression on autosomes: **Prader-Willi syndrome** (loss of *paternal* 15q) vs **Angelman's syndrome** (loss of *maternal* 15q); **Beckwith-Wiedemann syndrome** (dysregulated *IGF2* at 11p); Albright's hereditary osteodystrophy (*GNAS1*).

- ▶ **Mosaicism** — postzygotic somatic mutation (e.g. activating $GS\alpha$ in McCune-Albright syndrome).

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **AD vs AR pedigree charts** — draw two 3-generation pedigrees using standard symbols. Labels: *square = male, circle = female, filled = affected, half-filled = carrier, horizontal line = mating, double line = consanguineous union, arrow = proband*. For **AD**: affected individuals in every generation, male-to-male transmission, ~50% offspring affected. For **AR**: affected only in one sibship, unaffected carrier parents, consanguineous loop.
- ▶ **Punnett (segregation) square** — $Aa \times Aa$ cross giving **1 AA : 2 Aa : 1 aa** (AR 25% affected); and $Aa \times aa$ cross giving 50% affected (AD / pseudodominance). Label genotype ratios and risk percentages.

Clinical / Diagnostic significance

- ▶ **Family history & pedigree** are the essential first step — record first-degree relatives, ethnicity, ages, consanguinity, and update periodically because of age-dependent penetrance.
- ▶ **Genetic testing** — direct **DNA sequencing** (PCR-based), targeted variant panels, **multiplex gene panels** (useful for locus-heterogeneous diseases such as HCM, Charcot-Marie-Tooth), and **whole-exome/whole-genome sequencing** (WES/WGS) for undiagnosed syndromes; large rearrangements via FISH, MLPA, cytogenomic microarray (CNV detection).
- ▶ **Interpretation caveats** — allelic heterogeneity means a negative panel does not exclude disease; beware the **variant of uncertain significance** (VUS).
- ▶ **Counselling & prevention** — informed consent before testing, risk estimation, **carrier screening** (especially in consanguineous couples/high-risk ethnic groups), **cascade testing** of relatives, prenatal diagnosis, presymptomatic testing, and newborn screening for treatable metabolic AR disorders (e.g. PKU). Counsel about psychological impact and discrimination risk.
- ▶ **Population genetics** — Hardy-Weinberg equilibrium ($p^2 + 2pq + q^2 = 1$) allows carrier-frequency and disease-risk estimation in a population.

High-yield exam pointers

- ▶ Monogenic disorders $\approx$ **65% AD : 25% AR : 5% X-linked**.
- ▶ **AD** = vertical, every generation, M=F, 50% offspring risk, male-to-male transmission possible; mechanisms = gain-of-function / dominant-negative / haploinsufficiency.
- ▶ **AR** = horizontal, one sibship, carrier parents, 25% risk, linked to **consanguinity**; mechanism = loss of function (often enzymes).
- ▶ **Heterozygote advantage**: sickle trait protects against malaria — explains high β -globin allele frequency.

- ▶ **Anticipation** = worsening/earlier onset across generations from expanding triplet repeats (Huntington's, myotonic dystrophy).
- ▶ **Pseudodominance** (affected × carrier in AR) mimics AD inheritance.
- ▶ **Reduced penetrance** causes apparent generation-skipping in AD pedigrees.
- ▶ **Imprinting**: paternal 15q loss → Prader-Willi; maternal 15q loss → Angelman.
- ▶ **Knudson two-hit** underlies dominantly inherited tumour-suppressor syndromes (retinoblastoma, MEN 1, NF).
- ▶ Advanced **paternal age** increases new AD mutations (achondroplasia, Marfan's).

SOURCE & COVERAGE

- ▶ Harrison's Principles of Internal Medicine, 22e — "*Principles of Human Genetics*" (modes of Mendelian inheritance, AD/AR mechanisms, penetrance/expressivity, allelic & locus heterogeneity, trinucleotide repeat disorders, imprinting, population genetics, heterozygote advantage).
- ▶ Harrison's Principles of Internal Medicine, 22e — "*The Integration of Inherited Genetics into Clinical Practice*" (genetic testing strategy, gene panels, WES/WGS, VUS, counselling, cascade testing).

Coverage note: This is a core human-genetics topic with no dedicated subspecialty textbook assigned in the spec; the answer is fully grounded in Harrison 22e's two genetics chapters. CMDT was not required for this conceptual topic. All disease examples, repeat lengths, loci, and inheritance assignments are taken verbatim from Harrison's tables.

Biosimilar

Asked in: Paper III Nov 2022 — RGUHS MD General Medicine

Definition / Introduction — A **biosimilar** is a biological medicinal product that is **highly similar** to an already-licensed reference biologic (the *originator* or *innovator*), with **no clinically meaningful differences** from it in terms of safety, purity and potency (efficacy), despite minor differences in clinically inactive components. Because biologics are large, complex proteins manufactured in living cells, an exact copy is impossible; hence a biosimilar is *similar* — not *identical* — distinguishing it fundamentally from a small-molecule **generic**, which is a chemically identical copy. Biosimilars are approved through an **abbreviated, comparability-based pathway** that relies on the *totality of evidence* rather than repeating the full development programme of the reference product. They are increasingly important in internal medicine because they expand access to costly biologics (monoclonal antibodies, growth factors, insulins, anticytokines) once patents expire.

Biologic vs biosimilar vs generic — why a biosimilar is not a generic

- ▶ **Small molecules** (e.g., aspirin ~180 Da) are chemically synthesised, fully structurally defined, and can be reproduced exactly; a copy is therefore a true **generic**.
- ▶ **Biologics** (e.g., a monoclonal antibody ~150 kDa) are produced by **recombinant DNA technology in living cell lines**, carry post-translational modifications (e.g., glycosylation), and show inherent **batch-to-batch microheterogeneity** — even the originator varies slightly between lots.
- ▶ Consequently the copy can only be a **biosimilar**, demonstrated by a **stepwise comparability exercise**, not a simple pharmacokinetic bioequivalence study.

Feature	Generic (small molecule)	Biosimilar
Comparator	Chemical originator	Reference biologic
Size / complexity	Small (<1 kDa), simple	Large protein (often >100 kDa), complex
Manufacture	Chemical synthesis	Living cells (recombinant DNA)
Structural identity	Identical copy possible	“Highly similar”, not identical
Approval standard	Bioequivalence (PK only)	Biosimilarity / totality of evidence
US pathway	ANDA — section 505(j)	section 351(k) (BPCIA)
Comparative clinical trial	Not required	Required (PK/PD ± efficacy & immunogenicity)
Immunogenicity testing	Not relevant	Mandatory
Automatic substitution	Yes	Only if granted interchangeability

The biosimilar approval pathway — “totality of evidence”

Development is an **inverted pyramid** (reverse of the originator’s): the bulk of evidence is **analytical**, with a confirmatory, comparative clinical study at the apex.

- ▶ **Step 1 — Analytical / structural & functional characterisation** (foundation): primary/higher-order structure, glycosylation, charge variants, aggregates, and bioactivity, using state-of-the-art assays to confirm the molecule is *highly similar*.
- ▶ **Step 2 — Nonclinical comparison**: comparative in-vitro receptor-binding/functional assays and, where needed, animal **pharmacokinetic (PK)**, **pharmacodynamic (PD)** and **toxicology** studies.
- ▶ **Step 3 — Comparative clinical PK/PD study**: confirms similar exposure (C_{max}, AUC) and pharmacodynamic effect in humans — analogous to **phase 1** of drug development.
- ▶ **Step 4 — Comparative clinical efficacy & safety study** in a sensitive patient population, with **immunogenicity** as a co-primary safety endpoint — a focused version of **phase 3**.

- ▶ The aim is to **demonstrate biosimilarity, not to re-establish efficacy de novo**; any residual uncertainty after analytics is resolved by the targeted clinical step.

Key regulatory concepts

- ▶ **Immunogenicity** — the central safety concern unique to biologics. All biologics can provoke **anti-drug antibodies (ADAs)**, including **neutralising antibodies** that reduce efficacy or cause infusion/hypersensitivity reactions; biosimilars must show immunogenicity **no worse than** the reference product. (This is a *Type B*, idiosyncratic, often dose-independent adverse reaction in Harrison's classification.)
- ▶ **Extrapolation of indications** — if biosimilarity is robustly proven in one (sensitive) indication, the biosimilar may be licensed for **other approved indications of the reference product without separate trials**, provided there is scientific justification (same mechanism, receptor, PK).
- ▶ **Interchangeability** — a **separate, higher US designation (BPCIA)** permitting **pharmacy-level substitution without prescriber intervention**; it typically requires additional switching studies. *Biosimilar ≠ automatically interchangeable.*
- ▶ **Naming & traceability** — the FDA assigns a **4-letter suffix** to the nonproprietary name (e.g., *adalimumab-atto*) so that adverse events can be attributed to the exact product; **batch traceability** is essential for pharmacovigilance.
- ▶ **Pharmacovigilance** — because pre-licensing studies are small and short, **post-marketing surveillance** (risk-management plans, spontaneous reporting e.g. FDA MedWatch) is required to detect rare/late immunogenic and adverse events, exactly as for any new biologic.

Regulatory frameworks and representative examples

Region / body	Framework	Term used
USA (FDA)	BPCIA 2009 → 351(k) pathway; first US biosimilar filgrastim-sndz (Zarxio) , 2015	Biosimilar
EU (EMA)	First biosimilar guidelines (2005–06); first approval somatropin (Omnitrope) , 2006	Biosimilar
WHO	Guidelines on Similar Biotherapeutic Products (SBPs), 2009	SBP
India (CDSCO + DBT)	Guidelines on Similar Biologics, 2012 (revised 2016)	Similar Biologic

- ▶ **Examples of biosimilar molecules:** growth factors/hormones — **filgrastim, epoetin (erythropoietin), somatropin, insulin glargine**; monoclonal antibodies / fusion proteins — **infliximab, rituximab, trastuzumab, adalimumab, bevacizumab, etanercept**.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ “Totality-of-evidence” inverted pyramid (biosimilar) vs upright pyramid (originator). Draw two opposed triangles. *Biosimilar (inverted, wide top → narrow base)*: top wide band = Analytical structural & functional characterisation; next = Nonclinical (in-vitro, animal PK/PD/tox); next = Comparative human PK/PD; apex (smallest) = Comparative clinical efficacy, safety & immunogenicity. *Originator (upright)*: base = Discovery / analytics; widening up through Phase 1 → Phase 2 → Phase 3 (largest, efficacy). Label the contrast: “*emphasis reversed — analytics-heavy, clinically-light.*”
- ▶ Generic vs biosimilar molecule schematic. Small ring/molecule labelled “Small molecule, ~180 Da — identical generic” beside a large Y-shaped antibody labelled “Biologic mAb, ~150 kDa — biosimilar (highly similar, not identical)”, with arrows noting chemical synthesis vs living-cell production and glycosylation / microheterogeneity.

Clinical / Diagnostic significance

- ▶ **Cost & access**: biosimilars are markedly cheaper than originators, improving affordability of biologics in rheumatoid arthritis, IBD, psoriasis, oncology, anaemia of CKD and chemotherapy-induced neutropenia.
- ▶ **Switching**: non-medical (cost-driven) switching from originator to biosimilar is generally supported by accumulating real-world evidence, but **document the product and batch** at each switch and monitor for loss of response or immunogenic reactions.
- ▶ **Immunogenicity vigilance**: watch for **infusion reactions, secondary loss of efficacy and neutralising-antibody formation**; these may be indistinguishable clinically from those of the reference biologic and warrant ADA testing where available.
- ▶ **Reporting**: attribute and report adverse events to the **specific product by brand/suffix and batch number** (MedWatch / national pharmacovigilance) — generic prescribing by INN alone is inadequate for biologics.
- ▶ **Extrapolated indications** are legitimate; the candidate should not assume a biosimilar is “untested” in an indication merely because no dedicated trial exists.

High-yield exam pointers

- ▶ A biosimilar is “**highly similar with no clinically meaningful differences**” — *similar, never identical*; this is the single most examined definition.
- ▶ Generic = identical copy (bioequivalence); biosimilar = highly similar copy (biosimilarity/totality of evidence).
- ▶ Approval rests on a **stepwise comparability exercise** dominated by **analytical characterisation** (inverted pyramid), with a confirmatory comparative clinical + **immunogenicity** study.

- ▶ US pathway = 351(k) under the BPCIA 2009; EU EMA pioneered the field (first biosimilar Omnitrope, 2006); WHO term = SBP; India uses “Similar Biologic” (CDSCO/DBT 2012, rev 2016).
- ▶ Interchangeability is a separate designation requiring switching data — a biosimilar is *not* automatically substitutable.
- ▶ Extrapolation of indications is permitted with scientific justification.
- ▶ Immunogenicity (anti-drug / neutralising antibodies) is the key safety endpoint and a *Type B* adverse reaction.
- ▶ 4-letter suffix naming + batch traceability underpin biosimilar pharmacovigilance.

SOURCE & COVERAGE

Harrison 22e — Ch 71 “Principles of Clinical Pharmacology” (clinical-trial phases 1–3, premarketing vs postmarketing surveillance, Type A/Type B adverse drug reactions, FDA MedWatch reporting, and therapeutic monoclonal-antibody examples — rituximab, infliximab, abatacept).

Coverage note (gap flagged): The term *biosimilar* is **not defined in Harrison Ch 71**, which covers general clinical pharmacology and drug development but not biosimilars specifically. The biosimilar-specific content above — the definition, the small-molecule-generic vs biosimilar distinction, the *totality-of-evidence* comparability pathway, interchangeability, extrapolation, naming/traceability, and the regulatory frameworks (US BPCIA 351(k), EMA, WHO SBP, India CDSCO/DBT Similar Biologic guidelines 2012/2016) and named example products — is **universally accepted standard regulatory pharmacology** supplied to satisfy the ask, and is anchored to Ch 71 only for the underlying scaffolding (trial phases, ADR classification, immunogenicity as a Type B reaction, and post-marketing pharmacovigilance). Specific dates/identifiers (e.g., Zarxio 2015, Omnitrope 2006) are standard and accurate but lie outside the provided chapter.

Cell Culture Technique and Application

Asked in: Paper I Nov 2021 — RGUHS MD General Medicine

Definition / Introduction — Cell culture (tissue culture) is the *in-vitro* maintenance and propagation of living cells, isolated from a multicellular organism, under controlled physico-chemical conditions (sterility, defined nutrient medium, 37 °C, buffered pH, humidified CO₂). It allows cells to be grown outside the body for diagnostic, research and therapeutic purposes. The technique is foundational to **cytogenetics** (chromosome/karyotype analysis), **diagnostic virology**, **vaccine and biologic manufacture**, **stem-cell and disease modelling**, and **drug discovery/toxicology**. In internal medicine

its single most important clinical application is the cultured-cell **karyotype** used to characterise the numerical and structural chromosomal disorders that occur in ~1 % of the general population, 8 % of stillbirths and ~50 % of spontaneous abortions.

Types / Classification of Cell Culture

Basis of classification	Type	Key features / examples
Origin & lifespan	Primary culture	Cells freshly isolated from tissue by enzymatic/mechanical dissociation or <i>explant</i> outgrowth; retain donor karyotype; limited lifespan
	Finite (diploid) cell line	Subcultured (passaged) primary cells; divide a limited number of times (~50; <i>Hayflick limit</i>) then senesce; remain diploid — e.g., human diploid fibroblasts WI-38, MRC-5
	Continuous (immortalised) cell line	Transformed cells dividing indefinitely; often aneuploid — e.g., <i>HeLa</i> , <i>Vero</i> (used to isolate SARS-CoV-1)
Growth pattern / substrate	Adherent (monolayer)	Anchorage-dependent; grow as a sheet on treated plastic/glass; most fibroblasts/epithelia
	Suspension culture	Anchorage-independent; grow free in medium — e.g., haematopoietic/leukaemic cells
Architecture	Organ / explant & 3-D culture	Tissue fragment cultured with retained architecture; modern extension = organoids/assembloids and <i>organ-on-chip</i>

Requirements and General Methodology

- ▶ **Asepsis** — all manipulation in a **laminar-flow biosafety cabinet**; antibiotics (penicillin–streptomycin) and antifungals added to suppress contamination.
- ▶ **Growth medium** — a balanced salt solution with glucose, amino acids, vitamins and buffers (e.g., *Eagle's MEM*, *RPMI-1640*, *DMEM*), supplemented with **serum** (foetal calf serum) as a source of growth factors and hormones.
- ▶ **pH/gas control** — sodium-bicarbonate buffering equilibrated against 5 % CO₂ in a humidified 37 °C incubator; *phenol red* acts as a pH indicator.

- ▶ **Substrate & sub-culture (passage)** — adherent cells grow until *confluent*, then are detached with **trypsin-EDTA** and split (passaged) into fresh flasks.
- ▶ **Cryopreservation** — surplus cells frozen in serum + **DMSO** and stored in liquid nitrogen (−196 °C) as a cell bank.
- ▶ **Quality** — cultures monitored for confluence, viability (trypan-blue exclusion), and contamination (bacteria, fungi, mycoplasma).

Lymphocyte Culture and Karyotyping (the core cytogenetic technique)

Chromosomal (cytogenetic) disorders — *aneuploidy* and structural rearrangements (deletions, duplications, translocations, inversions, ring/dicentric chromosomes, Robertsonian translocations) — are characterised by analysing chromosomes at the **metaphase** stage, when they are maximally condensed and display the short (**p**) and long (**q**) arms about the centromere.

- ▶ **Sample** — peripheral venous blood in **sodium heparin**; alternatively bone marrow (direct/short culture for leukaemias), skin fibroblasts, **amniocytes** (amniocentesis) or **chorionic villi** (CVS) for prenatal work.
- ▶ **Mitogenic stimulation** — T-lymphocytes are driven into division by the mitogen **phytohaemagglutinin (PHA)**, cultured in medium + serum at 37 °C/5 % CO₂ for ~72 h.
- ▶ **Metaphase arrest** — **colchicine / colcemid** depolymerises the mitotic spindle, arresting cells in metaphase.
- ▶ **Hypotonic treatment** — 0.075 M KCl swells the cells and disperses the chromosomes.
- ▶ **Fixation** — **methanol : glacial acetic acid (3:1)** (*Carnoy's fixative*).
- ▶ **Spreading & banding** — cells dropped onto a slide and stained; **G-banding** (trypsin–Giemsa) is standard (also Q-, R-, C-banding) giving each chromosome a reproducible band pattern.
- ▶ **Analysis** — metaphase spreads are imaged and chromosomes ordered by size, centromere position and banding into a **karyogram**, reported in *ISCN* nomenclature (e.g., 47,XX,+21 for trisomy 21). Conventional karyotype resolution is ~5–10 Mb.
- ▶ **Indications (Harrison Table 479-4)** — *prenatal* (advanced maternal age, abnormal ultrasound, positive serum screen); *neonatal/childhood* (multiple congenital anomalies, intellectual disability/developmental delay, autism, failure to thrive, short stature, disorders of sexual development, childhood cancer); *adult* (infertility, recurrent miscarriage, familial cancer, familial chromosomal rearrangement).

Molecular cytogenetic methods now complement culture-based karyotyping: **FISH** (locus/probe-specific), and **chromosomal microarray (CMA)**, which detects copy-number variants (e.g., 22q11/DiGeorge) far below karyotype resolution.

Applications of Cell Culture

Field	Application	Detail (source-grounded)
Cytogenetics / genetics	Karyotyping; FISH; prenatal diagnosis	Constitutional & cancer chromosome analysis from cultured lymphocytes, amniocytes, CVS, marrow
Diagnostic virology	Virus isolation & quantification	Inoculation of <i>Vero</i> cell cultures → cytopathic effect (CPE) ; titres by plaque assay (PFU) and TCID₅₀ (endpoint-dilution)
Vaccines & biologics	Manufacture	Viral vaccines, vaccine vectors, gene-therapy vectors and oncolytic viruses are grown and precisely titrated in cell culture
Immunology	Monoclonal antibodies	B-cell × myeloma fusion (hybridoma , <i>Köhler & Milstein</i>) — standard immunology technique
Regenerative / disease modelling	iPSC, organoids	Somatic cells (skin fibroblasts/blood) reprogrammed with Oct3/4, Klf-4, Sox2, c-Myc (<i>Yamanaka factors</i>) — now via non-integrating <i>Sendai virus</i> / <i>mRNA</i> / <i>episomal</i> vectors — expanded indefinitely and differentiated; 3-D organoids/assembloids model neurologic disease
Pharmacology / toxicology	Drug & target screening	iPSC-derived cells/organoids screen therapeutic agents, detect off-target/toxic effects, uncover targets
Gene & cell therapy	Engineered cellular products	Platform for CRISPR-Cas9 gene-editing and <i>ex-vivo</i> cell products (e.g., CAR-T, isogenic disease/control lines)
Cancer cytogenetics	Diagnosis/prognosis	Cultured marrow reveals diagnostic/prognostic translocations in leukaemias and solid tumours

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- Metaphase chromosome / karyogram schematic — label: *short arm (p)*, *long arm (q)*, *centromere*, *telomere*, *G-band pattern*, *sister chromatids*; with an inset karyogram strip

Field	Application	Detail (source-grounded)
		showing autosome pairs 1–22 + sex chromosomes (e.g., 46,XY) — derived from Harrison Fig. 479-1. ► Flow diagram of lymphocyte culture for karyotyping — boxes: <i>Heparinised blood</i> → <i>PHA + medium/serum, 37 °C/5 % CO₂ × 72 h</i> → <i>Colcemid (metaphase arrest)</i> → <i>Hypotonic KCl</i> → <i>Carnoy's fixative</i> → <i>Drop on slide + G-banding</i> → <i>Microscopy/karyogram</i> → <i>ISCN report</i>.

Clinical / Diagnostic significance

- **Definitive diagnosis** of constitutional aneuploidies and structural rearrangements (Down, Turner, Klinefelter, cri-du-chat, translocation Down) and of cancer-associated chromosomal abnormalities guiding diagnosis, prognosis and **targeted therapy** (actionable lesions in leukaemias/solid tumours).
- **Prenatal diagnosis** — cultured amniocytes/chorionic villi give a foetal karyotype/CMA; a positive **non-invasive cfDNA screen (NIPT)** is generally confirmed by amniocentesis/CVS.
- **Virology** — culture isolation remains a reference method for replicating/infectious virus, complementing antigen and **PCR/NAAT** assays; precise infectious titres (PFU, TCID₅₀) are essential for safe vaccine/vector dosing.
- **Therapeutics & research** — patient-specific **iPSC lines/organoids** model monogenic and polygenic disease on the patient's own genetic background and serve as drug-screening and toxicity platforms; cell culture underpins monoclonal-antibody and engineered cell-therapy production.
- **Pitfalls** — culture failure/contamination (mycoplasma), maternal-cell contamination of prenatal samples, *confined placental mosaicism*, and the limited (~5–10 Mb) resolution of conventional karyotype (overcome by CMA/FISH).

High-yield exam pointers

- **Cell culture** = in-vitro growth of cells under sterile, nutrient-rich, 37 °C/5 % CO₂ conditions.
- **Primary culture** → finite cell line (Hayflick limit ~50 divisions, diploid) → continuous/immortalised line (aneuploid, e.g., HeLa/Vero).
- Karyotype recipe mnemonic: **blood** → **PHA (72 h)** → **colcemid** → **KCl (hypotonic)** → **3:1 methanol-acetic fixative** → **G-banding** → **metaphase analysis**.
- Chromosomes are studied at **metaphase**; **p** = short, **q** = long arm; report by **ISCN** (e.g., 47,XX,+21).
- Cytogenetic disorders occur in ~1 % of population, ~50 % of spontaneous abortions.
- Virology titres: **TCID₅₀** (endpoint dilution) and **plaque-forming units (PFU)**; Vero cells, CPE.

- ▶ **iPSC** = somatic cells reprogrammed by **Oct3/4, Klf-4, Sox2, c-Myc** (Yamanaka factors); now via non-integrating Sendai/mRNA/episomal vectors → organoids.
- ▶ **CMA/FISH** detect sub-microscopic copy-number variants missed by routine karyotype.

SOURCE & COVERAGE

- ▶ **Harrison's Principles of Internal Medicine, 22e** — “Principles of Human Genetics” (chromatin/metaphase chromosome structure, p/q arms, cytogenetic disorders, indications for cytogenetic/cytogenomic analysis — Table 479-4); “Principles of Medical Virology” (cell-culture viral isolation, *Vero* cells, CPE, plaque assay/PFU, TCID₅₀, vaccine/vector titration); “Pathobiology of Neurologic Diseases” (induced pluripotent stem cells, Yamanaka reprogramming factors, non-integrating vectors, organoids/assembloids, drug screening); “Circulating Nucleic Acids as Liquid Biopsies / Prenatal diagnosis” (amniocentesis, CVS, traditional karyotype resolution ~5–10 Mb, chromosomal microarray).

Coverage note: Harrison 22e explicitly states that **chromosomal-analysis (cell-culture karyotyping) techniques were detailed in previous editions** and gives only the indications and chromosome biology in the current text. Accordingly, the **step-by-step lymphocyte-culture/karyotyping protocol** (PHA stimulation, colcemid arrest, hypotonic KCl, Carnoy's fixative, G-banding), the **Hayflick limit**, media (RPMI/DMEM/MEM), and the **hybridoma (Köhler–Milstein)** method are presented as *universally accepted standard cytogenetics/immunology* rather than verbatim 22e content; all chapter-specific numbers, cell lines and reprogramming factors cited above are taken faithfully from the corpus. No dedicated subspecialty textbook or CMDT chapter was specified for this lab-technique topic.

Circle of Willis

Asked in: Paper III May 2019 — RGUHS MD General Medicine

Definition / Introduction — The *circle of Willis* is the anastomotic arterial polygon (a heptagon) lying on the ventral surface of the brain within the **interpeduncular fossa/cistern** at the base of the brain, encircling the optic chiasm, infundibulum and midbrain. It is the single most important intracranial anastomosis: the carotid (anterior) and vertebrobasilar (posterior) arterial systems unite here so that, with a *competent* circle, occlusion of one feeding vessel may pass unnoticed. A truly **complete** circle is found in only ~20–25% of subjects; configurational variation is the rule, not the exception.

Constituent arteries (the seven-sided ring)

The circle is closed by paired vessels linked anteriorly and posteriorly by single/short communicating arteries:

Position	Contributing artery	Connects
Anterior (single)	Anterior communicating artery (AComA)	the two A1 segments of the ACAs — closes the <i>rostral</i> part of the circle
Anterolateral (paired)	Anterior cerebral arteries (A1 / precommunal segment)	ICA terminus → AComA
Lateral (paired)	Internal carotid arteries (terminal/supraclinoid)	the carotid “input” to the circle
Posterolateral (paired)	Posterior communicating arteries (PComA)	ICA → PCA; the <i>link between anterior and posterior circulations</i>
Posterior (paired)	Posterior cerebral arteries (P1 / precommunal segment)	basilar bifurcation → PComA
Posterior apex (single)	Basilar artery bifurcation	vertebrobasilar “input” to the circle

- ▶ The two **vertebral arteries** (segments V1–V4) join at the *pontomedullary junction* to form the **basilar artery**, which runs the length of the pons and bifurcates into the two PCAs at the *pontine–midbrain junction* within the interpeduncular cistern.
- ▶ Vessels that **arise from** the circle but are **not** structural members of the ring include the **middle cerebral artery (MCA)**, **anterior choroidal artery**, the deep perforators, and (from the posterior limb) the superior cerebellar and pontine branches.
- ▶ **Origin of the feeding trunks:** the **brachiocephalic trunk**, **left common carotid** and **left subclavian** arise from the aortic arch; the brachiocephalic trunk divides into the right subclavian and right common carotid; the **vertebral arteries arise from the subclavians**. Thus the circle ultimately receives blood from *all three* arch vessels.
- ▶ **Embryological note:** the PCA is developmentally a branch of the ICA (carried on the PComA); as the basilar system matures the P1 segment takes over — failure of this transition leaves the *fetal-type* PCA.

Internal carotid artery and its circle-related branches

The ICA is divided into four portions — **cervical (C1, no branches)**, **petrous (C2)**, **cavernous (C3)** and **supraclinoid/intracranial (C4)**. After piercing the dura, the intracranial ICA, in order, gives off:

- ▶ **Ophthalmic artery** — first major intradural branch (orbital, extraorbital, ocular branches; *central retinal artery* at the “bayonet” point; long & short posterior ciliary arteries) — basis of *amaurosis fugax* in carotid disease.
- ▶ **Superior hypophyseal artery** — to pituitary/hypothalamus.

- ▶ **Posterior communicating artery (PComA)** — joins the PCA to form the **posterolateral portion** of the circle; its penetrating branches supply the **anterior & posterior hypothalamus, optic tract and posterior optic chiasm, and the anterior & ventral thalamic nuclei**.
- ▶ **Anterior choroidal artery (AChA)** — arises from the posterior wall of the ICA *distal to PComA, proximal to the ICA terminus* (so it is **not** part of the circle). It supplies the **posterior limb of the internal capsule, optic tract, lateral geniculate body, medial globus pallidus, tail of caudate, midbrain/cerebral peduncle** and the choroid plexus of the temporal horn — a strategic vessel vulnerable during aneurysm clipping.
- ▶ ICA finally **bifurcates into the ACA and MCA**.

Deep penetrating (perforating) branches of the circle

The communicating and proximal cerebral segments give off small **central/ganglionic perforators** to the diencephalon and basal ganglia — these are *functional end-arteries* and account for lacunar syndromes:

- ▶ **Anteromedial group** — from the ACA (A1) and AComA → anterior hypothalamus, septal region, optic chiasm, anterior commissure, columns of fornix.
- ▶ **Anterolateral group (lateral striate / lenticulostriate)** — from the **stem of the MCA** → putamen, outer globus pallidus, posterior limb of internal capsule, caudate body, corona radiata.
- ▶ **Posteromedial group** — from PComA and P1 PCA → hypothalamus, subthalamus, medial thalamus, rostral midbrain.
- ▶ **Posterolateral group (posterior/thalamogeniculate striate)** — from the postcommunal PCA → thalamus and geniculate bodies.
- ▶ **Medial striate artery (recurrent artery of Heubner)** — from the A1–A2 junction → anteroinferior limb of internal capsule, anterior putamen/caudate, tip of outer globus pallidus.

Collectively the **medial, lateral and posterior striate arteries** perfuse the **striatum and thalamus**; their occlusion produces pure-motor, pure-sensory or sensorimotor *lacunar* strokes.

Anatomical variations and persistent fetal anastomoses

- ▶ **Incomplete circle** in ~75–80% of people — most often a hypoplastic/absent communicating segment or A1 atresia.
- ▶ **Fetal (embryonic) PCA** in ~20–25%: the PCA arises from the ICA via a large PComA and the **P1 segment is atretic**, so the occipital lobe depends on the *anterior* circulation (carotid occlusion can then infarct the PCA territory). Harrison: both PCAs arise from the basilar in 75%, one from the ipsilateral ICA in 20%, and both from the ICAs in 5%.
- ▶ **Persistent primitive carotid–vertebrobasilar anastomoses** (failed embryonic regression) — *persistent trigeminal artery* (the **most frequent**, ~0.2% of adults), *persistent acoustic (otic) artery*, *persistent hypoglossal artery*, and *persistent proatlantal artery*.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Diagram 1 — Circle of Willis (inferior/basal view).** Draw the heptagon and label: *Anterior communicating artery, Anterior cerebral artery (A1), Internal carotid artery, Middle cerebral artery, Anterior choroidal artery, Posterior communicating artery, Posterior cerebral artery (P1), Basilar artery, Superior cerebellar artery, Vertebral artery, Anterior spinal artery.* Add the four perforator groups: *anteromedial, anterolateral, posteromedial, posterolateral.*
- ▶ **Diagram 2 — Vascular territories on a coronal hemisphere section.** Label: *ACA, MCA (superior & inferior divisions), MCA deep (lenticulostriate) branches, anterior choroidal artery, PCA, PCA deep branches; caudate, putamen, globus pallidus, internal capsule (anterior & posterior limbs), thalamus, hippocampal formation.*

Clinical / Diagnostic significance

- ▶ **Collateral reserve:** with a competent circle, even complete ICA occlusion may be asymptomatic; an incomplete circle predisposes to **border-zone (watershed) infarction** during systemic hypotension or carotid stenosis.
- ▶ **Saccular (“berry”) aneurysms** cluster at the branch points of the circle — classically the **ACoMA**, the **PCoMA–ICA junction**, and the **MCA bifurcation** — and rupture causes **subarachnoid haemorrhage**. A **PCoMA aneurysm** characteristically produces a *painful, pupil-involving third (oculomotor) nerve palsy*.
- ▶ **Imaging:** the circle and its variants are mapped by **CT/MR angiography** and **digital subtraction angiography (DSA)**; transcranial Doppler assesses collateral flow and vasospasm.
- ▶ **Surgical relevance:** balloon test occlusion before carotid sacrifice tests circle competence; **AChA** and lenticulostriate perforators are “eloquent” end-arteries readily injured during aneurysm clipping.
- ▶ **Stroke localisation:** deep perforator occlusion → lacunar syndromes; proximal large-vessel occlusion → cortical territorial syndromes (MCA, ACA, PCA).

High-yield exam pointers

- ▶ Circle lies in the **interpeduncular fossa**, encircling optic chiasm, infundibulum and midbrain; it is a **heptagon**.
- ▶ **Anterior half** = carotid system (ICA, A1-ACA, ACoMA); **posterior half** = vertebrobasilar system (P1-PCA, basilar); **PCoMA is the bridge** between them.
- ▶ **ACoMA** closes the circle anteriorly; **two PCoMAs** close it posterolaterally.
- ▶ **MCA and anterior choroidal artery are NOT part of the circle** — common viva trap.
- ▶ **Complete circle in only ~20–25%; fetal PCA in ~20–25% (atretic P1).**

- ▶ AComA = commonest site of berry aneurysm; PComA aneurysm = pupil-involving CN III palsy.
- ▶ Recurrent artery of Heubner = medial striate branch of ACA; lenticulostriate = deep branches of MCA (lacunar strokes, hypertensive haemorrhage).
- ▶ Persistent trigeminal artery = commonest persistent carotid–basilar anastomosis (~0.2%).

SOURCE & COVERAGE

- ▶ Harrison's Principles of Internal Medicine, 22e — "Introduction to Cerebrovascular Diseases" (anterior vs posterior circulation, ICA/ACA/MCA/PCA segments, PCA-origin percentages, lacunar/lenticulostriate anatomy, competent-circle collateral concept).
- ▶ Brazis, Masdin & Biller, *Localization in Clinical Neurology* — "Vascular Syndromes of the Forebrain, Brainstem, and Cerebellum" (dedicated neurovascular anatomy: ICA C1–C4 segments and branches, PComA/AChA/Heubner territories, perforator groups, circle constituents, ~20–25% complete-circle figure, persistent carotid–vertebrobasilar anastomoses).

Coverage note: This is pure vascular anatomy; Harrison covers it only as background to stroke syndromes, so the structural depth (segmental nomenclature, perforator groups, persistent fetal anastomoses) is drawn from Brazis. Aneurysm-site frequency and the PComA-aneurysm CN III palsy are universally accepted standard internal-medicine points included for completeness.

Classify newer anticoagulants. What is the site of action and the approved indications for use

Asked in: Paper I May 2025 — RGUHS MD General Medicine

Definition / Introduction — Anticoagulants are drugs that prevent and treat thrombosis by inhibiting the coagulation cascade and thus fibrin formation; they are the mainstay of venous thromboembolism (VTE) management because fibrin is the predominant component of venous thrombi. "Newer anticoagulants" denotes the agents introduced after unfractionated heparin and warfarin — the synthetic pentasaccharide (**fondaparinux**), the parenteral **direct thrombin inhibitors**, and, most importantly, the **direct oral anticoagulants (DOACs)**, formerly called novel/non-vitamin-K oral anticoagulants (NOACs): **dabigatran** (oral thrombin inhibitor) and **rivaroxaban, apixaban, edoxaban** (oral factor Xa inhibitors). Unlike warfarin, DOACs target a *single* clotting enzyme at its active site, have a rapid onset/offset, and are given in fixed doses without routine coagulation monitoring.

Classification of newer anticoagulants

Class	Mechanism / target	Agents	Route
Synthetic pentasaccharide (indirect Xa inhibitor)	Binds antithrombin → catalyses factor Xa inhibition only (too short to bridge thrombin)	Fondaparinux	SC
Parenteral direct thrombin (IIa) inhibitors	Bind thrombin directly	Argatroban (univalent, active site), Bivalirudin (bivalent, active site + exosite 1), Desirudin	IV / SC
Direct oral anticoagulants — oral thrombin inhibitor	Reversible active-site inhibition of thrombin (factor IIa)	Dabigatran etexilate	Oral
Direct oral anticoagulants — oral factor Xa inhibitors (“-xabans”)	Reversible active-site inhibition of factor Xa	Rivaroxaban, Apixaban, Edoxaban	Oral

- ▶ The unifying feature of the DOACs is that they are small molecules that bind **reversibly to the active site** of a single target enzyme, in contrast to warfarin (which lowers synthesis of factors II, VII, IX, X) and heparins (which act indirectly through antithrombin).
- ▶ Dabigatran is administered as the **prodrug dabigatran etexilate**, which is converted to the active moiety; the three factor Xa inhibitors are active drugs and are not prodrugs.

Site of action within the coagulation cascade

- ▶ **Factor Xa inhibitors (rivaroxaban, apixaban, edoxaban):** directly and reversibly inhibit **factor Xa**, the enzyme at the convergence of the intrinsic and extrinsic pathways that assembles into the **prothrombinase complex** to convert prothrombin (II) to thrombin. A key pharmacodynamic advantage over heparin is that DOACs inhibit factor Xa **even when it is incorporated into the prothrombinase complex** — a site where the heparin–antithrombin complex is ineffective.
- ▶ **Direct thrombin inhibitor (dabigatran):** reversibly inhibits **thrombin (factor IIa)**, the final effector enzyme, blocking conversion of fibrinogen → fibrin and inhibiting thrombin-mediated feedback activation of factors V, VIII, XI and platelets. Unlike heparin, dabigatran also inhibits **fibrin-bound (clot-bound) thrombin**.
- ▶ **Fondaparinux:** an *indirect* inhibitor — it binds antithrombin via the pentasaccharide sequence, accelerating factor Xa inhibition; being only 5 saccharide units long it cannot bridge antithrombin to thrombin, so it has **no anti-IIa activity**.

Pharmacologic properties of the DOACs (Harrison Table 123-9)

Property	Rivaroxaban	Apixaban	Edoxaban	Dabigatran
Target	Factor Xa	Factor Xa	Factor Xa	Thrombin (IIa)
Prodrug	No	No	No	Yes
Bioavailability	80%	60%	50%	6%
Dosing	od (bid)	bid	od	bid (qd)
Half-life	7–11 h	12 h	9–11 h	12–17 h
Renal excretion	33% (66%)	25%	35%	80%
Drug interactions	CYP3A4 / P-gp	CYP3A4 / P-gp	P-gp	P-gp

- ▶ **Apixaban has the lowest renal clearance (25%)** and the lowest bleeding risk of the group, making it preferred in chronic kidney disease; **dabigatran is the most renally dependent (80%)** and is contraindicated/avoided in severe renal impairment.
- ▶ All are substrates of **P-glycoprotein (P-gp)**; the factor Xa inhibitors rivaroxaban and apixaban are additionally metabolised by **CYP3A4**. Strong dual P-gp/CYP3A4 *inducers* (rifampin, carbamazepine, phenytoin, St John's wort) reduce efficacy and should be avoided; potent *inhibitors* (ketoconazole, itraconazole, ritonavir) increase bleeding risk.

Approved indications and dosing

- ▶ **Stroke prevention in non-valvular atrial fibrillation (AF):** *all four* DOACs are licensed, *except* in patients with **mechanical heart valves or moderate–severe (rheumatic) mitral stenosis**, where warfarin remains mandatory.
 - Rivaroxaban **20 mg od** (15 mg od if CrCl 15–49 mL/min); take with food.
 - Dabigatran **150 mg bid** (75 mg bid if CrCl 15–30 mL/min).
 - Apixaban **5 mg bid**, reduced to **2.5 mg bid** if ≥ 2 of the “ABC” criteria — Age >80 y, Body weight <60 kg, serum Creatinine ≥ 1.5 mg/dL.
 - Edoxaban **60 mg od** (CrCl 50–95 mL/min); reduce to **30 mg od** if CrCl 15–50 mL/min, weight ≤ 60 kg, or concurrent potent P-gp inhibitor (verapamil, quinidine).
- ▶ **Treatment of VTE (DVT/PE):**
 - Dabigatran and edoxaban require a **≥ 5 -day parenteral (LMWH) lead-in** (dabigatran 150 mg bid if CrCl >30 ; edoxaban as for AF).
 - Rivaroxaban and apixaban are **all-oral, single-drug regimens**: rivaroxaban 15 mg bid $\times$ 21 days $\rightarrow$ 20 mg od; apixaban 10 mg bid $\times$ 7 days $\rightarrow$ 5 mg bid.
- ▶ **Extended/secondary VTE prevention** (after 6 months of full-dose therapy): apixaban **2.5 mg bid**; rivaroxaban **10 mg od**.

- ▶ **Thromboprophylaxis after elective hip or knee arthroplasty:** dabigatran 220 mg od, rivaroxaban 10 mg od, apixaban 2.5 mg bid (edoxaban licensed for this only in Japan); continued ~30 days after hip and 10–14 days after knee replacement.
- ▶ **VTE prophylaxis in selected adults hospitalised for acute medical illness:** rivaroxaban (per CMDT 2026).
- ▶ **Secondary prevention in stable coronary or peripheral artery disease: low-dose rivaroxaban 2.5 mg bid added to aspirin** (81–100 mg od) reduces major adverse cardiac and limb events; low-dose rivaroxaban added to dual-antiplatelet therapy also reduces recurrent ischaemic events after acute coronary syndrome.

Monitoring, reversal and safety

- ▶ **Routine coagulation monitoring is not required.** When assessment is needed (adherence, suspected overdose, before urgent surgery, in extremes of body weight or renal failure): qualitatively, PT screens for factor Xa inhibitors (rivaroxaban/edoxaban prolong PT more than apixaban, which needs a dedicated assay) and aPTT for dabigatran. Quantitative assays are the **chromogenic anti-factor Xa assay** (Xa inhibitors) and the **dilute thrombin time / ecarin clot time** (dabigatran).
- ▶ **Specific reversal agents:**
 - **Idarucizumab** — a humanised antibody fragment, **5 g IV bolus**, binds dabigatran with high affinity for emergency reversal.
 - **Andexanet alfa** — a recombinant catalytically-inactive factor Xa “decoy” that sequesters rivaroxaban and apixaban (low-dose 400 mg bolus + 4 mg/min; high-dose 800 mg bolus + 8 mg/min).
 - **Four-factor prothrombin complex concentrate (25–50 units/kg)** is the non-specific alternative; vitamin K is of **no benefit** for DOAC bleeding.
- ▶ **Bleeding** is the major adverse effect, but DOACs cause **less intracranial haemorrhage than warfarin**; higher-dose dabigatran, rivaroxaban and edoxaban cause **more GI bleeding**. **Dyspepsia** occurs in up to 10% with dabigatran.
- ▶ **Periprocedural:** hold for 1–2 days (longer if renal impairment) before procedures with moderate/high bleeding risk.
- ▶ **Contraindications:** pregnancy and breastfeeding (small molecules cross the placenta and enter breast milk), mechanical heart valves, severe rheumatic mitral stenosis, severe renal impairment (drug-specific), and severe active bleeding.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Coagulation cascade showing sites of action.** Labels: *Tissue factor + Factor VIIa* → *Factor X* → *Factor Xa* (block here labelled **Rivaroxaban / Apixaban / Edoxaban**; and

Fondaparinux → via Antithrombin → Prothrombin (II) → Thrombin (IIa) (block here labelled Dabigatran; also Argatroban / Bivalirudin) → Fibrinogen → Fibrin clot. Mark warfarin acting on synthesis of Factors II, VII, IX, X for contrast.

- ▶ **DOAC summary box:** four boxes — Dabigatran (anti-IIa, prodrug, 80% renal) vs Rivaroxaban / Apixaban / Edoxaban (anti-Xa) — with target, bioavailability and half-life beside each.

Clinical / Diagnostic significance

- ▶ DOACs are now **first-line over warfarin** for non-valvular AF and for most VTE because of fixed dosing, predictable pharmacokinetics, fewer food/drug interactions and lower intracranial bleeding.
- ▶ **Drug selection by patient factor:** apixaban (lowest renal clearance, lowest bleeding) in CKD/high bleeding risk; avoid dabigatran in severe renal impairment; check P-gp/CYP3A4 interactions before prescribing.
- ▶ DOACs are **contraindicated in mechanical valves and rheumatic mitral stenosis** — a high-yield safety point (the RE-ALIGN trial showed harm with dabigatran in mechanical valves).
- ▶ Availability of **idarucizumab** and **andexanet alfa** has largely removed the historical objection that DOACs “have no antidote.”

High-yield exam pointers

- ▶ **One sentence classification:** newer anticoagulants = fondaparinux (indirect Xa) + parenteral DTIs (argatroban, bivalirudin) + DOACs = oral IIa inhibitor *dabigatran* and oral Xa inhibitors *rivaroxaban*, *apixaban*, *edoxaban*.
- ▶ “-xa-ban” in the name = factor Xa inhibitor; “-gatan” = thrombin inhibitor.
- ▶ Dabigatran is the only DOAC that is a **prodrug**, has the **lowest bioavailability (6%)** and **highest renal excretion (80%)**.
- ▶ Apixaban = lowest renal clearance, lowest bleeding, taken **bid**; rivaroxaban must be taken **with food** at the 15/20 mg dose.
- ▶ **AF dose-reduction triggers:** apixaban = ABC (Age >80, BW <60 kg, Cr ≥1.5 mg/dL); edoxaban = CrCl 15–50, weight ≤60 kg, or P-gp inhibitor.
- ▶ VTE: dabigatran & edoxaban need a **5-day heparin lead-in**; rivaroxaban & apixaban are single-drug oral regimens.
- ▶ **Reversal:** *idarucizumab* → dabigatran; *andexanet alfa* → rivaroxaban/apixaban; 4F-PCC if unavailable; vitamin K useless.
- ▶ **Absolute “do-not-use”:** mechanical heart valves, severe rheumatic mitral stenosis, pregnancy/lactation.

SOURCE & COVERAGE

- ▶ **Harrison's Principles of Internal Medicine, 22e** — “Antiplatelet, Anticoagulant, and Fibrinolytic Drugs” (J.I. Weitz) — classification of antithrombotic drugs, DOAC mechanism/site of action, Table of pharmacologic properties, indications, dosing, monitoring and reversal.
- ▶ **CMDT 2026** — “Disorders of Hemostasis, Thrombosis, & Antithrombotic Therapy” — current DOAC indications (incl. VTE prophylaxis in acute medical illness), drug-interaction cautions and transitioning between anticoagulants.

Classify oral antifungal therapy and the mechanisms of action and indications for use

Asked in: Paper I 06 Apr 2026 — RGUHS MD General Medicine

Definition / Introduction — Antifungal agents are drugs that selectively kill (fungicidal) or inhibit (fungistatic) fungi while sparing the eukaryotic human host. Because fungi, like human cells, are eukaryotes, the number of exploitable selective targets is small, so far fewer antifungal than antibacterial agents exist. **Orally bioavailable** agents are the backbone of outpatient and step-down therapy and act on one of four fungus-specific targets: the **cell-membrane sterol ergosterol** (azoles, allylamines, polyenes), the **cell-wall β -1,3-glucan** (triterpenoids/echinocandins), **nucleic-acid synthesis** (flucytosine) and the **mitotic spindle** (griseofulvin). Early appropriate therapy plus source control and immune reconstitution determine outcome.

Classification of antifungal agents by target (oral agents in bold)

Target site	Class	Agents	Oral availability
Cell membrane — ergosterol synthesis (inhibit lanosterol 14 α -demethylase)	Azoles (triazoles/tetrazole)	Fluconazole, Itraconazole, Voriconazole, Posaconazole, Isavuconazole, Oteseconazole (older imidazoles—ketoconazole, clotrimazole, miconazole—mainly topical)	Oral + IV (oteseconazole oral only)
Cell membrane — squalene epoxidase	Allylamine	Terbinafine (naftifine topical)	Oral + topical

Target site	Class	Agents	Oral availability
Cell membrane — bind/extract ergosterol	Polyene	Amphotericin B (IV); Nystatin (oral non-absorbed, topical)	AmB IV only; nystatin oral-luminal
Cell wall — β -1,3-glucan synthase	Triterpenoid	Ibrexafungerp	Oral
Cell wall — β -1,3-glucan synthase	Echinocandins	Caspofungin, anidulafungin, micafungin, rezafungin	IV only
Nucleic-acid (DNA/RNA) synthesis	Pyrimidine analogue	Flucytosine (5-FC)	Oral (+ IV)
Mitotic spindle / microtubules	—	Griseofulvin	Oral

Oral azoles — mechanism, spectrum and indications

- ▶ **Mechanism:** inhibit fungal cytochrome-P450 lanosterol 14 α -demethylase, blocking conversion of lanosterol to ergosterol; accumulation of toxic methylated sterol intermediates and ergosterol depletion arrest growth — azoles are **fungistatic**. Advantages over amphotericin B: oral + IV forms and absence of nephrotoxicity.
- ▶ **Fluconazole** — oral/IV, long half-life, excellent penetration of CSF, ocular fluid and urine; minimal toxicity (rare hepatotoxicity; high dose $\rightarrow$ alopecia, dry mouth, metallic taste; even low doses in pregnancy linked to miscarriage/stillbirth). *No activity against molds or most endemic dimorphic fungi*; weaker against *C. glabrata*/*C. krusei*. **Indications:** preferred for **coccidioidal meningitis**; consolidation/maintenance therapy of **cryptococcal meningitis**; **mucosal (oropharyngeal, oesophageal, vulvovaginal) candidiasis**; candidaemia in non-critically-ill, non-neutropenic patients; step-down once a susceptible *Candida* is identified; prophylaxis in high-risk liver and allogeneic marrow transplant.
- ▶ **Itraconazole** — oral capsule/suspension + IV; *broader than fluconazole* (molds, endemic dimorphic fungi). **Drug of choice for mild-moderate histoplasmosis and blastomycosis**; also sporotrichosis, chronic coccidioidomycosis, phaeohyphomycosis, tinea/onychomycosis. Limitations: poor CSF penetration, erratic capsule absorption (monitor levels), potent CYP3A4 inhibitor, hepatotoxicity and **negative inotropy** $\rightarrow$ **may precipitate CHF**. *SUBA-itraconazole* gives improved/predictable absorption.
- ▶ **Voriconazole** — oral/IV; far broader than fluconazole (covers *C. glabrata*/*C. krusei*, **Aspergillus**, *Scedosporium*, endemic dimorphs) **but NOT Mucorales**; penetrates CSF and ocular fluid. **Preferred agent for invasive aspergillosis**. Metabolised by CYP2C9/3A4/2C19 (genetic polymorphism $\rightarrow$ variable levels — *monitor*); toxicities: visual disturbances,

photosensitivity/skin-cancer risk, hepatotoxicity, and the azole-unique **fluorosis-associated periostitis**.

- ▶ **Posaconazole** — oral suspension/tablet + IV; *broader than voriconazole, includes Mucorales*. Antifungal prophylaxis in neutropenic leukaemia and allogeneic HSCT; **treatment of fluconazole/itraconazole-refractory oropharyngeal candidiasis; salvage for aspergillosis, mucormycosis, fusariosis**. Tablet > suspension absorption; may cause pseudohyperaldosteronism** (hypokalaemia, oedema, hypertension).
- ▶ **Isavuconazole** — oral/IV; broad spectrum like posaconazole. FDA-approved for **aspergillosis** (non-inferior to voriconazole) and **mucormycosis**; less hepatotoxic, fewer P450 interactions, no skin/bone/visual toxicity.
- ▶ **Oteseconazole** — newest azole (a **tetrazole**), oral only; potent anti-*Candida* (incl. azole-resistant) and endemic-dimorph activity; long half-life allows **once-weekly** dosing. Approved for **recurrent vulvovaginal candidiasis**; no hepatotoxicity/P450 interactions but **contraindicated in women of reproductive potential** (fetal ocular toxicity).

Other oral agents

- ▶ **Terbinafine (allylamine)**: inhibits **squalene epoxidase**, blocking ergosterol synthesis and causing toxic squalene accumulation (fungicidal). Penetrates poorly beyond skin/nails, so reserved for **onychomycosis and dermatophytosis (ringworm)** — as effective as itraconazole; usual dose **250 mg orally daily** (≈ 6 weeks fingernail, ≈ 12 weeks toenail). Risk of **hepatotoxicity** (and rare cutaneous reactions).
- ▶ **Flucytosine (5-fluorocytosine)**: taken up by fungal cytosine permease and **converted intracellularly to 5-fluorouracil**, which inhibits fungal DNA/RNA synthesis. Always used in **combination** (synergy + avoids resistance) — chiefly with **amphotericin B for induction of cryptococcal meningitis** (good CSF penetration, rapid CSF sterilisation) and for candidal meningitis/endocarditis. Toxicity: **bone-marrow suppression** and hepatotoxicity (worse when combined with AmB).
- ▶ **Ibrexafungerp (triterpenoid)**: oral **β -1,3-glucan synthase inhibitor** (cell-wall target) with potent anti-*Candida* activity that is retained at the low pH of the vaginal mucosa; approved for **acute and recurrent vulvovaginal candidiasis**; contraindicated in pregnancy/lactation.
- ▶ **Griseofulvin**: binds fungal microtubules and disrupts the mitotic spindle; deposited in keratin precursor cells, rendering new keratin resistant to dermatophyte invasion. Approved for **dermatophyte infection of skin, hair and nails** — particularly **tinea capitis** (given with selenium sulfide/ketoconazole shampoo; examine family members). Side-effects: GI upset, headache, urticaria, photosensitivity.
- ▶ **Nystatin (oral polyene)**: binds ergosterol; not absorbed from the gut, so the **oral suspension** (“swish-and-swallow”) acts luminally for **oropharyngeal candidiasis**; also topical for vaginal candidiasis.

Parenteral comparators (for completeness — no oral form)

- ▶ **Amphotericin B (polyene):** broadest-spectrum, **fungicidal** — forms extramembranous sponge-like aggregates that **extract ergosterol** from the fungal membrane. **No licensed oral formulation**; remains preferred for **mucormycosis, fusariosis**, and induction of cryptococcal meningitis and severe endemic mycoses. Limited by **nephrotoxicity** and infusion reactions (fever, chills); **lipid formulations** (liposomal AmB, AmB lipid complex) reduce toxicity.
- ▶ **Echinocandins (caspofungin, anidulafungin, micafungin, rezafungin):** **IV only**; inhibit **β -1,3-glucan synthase**; fungicidal for *Candida*, fungistatic for *Aspergillus*; no activity vs *Cryptococcus*, Mucorales or endemic dimorphs. **First-line for candidaemia/invasive candidiasis** (minimal toxicity and interactions, active vs all *Candida*). Rezafungin allows weekly dosing.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **“Antifungal targets on the fungal cell” schematic:** draw a fungal cell with labelled concentric layers — **Cell wall (β -1,3-glucan)** → arrow from *Echinocandins* and *Ibrexafungerp* (triterpenoid) labelled “inhibit β -1,3-glucan synthase”; **Cell membrane (ergosterol)** → *Azoles* labelled “inhibit lanosterol 14 α -demethylase / ergosterol synthesis”, *Terbinafine* labelled “inhibit squalene epoxidase”, *Amphotericin B* / *Nystatin* (*polyenes*) labelled “bind & extract ergosterol → pore”; **Nucleus/DNA** → *Flucytosine* labelled “5-FC → 5-FU, inhibits DNA/RNA”; **Microtubules/mitotic spindle** → *Griseofulvin*.
- ▶ **Ergosterol biosynthesis pathway bar:** Squalene → (squalene epoxidase, blocked by *terbinafine*) → Lanosterol → (14 α -demethylase, blocked by *azoles*) → Ergosterol → (bound/extracted by *amphotericin B*, *nystatin*). Labels: Squalene, Squalene epoxidase, Lanosterol, 14 α -demethylase, Ergosterol.

Clinical / Diagnostic significance

- ▶ **Route dictates use:** oral azoles, terbinafine, flucytosine, ibrexafungerp and griseofulvin enable outpatient and **step-down (“IV-to-oral switch”)** therapy after initial IV induction; AmB and echinocandins anchor severe/inpatient disease.
- ▶ **Spectrum gaps to remember:** fluconazole — *no molds*; voriconazole — *no Mucorales*; echinocandins — *no Cryptococcus/Mucorales/dimorphs*; **posaconazole and isavuconazole cover Mucorales** (the only azoles that do).
- ▶ **Therapeutic drug monitoring** is required for itraconazole (capsule), voriconazole (CYP2C19 polymorphism) and posaconazole suspension to ensure efficacy and limit toxicity.
- ▶ **Drug interactions:** azoles are CYP inhibitors (itraconazole/voriconazole/posaconazole — clinically major); echinocandins and oteseconazole have minimal interactions.

- ▶ **Resistance:** rising azole/echinocandin-resistant *C. glabrata* and *C. auris* and azole-resistant *A. fumigatus* — echinocandins are preferred empirically for candidaemia, de-escalated to fluconazole once susceptibility is known.

High-yield exam pointers

- ▶ **Four targets:** ergosterol membrane (azoles, allylamines, polyenes), glucan cell wall (echinocandins, triterpenoids), DNA (flucytosine), spindle (griseofulvin).
- ▶ **Azoles inhibit 14 α -demethylase** → fungistatic; **AmB extracts ergosterol** → fungicidal; **terbinafine inhibits squalene epoxidase**.
- ▶ **Itraconazole = DOC for mild–moderate histoplasmosis & blastomycosis; voriconazole = DOC for invasive aspergillosis; fluconazole = DOC for coccidioidal meningitis + cryptococcal consolidation.**
- ▶ **AmB + flucytosine = induction for cryptococcal meningitis** (synergy, CSF penetration).
- ▶ **Posaconazole/isavuconazole cover Mucorales; voriconazole does not.**
- ▶ **Terbinafine/griseofulvin = dermatophytes (onychomycosis, tinea capitis); nystatin oral = oral thrush.**
- ▶ **Signature toxicities:** voriconazole — visual disturbance + periostitis + photosensitivity; posaconazole — pseudohyperaldosteronism; itraconazole — CHF; flucytosine — marrow suppression; AmB — nephrotoxicity; terbinafine — hepatotoxicity.
- ▶ **Newer oral agents: ibrexafungerp & oteseconazole for (recurrent) vulvovaginal candidiasis.**

SOURCE & COVERAGE

- ▶ **Harrison's Principles of Internal Medicine, 22e** — “Pathogenesis, Diagnosis, and Treatment of Fungal Infections” (antifungal drugs: amphotericin B, azoles, echinocandins, ibrexafungerp, flucytosine, terbinafine, topical agents) — primary source for mechanisms, spectra and indications.
- ▶ **Harrison's 22e** — “Fungal Skin Infections / Dermatophytes” (griseofulvin, terbinafine, itraconazole for skin–hair–nail dermatophytosis).
- ▶ **CMDT 2026** — “Mycotic Infections” and “Dermatologic Disorders” (oral dosing and use: terbinafine 250 mg/day, itraconazole 200 mg/day, griseofulvin for tinea capitis, fluconazole for tinea versicolor).

Coverage note: Harrison 22e does not list griseofulvin in its core antifungal-drug section; its dermatophyte use is taken from Harrison's fungal-skin material and CMDT, and griseofulvin's microtubule/mitotic-spindle mechanism is standard, universally accepted textbook pharmacology.

Clinical implications of bioavailability and protein binding of drugs

Asked in: Paper I May 2019 — RGUHS MD General Medicine

Definition / Introduction — **Bioavailability (F)** is the *fraction of an administered dose that reaches the systemic circulation in an unchanged, active form* after a non-intravenous route; by definition an intravenous dose has $F = 1$ (100%). **Plasma protein binding** describes the reversible association of drug with circulating proteins (chiefly albumin and α_1 -acid glycoprotein); only the **unbound (free) fraction** can cross membranes, reach target receptors, undergo glomerular filtration and hepatic metabolism, and so determines pharmacological effect. Both parameters are key determinants of drug *disposition* (absorption, distribution, metabolism, excretion) and explain much of the inter-individual and disease-related variability in drug response that the clinician must anticipate.

Bioavailability — concept and determinants

- ▶ F integrates two events: (1) the *fraction absorbed* across the gut wall, and (2) the *fraction surviving presystemic (first-pass) elimination* in gut wall and liver.
- ▶ Bioavailability is <100% for two main reasons (Harrison): **incomplete absorption**, or **metabolism/elimination before entering the systemic circulation** (first-pass effect).
- ▶ Compared with the same intravenous dose, a non-IV dose shows a **later and lower peak plasma concentration** and a **smaller area under the time–concentration curve (AUC)**; F is estimated as the ratio $AUC(\text{oral})/AUC(\text{IV})$, dose-corrected.
- ▶ **Factors reducing absorption**: incomplete release from the dosage form, destruction at the site of administration, poor solubility/lipophilicity, GI transit and gastric pH, food, and gut efflux transporters.
- ▶ **P-glycoprotein** (product of the *ABCB1/MDR1* gene) on the apical enterocyte and canalicular hepatocyte pumps drug back into lumen/bile, limiting bioavailability (e.g. digoxin); it is also a key element of the blood–brain barrier.

Route	Bioavailability	First-pass effect	Comment
Intravenous	100% (reference)	Bypassed	Most rapid, fully predictable
Intramuscular / subcutaneous	High, usually ~75–100%	Bypassed	Depends on perfusion, solubility
Sublingual / buccal / transdermal	Variable–high	Bypassed	Route for high first-pass drugs (GTN)
Rectal	Partial bypass	Partial	Lower haemorrhoidal veins skip liver
Oral	Lowest / most variable	Maximal	Gut wall + portal–hepatic extraction

First-pass (presystemic) elimination — and its clinical exploitation

- ▶ An orally administered drug must traverse **enterocyte** → **portal vein** → **liver** before reaching the systemic circulation; metabolism or biliary/luminal excretion at any step constitutes **presystemic (first-pass) extraction** (Harrison).
- ▶ **Drugs unusable orally:** *Nitroglycerin* is almost completely extracted presystemically, so it is given by the **sublingual, transdermal or intravascular** routes that bypass the liver.
- ▶ **High first-pass drugs needing larger oral doses:** *verapamil* — typical IV dose 1–5 mg versus a usual single oral dose of 40–120 mg (Harrison) — also propranolol, morphine, lidocaine, nifedipine, midazolam.
- ▶ **First-pass exploited therapeutically:** *low-dose aspirin* irreversibly acetylates cyclo-oxygenase in platelets within the portal blood, yet is **deacylated on first pass through the liver**, giving platelet inhibition with relative systemic sparing.

Clinical implications of altered bioavailability

- ▶ **Liver disease (cirrhosis):** reduced first-pass metabolism (hepatocyte dysfunction, altered architecture, **porto-systemic shunts**) raises oral bioavailability — for high-extraction drugs such as **morphine, meperidine (pethidine), midazolam and nifedipine** the oral bioavailability is **almost doubled**, so oral doses must be reduced (Harrison).
- ▶ **Heart failure / shock:** gut hypoperfusion and mucosal oedema slow or reduce drug absorption, blunting the effect of oral therapy; parenteral routes are preferred in the unstable patient.
- ▶ **Formulation matters:** slow-/sustained-release products deliberately slow absorption to smooth peak–trough swings; altered dissolution explains why expired or degraded drug fails.
- ▶ **Bioequivalence & generic substitution:** two products are *bioequivalent* when their rate (C_{max} , T_{max}) and extent (AUC) of absorption are statistically comparable; for **narrow-therapeutic-index drugs** (warfarin, phenytoin, digoxin, levothyroxine, antiepileptics, immunosuppressants) even small bioavailability differences between brands/generics can cause sub-therapeutic failure or toxicity, so switching warrants monitoring.
- ▶ **Drug interactions affecting F:** antacids/cholestyramine bind drugs in the gut (↓ absorption); proton-pump inhibitors/H₂-blockers raise gastric pH and reduce dissolution of weak bases (e.g. ketoconazole); P-glycoprotein/CYP3A inducers (rifampin, St John's wort) lower bioavailability of substrates.

Plasma protein binding — principles

- ▶ Only **free (unbound) drug** is pharmacologically active and available for distribution, metabolism and renal filtration; **drug response correlates with free, not total, plasma concentration** (Harrison).
- ▶ Bound and free drug exist in rapid equilibrium; binding acts as a **circulating reservoir** that buffers fluctuations and prolongs duration of action.

Binding protein	Drugs bound	Behaviour in disease
Albumin	Acidic / neutral drugs — warfarin, phenytoin, NSAIDs/salicylates, sulfonamides, valproate, diazepam	Falls in nephrotic syndrome, cirrhosis, malnutrition, burns, pregnancy → ↑ free fraction
α1-acid glycoprotein (AAG)	Basic drugs — lidocaine, quinidine/quinine, propranolol, verapamil, tricyclics	Acute-phase reactant — rises in MI, infection, surgery, malaria, cancer → ↓ free fraction
Lipoproteins / globulins	Lipophilic drugs (e.g. cyclosporine)	Vary with lipid status

- ▶ *Corpus example:* in malaria, plasma **protein binding of quinine to α1-acid glycoprotein increases to ~90%**, reducing free drug — illustrating how an acute illness alters the active fraction (Harrison, antimalarials chapter).

Clinical implications of altered protein binding

- ▶ The “**highly bound drug**” rule: the smaller the free fraction, the greater the effect of any change — *a fall in binding from 99% to 98% doubles the free concentration (1% → 2%)* and can precipitate toxicity even though *total* level is unchanged (Harrison).
- ▶ **Hypoalbuminaemia / uraemia (CKD, cirrhosis, nephrosis):** reduced binding **increases free drug and drug effect**; uraemia additionally displaces phenytoin from albumin (uraemic toxins compete) — hence free drug should be monitored.
- ▶ **Acute-phase states (MI, sepsis, surgery, trauma):** transient rise in AAG **increases binding of basic drugs and may reduce efficacy** (Harrison).
- ▶ **Displacement (protein-binding) drug interactions** (*universally taught examples*): sulfonamides / phenylbutazone / NSAIDs displace **warfarin** (transient ↑ INR, bleeding); **valproate** displaces **phenytoin**; sulfonamides and ceftriaxone displace **bilirubin** from neonatal albumin, risking **kernicterus**. Clinically, displacement alone is usually transient because the liberated drug is rapidly redistributed and cleared — it becomes dangerous mainly when **clearance is simultaneously impaired** and the drug is narrow-index.
- ▶ **Therapeutic drug monitoring (TDM) caveat:** for highly bound drugs, total levels mislead when binding is abnormal. For **phenytoin** the usual total target is **10–20 mg/L**, but falls to **~5–10 mg/L in uraemia and severe hypoalbuminaemia**; the **free phenytoin** target is **0.5–2.0 mg/L** and should be measured (or a corrected/Sheiner–Tozer estimate used) in renal/hepatic disease and low albumin (CMDT, therapeutic drug monitoring).
- ▶ **Distribution & special compartments:** highly bound drugs have limited tissue and CNS penetration; binding influences volume of distribution and the success of removal by dialysis (poorly bound drugs are dialysable).

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Plasma concentration–time curves (IV vs oral):** x-axis *Time*, y-axis *Plasma concentration*; overlay an **IV bolus curve** (high early peak, single exponential decline) and an **oral curve** (delayed lower C_{max} , later T_{max} , smaller AUC). Label: C_{max} , T_{max} , $AUC(IV)$, $AUC(oral)$, “ $F = AUC(oral)/AUC(IV)$ ”, and shade the area difference as “incomplete bioavailability”.
- ▶ **First-pass elimination schematic:** boxes/arrows *Gut lumen* → *Enterocyte* → *Portal vein* → *Liver* → *Systemic circulation*; label **P-glycoprotein efflux** (enterocyte apex), **CYP3A4 metabolism** (enterocyte + hepatocyte), **biliary excretion**, and the routes that *bypass* it: **sublingual / transdermal / IV / rectal (lower veins)**.

Clinical / Diagnostic significance

- ▶ Predicts when to **avoid the oral route** (GTN) or **escalate the oral dose** (verapamil, propranolol) for high first-pass drugs.
- ▶ Mandates **dose reduction of high-extraction oral drugs in cirrhosis** and a **switch to parenteral therapy in shock/heart failure**.
- ▶ Justifies **monitoring free (not total) drug** for phenytoin (and other highly bound, narrow-index drugs) in **renal failure, hepatic failure and hypoalbuminaemia**.
- ▶ Explains brand–generic non-equivalence concerns and the need for re-titration/monitoring after switching narrow-index drugs.
- ▶ Frames clinically important **drug interactions** at absorption (chelation, pH, P-gp/CYP induction) and at protein-binding/displacement levels.

High-yield exam pointers

- ▶ **F = fraction reaching systemic circulation in active form; $IV = 100\%$; $F = AUC(oral)/AUC(IV)$.**
- ▶ Two causes of low F : **incomplete absorption + presystemic (first-pass) elimination**.
- ▶ **GTN** — complete first-pass extraction → never oral; **verapamil** IV 1–5 mg vs oral 40–120 mg.
- ▶ **Cirrhosis doubles oral bioavailability** of morphine, pethidine, midazolam, nifedipine → reduce dose.
- ▶ **Only free drug is active**; for a 99%-bound drug a 1% fall in binding **doubles free concentration**.
- ▶ **Albumin** → **acidic drugs** (warfarin, phenytoin); **α_1 -acid glycoprotein** → **basic drugs** (lidocaine, quinidine) and **rises as an acute-phase reactant**.
- ▶ **Hypoalbuminaemia/uraemia** ↑ free phenytoin → **monitor free level (0.5–2.0 mg/L)**; total target falls to 5–10 mg/L.
- ▶ Classic displacement: **sulfonamides** → **warfarin** (bleeding); **sulfonamides** → **bilirubin** → **kernicterus** in neonates.

- ▶ **Narrow-therapeutic-index drugs** (warfarin, digoxin, phenytoin, levothyroxine, immunosuppressants) are most vulnerable to both bioavailability and protein-binding changes.

SOURCE & COVERAGE

- ▶ **Harrison's Principles of Internal Medicine, 22e** — “*Principles of Clinical Pharmacology*” (absorption and bioavailability, first-pass/presystemic elimination, P-glycoprotein, clinical implications of altered protein binding and clearance, disease effects on drug disposition); and the antimalarial-agents chapter (quinine binding to α 1-acid glycoprotein in malaria; phenytoin/warfarin as highly protein-bound drugs).
- ▶ **CMDT 2026** — Appendix “*Therapeutic Drug Monitoring*” (phenytoin total vs free target ranges; protein binding reduced in uraemia/hypoalbuminaemia; free-level monitoring).
- ▶ *Coverage note*: the quantitative bioequivalence limits (FDA 80–125% AUC/C_{max}), the explicit albumin-vs-AAG drug lists, the Sheiner–Tozer corrected-phenytoin equation, and the classic displacement examples (warfarin–sulfonamide, valproate–phenytoin, bilirubin–kernicterus) are standard, universally accepted clinical pharmacology included to complete the answer; Harrison 22e states the underlying free-drug and altered-binding principles but does not tabulate these specific examples.

Cloning: Principle and Methods

Asked in: Paper I Nov 2019 — RGUHS MD General Medicine

Definition / Introduction — *Cloning* is the production of multiple genetically **identical** copies of a biological entity — a defined segment of DNA (a gene), a cell, or a whole organism. In clinical molecular medicine the term usually means **molecular (gene/DNA) cloning**: the insertion of a defined DNA fragment of interest into a self-replicating DNA molecule (a **vector**), introduction of this **recombinant DNA** into a host cell (commonly *Escherichia coli*), and faithful amplification of the fragment as the host divides — yielding limitless identical copies for sequencing, expression or therapy. The technique exploits two universal properties of DNA emphasised in Harrison: its **double-stranded base-pair complementarity** (A–T, G–C) and its **faithful semiconservative replication**, which together permit a fragment to be copied with high fidelity. Recombinant DNA and RNA technology underpins the large-scale manufacture of peptide hormones, growth factors, cytokines, clotting factors and vaccines (e.g., recombinant insulin analogues, mRNA SARS-CoV-2 vaccines, siRNA therapeutics).

Types of cloning

Type	What is copied	Core method	Product/use
Molecular / gene (DNA) cloning	A DNA fragment / gene	Recombinant DNA technology — vector + host	Gene amplification, sequencing, recombinant proteins
Cellular cloning	A single cell	Clonal expansion in culture	Cell lines, hybridomas (monoclonal antibodies)
Reproductive (organism) cloning	A whole organism	Somatic cell nuclear transfer (SCNT)	<i>Dolly the sheep</i> (1996); identical animal
Therapeutic cloning	Patient-specific stem cells	SCNT into enucleated oocyte → blastocyst	Autologous embryonic stem cells / iPSC-type cells for regenerative therapy

Principle — recombinant DNA technology

- ▶ **Restriction–ligation principle:** sequence-specific bacterial enzymes cut DNA at defined sites; the same cut ends on insert and vector are **complementary**, so they can be re-joined by a ligase to create a single hybrid (**recombinant**) molecule.
- ▶ **Self-replication principle:** the vector carries an **origin of replication**, so once inside a dividing host cell it (and its insert) is copied many-fold — *amplification by biological cloning*.
- ▶ **Selection principle:** a marker (usually antibiotic resistance) on the vector lets only successfully transformed cells survive, so that each surviving colony is a **clone** descended from one cell carrying one recombinant molecule.
- ▶ **Complementarity** also allows the alternative *in vitro* amplification route — the **polymerase chain reaction (PCR)** — and the detection of clones by **hybridisation** with labelled probes.

Essential tools — enzymes and vectors

Tool	Function in cloning
Restriction endonucleases (Type II)	Cut double-stranded DNA at specific <i>palindromic</i> recognition sites (e.g., <i>EcoRI</i> = GAATTC), generating either staggered “sticky” (cohesive) ends or blunt ends
DNA ligase (T4)	Seals the phosphodiester backbone, covalently joining insert to vector → recombinant DNA
Reverse transcriptase	Synthesises complementary DNA (cDNA) from an mRNA template (intron-free copy of a gene)
DNA polymerase / thermostable Taq polymerase	Fills/extends strands; drives PCR-based amplification of the insert

Tool	Function in cloning
Alkaline phosphatase / terminal transferase, nucleases	Prevent vector self-ligation; tailor ends
Vectors	Carrier DNA that replicates in the host and carries the insert (see range below)

Vector hierarchy by insert capacity (choice depends on fragment size):

- ▶ **Plasmids** — small circular bacterial DNA; inserts up to ~10 kb; carry *ori* + selectable marker (e.g., ampicillin resistance) + a multiple-cloning site.
- ▶ **Bacteriophage λ** (~15–20 kb) and **cosmids** (~45 kb) — larger inserts, packaged into phage.
- ▶ **Bacterial artificial chromosomes (BACs)** — up to ~300 kb; **yeast artificial chromosomes (YACs)** — up to ~1 Mb; used for genomic libraries and genome mapping.
- ▶ **Expression vectors** — contain a promoter/enhancer so the cloned gene is *transcribed and translated* into protein in the host.
- ▶ **Viral vectors** (for mammalian cells / gene therapy) — retroviral, **lentiviral**, **adeno-associated viral (AAV)**, adenoviral, herpesviral; AAV cargo is limited to ~5 kb because the wild-type genome is only ~4.7 kb.

Steps of molecular cloning

- ▶ **Generate the DNA fragment (insert):** isolate genomic DNA and digest it with a restriction enzyme, **or** copy an expressed gene into intron-free **cDNA** using reverse transcriptase, **or** amplify the target by **PCR** with specific primers.
- ▶ **Cut the vector** with the *same* restriction enzyme so its ends are complementary to the insert's ends.
- ▶ **Ligation:** mix insert + linearised vector with **DNA ligase** → covalently sealed **recombinant DNA** molecules.
- ▶ **Introduce into a host cell** (**transformation** of *E. coli* by heat-shock/electroporation, **or** **transfection/transduction** of mammalian cells with a viral vector).
- ▶ **Selection and screening:** plate on antibiotic-containing medium so only vector-bearing cells grow; identify clones carrying the *insert* by **blue–white (α -complementation, X-gal/IPTG) screening**, **colony hybridisation** with a labelled probe, **colony PCR**, or restriction mapping.
- ▶ **Amplify and harvest:** grow a positive colony (a pure **clone**) to mass-produce identical copies of the fragment for sequencing, probe production, **or** — with an expression vector — recombinant protein.

Gene libraries and alternative methods

- ▶ **Genomic library** — clones representing the *entire* genome (introns + exons + regulatory + non-coding DNA), made from restriction fragments of total genomic DNA.

- ▶ **cDNA library** — clones of only the *expressed* genes of a tissue (made from its mRNA via reverse transcriptase); tissue-specific and intron-free.
- ▶ **PCR cloning** — rapid *in vitro* amplification of a defined sequence; can replace biological cloning for sequence analysis and enables genetic testing on minute DNA amounts (blood, buccal cells, archival tumour) — heavily used in molecular diagnostics.
- ▶ **Expression cloning** — selecting clones by the *function/protein* they produce.

Reproductive and therapeutic cloning (organism-level)

- ▶ **Somatic cell nuclear transfer (SCNT)**: the nucleus of an adult somatic (donor) cell is transferred into an **enucleated oocyte**; the reconstructed egg is activated to develop. Transferred to a surrogate it yields a genetically identical animal (**reproductive cloning** — *Dolly*, 1996).
- ▶ **Therapeutic cloning**: the SCNT blastocyst is used instead to derive **patient-specific pluripotent stem cells** for autologous regenerative therapy, avoiding immune rejection. (Human reproductive cloning is banned on ethical grounds.)

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Plasmid gene-cloning workflow**: draw a circular **plasmid vector** labelling *origin of replication*, *selectable marker* (amp^R), and *multiple-cloning/restriction site*; show a **foreign DNA fragment** cut by the *same restriction enzyme*; arrows to **DNA ligase** → **recombinant plasmid** → **transformation into E. coli** → **selection on antibiotic plate** → **colony (clone) amplification**. Labels: *target DNA*, *restriction enzyme*, *sticky ends*, *vector*, *ligase*, *recombinant DNA*, *host cell*, *antibiotic selection*, *clone*.
- ▶ **Sticky-end ligation inset**: two complementary single-stranded overhangs (e.g., ...G / AATTC... of *EcoRI*) annealing and being sealed; label *5' overhang*, *complementary base pairing*, *phosphodiester bond*, *DNA ligase*.

Clinical / Diagnostic significance

- ▶ **Recombinant therapeutics (expression cloning)**: human insulin and insulin analogues with favourable kinetics, growth hormone, erythropoietin, clotting factor concentrates, GLP-1 agonists, recombinant hepatitis B (HBsAg) and **mRNA** vaccines, and **siRNA** drugs (e.g., for hypercholesterolaemia) — all enabled by cloning genes into expression systems.
- ▶ **Monoclonal antibodies** via cloned/hybridoma technology underpin much of modern targeted therapy.
- ▶ **Gene therapy (cloning into viral vectors)**: therapeutic genes are cloned as **cDNA** into **lentiviral** vectors (β -thalassaemia, sickle cell disease, X-linked SCID, adrenoleukodystrophy, metachromatic leukodystrophy) or **AAV** vectors (spinal muscular atrophy, RPE65 retinal dystrophy, haemophilia A/B with *factor IX Padua*, Duchenne microdystrophin). Vectors are

classed as **integrating** (retro-/lentiviral, risk of insertional mutagenesis/LMO-2 leukaemia) vs **non-integrating/episomal** (AAV, adenoviral, plasmid).

- ▶ **Genome editing** extends cloning: a **CRISPR–Cas9/guide-RNA** complex (e.g., disrupting *BCL11A* to re-activate fetal haemoglobin) is delivered for sickle cell disease/thalassaemia, with optional AAV-supplied repair templates via homology-directed repair.
- ▶ **Molecular diagnostics built on the same principles**: PCR/qPCR, RFLP, Southern blotting, FISH, microarray/DNA chips, MLPA, and next-generation (massively parallel) sequencing for inherited-disease, oncology and infectious-pathogen testing.

High-yield exam pointers

- ▶ **Recombinant DNA** = insert + vector joined by **ligase** after cutting with the same **restriction endonuclease**.
- ▶ **Restriction enzymes** recognise short **palindromes** and give **sticky** or **blunt** ends (Arber, Smith, Nathans — Nobel 1978).
- ▶ Cloning vectors in ascending capacity: **plasmid** < **phage λ** < **cosmid** < **BAC** < **YAC**; expression vectors add a promoter; viral vectors transduce mammalian cells.
- ▶ **cDNA** (reverse transcriptase) is **intron-free**; a **cDNA library** = expressed genes, a **genomic library** = whole genome.
- ▶ **Selection** by antibiotic resistance; **screening** by **blue–white (α-complementation)**, colony hybridisation or colony PCR.
- ▶ **PCR** = rapid cell-free amplification alternative; requires **primers** + **thermostable polymerase** (Mullis — Nobel 1993).
- ▶ **SCNT** produced **Dolly (1996)** — reproductive cloning; therapeutic cloning yields **patient-specific stem cells**.
- ▶ Cloning into **expression/viral vectors** delivers recombinant insulin, vaccines, clotting factors and **gene therapies** (lentiviral vs AAV; integrating vs episomal).

SOURCE & COVERAGE

- ▶ **Harrison’s Principles of Internal Medicine, 22e** — “Principles of Human Genetics” (DNA structure, base-pair complementarity, replication, recombinant DNA/RNA technology, PCR, recombinant therapeutics); “The Practice of Genetics in Clinical Medicine” (PCR, RFLP, Sanger vs massively-parallel/next-generation sequencing, FISH, Southern blotting, MLPA, DNA microarrays); “Gene and Cell-Based Therapy in Clinical Medicine” (cloning into retroviral/lentiviral/AAV/adenoviral vectors, cDNA inserts, integrating vs non-integrating vectors, CRISPR–Cas9 genome editing, insertional mutagenesis).
- ▶ **Coverage note (spec gap = true)**: Harrison 22e is a clinical-genetics text and does **not** detail the classical wet-lab molecular-cloning workflow (restriction-enzyme digestion,

sticky/blunt-end ligation, plasmid/cosmid/BAC/YAC vectors, bacterial transformation, antibiotic selection, blue–white screening, and genomic vs cDNA libraries) or somatic-cell nuclear transfer. These elements are supplied here from **universally accepted standard molecular biology** (consistent with Harrison’s stated principles of DNA complementarity, replication and recombinant DNA technology) and are flagged as such; every Harrison-grounded specific (PCR, RFLP, FISH, Southern blot, NGS, viral vectors, AAV ~5 kb cargo limit, CRISPR/BCL11A, factor IX Padua, recombinant insulin/mRNA/siRNA) has been verified against the chapters above.

Complement Pathway, Functions and Regulation

Asked in: Paper I Nov 2019 — RGUHS MD General Medicine

Definition / Introduction — The **complement system** is a tightly regulated cascade of more than 30 plasma and membrane proteins that forms a major effector arm of **innate immunity** and bridges it to **adaptive immunity**. Activation proceeds through three initiating routes — the **classical**, **lectin (mannose-binding)** and **alternative** pathways — that all converge on the cleavage of C3, feed into a common **terminal pathway**, and culminate in the lytic **membrane attack complex (MAC, C5b–9)**. Its central outputs are **opsonisation** of microbes, generation of **inflammatory anaphylatoxins**, **cytolysis** of pathogens, and **clearance of immune complexes and apoptotic cells**. Because uncontrolled activation injures host tissue, the system is restrained by a panel of soluble and membrane-bound **regulatory proteins** whose failure produces a distinct group of human diseases.

Activation pathways

Feature	Classical pathway	Lectin (MBL) pathway	Alternative pathway
Principal trigger	Antigen–antibody immune complexes (IgM, IgG1/2/3) binding C1q	Mannose / terminal sugars on microbial surfaces	Spontaneous C3 “tick-over” (C3(H ₂ O)); microbial, fungal, viral, tumour and “altered-self” surfaces — antibody-independent
Recognition / initiating proteins	C1 complex = C1q–C1r–C1s → C4, C2	MBL / ficolins + MASP-1, MASP-2 → C4, C2	C3, factor B, factor D, properdin (P)
C3 convertase	C4b2a	C4b2a	C3bBb (stabilised by properdin)
C5 convertase	C4b2a3b	C4b2a3b	C3bBbC3b

Feature	Classical pathway	Lectin (MBL) pathway	Alternative pathway
Immune link	Links innate + adaptive (specific antibody)	Innate pattern recognition	Innate amplification loop

- ▶ **Terminal (common) pathway:** all three converge on **C3 cleavage** → C3a + C3b, then C5 → C5a + C5b; C5b sequentially recruits C6, C7, C8 and **multiple C9** molecules to form the **MAC (poly-C9 pore)** that inserts into and lyses target membranes.
- ▶ An **amplification loop** (factor D, factor B, properdin generating C3bBb) means a small initial stimulus from *any* pathway is greatly magnified through the alternative pathway.

Biological functions

- ▶ **Opsonisation / phagocytosis:** surface-bound **C3b and iC3b** (and C4b) coat microbes and are recognised by complement receptors (CR1/CD35, CR3) on neutrophils and macrophages — the dominant antibacterial role; deficiency predisposes to **encapsulated pyogenic organisms** (*S. pneumoniae*, *H. influenzae*).
- ▶ **Inflammation (anaphylatoxins):** small cleavage fragments **C3a and C5a** trigger mast-cell/basophil mediator release, increase vascular permeability and smooth-muscle contraction; C5a is a powerful **neutrophil chemoattractant** and activator.
- ▶ **Cytolysis:** the MAC (C5b–9) lyses bacteria and cells; it is the **only effective defence against Neisseria**** (thick wall lysed only by MAC).
- ▶ **Immune-complex handling:** early components (C1q, C4, C3) **solubilise and clear circulating immune complexes**; C3b-coated complexes bind erythrocyte CR1 and are transported to liver/spleen — failure causes deposition and **vasculitis / glomerulonephritis**.
- ▶ **Clearance of apoptotic cells** and cellular debris (C1q, C3) — important in preventing autoimmunity.
- ▶ **Bridge to adaptive immunity:** C3d bound to antigen engages CR2 (CD21) on B cells, lowering the threshold for B-cell activation and antibody production.

Regulation of complement

Regulation is essential because activated C3b and the convertases would otherwise deposit indiscriminately on host cells. Control acts at three checkpoints — **initiation, the C3/C5 convertases, and MAC assembly** — by both **fluid-phase** and **membrane-bound** inhibitors. **Properdin** is the only *positive* regulator.

Regulator	Location / type	Action
C1 inhibitor (C1-INH; SERPING1)	Plasma serpin	Inactivates C1r/C1s and MASP-2; also inhibits kallikrein and factor XIIa (limits bradykinin)

Regulator	Location / type	Action
C4b-binding protein (C4BP)	Plasma	Decays the classical C3 convertase; cofactor for factor I cleavage of C4b
Factor H	Plasma	Decays the alternative C3 convertase; cofactor for factor I cleavage of C3b; discriminates host vs microbial surfaces
Factor I	Plasma serine protease	Cleaves/inactivates C3b and C4b (requires cofactors H, C4BP or MCP)
Decay-accelerating factor (CD55, DAF)	Membrane, GPI-anchored	Accelerates decay of C3 and C5 convertases
Membrane cofactor protein (MCP, CD46)	Membrane	Cofactor for factor I cleavage of surface-bound C3b/C4b
CD59 (protectin / MIRL)	Membrane, GPI-anchored	Blocks incorporation of C9 into C5b-8 → prevents MAC formation
Properdin (factor P)	Plasma — <i>stabiliser</i>	Stabilises the alternative-pathway C3 convertase (C3bBb)

- Two regulators — **CD55 and CD59** — are attached to the membrane through a **glycosylphosphatidylinositol (GPI) anchor**; their loss (PNH) removes host protection from autologous complement.

Diseases of complement deficiency and dysregulation

Defect	Disorder	Mechanism
Classical components C1q, C1r/s, C4, C2	SLE / lupus-like syndromes, immune-complex disease, pyogenic infection	Defective clearance of immune complexes & apoptotic cells (C1q deficiency = strongest genetic link to SLE)
C3, factor I, factor H	Pyogenic infections; factor H → haemolytic-uraemic syndrome	Loss of opsonisation; factor I/H deficiency causes secondary C3 consumption
Alternative pathway factor D, properdin	Recurrent **Neisseria (meningococcal)** infection	Failure of alternative-pathway amplification
Terminal C5, C6, C7, C8 (±C9)	Recurrent *Neisseria* infection	Cannot assemble MAC to lyse <i>Neisseria</i>
C1-INH deficiency (<i>SERPING1</i>)	Hereditary angioedema (HAE)	Unopposed C1/kallikrein activation → excess bradykinin ; ↓C4, ↓C2

Defect	Disorder	Mechanism
PIGA mutation → loss of CD55 + CD59	Paroxysmal nocturnal haemoglobinuria (PNH)	Complement-mediated intravascular haemolysis + thrombosis
Alternative-pathway dysregulation — CFH, CFI, CD46, C3, CFB, THBD	Atypical HUS (aHUS)	Endothelial complement injury → thrombotic microangiopathy + AKI
C3 nephritic factor / CFHR mutations	C3 glomerulopathy (dense-deposit disease, C3GN)	Persistent alternative-pathway activation; glomerular C3 deposition with low C3

- **Hereditary angioedema:** autosomal dominant, fully penetrant; **Type 1** (~85%) low C1-INH antigen, **Type 2** dysfunctional protein, **Type 3** normal complement (often factor XII mutation). Features — non-pruritic, non-urticarial angioedema, recurrent **GI colic**, **laryngeal oedema**; **chronically low C4** is the best screening clue. Treatment: acute — C1-INH concentrate, **icatibant** (B2-receptor antagonist), **ecallantide** (kallikrein inhibitor); prophylaxis — C1-INH, **lanadelumab**, **berotralstat**, attenuated androgens (danazol).
- **PNH:** somatic PIGA mutation in a haematopoietic clone → GPI-anchor deficiency → red cells lacking CD55/CD59 are exquisitely sensitive to complement; intravascular haemolysis, haemoglobinuria, **thrombosis**, and marrow failure (links with aplastic anaemia). Diagnosis — **flow cytometry** showing CD55/CD59-negative cells (Ham acidified-serum test historically).

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- **Diagram 1 — The three activation pathways converging on the terminal pathway.** Three vertical limbs: (left) **Classical** — labels *Immune complex* → *C1q-C1r-C1s* → *C4, C2* → *C4b2a* (*C3 convertase*); (middle) **Lectin** — labels *Mannose on microbe* → *MBL/ficolin* + *MASP-1/MASP-2* → *C4, C2*; (right) **Alternative** — labels *C3(H₂O) / microbial surface* → *factor B + factor D + properdin* → *C3bBb* (*C3 convertase*). All converge at a central box *C3* → *C3a* + *C3b*, then *C5* → *C5a* + *C5b*, then *C5b-6-7-8-9* (*MAC / poly-C9*) → **membrane lysis**. Side arrows label *C3a*, *C5a* = **anaphylatoxins** and *C3b* = **opsonin**.
- **Diagram 2 — Regulators superimposed on the cascade.** Mark inhibitory points: **C1-INH** on *C1r/C1s* & *MASP*; **C4BP + factor I** on *C4b*; **factor H + factor I** and **CD55 (DAF)** on the *C3 convertase*; **MCP/CD46** as *factor-I* cofactor; **CD59 (protectin)** blocking *C9/MAC*. Show **properdin** as a green “+” stabilising *C3bBb*.

Clinical / Diagnostic significance

- **Functional screening:** **CH50** assesses the *classical* + terminal pathway; **AP50 (AH50)** assesses the *alternative* + terminal pathway. A **low CH50 with normal AP50** localises the defect to early

classical components, and vice-versa; a profoundly low value prompts measurement of individual components.

- ▶ **C3 and C4 levels** are key serological clues: **low C3 + low C4** indicates **classical-pathway consumption** (active SLE, immune-complex disease); **low C3 with normal C4** indicates **alternative-pathway activation** (post-streptococcal GN, C3 glomerulopathy, aHUS).
- ▶ **Disease-specific tests**: **flow cytometry** for CD55/CD59-deficient clones (PNH); **C1-INH antigen + functional assay with C4 (HAE)**; **anti-factor H antibodies / complement gene panel** (aHUS); **C3 nephritic factor** (dense-deposit disease).
- ▶ **Therapeutics**: terminal-complement blockade with the **anti-C5 monoclonal antibody eculizumab** (and longer-acting **ravulizumab**) is transformative in PNH, aHUS, and C3 glomerulopathy. Because anti-C5 therapy abolishes MAC, patients are at high risk of *Neisseria* and **must receive meningococcal vaccination** ($\pm$ penicillin prophylaxis) before treatment.
- ▶ **Infection prophylaxis**: patients with classical-, alternative- or terminal-pathway deficiency need appropriate vaccination (**meningococcal, pneumococcal, Hib**) and often **oral penicillin** prophylaxis.

High-yield exam pointers

- ▶ Three activation pathways (classical, lectin, alternative) $\rightarrow$ **all cleave C3** $\rightarrow$ common terminal MAC (C5b-9).
- ▶ **C3 convertases**: classical/lectin = **C4b2a**; alternative = **C3bBb**. **C5 convertases**: **C4b2a3b** and **C3bBbC3b**.
- ▶ **C3a + C5a = anaphylatoxins** (C5a chemotactic); **C3b = opsonin**; **MAC = lysis**, the sole defence against *Neisseria*.
- ▶ **Early classical deficiency (C1q/C4/C2)** $\rightarrow$ **SLE & immune-complex disease**; **terminal/alternative deficiency $\rightarrow$ recurrent Neisseria****.
- ▶ **Regulators**: C1-INH (HAE), factor H/I & MCP (aHUS), CD55/CD59 GPI-anchored (PNH), C4BP, properdin (only positive regulator).
- ▶ **HAE = C1-INH deficiency**, bradykinin-mediated, **persistently low C4**, no urticaria/pruritus, treat with C1-INH/icatibant/ecallantide.
- ▶ **PNH = PIGA mutation**, loss of CD55/CD59, intravascular haemolysis + thrombosis, diagnosed by **flow cytometry**.
- ▶ **Eculizumab (anti-C5)** for PNH/aHUS/C3G — give **meningococcal vaccine first**.
- ▶ **CH50 (classical)** and **AP50 (alternative)** are the functional screening tests; combine with C3/C4 levels.

SOURCE & COVERAGE

- ▶ **Harrison's Principles of Internal Medicine, 22e** — “Introduction to the Immune System” (complement pathways, anaphylatoxins, opsonisation, MAC, Table 360-12 Complement Deficiencies and Associated Diseases); “Primary Immune Deficiency Diseases” (complement deficiency, CH50/AP50, *Neisseria* and SLE associations); “Hemolytic Anemias” (PNH — PIGA/GPI/CD55/CD59, aHUS — CFH/CFI/CD46/C3/CFB/THBD, eculizumab); “Urticaria, Angioedema, and Allergic Rhinitis” (hereditary angioedema, C1-INH/SERPING1, bradykinin, icatibant/ecallantide/lanadelumab/berotralstat); “Glomerular Diseases” (C3 glomerulopathy, dense-deposit disease, C3 nephritic factor, CFHR mutations).
- ▶ **Coverage note:** Harrison provides full pathway, function, deficiency and disease detail and uses the CD55/CD59/CD46 nomenclature; the synonymous regulator labels DAF, protectin/MIRL, MCP and C4b-binding protein, and the convertase composition diagram, are standard, universally accepted immunology added for completeness and are consistent with the cascade as depicted in Harrison's Fig. 360-5 and Fig. 105-10. No dedicated subspecialty immunology text was listed in the spec; grounding is Harrison-based and internally cross-verified.

Cytochrome P450 enzyme system and drug metabolism

Asked in: Paper I Jul 2021 — RGUHS MD General Medicine

Definition / Introduction — *Drug metabolism* (biotransformation) is the enzymatic conversion of a drug into more polar, more readily excretable products, occurring predominantly in the liver but also in kidney, intestinal epithelium, lung and plasma. The **cytochrome P450 (CYP)** superfamily is a group of heme-containing **mono-oxygenase** enzymes (named for the 450-nm absorbance peak of their reduced carbon-monoxide complex) that catalyse most **Phase I** oxidative reactions and so determine the clearance, bioavailability and interaction profile of a large fraction of drugs in clinical use. Variability in CYP function — from genetic polymorphism, enzyme induction/inhibition or disease — is a principal source of the wide inter-individual variability seen in drug response and adverse drug reactions (ADRs).

Phases of drug metabolism (biotransformation)

- ▶ **Phase I (functionalisation):** chemical modification — *most often oxidation* — that introduces or unmasks a reactive group (–OH, –NH₂, –SH). This is accomplished chiefly by members of the **cytochrome P450 mono-oxygenase superfamily**; reactions also include reduction and hydrolysis. The product may be active, inactive or toxic.
- ▶ **Phase II (conjugation):** covalent attachment of an endogenous moiety to the drug or its Phase I metabolite, generating a highly polar, usually inactive conjugate. Enzymes include **glucuronyl-**

acetyl-, sulfo- and methyl-transferases (e.g., UGT1A1, N-acetyltransferase, thiopurine S-methyltransferase).

- ▶ **Net effect:** metabolites are *more polar and more readily excreted* than the parent drug (renally or in bile). Drug efflux/uptake **transporters** (e.g., the P-glycoprotein efflux pump, product of the *ABCB1/MDR1* gene, on the apical enterocyte and canalicular hepatocyte membranes) act in concert with metabolism to limit drug delivery to the systemic circulation.
- ▶ **First-pass (presystemic) elimination:** an orally administered drug must traverse the enterocyte, portal vein and hepatocyte before reaching the systemic circulation; CYP-mediated metabolism (especially intestinal/hepatic CYP3A) plus efflux at these sites reduces **bioavailability**.

The cytochrome P450 superfamily — organisation

- ▶ **Nomenclature:** root “CYP”, then a **family** number (e.g., 3), a **subfamily** letter (e.g., A) and an **individual gene** number (e.g., 4) → *CYP3A4*; families/subfamilies are grouped by amino-acid sequence homology.
- ▶ The families most important for human drug metabolism are **CYP1, CYP2 and CYP3**.
- ▶ **CYP3A (CYP3A4, CYP3A5)** metabolises the **greatest number of drugs in therapeutic use**; CYP3A4 activity varies up to an order of magnitude between individuals, largely from variation in *regulatory* regions rather than coding mutations.
- ▶ **CYP2D6** is *second to CYP3A4* in the number of commonly used drugs it handles, and is highly polymorphic.
- ▶ CYPs may **bioactivate** procarcinogens and generate **reactive electrophilic metabolites** that covalently bind tissue macromolecules (protein/DNA) close to the site of production (typically the liver), mediating certain ADRs.

Major drug-metabolising CYP isoforms — representative substrates and inhibitors

Isoform	Representative substrates	Representative inhibitors
CYP3A	Calcium-channel blockers; antiarrhythmics (lidocaine, quinidine, mexiletine); HMG-CoA reductase inhibitors (statins); erythromycin, clarithromycin; cyclosporine, tacrolimus; HIV protease inhibitors (indinavir, saquinavir, ritonavir)	Amiodarone; ketoconazole, itraconazole; ritonavir; gemfibrozil/fibrates
CYP2D6	β -blockers (timolol, metoprolol, carvedilol); propafenone, flecainide; tricyclic	Quinidine (even ultra-low doses); fluoxetine, paroxetine

Isoform	Representative substrates	Representative inhibitors
	antidepressants; bupropion; codeine, tamoxifen (prodrugs)	
CYP2C9	Warfarin; phenytoin; glipizide; losartan (prodrug)	Amiodarone; fluconazole; phenytoin
CYP2C19	Omeprazole; mephenytoin; clopidogrel (prodrug)	Omeprazole; ritonavir; fluoxetine, fluvoxamine
CYP2B6	Efavirenz	Ticlopidine

- ▶ **Non-CYP pathways also tested in exams:** thiopurine S-methyltransferase (6-mercaptopurine, azathioprine); N-acetyltransferase/NAT2 (isoniazid, procainamide, hydralazine, some sulfonamides); UGT1A1 (irinotecan); pseudocholinesterase (succinylcholine); xanthine oxidase (azathioprine/6-MP — inhibited by allopurinol). Transporters: P-glycoprotein (digoxin, HIV protease inhibitors) and SLCO1B1/OATP1B1 (simvastatin and some statins).

Enzyme induction and inhibition — basis of drug–drug interactions

- ▶ **Induction** (increased synthesis/activity → *reduced* drug levels and effect, or increased toxic-metabolite formation): classic inducers are **rifampin**, **carbamazepine**, **phenytoin**, **St John's wort** and **glutethimide**, plus *smoking*, *chlorinated insecticides* and *chronic alcohol ingestion*. Induction lowers concentrations of warfarin, quinidine, cyclosporine, losartan, **oral contraceptives** (→ contraceptive failure), methadone and dabigatran.
- ▶ **Inhibition** (→ *increased* drug levels and dose-related toxicity): **cimetidine** inhibits many CYPs (raises warfarin, theophylline, phenytoin); **amiodarone** inhibits multiple CYPs and P-glycoprotein (raises warfarin, digoxin, dabigatran); CYP3A inhibitors precipitate statin and colchicine toxicity; CYP2D6 inhibitors potentiate β -blockade.
- ▶ **Clinical sentinels:** prescribers must be especially alert when *starting or stopping* **CYP2D6**, **CYP3A** or **P-glycoprotein inhibitors** and **CYP3A/P-glycoprotein inducers**, e.g., a stable warfarin patient who bleeds after **amiodarone** is added (warfarin metabolism inhibited), not a direct amiodarone reaction.
- ▶ **Reactive-metabolite toxicity (acetaminophen/paracetamol):** CYP-generated reactive metabolite is normally detoxified by hepatic **glutathione**; once glutathione is depleted it binds hepatic protein → hepatocyte necrosis. Risk is *increased* by enzyme inducers (phenobarbital, phenytoin) and by ethanol (which exhausts glutathione stores). Antidote: **N-acetylcysteine** (IV 140 mg/kg loading, then 70 mg/kg every 4 h), which replenishes sulfhydryl/glutathione.

Pharmacogenomics of CYP — metaboliser phenotypes

- ▶ Polymorphism produces a **multimodal population distribution** of enzyme activity (classically demonstrated for CYP2D6):

- **Poor metabolisers (PM):** two loss-of-function alleles → slow clearance, higher steady-state levels, longer time to steady state.
 - **Intermediate metabolisers (IM):** one functional / reduced-function allele.
 - **Extensive (normal) metabolisers (EM):** one or two functional alleles.
 - **Ultra-rapid metabolisers (UM):** gene duplication (2–12 active copies) → very low parent-drug levels.
- ▶ **CYP2D6:** PM phenotype in 5–10% of European- and African-derived populations (few Asians); UMs frequent in East Africa, the Middle East and Oceania. **Codeine** is bioactivated to **morphine** by CYP2D6 — analgesia is *blunted in PMs* and *dangerous (respiratory depression) in UMs*; deaths in children after tonsillectomy led the FDA to a black-box warning and to **forbid codeine in children <12 years**. PMs show exaggerated β -blockade (metoprolol, carvedilol, timolol, propafenone).
 - ▶ **CYP2C19:** PM common (~20%) in Asians, ~2–3% in others, >50% in Oceania. Reduced bioactivation of **clopidogrel** → less antiplatelet effect and more stent thrombosis/ischaemic events; omeprazole both is a substrate and phenocopies the defect by inhibition.
 - ▶ **CYP2C9 + VKORC1:** together account for up to 50% of variability in stable **warfarin** dose; CYP2C9 variants also cause phenytoin neurotoxicity and glipizide hypoglycaemia, and impair bioactivation of the prodrug **losartan**.
 - ▶ **CYP3A5:** a splicing polymorphism (common in Europeans/Asians) reduces activity; African-origin “expressers” clear **tacrolimus** faster (reduced efficacy at standard dose).
 - ▶ **Implementation:** the **Clinical Pharmacogenetics Implementation Consortium (CPIC)** and the Dutch Pharmacogenetics Working Group publish drug–gene dosing guidance; “point-of-care” vs “pre-emptive” genotyping models are in use.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Diagram 1 — Two-phase hepatocyte metabolism schema:** *Lipophilic drug* → arrow into a box labelled “Phase I: CYP450 oxidation (–OH/–NH₂/–SH added)” → *intermediate metabolite* → arrow into a box labelled “Phase II: conjugation (glucuronyl-/sulfo-/acetyl-/methyl-transferase)” → *polar conjugate* → arrows to “Bile” and “Urine.” Side label: “P-glycoprotein (ABCB1) efflux.” Annotate the CYP box with “Inducers: rifampin, carbamazepine, phenytoin, St John’s wort” and “Inhibitors: amiodarone, ketoconazole, cimetidine, fluoxetine.”
- ▶ **Diagram 2 — Population distribution of CYP2D6 activity:** x-axis “enzyme activity (low → high)”, y-axis “population frequency”, with labelled peaks “Poor metaboliser (2 LOF alleles),” “Extensive/normal metaboliser,” “Ultra-rapid metaboliser (gene duplication)” and a vertical “antimode” line separating PMs.

Clinical / Diagnostic significance

- ▶ **Prodrugs requiring CYP bioactivation:** codeine (→morphine, CYP2D6), clopidogrel (CYP2C19), losartan (CYP2C9), tamoxifen (CYP2D6), many ACE inhibitors, irinotecan — failure of activation = therapeutic failure.
- ▶ **“High-risk pharmacokinetics”:** when an active drug depends on a *single* CYP pathway, any inhibitor (drug, gene or disease) causes large swings in concentration — dangerous for narrow-therapeutic-index drugs (warfarin, phenytoin, ciclosporin, theophylline, digoxin).
- ▶ **Therapeutic drug monitoring & genotyping:** anticonvulsants, antiarrhythmics, immunosuppressants and some antibiotics benefit from level monitoring; targeted CYP2C19/CYP2D6/CYP2C9 genotyping guides clopidogrel, codeine and warfarin use.
- ▶ **Disease modifiers:** in cirrhosis, oral bioavailability of high first-pass drugs (morphine, meperidine, midazolam, nifedipine) is nearly *doubled* — reduce oral doses. In the **porphyrias**, CYP inducers can precipitate acute attacks.
- ▶ **Special groups:** neonates have immature CYP pathways; the elderly on polypharmacy are prone to CYP-mediated interactions and ADRs.

High-yield exam pointers

- ▶ CYP = heme-thiolate **mono-oxygenase**; named for **450-nm** CO-complex absorbance; chiefly hepatic endoplasmic reticulum.
- ▶ **CYP3A4** metabolises the most drugs; **CYP2D6** is second and highly polymorphic.
- ▶ **Inducers** (Rifampin, Carbamazepine, Phenytoin, St John’s wort, chronic alcohol, smoking) ↓ drug levels → e.g., **OCP failure, warfarin resistance**.
- ▶ **Inhibitors** (amiodarone, azole antifungals, macrolides, cimetidine, grapefruit-type CYP3A inhibition, fluoxetine/paroxetine) ↑ drug levels → toxicity (statin myopathy, colchicine, warfarin bleeding).
- ▶ Metaboliser phenotypes: **PM / IM / EM / UM**; **UM + codeine = fatal respiratory depression** (FDA bans codeine <12 y after tonsillectomy).
- ▶ **Clopidogrel = CYP2C19** (loss-of-function → stent thrombosis); **warfarin = CYP2C9 + VKORC1** (≈50% of dose variance).
- ▶ **Paracetamol** reactive metabolite detoxified by **glutathione**; antidote **N-acetylcysteine**; alcohol/inducers raise risk.
- ▶ Phase II = **conjugation** (glucuronidation by UGT1A1 → Gilbert’s/irinotecan; acetylation by NAT2 → slow acetylators → INH hepatitis, drug-induced lupus).

SOURCE & COVERAGE

- ▶ **Harrison’s Principles of Internal Medicine, 22e** — “Principles of Clinical Pharmacology” (drug metabolism, Phase I/II, CYP substrate–inhibitor–inducer tables, first-pass effect,

high-risk pharmacokinetics, drug interactions, reactive-metabolite/acetaminophen toxicity) and “Pharmacogenomics” (CYP3A/2D6/2C19/2C9 polymorphisms, PM/IM/EM/UM phenotypes, codeine/clopidogrel/warfarin/tacrolimus pharmacogenetics, CPIC).

- ▶ **Harrison’s 22e** — “Toxic and Drug-Induced Hepatitis” (acetaminophen reactive-metabolite mechanism, glutathione, N-acetylcysteine dosing; CYP-inducer enhancement of toxicity).
- ▶ **Coverage note:** This is a pharmacology topic with no dedicated subspecialty textbook in the spec (specialty_books empty; CMDT not flagged); the answer is grounded entirely in the two Harrison clinical-pharmacology chapters plus the drug-induced hepatitis chapter. CYP nomenclature convention (family/subfamily/gene) and the 450-nm naming are stated as universally accepted standard pharmacology, as exact homology thresholds are not specified in the corpus.

Cytokines physiology and clinical implications

Asked in: Paper I May 2022 — RGUHS MD General Medicine

Definition / Introduction — Cytokines are soluble, low-molecular-weight proteins produced by a wide variety of cell types that act through specific cell-surface receptors to regulate the **growth, development, and activation** of immune cells and to mediate the **inflammatory response**. They are pivotal to both **innate and adaptive immunity**, and their expression is perturbed in most immune, inflammatory, and infectious disease states. Functionally overlapping molecules that primarily attract and direct leukocyte movement are called **chemokines**. The cytokine system is the molecular target of an expanding class of “biologic” therapies, making its physiology directly relevant to internal-medicine practice.

General properties (physiology)

- ▶ **Mode of action** — cytokines act (1) in an **autocrine** manner when the target cell is the same cell that secreted it, (2) in a **paracrine** manner when the target is a nearby cell, and (3) in an **endocrine** manner when secreted into the circulation to act on distant tissue.
- ▶ **Pleiotropy** — a single cytokine acts on many different cell types, because receptors for it are expressed on multiple lineages.
- ▶ **Redundancy** — different cytokines exert similar (overlapping) biologic functions.
- ▶ **Synergy / antagonism and networks** — one cytokine commonly induces another, producing interlinked “**cytokine networks**”; effects may be additive (synergy) or opposing (antagonism).

- ▶ **Nomenclature** — cytokines thought primarily to target leukocytes were named **interleukins** (IL-1, IL-2, IL-3 ...); those described by an original function retained that name (e.g., **granulocyte colony-stimulating factor** [G-CSF], interferons, tumour necrosis factor).
- ▶ **Mechanism** — they alter **gene activation**, producing cellular activation, growth, differentiation, surface-molecule expression, and effector function. The **TH1/TH2/TH17** classification of helper T cells is itself defined by the *pattern of cytokines* the cell secretes (TH1 → cell-mediated immunity; TH2 → humoral immunity; TH17 → mucosal defence against extracellular bacteria/fungi).

Structural classification of cytokines and their receptors

- ▶ Cytokines fall into **three major structural families**: the **hematopoietin family**; the **TNF / IL-1 / PDGF / TGF- β family**; and the **CXC and C-C chemokine families** (chemokines have a distinctive 3-D structure and act via G-protein-coupled receptors).
- ▶ Cytokine receptors are grouped into **five families** by their conserved extracellular domains:

Receptor family	Representative members	Note
Immunoglobulin (Ig) superfamily	IL-1 receptors (type I, type II)	Extracellular Ig domains
Hematopoietic growth-factor (type I) receptor family	Receptors sharing the common γ chain (γ_c) — IL-2, IL-4, IL-7, IL-9, IL-15, IL-21; gp130-using receptors (IL-6, IL-11)	γ_c mutation causes X-linked SCID (X-SCID)
Interferon (type II) receptor family	Receptors for IFN- γ and IFN- β	Conserved cysteine-paired ~210-aa binding domain
TNF (type III) receptor family	TNF-R1 (p55), TNF-R2 (p75), CD40, Fas/Apo-1, CD27, CD30, NGF receptor	Cysteine-rich repeats; Fas triggers apoptosis
Seven-transmembrane (G-protein-coupled) family	Chemokine receptors (e.g., CXCR4, CCR5)	CXCR4 & CCR5 are the major HIV-1 co-receptors

Major cytokines and their physiological actions

Cytokine	Principal source	Key biologic action
IL-1 α/β	Monocytes-macrophages, endothelium	Upregulates adhesion molecules, fever, shock , hepatic acute-phase protein production, hematopoiesis
IL-2	T cells	T-cell activation & proliferation, B-cell growth, NK proliferation/activation

Cytokine	Principal source	Key biologic action
IL-4	T cells, mast cells, basophils	Drives TH2 differentiation; B-cell Ig class-switch to IgG1 and IgE; anti-inflammatory
IL-5	T cells, mast cells, eosinophils	Regulates eosinophil migration and activation
IL-6	Monocytes-macrophages, fibroblasts	Acute-phase protein induction, T/B differentiation, myeloma & osteoclast growth
IL-8 (CXCL8)	Monocytes, neutrophils, endothelium	Neutrophil chemotaxis and adhesion (via CXCR1/CXCR2)
IL-10	Monocytes-macrophages, T cells	Anti-inflammatory — inhibits macrophage proinflammatory cytokine production, downregulates MHC class II
IL-12	Activated macrophages, dendritic cells	Induces TH1 formation; ↑IFN-γ, ↓IL-17; ↑CD8 CTL activity
IL-17	CD4 ⁺ (TH17) T cells	Enhances cytokine/chemokine secretion; promotes delayed-type reactions
IL-23	Macrophages	Opposite of IL-12 — ↑IL-17, ↑IFN-γ; sustains TH17
IFN-α / IFN-β	All cells (type I IFN)	Antiviral; activate T cells/macrophages/NK; upregulate MHC class I; antitumour
IFN-γ	T cells, NK cells (type II)	Activates macrophages & NK; induces MHC class II; drives TH1
TNF-α	Monocytes-macrophages, mast cells	Fever, anorexia, shock, capillary-leak syndrome, proinflammatory cytokine induction
G-CSF / GM-CSF	Macrophages, fibroblasts, T cells	Regulate myelopoiesis; reverse chemotherapy-induced neutropenia; GM-CSF aids DC maturation
TGF-β	Most cell types	Immunosuppressive — downregulates T-cell/macrophage/granulocyte responses; stimulates matrix synthesis & angiogenesis

Cytokine signalling — the JAK-STAT pathway

- ▶ Hematopoietin-receptor signalling uses the Janus kinase (JAK) family — JAK1, JAK2, JAK3, and Tyk2, which preferentially associate with different receptor subunits.
- ▶ Cytokine binding **juxtaposes receptor subunits**, allowing paired JAKs to **transphosphorylate** and activate one another; JAKs then phosphorylate receptor tyrosines.
- ▶ STAT (signal transducer and activator of transcription) factors dock via **SH2 domains**, are phosphorylated by JAKs, dissociate, **translocate to the nucleus**, and bind specific DNA motifs to regulate gene transcription.
- ▶ **Clinical correlate** — JAK3 mutation produces an X-SCID-like phenotype (but affects both sexes, as JAK3 is on chromosome 19). **JAK inhibitors** (small molecules) are approved for rheumatoid arthritis, psoriatic arthritis, ulcerative colitis, atopic dermatitis, and alopecia areata.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Diagram 1 — Modes of cytokine action.** Draw three cells with arrows: *Autocrine* (cytokine loops back to its own secreting cell), *Paracrine* (acts on an adjacent cell), *Endocrine* (enters a blood vessel to act on a distant cell). Labels: **Secreting cell, Cytokine, Receptor, Autocrine, Paracrine, Endocrine, Bloodstream, Distant target cell.**
- ▶ **Diagram 2 — JAK-STAT signalling.** Draw a transmembrane cytokine receptor dimer. Labels: **Cytokine (ligand), Receptor subunits, JAK1/JAK2/JAK3/Tyk2, Transphosphorylation, Tyrosine-P residues, STAT with SH2 domain, STAT phosphorylation, STAT dimer, Nucleus, DNA/gene transcription.**

Clinical / Diagnostic significance

- ▶ Anti-cytokine biologic therapy is a mainstay for autoimmune/inflammatory disease:

Target	Agent(s)	Main indication(s)
TNF- α	Adalimumab, infliximab, golimumab, certolizumab pegol (mAbs); etanercept (soluble Fc:TNF-receptor trap)	RA, psoriasis/psoriatic arthritis, ankylosing spondylitis, Crohn's disease, ulcerative colitis
IL-1	Anakinra (IL-1 receptor antagonist), canakinumab, rilonacept (IL-1 trap)	Cryopyrin-associated/auto-inflammatory syndromes, gouty arthritis, juvenile arthritis
IL-6 / IL-6R	Tocilizumab (anti-IL-6R); siltuximab (anti-IL-6)	RA, juvenile idiopathic arthritis; Castleman's disease
IL-12 / IL-23	Anti-IL-12/IL-23 (p40) mAb (e.g., ustekinumab)	Psoriasis, inflammatory bowel disease (block TH17 differentiation)

Target	Agent(s)	Main indication(s)
IL-17	Anti-IL-17 mAb (e.g., <i>secukinumab</i>)	Psoriasis, psoriatic arthritis
IL-4R α	Dupilumab	Atopic dermatitis, steroid-dependent asthma
IgE	Omalizumab	Allergic asthma
BAFF	Belimumab	Systemic lupus erythematosus
VEGF	Bevacizumab, ramucirumab, ranibizumab, aflibercept	Tumour angiogenesis; macular degeneration/diabetic macular edema

- ▶ **Therapeutic cytokines (replacement/augmentation):** IFN- α/β in viral and autoimmune disease; IFN- γ corrects the phagocyte defect of **chronic granulomatous disease**; G-CSF/GM-CSF reverse chemotherapy-induced neutropenia; IFN- β and IL-11 lower IL-1/TNF- α and are used as inhibitory agents in inflammation.
- ▶ **Cytokine excess (cytokine release syndrome, CRS):** uncontrolled cytokine release with systemic inflammation is the dose-limiting toxicity of CAR T-cell therapy; IL-6/IL-6R blockade (tocilizumab) is a key antidote — illustrating the “cytokine storm” concept.
- ▶ **Autoantibodies to cytokines** cause distinctive disease: anti-IFN- γ $\rightarrow$ disseminated mycobacterial/bacterial infection and VZV reactivation; anti-GM-CSF $\rightarrow$ **pulmonary alveolar proteinosis** and fungal infection; anti-IL-17A/IL-17F $\rightarrow$ **chronic mucocutaneous candidiasis**; anti-IL-6 $\rightarrow$ severe bacterial infections; anti-IL-1/TNF autoantibodies seen in RA, systemic sclerosis, SLE.
- ▶ **Diagnostic use:** acute-phase reactants (CRP, driven by IL-6) and the febrile/inflammatory response are downstream cytokine readouts; chemokine receptors CXCR4/CCR5 are exploited for HIV tropism testing and CCR5-antagonist therapy.

High-yield exam pointers

- ▶ Three cytokine actions: **autocrine, paracrine, endocrine**; two cardinal properties: **pleiotropy** and **redundancy**, forming cytokine networks.
- ▶ **Five cytokine-receptor families:** Ig superfamily, hematopoietic (type I), interferon (type II), TNF (type III), and 7-transmembrane (GPCR/chemokine).
- ▶ **Common γ -chain cytokines** = IL-2, -4, -7, -9, -15, -21; γ c or JAK3 mutation = SCID.
- ▶ **Pro-inflammatory triad:** IL-1, IL-6, TNF- α (fever, shock, acute-phase response). **Anti-inflammatory:** IL-10, TGF- β .
- ▶ **TH1** = IFN- γ /IL-2 (cell-mediated); **TH2** = IL-4/IL-5/IL-13 (humoral, IgE/eosinophils); **TH17** = IL-17/IL-23 axis (mucosal, psoriasis/IBD).

- ▶ IFN type I (α , β) $\rightarrow$ MHC class I & antiviral; IFN- γ (type II) $\rightarrow$ MHC class II & macrophage activation.
- ▶ Signalling = JAK-STAT; targeted by oral JAK inhibitors (RA, UC, atopic dermatitis, alopecia areata).
- ▶ Know the biologic targets: TNF (etanercept/infliximab), IL-1 (anakinra), IL-6R (tocilizumab), IL-17/IL-23 (psoriasis), IL-4R α (dupilumab), IgE (omalizumab), BAFF (belimumab).
- ▶ IFN- γ is therapeutic in **chronic granulomatous disease**; CRS is the cytokine-storm toxicity of CAR T-cell therapy.

SOURCE & COVERAGE

Harrison 22e — Ch 360 “Introduction to the Immune System” (cytokine biology, Table 360-7 Cytokines and Cytokine Receptors, Table 360-8 chemokine families, receptor families and JAK-STAT signalling) and Ch 361 “Mechanisms of Regulation and Dysregulation of the Immune System” (anti-cytokine biologics — Table 361-5, cytokine autoantibodies, cytokine release syndrome). **Coverage note:** Both chapters fully support the physiology and the biologic-target list. Brand/generic names *ustekinumab* and *secukinumab* are not spelled out in the provided text (which states only “anti-IL-12/IL-23” and “anti-IL-17” antibodies) — they are added as universally accepted standard internal medicine and flagged in italics. The term “cytokine storm” is standard terminology; the source explicitly describes **cytokine release syndrome** with CAR T-cell therapy.

Smoking-Related Health Hazards and Nicotine De-addiction Measures

Asked in: Paper IV May 2019 — RGUHS MD General Medicine

Definition / Introduction — *Nicotine addiction* is a chronic, relapsing disorder in which reversible binding of nicotine to **nicotinic acetylcholine receptors (nAChRs)** in brain reward circuits produces compulsive, repetitive use and a withdrawal syndrome on abstinence. While nicotine itself drives the dependence (and some pregnancy harm), the **vast majority of tobacco-attributable disease results from repeated exposure to the carcinogens and toxicants in combusted tobacco smoke**, not nicotine per se. Approximately **40% of cigarette smokers die prematurely** of smoking-related disease unless they quit, and globally tobacco accounts for ~13.6% of all deaths. Tobacco dependence is a treatable medical condition: structured counselling plus pharmacotherapy can roughly **triple** cessation success.

Mechanism of Nicotine Addiction (basis of de-addiction)

- ▶ Inhaled/absorbed nicotine reaches the brain within seconds and **reversibly attaches to nicotinic ACh receptors** active in networks subserving mood, reward, joy and excitement; chronic high exposure causes **upregulation of nicotinic receptors**.
- ▶ As blood nicotine falls between doses, nicotine detaches from receptors; the addicted user no longer feels “normal”, generating a **compulsive need for the next dose** — the diagnostic hallmark is *loss of control over the next use*.
- ▶ **Withdrawal symptoms** (irritability, craving, anxiety, restlessness) appear within a day of cessation and may persist **4–6 weeks**.
- ▶ Addictiveness is driven by **speed and arterial concentration** of nicotine reaching the brain. Mildly acidic aerosols (cigarettes, nicotine-salt vapes) reduce airway irritation, permitting deep inhalation; lung pH (~7.4) then converts nicotine to the rapidly absorbed **unprotonated (freebase)** form — explaining why cigarettes and nicotine-salt devices are the most addictive forms.
- ▶ **Genetic susceptibility** (genes reducing nicotine clearance or increasing dependence/depression risk) influences whether adolescent experimentation progresses to adult addiction.

Smoking-Related Health Hazards (system-wise)

- ▶ **Cardiovascular** — promotes both large-vessel atherosclerosis and small-vessel disease, and raises MI/sudden cardiac death risk by enhancing **platelet aggregation and vascular occlusion**. Attributable fractions: **~90% of peripheral vascular disease** (non-diabetic), **~50% of aortic aneurysms**, **~24% of coronary artery disease**, **~11% of ischaemic and haemorrhagic strokes**. There is a **multiplicative interaction** with hypertension and dyslipidaemia.
- ▶ **Cancer** — causes cancers of lung; lip, oral cavity, naso-/oro-/hypopharynx; nasal cavity/paranasal sinuses; larynx; oesophagus; stomach; pancreas; liver (HCC); colon and rectum; kidney and renal pelvis; ureter; urinary bladder; uterine cervix; and **acute myeloid leukaemia**. Risk rises **linearly with cigarettes/day** and **logarithmically with duration**. Synergy occurs with **alcohol** (oral cavity, oesophagus) and with **asbestos/radon** (lung).
- ▶ **Respiratory** — responsible for **~80% of COPD**; chronic mucous hyperplasia causes productive cough in up to 80% of smokers >60 yr; **~15–25%** develop clinically significant airflow obstruction (chronic bronchitis/emphysema).
- ▶ **Pregnancy** — premature rupture of membranes, abruptio placentae, placenta praevia, spontaneous abortion; offspring show preterm delivery, **small-for-gestational-age**, higher perinatal mortality, infant respiratory distress, **SIDS** and developmental lag.
- ▶ **Other** — delayed peptic-ulcer healing; periodontal disease; diabetes; active tuberculosis; rheumatoid arthritis; osteoporosis; senile cataract; macular degeneration; premature menopause; skin wrinkling; gallstones/cholecystitis (women); male impotence; and **poorer chemo-/radiotherapy outcomes**.

- ▶ **Environmental tobacco smoke (passive smoking)** — increases lung cancer and CAD in non-smokers; in children causes respiratory infections, chronic otitis media and asthma (incidence and exacerbation).
- ▶ **“Low-tar/low-nicotine” and filtered cigarettes confer no real benefit** — smokers compensate by deeper/more frequent puffing; design changes have driven the rise in **lung adenocarcinoma**.

Relative Risks for Current Smokers (Harrison Table 465-1)

Disease (current vs never smoker)	Male	Female
Lung cancer (age 45–64)	19.0	19.0
COPD (age 35–44)	29.7	38.9
Coronary heart disease (35–44)	3.9	5.0
Cerebrovascular disease (35–44)	2.2	2.3
Larynx cancer	14.6	13.0
Lip/oral cavity/pharynx	10.9	5.1
Oesophagus	6.8	7.8
Bladder	3.3	2.2

Relative risk for most cancers and COPD rises with age; for CVD the relative risk falls with age but the absolute excess death rate keeps rising (cumulative injury).

Benefits of Cessation (motivational pearls)

- ▶ Risk of a **second coronary event falls within 6–12 months**; rates of first MI and CHD death decline within 2–4 years.
- ▶ After **15 years** of abstinence, risk of stroke, MI and CHD death approaches that of a never-smoker.
- ▶ Cancer risk begins to fall after ~4 years, but a residual **3- to 4-fold lung cancer risk persists even 20 years** after quitting.
- ▶ Small-airway changes in young smokers reverse within 1–2 years; in established COPD, cessation mainly **slows the rate of decline** in lung function.

Nicotine De-addiction — Behavioural Framework (“5 A’s”)

- ▶ Cessation is typically **cyclical** — ~70–80% of smokers want to quit and >50% attempt yearly, but only ~6% remain abstinent at 6 months and ~3% at 2 years (CMTD: 5–10% unaided success). Repeated, structured intervention is therefore essential.
- ▶ **Ask** — systematically identify all tobacco/nicotine use at every visit (record cumulative daily episodes across *all* products — cigarettes, cigars, roll-your-own, vapes, oral nicotine).

- ▶ **Advise** — give a clear, strong, personalised message to quit; brief clinician advice at the time of an acute illness triggers a quit attempt in up to half of patients and makes quitting **1.6×** more likely.
- ▶ **Assess** — gauge readiness to change and intensity of addiction (uses/day, use within ~30 min of waking, prior quit history, craving on abstinence).
- ▶ **Assist** — negotiate a **quit date** (usually within a few weeks, not the visit day); offer pharmacotherapy to all who accept plus counselling; address anticipated **weight gain** (~80% gain, average ~2 kg; 10–15% gain >13 kg).
- ▶ **Arrange** — schedule follow-up contact around the quit date; system-wide tracking/outreach can raise 12-month abstinence to ~25%.
- ▶ *Counselling formats*: individual or group sessions (≥4–7 sessions of 20–30 min), telephone **quitlines** and text-messaging are all proven and highly cost-effective.

Pharmacotherapy for Nicotine De-addiction

Offer to all quit attempters **except** those with medical contraindications, pregnant/breastfeeding women and adolescents. Numbers in parentheses are the **multiple of cessation success vs no intervention** (Harrison Table 465-2).

Agent	Mechanism	Regimen	Efficacy (× vs none)
Nicotine patch	Transdermal NRT	7/14/21 mg per 24 h, 1 patch/day	1.9
Nicotine gum	Oral mucosal NRT	2 or 4 mg, 8–24 pieces/day	1.5
Nicotine lozenge	Oral mucosal NRT	2 mg (2.0) / 4 mg (2.8), up to 20/day	2.0–2.8
Nicotine nasal spray	Rapid NRT (Rx)	1–2 sprays, max 10/h	2.3
Nicotine oral inhaler	NRT (Rx)	4–16 cartridges/day	2.1
Bupropion SR	Dopamine–noradrenaline reuptake inhibitor	150 mg OD ×3 days → 150 mg BID; up to 6 months; start 1–2 wk before quit date	2.0
Varenicline	Partial agonist at nicotinic ACh receptor	0.5 mg OD ×3 days → 0.5 mg BID days 4–7 → 1 mg BID ; up to 6 months; start 1–2 wk pre-quit	3.1
Exclusive e-cigarette	Nicotine-salt aerosol (harm reduction)	Caution: avoid dual use	3.0

- ▶ NRT roughly **doubles** quit success; usual course **3–6 months**, higher doses for heavier smokers, with longer maintenance for those who relapse. Combining a **patch (basal) plus gum/lozenge (acute craving)** improves outcomes.
- ▶ **Bupropion** boosts dopamine/noradrenaline (mimicking nicotine), causes minimal weight gain, but is **contraindicated in seizure disorders**; especially useful where depression coexists.
- ▶ **Varenicline** is the single most effective monotherapy (partial agonism reduces craving while blunting reward); start 1–2 weeks before the quit date.
- ▶ **Combination therapy > single agent**. Pre-treatment (NRT, bupropion or varenicline) before the quit date improves results. The best outcomes (nearly **3-fold**) come from **advice + pharmacotherapy + counselling** together.
- ▶ **Harm reduction**: switching completely from combusted cigarettes to exclusive nicotine-salt e-cigarettes is at least as effective as FDA-approved drugs and markedly lowers toxicant biomarkers, but must avoid **dual use** (which negates benefit) — reserved chiefly for those failing or refusing approved therapy; never recommended to never-smokers.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Reward-pathway / addiction cycle**: Inhaled nicotine → arterial blood → brain → **nicotinic ACh receptor** binding on VTA dopaminergic neurons → dopamine release in **nucleus accumbens** (pleasure/reward) → receptor upregulation → falling nicotine → **withdrawal/craving** → next dose. Labels: *nicotine, nAChR, ventral tegmental area, nucleus accumbens, dopamine, reward, withdrawal/craving, compulsive use*.
- ▶ **Body-map of smoking hazards (whole-body schematic)**: label *brain/stroke; oral cavity–larynx–pharynx cancer; lung cancer & COPD; coronary artery disease; aortic aneurysm; peripheral vascular disease; oesophagus/stomach/pancreas/liver/colorectal cancer; kidney & bladder cancer; cervix & AML; pregnancy complications; passive-smoke effects in children*.

Clinical / Diagnostic significance

- ▶ **Diagnosis is clinical** — loss of control over next nicotine use; quantify via uses/day, time-to-first-use after waking, craving on abstinence and prior failed quits.
- ▶ Smoking **induces hepatic CYP450**, lowering levels of drugs such as **warfarin** (anticoagulation may destabilise on admission/discharge), increases first-pass clearance of **lidocaine/theophylline**, and blunts effects of **benzodiazepines and beta-blockers** — review doses when patients are hospitalised and abstinent.
- ▶ Continued smoking during cancer chemotherapy/radiotherapy worsens survival — cessation is part of oncologic care.
- ▶ Counsel about **screening** (low-dose CT lung-cancer screening for eligible heavy smokers) and aggressive control of co-existing CVD risk factors given multiplicative interaction.

High-yield exam pointers

- ▶ ~40% of smokers die prematurely; tobacco ≈ 13.6% of global deaths; ~480,000 US deaths/year.
- ▶ Top three killers: **cancer, cardiovascular disease, COPD** (~80% of COPD).
- ▶ Attributable fractions: **90% PVD, 50% aortic aneurysm, 24% CAD, 11% stroke**.
- ▶ Cancer risk: **linear** with cigarettes/day, **logarithmic** with duration; lung-adenocarcinoma rise linked to filter/design changes.
- ▶ Withdrawal lasts **4–6 weeks**; nicotine-salt/cigarette acidic aerosols → fast **freebase** absorption → high addictiveness.
- ▶ **5 A's**: Ask–Advise–Assess–Assist–Arrange; brief advice makes quitting **1.6×** more likely.
- ▶ **Varenicline** (partial nicotinic agonist) is most effective monotherapy (**3.1×**); **NRT doubles** success; **bupropion** contraindicated in seizures.
- ▶ Cessation benefits: coronary risk falls in **6–12 months**; risk approaches never-smoker by **15 years**; residual 3–4× lung-cancer risk persists.

SOURCE & COVERAGE

- ▶ **Harrison's Principles of Internal Medicine, 22e** — “Nicotine Addiction” (mechanism, relative-risk table, disease manifestations, environmental tobacco smoke, cessation framework, pharmacologic efficacy multipliers and dosing); “Promoting Good Health” (preventive context).
- ▶ **CMDT 2026** — “Disease Prevention & Health Promotion” (smoking-cessation counselling, Table 1–4 inquiries, Table 1–5 medication doses for NRT/bupropion/varenicline, weight gain, e-cigarette/EVALI caution).

Coverage note: The spec lists no dedicated subspecialty textbook (specialty = GENERAL); the answer is fully grounded in Harrison 22e and CMDT 2026. The “5 A's” labelling follows the standard AT/USPHS clinical-practice framework — Harrison's Table 465-2 lists the same actions (Ask, Advise, Identify-those-willing/Assess, Assist, Arrange).

Delayed (Type IV) Hypersensitivity Reactions

Asked in: Paper I Jul 2021 — RGUHS MD General Medicine

Definition / Introduction — *Hypersensitivity* denotes an exaggerated or inappropriate adaptive immune response to an antigen that causes tissue injury. In the **Gell and Coombs classification** (Types I–IV), **Type IV (delayed, cell-mediated) hypersensitivity** is the only type that is *antibody-independent*: it is mediated by **antigen-specific T lymphocytes** (CD4⁺ T-helper and CD8⁺ cytotoxic T cells) and the macrophages/eosinophils/neutrophils they recruit. It is termed “delayed” because the reaction develops **48–72 hours** after antigen exposure in a sensitised host — the time required to recruit and activate

effector T cells — in contrast to the immediate (minutes) reaction of Type I. The classic prototypes are the tuberculin (Mantoux) skin reaction, allergic contact dermatitis, granuloma formation, and severe cutaneous adverse drug reactions (SJS/TEN, DRESS).

Gell and Coombs classification — placing Type IV in context

Type	Eponym / name	Principal mediator	Onset	Representative examples
I	Immediate / anaphylactic	IgE on mast cells & basophils (TH2/ILC2: IL-4, IL-5, IL-13)	Minutes	Anaphylaxis, urticaria, angioedema, allergic asthma/rhinitis
II	Cytotoxic (antibody-mediated)	IgG/IgM + complement; ADCC by NK cells/phagocytes	Variable	Autoimmune haemolytic anaemia, drug-induced cytopenias, Goodpasture, Graves
III	Immune-complex	Antigen–antibody (IgG/IgM) complexes → complement, neutrophils	Hours–days	Serum sickness, Arthus reaction, SLE, post-streptococcal glomerulonephritis, drug-induced vasculitis
IV	Delayed / cell-mediated	T cells (CD4 TH1/TH2/TH17, CD8 CTL) + macrophages/eosinophils/neutrophils	48–72 h	Tuberculin reaction, contact dermatitis, granulomas, SJS/TEN, DRESS, allograft rejection

- Types I–III are antibody (humoral)-mediated and transferable by serum; Type IV is cell-mediated and transferable only by sensitised T cells/lymphocytes, not by serum.

Mechanism — two sequential phases

1. Sensitisation (afferent/induction) phase — occurs on *first* contact, evolving over ~10–14 days, and is clinically silent:

- The antigen is often a **low-molecular-weight hapten** (e.g., nickel, urushiol of poison ivy, a drug or its metabolite) that must **covalently bind a self carrier-protein** to become immunogenic (*hapten–prohapten model*); some drugs bind **non-covalently** to the HLA molecule or T-cell receptor (the **pharmacological interaction “p-i” model**, e.g., abacavir within HLA-B*57:01).

- ▶ **Antigen-presenting cells** — cutaneous **Langerhans/dendritic cells** — process the antigen and migrate to regional lymph nodes, presenting peptide on MHC class II to naïve CD4⁺ T cells and on MHC class I to CD8⁺ T cells.
- ▶ Under IL-12/IFN- γ this drives **clonal expansion and differentiation into effector and memory TH1 (also TH2, TH17) and cytotoxic CD8⁺ T cells**.

2. Effector (elicitation) phase — occurs on *re-exposure*, peaking at 48–72 h:

- ▶ Sensitised CD4⁺ TH1 cells recognise antigen and secrete IFN- γ , TNF- α and IL-2, which **recruit and activate macrophages**, increasing their microbicidal and tissue-damaging capacity.
- ▶ CD8⁺ cytotoxic T cells kill target cells directly via **perforin, granzyme B and granulysin** (the dominant cytolytic mediator of keratinocyte death in SJS/TEN).
- ▶ Persistent, indigestible antigen $\rightarrow$ chronic macrophage activation $\rightarrow$ transformation into **epithelioid and multinucleate giant cells** $\rightarrow$ **granuloma** formation (e.g., tuberculosis, leprosy, sarcoidosis, fungal infection).

Subclassification of Type IV (Pichler) — by effector cell and cytokine

Harrison (adapted from Jutel *et al*, *Allergy* 2023) subdivides cell-mediated reactions by the dominant effector arm:

Subtype	Effector cells	Key cytokines/mediators	Final effector	Clinical correlate
IVa (T1)	TH1, ILC1, Tc1, NK	IFN- γ , TNF- α , granzyme B, perforin, granulysin	Macrophage activation $\rightarrow$ granuloma	Tuberculin reaction, granulomatous disease, allergic contact dermatitis
IVb (T2)	TH2, ILC2, Tc2, NK-T	IL-4, IL-5, IL-9, IL-13, IL-31	Eosinophil inflammation	DRESS/DIHS, maculopapular exanthem with eosinophilia
IVc (T3)	TH17, ILC3, Tc17	IL-17, IL-22, IL-23, CXCL8 (IL-8), GM-CSF	Neutrophil inflammation	AGEP, neutrophilic drug eruptions

- ▶ The *classic four-part Pichler scheme* additionally separates **Type IVc = CD8⁺ cytotoxic reactions** (SJS/TEN, fixed drug eruption) and **Type IVd = neutrophil-rich reactions** (AGEP) — both are universally taught and worth naming.

Clinical examples — organised by category

- ▶ Diagnostic skin tests (in-vivo DTH):

- **Tuberculin / Mantoux (TST):** intradermal PPD (purified protein derivative, standard PPD-S/RT23); reaction read at **48–72 h** as induration. Cellular basis = previously sensitised **CD4⁺ T cells** attracted to the skin site producing cytokines. CDC cut-offs: **≥5 mm** (HIV, recent TB contacts, organ-transplant/immunosuppressed, fibrotic CXR), **≥10 mm** (recent immigrants, injection drug users, lab/congregate-setting staff, children <5 y), **≥15 mm** (low-risk persons). Modern equivalents — **TBST** and **IGRAs** (QuantiFERON-TB Gold Plus, T-SPOT.TB) use TB-specific antigens **ESAT-6 and CFP-10**.
- **Lepromin test** (tuberculoid leprosy), **Candida**, **mumps**, **trichophyton** (anergy panel) — assess intact cell-mediated immunity; *anergy* indicates impaired DTH (HIV, sarcoid, malnutrition, overwhelming TB).
- ▶ **Infective / granulomatous DTH:** tuberculosis (caseating granuloma; the tissue damage and cavitation are largely DTH-mediated), tuberculoid leprosy, leishmaniasis, deep fungal infection, schistosome-egg granuloma.
- ▶ **Allergic contact dermatitis (prototype skin DTH):** sensitisers include **nickel**, **urushiol** (poison ivy/oak), **potassium dichromate**, **neomycin/bacitracin/polymyxin B**, **formaldehyde**, **paraphenylenediamine**, **adhesive tape**. *Allergic* contact dermatitis (a DTH, lag ~48 h on re-challenge) is distinguished from *irritant* dermatitis (non-immune, onset within hours); confirmed by **patch testing**. *Systemic contact dermatitis/SDRIFE* follows systemic exposure to a previously contact-sensitising drug.
- ▶ **Drug-induced delayed hypersensitivity (T-cell-mediated):** **morbilliform/maculopapular exanthem** (commonest), **fixed drug eruption** (sulfonamides, NSAIDs, tetracyclines), **DRESS/DIHS** (eosinophilia, facial oedema, hepatitis; aromatic anticonvulsants, allopurinol, vancomycin, sulfonamides), **AGEP** (sterile pustules), **SJS/TEN** (full-thickness epidermal necrosis; granulysin-mediated). Strong **HLA-restricted pharmacogenomic associations:** ***HLA-B57:01**–abacavir (**100% negative predictive value; PREDICT-1**), **HLA-B15:02**–*carbamazepine* **SJS/TEN** (*Han Chinese*), **HLA-B58:01**–allopurinol **DRESS/SJS-TEN**, **HLA-A32:01**–*vancomycin* **DRESS**, **HLA-B13:01**–dapson; **CYP2C93*** slow metabolism predisposes to phenytoin reactions.
- ▶ **Transplantation: acute cellular allograft rejection** and **graft-versus-host disease** are T-cell-mediated (Type IV).
- ▶ **Cell-mediated autoimmunity (DTH component):** type 1 diabetes mellitus, Hashimoto thyroiditis, multiple sclerosis, rheumatoid arthritis.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Diagram 1 — Two-phase mechanism of Type IV hypersensitivity.** Labels: *Hapten + carrier protein; Langerhans/dendritic cell (APC); MHC II → naïve CD4⁺ T cell; MHC I → CD8⁺ T cell; regional lymph node — clonal expansion; Sensitisation phase (10–14 days); Memory/effector TH1 + cytotoxic CD8⁺ T cells; Re-exposure; Effector phase (48–72 h); IFN-*

γ , TNF- α $\rightarrow$ macrophage activation; Perforin/granzyme/granulysin $\rightarrow$ target-cell death; epithelioid & giant cells $\rightarrow$ granuloma.

- ▶ **Diagram 2 — Tuberculin (Mantoux) reaction.** Labels: Intradermal PPD (forearm); Read at 48–72 h; measure induration (not erythema) in mm; cut-offs ≥ 5 / ≥ 10 / ≥ 15 mm.

Clinical / Diagnostic significance

- ▶ **Diagnostic use:** DTH skin tests (tuberculin, lepromin, anergy panel) detect prior sensitisation and gauge intact cell-mediated immunity; *anergy* flags immunodeficiency.
- ▶ **Granuloma = protective yet pathogenic:** the same DTH that walls off intracellular organisms (*M. tuberculosis*, *M. leprae*) also causes the caseation, cavitation and tissue destruction of disease.
- ▶ **Management of contact dermatitis:** identify and remove the allergen; **patch testing** to confirm; topical (or short systemic) glucocorticoids; emollients.
- ▶ **Severe cutaneous adverse drug reactions (SCARs):** SJS/TEN, DRESS and AGEP are dermatological emergencies — **immediate withdrawal of the culprit drug**, supportive/burns-unit care, and monitoring for late autoimmune sequelae (thyroiditis, diabetes) in DRESS.
- ▶ **Pharmacogenomic screening prevents disease:** pre-prescription *HLA-B57:01 testing before **abacavir**, and HLA-B15:02 before **carbamazepine** (and HLA-B58:01** before **allopurinol** in at-risk groups) avert life-threatening reactions.
- ▶ DTH underlies the efficacy read-out of **BCG vaccination** and the immunology of **granulomatous diseases** (sarcoidosis, Crohn's, berylliosis).

High-yield exam pointers

- ▶ Type IV is the **only antibody-independent Gell–Coombs type** — T-cell mediated, transferable by lymphocytes, not serum.
- ▶ Reaction is “**delayed**” — **peaks at 48–72 h**; two phases: **sensitisation (10–14 d)** then **elicitation (48–72 h)**.
- ▶ Effector arms: CD4 TH1 $\rightarrow$ IFN- γ $\rightarrow$ macrophage activation/granuloma; CD8 CTL $\rightarrow$ perforin, granzyme, granulysin $\rightarrow$ cytotoxicity.
- ▶ **Tuberculin test** read at 48–72 h; measure **induration in mm** (not erythema); cut-offs 5/10/15 mm; modern IGRA uses **ESAT-6 & CFP-10**.
- ▶ **Allergic contact dermatitis** (nickel, poison ivy/urushiol, chromate, neomycin) — diagnosed by **patch test**; *irritant* type is non-immune and faster.
- ▶ **SCARs are Type IV:** SJS/TEN, DRESS, AGEP, morbilliform, fixed drug eruption — first step is **stop the drug**.
- ▶ **Memorise HLA links:** B57:01–**abacavir**, B15:02–**carbamazepine**, B58:01–**allopurinol**, A32:01–**vancomycin**, B*13:01–**dapsone**.

- ▶ Acute cellular allograft rejection and GVHD are clinically important Type IV reactions.

SOURCE & COVERAGE

- ▶ **Harrison's Principles of Internal Medicine, 22e** — “Introduction to the Immune System” (T-cell subsets, TH1/TH17, granuloma/macrophage activation); “Cutaneous Drug Reactions” (Revised immune-pathway classification Table 63-1 with Type IVa/IVb/IVc, HLA-pharmacogenomic associations, SJS/TEN/DRESS/AGEP); “Eczema, Psoriasis... (dermatitis)” (allergic vs irritant contact dermatitis, patch testing); “Tuberculosis” (skin-test reactivity as delayed-type hypersensitivity, PPD, TST cut-offs Table 183-5, IGRA/ESAT-6/CFP-10).
- ▶ **Coverage note:** The Gell–Coombs four-type framework is presented across the immunology, allergy/pulmonary-diagnostics and drug-reaction chapters rather than as a single dedicated table; the classic two-phase DTH mechanism, the 10–14-day sensitisation interval, the Pichler IVc/IVd cytotoxic-vs-neutrophil subdivision, and standard contact allergens/anergy-panel antigens are universally accepted textbook immunology used to complete the answer.

Nucleotide Repeat Expansion Disorders

Asked in: Paper I Nov 2020 — RGUHS MD General Medicine

Definition / Introduction — Nucleotide (most commonly *trinucleotide* / *triplet*) repeat expansion disorders are a distinct class of human genetic disease caused by **dynamic mutations** — tandemly repeated short DNA sequences that are intrinsically unstable and **expand beyond a critical threshold copy number**, with progressive lengthening of the repeat both across generations (germline) and within tissues (somatic). They were first recognised as the cause of *fragile X syndrome*, and now encompass several common neurological diseases (Huntington's disease, myotonic dystrophy, Friedreich's ataxia, spinocerebellar ataxias). Their hallmark clinical signature is **genetic anticipation** — earlier onset and greater severity in successive generations.

Molecular basis and key concepts

- ▶ **Mechanism of expansion** — repeats expand through **unequal recombination (crossing-over)** and **slipped-strand mispairing** during DNA replication; once an expansion is present the DNA fragment is unstable and tends to expand further during cell division.
- ▶ **Premutation → full mutation** — a *premutation* is a small increase in repeat copy number; the carrier may be phenotypically normal or mildly affected, but in subsequent generations the expanded repeat may increase further in length, producing an increasingly severe phenotype — the essence of a **dynamic mutation**.

- ▶ **Anticipation** — when repeat length increases from one generation to the next, disease manifests earlier and more severely. In Huntington's disease there is a direct correlation between age of onset and triplet-codon length; documented across many repeat disorders.
- ▶ **Repeat length–phenotype correlation** — larger expansions → younger onset and more aggressive disease (well shown in SCA1, SCA7, DRPLA, SBMA).
- ▶ **Somatic / tissue-specific instability** — repeat number can vary between tissues; e.g., in myotonic dystrophy the CTG repeat may be ~10-fold larger in muscle than in lymphocytes.
- ▶ **Parent-of-origin effect** — paternal transmission tends to cause greater expansion (HD, SCA7, DRPLA), whereas the severe **congenital form of myotonic dystrophy** occurs almost exclusively with maternal transmission.

Classification by repeat location and pathogenic mechanism

Repeat disorders are best grouped by *where* the repeat lies and *how* it injures the cell:

Group	Repeat / location	Pathogenic mechanism	Examples
Coding (exonic) CAG	CAG in coding exon → polyglutamine (polyQ) tract	Toxic gain-of-function of mutant protein; β -pleated aggregates form neuronal intranuclear inclusions	Huntington's disease, SBMA (Kennedy), SCA1/2/3/6/7/12/17, DRPLA
Non-coding — loss of function	CGG in 5'UTR; GAA in intron	Hypermethylation/gene silencing or reduced gene expression	Fragile X (FMR1), Friedrich's ataxia (frataxin)
Non-coding — RNA toxic gain	CTG/CCTG in untranslated region/intron	Mutant RNA forms nuclear foci that sequester splicing proteins	Myotonic dystrophy DM1 (DMPK), DM2 (CNBP)
Larger/other repeats (non-coding)	Hexanucleotide GGGGCC; pentanucleotide AAGGG; intronic GAA	RNA foci, dipeptide-repeat proteins, haploinsufficiency	C9orf72 ALS/FTD, RFC1-CANVAS, SCA27B (FGF14)

- ▶ **Polyglutamine (polyQ) diseases** share a unifying biology: expanded CAG encodes glutamine; ataxins/huntingtin with >~40 glutamines undergo conformational change to a β -pleated structure, accumulate in neuronal nuclei, bind and impair the TATA-binding protein and CREB-binding protein, overwhelm the **ubiquitin–proteasome system**, impair autophagy, and induce neuronal apoptosis.

Representative disorders (with genetic detail)

Selected trinucleotide repeat disorders (Harrison *Table 479-5*):

Disease	Locus	Repeat	Normal / Disease range	Inheritance	Gene product
Spinobulbar muscular atrophy (Kennedy, SBMA)	Xq12	CAG	11–34 / 40–62	XR	Androgen receptor
Fragile X (FRAXA)	Xq27.3	CGG	6–50 / 200–300	XR	FMR-1 protein (FMRP)
Fragile X (FRAXE)	Xq28	GCC	6–25 / >200	XR	FMR-2 protein
Myotonic dystrophy (DM1)	19q13.32	CTG	5–30 / 200–1000	AD	Myotonin protein kinase (DMPK)
Huntington's disease (HD)	4p16.3	CAG	6–34 / 37–180	AD	Huntingtin
SCA1	6p22.3	CAG	6–39 / 40–88	AD	Ataxin-1
SCA2	12q24.12	CAG	15–31 / 34–400	AD	Ataxin-2
SCA3 / Machado-Joseph disease	14q32.12	CAG	13–36 / 55–86	AD	Ataxin-3
SCA6	19p13	CAG	4–16 / 20–33	AD	$\alpha 1A$ voltage-gated Ca^{2+} channel (CACNA1A)
SCA7	3p14.1	CAG	4–19 / 37 to >300	AD	Ataxin-7
SCA12	5q32	CAG	6–26 / 66–78	AD	Protein phosphatase 2A
DRPLA	12p13.31	CAG	7–23 / 49–75	AD	Atrophin-1
Friedreich's ataxia (FRDA1)	9q21.11	GAA	7–22 / 200–900	AR	Frataxin

- **Huntington's disease** — AD, *huntingtin* on 4p16.3, CAG >40 fully penetrant (intermediate 36–39 with reduced penetrance). Onset 25–45 yr; chorea early, evolving to dystonia, rigidity, bradykinesia and myoclonus; behavioural disturbance, depression with suicidality, and dementia. The **Westphal variant** (akinetic-rigid) affects ~10%, usually juvenile-onset. MRI shows

caudate (head) and putamen atrophy with enlarged frontal horns; intranuclear ubiquitin + huntingtin inclusions. Expansion is greater with **paternal** transmission. Tetrabenazine, **deutetrabenazine** and valbenazine treat chorea; antisense oligonucleotide trials ongoing.

- ▶ **Myotonic dystrophy** — commonest adult muscular dystrophy. **DM1** = unstable CTG repeat in 3' untranslated region of *DMPK* (chr 19); “hatchet face”, frontal balding, grip/percussion myotonia, posterior subcapsular cataracts, cardiac conduction block (sudden death), insulin resistance, hypersomnia, testicular atrophy. **Congenital DM1** in ~25% of infants of affected mothers. **DM2 / PROMM** = CCTG repeat in intron 1 of *CNBP (ZNF9)*, predominantly proximal. Both act by an **RNA toxic gain-of-function** — mutant RNA forms intranuclear inclusions that sequester splicing proteins, causing mis-splicing of multiple transcripts. Mexiletine for myotonia; pacemaker/ICD for conduction disease.
- ▶ **Friedreich’s ataxia** — most common inherited ataxia (AR); homozygous **GAA** expansion in intron 1 of *frataxin* (chr 9) in >95%; **loss of frataxin expression**. Onset <25 yr: progressive gait ataxia, **areflexia with extensor plantar responses**, loss of vibration/position sense, dysarthria, pes cavus, scoliosis; **hypertrophic cardiomyopathy in 90%** and **diabetes in 20%**. Frataxin is a mitochondrial iron-homeostasis protein; its loss causes mitochondrial iron accumulation and oxidative injury. **Omaveloxolone** (NRF2 agonist) is the first FDA-approved drug.
- ▶ **Spinocerebellar ataxias** — polyQ “ataxins”; **SCA3/MJD** is the most common AD ataxia worldwide; **SCA7** is uniquely associated with **retinal pigmentary/macular degeneration** (blue-yellow colour blindness). Genotype is the diagnostic gold standard.
- ▶ **SBMA (Kennedy’s disease)** — XR, CAG in exon 1 of the **androgen receptor**; lower-motor-neuron bulbar and limb weakness with **androgen insensitivity** (gynaecomastia, reduced fertility); inverse correlation between repeat number and age of onset.
- ▶ **Fragile X syndrome** — commonest inherited cause of intellectual disability; CGG in 5'UTR of *FMRI*; **full mutation (>200)** triggers promoter **hypermethylation and gene silencing**, loss of FMRP.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Diagram 1 — Dynamic mutation and anticipation (pedigree):** A three-generation pedigree (I → II → III) with the repeat tract drawn beside each affected member showing increasing length. Labels: *Normal (stable allele) → Premutation → Full mutation; Slipped-strand mispairing / unequal crossing-over; Increasing CAG repeat number; Anticipation = earlier onset + increasing severity; Paternal vs maternal transmission bias.*
- ▶ **Diagram 2 — Classification tree by repeat location/mechanism:** Root “Repeat expansion disorders” branching to (a) *Coding CAG → polyglutamine → toxic protein gain-of-function* (HD, SCA1/2/3/6/7, SBMA, DRPLA — neuronal intranuclear inclusions); (b) *Non-coding loss-of-function* (CGG–FMR1 fragile X; GAA–frataxin Friedreich’s); (c) *Non-coding RNA*

toxic gain (CTG–DMPK DM1; CCTG–CNBP DM2 — RNA nuclear foci). Label each branch with repeat type, gene and mechanism.

Clinical / Diagnostic significance

- ▶ **Diagnosis** — repeat sizing by PCR (small alleles) and Southern blot (large expansions); genotype is the gold standard for SCAs and confirms HD, DM, FRDA. Triplet-repeat sizing also enables **prenatal diagnosis** (e.g., myotonic dystrophy).
- ▶ **Genetic counselling is mandatory** — presymptomatic/predictive HD testing must be done with trained counsellors because disclosure can precipitate depression and suicide; anticipation and parent-of-origin effects must be explained to families.
- ▶ **Phenotype prediction** — repeat length broadly predicts severity and age of onset and helps anticipate the more severe congenital DM1 in offspring of affected mothers.
- ▶ **Therapeutics** — symptomatic for most (tetrabenazine/deutetrabenazine for HD chorea; mexiletine + cardiac pacing for DM); **omaveloxolone** for Friedreich's ataxia; **antisense oligonucleotide / RNA-lowering and gene-editing (CRISPR)** strategies are in trials for HD and others.

High-yield exam pointers

- ▶ **Dynamic mutation** = unstable repeat expanding beyond a threshold; **first described in fragile X**.
- ▶ **Anticipation** = earlier onset + worse disease in successive generations with longer repeats — the defining clue.
- ▶ **CAG = polyglutamine diseases** (HD, SCA1/2/3/6/7/17, SBMA, DRPLA) → **toxic gain-of-function**, neuronal **intranuclear inclusions**, threshold ~**40 glutamines**.
- ▶ **HD**: chr 4p16.3, CAG >40 (36–39 reduced penetrance); caudate atrophy; Westphal variant; paternal anticipation.
- ▶ **Myotonic dystrophy**: DM1 = CTG in DMPK 3'UTR (chr 19); DM2 = CCTG in CNBP/ZNF9; **RNA gain-of-function**; congenital form via affected mother.
- ▶ **Friedreich's ataxia**: GAA in intron 1 of frataxin, AR, **loss of function**; areflexia + upgoing plantars, HCM, diabetes; omaveloxolone.
- ▶ **Fragile X** (CGG, FMR1) and **Friedreich's** (GAA) = **loss-of-function**; remember they are the non-coding exceptions to the polyQ rule.
- ▶ **SCA7** = ataxia + **retinal degeneration**; **SCA3/MJD** = commonest AD ataxia.
- ▶ Newer **non-triplet repeats**: C9orf72 GGGGCC hexanucleotide (commonest familial ALS/FTD), RFC1 AAGGG (CANVAS), FGF14 GAA (SCA27B).

SOURCE & COVERAGE

- ▶ Harrison's *Principles of Internal Medicine*, 22e — “Principles of Human Genetics” (Jameson & Kopp; unstable DNA sequences, dynamic mutation, anticipation, *Table 479-5* Selected Trinucleotide Repeat Disorders); “Ataxic Disorders” (SCAs, Machado-Joseph, Friedreich's ataxia, DRPLA, polyglutamine biology); “Tremor, Chorea, and Other Movement Disorders” (Huntington's disease genetics, MRI, treatment, HDL disorders); “Muscular Dystrophies and Other Muscle Diseases” (myotonic dystrophy DM1/DM2, DMPK/CNBP, RNA toxicity); plus the motor neuron disease chapter (Kennedy's/SBMA) and the ALS/frontotemporal dementia chapters (C9orf72 GGGGCC hexanucleotide expansion).
- ▶ Coverage note: The corpus covers this topic well. Fragile X is detailed mainly through *Table 479-5* genetics (gene, locus, repeat ranges, loss-of-function silencing) rather than a dedicated clinical fragile-X chapter; FXTAS (the premutation-associated tremor/ataxia syndrome) is not separately described in the searched chapters, so it is not emphasised here.

Problems in Old Age and Their Management (Geriatric Syndromes)

Asked in: Paper IV Jun 2024 — RGUHS MD General Medicine

Definition / Introduction — *Geriatric medicine* addresses the health of older adults (conventionally ≥ 65 years), in whom illness is shaped less by single organ disease than by *multimorbidity*, diminished physiologic reserve and impaired function. Ageing itself is not a disease: normal ageing changes do not cause symptoms but increase susceptibility to disease. The characteristic clinical problems of old age — the *geriatric syndromes* (falls, incontinence, delirium/dementia, frailty, polypharmacy) — are multifactorial, often atypical in presentation, under-diagnosed and frequently reversible. Their management is *person-centred*: function, comfort, quality of life and what “matters most” to the patient supersede cure.

Principles of care — the “5 M's” and comprehensive geriatric assessment

- ▶ The modern framework for caring for older adults is the 5 M's of geriatrics: **Mentation** (cognition, mood, delirium), **Mobility** (gait, falls), **Medication** (polypharmacy, deprescribing), **Multicomplexity** (multimorbidity, geriatric syndromes) and **Matters Most** (goals of care). This reframes care from a disease-driven to a person-centred paradigm.
- ▶ **Comprehensive Geriatric Assessment (CGA)** is the cornerstone — a multidimensional, interdisciplinary evaluation of medical conditions, functional status (basic and instrumental

Activities of Daily Living), cognition/affect, social support, nutrition and a “geriatric review of systems” using validated screens.

- ▶ Key principles: conditions are multiple and multifactorial; iatrogenic illness (adverse drug reactions, immobility, deconditioning) is common; many treatable problems (fall risk, incontinence, elder abuse) are missed; and care is mostly delivered outside hospital with vulnerable *care transitions*.

Falls and immobility

- ▶ **Epidemiology:** about *one in three* community-dwelling older people and *one in two* long-term-care residents fall annually; complications (hip/wrist fracture, subdural haematoma) are a leading cause of injury death after 65.
- ▶ **Causes are multifactorial** — intrinsic (postural hypotension, arrhythmia, aortic stenosis, Parkinson’s disease, neuropathy, visual impairment, cognitive impairment, muscle weakness, foot disorders) and extrinsic (sedatives, antihypertensives, environmental hazards). Up to half of “unexplained falls” in dementia are due to near-syncope from postural hypotension. Always exclude *syncope* and *seizure*.
- ▶ **Screen** every older person: “Have you fallen in the past year?”, “Are you afraid of falling?”, “Trouble rising from a chair?” Assess with the **Get Up and Go test**.
- ▶ **Management** is multifactorial: physical therapy for strength and balance, ***Tai Chi** (*proven in trials*), medication review/*withdrawal*, treat postural hypotension and arrhythmia, correct vision, podiatry/footwear, home-hazard modification, fall-alert system and hip protectors in selected patients. Vitamin D ≥ 800 IU/day is reasonable, but high-dose vitamin D (60,000 IU monthly) increases falls and should be avoided. Patients fracturing after a fall must be evaluated and treated for osteoporosis*.
- ▶ *Immobility* and hospital bed-rest cause deconditioning, muscle loss, pressure injury, venous thromboembolism and functional decline — early mobilisation is preventive.

Polypharmacy and prescribing

- ▶ **Polypharmacy** (commonly ≥ 5 simultaneous drugs): ~40% of those ≥ 65 take 5–9 drugs and ~20% take ≥ 10 . It magnifies adverse drug events ($>100,000$ hospitalisations/year), chiefly from *warfarin/antiplatelets*, *insulin/hypoglycaemics* and cardiovascular drugs.
- ▶ **Evaluation:** medication reconciliation at every visit and especially at care transitions; match each drug to an indication; watch for the **prescribing cascade** (e.g. treating amlodipine-induced oedema with a diuretic).
- ▶ **Deprescribing tools:** the AGS *Beers criteria* (potentially inappropriate medications) and the STOPP** (Screening Tool of Older Persons’ Prescriptions) criteria. Common deprescribing targets: benzodiazepines/hypnotics, anticholinergics, PPIs without indication, hypoglycaemics causing tight control, and statins near end of life.

- **Safe geriatric prescribing:** “start low, go slow”; minimise drug number; estimate renal function (Cockcroft–Gault, which safely under-estimates clearance) and adjust renally-cleared drugs; simplify regimens and use adherence aids.

Cognitive disorders — delirium and dementia

Feature	Delirium	Dementia
Onset	Acute, <i>fluctuating</i>	Insidious, progressive
Attention	Impaired (hallmark)	Preserved early
Course	Usually reversible	Chronic, often irreversible
Consciousness	Often altered	Clear until late

- **Delirium** occurs in up to **40% of hospitalised** older patients; it is a *medical emergency* signalling underlying illness. Diagnose with the **Confusion Assessment Method (CAM)**: acute onset + fluctuating course **and** inattention **plus** disorganised thinking *or* altered consciousness. Identify precipitants (drugs, infection, electrolytes, hypoxia, pain, retention, impaction). Manage by treating the cause, reorientation, sensory aids, mobilisation, sleep hygiene; reserve low-dose **risperidone (0.25–0.5 mg)** or **quetiapine (12.5–50 mg)** for danger or psychosis. Avoid benzodiazepines (except alcohol withdrawal).
- **Dementia:** by age 85, **30–40%** have dementia; **>20%** of those over 70 have mild cognitive impairment (MCI), **15–20%/year** of whom progress. Alzheimer’s and vascular dementia (often coexisting) predominate; *dementia with Lewy bodies* (~25%) features early parkinsonism, fluctuating attention and visual hallucinations. Screen with the **Mini-Cog** (3-item recall + clock draw); confirm with MoCA/MMSE plus neuroimaging and reversible-cause labs (B12, TSH, metabolic). Manage with non-pharmacological measures, cholinesterase inhibitors/memantine (modest benefit, GI and bradycardia effects), treat depression, and avoid antipsychotics for behavioural symptoms unless dangerous.

Urinary incontinence, sleep, frailty and other syndromes

- **Urinary incontinence/overactive bladder:** affects ~1 in 3 older women and 15–20% of men; precipitates falls, social isolation and institutionalisation. Types: **stress, urge, mixed, overflow, functional**; distinguish with the **3 Incontinence Questions (3IQ)**. Exclude reversible causes (UTI, atrophic vaginitis, drugs, impaction, hyperglycaemia, CHF). Check **post-void residual** (>200 mL abnormal). Treat with pelvic-floor (*Kegel*) and behavioural therapy, **antimuscarinics** or **β3-agonists** for urge, α-blockers ± 5α-reductase inhibitor in men.
- **Sleep disorders:** insomnia (~30%), obstructive sleep apnoea (~10%), restless legs (5–10%) and periodic limb movements. Treat with sleep hygiene/stimulus-control first; if needed use **melatonin** or **low-dose trazodone** — avoid chronic benzodiazepine hypnotics (hangover, falls).

- ▶ **Frailty:** a syndrome of reduced physiologic reserve. The **Fried phenotype** requires ≥ 3 of five criteria — *unintentional weight loss, weakness (grip), exhaustion, slowness (gait speed), low physical activity*; the **Rockwood Frailty Index** is a deficit-accumulation measure. Prevalence $\sim 10\text{--}14\%$ in the community, rising with age. Manage with structured **exercise (resistance + aerobic)**, protein/nutritional supplementation, polypharmacy reduction and treatment of comorbidity.
- ▶ **Pressure injuries, malnutrition/weight loss, sensory (vision, hearing) impairment and chronic pain** (commonly osteoarthritis) round out the syndromes. For pain, prefer **acetaminophen 1 g 2–3 times daily**, topical NSAIDs/lidocaine, and *duloxetine*; avoid systemic NSAIDs (GI bleed, renal, CHF) in the multimorbid.
- ▶ **Elder abuse and neglect** (incidence $\geq 8\text{--}10\%$ /year, under-reported): physical, psychological, financial, sexual and neglect/self-neglect. Screen privately (“Do you feel unsafe?”, “Has anyone taken your money?”); treat injuries and report to adult protective services.

Management of common chronic diseases — geriatric tailoring

- ▶ **Hypertension:** treat to individualised targets; *HYVET* (≥ 80 years, target ≤ 150 mmHg) reduced stroke, heart failure and mortality; *SPRINT* supported lower systolic targets in selected fit elderly — but beware postural hypotension, falls and syncope.
- ▶ **Diabetes:** relax control — **HbA1c target** $\sim 7.5\%$ in most older adults; **metformin** first line; *avoid glyburide* (hypoglycaemia); avoid sliding-scale insulin. SGLT2 inhibitors aid heart-failure/renal outcomes.
- ▶ **Prevention:** individualise cancer screening to life expectancy; vaccinate against **influenza, pneumococcus, herpes zoster, COVID-19 and RSV**.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **The 5 M’s of geriatrics** — a central hub “Matters Most” with four spokes labelled *Mentation, Mobility, Medication, Multicomplexity*.
- ▶ **Multifactorial falls model** — a circle “FALL” with arrows from labelled risk factors: *Postural hypotension, Medications (sedatives/antihypertensives), Visual impairment, Gait/balance & muscle weakness, Cognitive impairment, Foot/footwear problems, Environmental hazards* → leading to outcomes *Hip/wrist fracture, Subdural haematoma, Fear of falling, Loss of function*.

Clinical / Diagnostic significance

- ▶ Atypical disease presentation is the rule — infection may present as delirium or a fall rather than fever; myocardial infarction may be painless.
- ▶ A new **fall, delirium or incontinence** should trigger a search for acute illness, not be dismissed as “ageing”.

- ▶ CGA-based, interdisciplinary models — **Acute Care for the Elderly (ACE) units**, co-management (e.g. ortho-geriatric hip-fracture care) and structured **care-transition programmes** — reduce complications, length of stay and readmission.
- ▶ End-of-life planning matters: **CPR survival is <20%** in hospitalised patients ≥ 65 and near-zero in nursing-home residents; advance directives (living will, POLST, durable power of attorney) and avoidance of feeding tubes in advanced dementia are person-centred standards.

High-yield exam pointers

- ▶ **Geriatric giants/syndromes**: Falls, Incontinence, Delirium/Dementia, Frailty, Polypharmacy (plus immobility, pressure injury, malnutrition, sensory loss).
- ▶ **5 M's**: Mentation, Mobility, Medication, Multicomplexity, Matters Most.
- ▶ **CAM** = acute/fluctuating + inattention + (disorganised thinking *or* altered consciousness).
- ▶ **Fried frailty phenotype** = weight loss, weakness, exhaustion, slowness, low activity (≥ 3 of 5).
- ▶ **Beers and STOPP** criteria identify potentially inappropriate medications; use **Cockcroft–Gault** for renal dosing.
- ▶ Falls: screen (“fallen in past year?”), **Get-Up-and-Go**, Tai Chi, vitamin D 800 IU (avoid high-dose monthly).
- ▶ Older-adult targets: **HbA1c** $\sim 7.5\%$, metformin first line, avoid glyburide; HTN — HYVET/SPRINT.
- ▶ Avoid benzodiazepines for insomnia/delirium; prefer melatonin or low-dose trazodone.

SOURCE & COVERAGE

- ▶ **Harrison's Principles of Internal Medicine, 22e** — “Caring for the Geriatric Patient” (5 M's, CGA, falls, polypharmacy/Beers–STOPP, delirium and dementia, incontinence, sleep, frailty, elder abuse, hypertension/diabetes/pain in older adults, models of care) and “Biology of Aging” (hallmarks of ageing — genomic instability, telomere attrition, cellular senescence, stem-cell exhaustion).
- ▶ **CMDT 2026** — “Geriatric Disorders” (functional screening, delirium work-up, falls risk-factor table and targeted interventions, immobility).

Thermoregulation

Asked in: Paper I Nov 2020 — RGUHS MD General Medicine

Definition / Introduction — Thermoregulation is the homeostatic process by which the body maintains its **core temperature within a narrow range of 36.5–37.5°C (97.7–99.5°F)** despite wide swings in environmental temperature and in metabolic heat production. It is a classic negative-feedback control system with a central integrator (the **hypothalamic thermoregulatory centre**), afferent thermosensors,

and efferent autonomic, somatic, endocrine and behavioural effectors that continuously balance heat production/gain against heat loss. In a thermoneutral environment the resting metabolic rate generates *more* heat than is needed to hold the core temperature, so the system is biased toward controlled heat dissipation. Disturbance of this loop underlies fever, hyperthermia/heatstroke and hypothermia.

The thermoregulatory control loop — afferent, central, efferent

- ▶ **Central integrator (the “thermostat”):** the **preoptic anterior hypothalamus (POAH)** is the central thermostat; the posterior hypothalamus also participates. Neurons here receive **two kinds of input** which they integrate against a regulated **set point** ($\sim 37^{\circ}\text{C}$):
 - signals from **peripheral warmth/cold receptors in the skin** (cutaneous thermoreception), carried by peripheral nerves; and
 - the temperature of the **blood bathing the hypothalamus** itself (central/core thermoreception).
- ▶ **Comparator action:** if integrated temperature exceeds the set point, heat-loss effectors are driven; if it falls below, heat-conservation and heat-production effectors are driven — until blood temperature again matches the set point.
- ▶ **Efferent (output) limbs:**
 - **Autonomic (immediate defence):** sympathetic control of **cutaneous vasomotor tone** (vasoconstriction to conserve / vasodilation to dissipate heat), **sudomotor (sweating)** activity, and release of **norepinephrine** with increased muscle tone. The autonomic limb is the rapid first responder.
 - **Somatic:** **shivering** thermogenesis via skeletal muscle.
 - **Endocrine (delayed defence):** prolonged cold stimulates the **thyroid axis**, raising basal metabolic rate; antidiuretic hormone and aldosterone also rise with heat stress.
 - **Behavioural:** adding/removing clothing, seeking shade or warmth, altering posture and activity — quantitatively the most powerful and the cheapest defence.

Heat production (thermogenesis) and heat gain

- ▶ **Obligatory (basal) heat:** generated continuously by metabolism in **muscle and liver**; even at rest this exceeds the heat needed to maintain core temperature.
- ▶ **Shivering thermogenesis:** rhythmic involuntary skeletal-muscle contraction; the principal acute mechanism to raise core temperature in cold.
- ▶ **Non-shivering thermogenesis:** heat from the **liver** and metabolic tissues, augmented by sympathetic/thyroid drive, contributing to the rise in core temperature without shivering.
- ▶ **Exercise / exertion:** strenuous exercise can increase heat generation up to **twentyfold**, making exertional heat illness possible even in cool conditions.

- ▶ **Exogenous heat gain:** by **radiation** (a major source of gain in hot climates) and by conduction/convection when ambient temperature exceeds skin temperature.

Heat loss (dissipation) — the four/five physical mechanisms

The skin surface acts as the **radiator** and is the principal site of heat loss; cutaneous **skin blood flow** can increase 25–30 times above basal rate to deliver core heat to the surface, with **compensatory vasoconstriction of the splanchnic and renal beds** to support blood pressure.

Mechanism	Definition	Key quantitative / clinical points
Radiation	Emission of infrared electromagnetic energy to surroundings	~55–65% of heat loss at rest; <i>reverses</i> to become a major heat gain in hot climates
Conduction	Direct transfer of heat to a cooler contacting object	~10–15%; greatly increased in cold water (thermal conductivity of water is 25× that of air); ineffective once ambient > skin temperature
Convection	Loss of heat to moving air currents	Increased in wind ; ineffective once ambient > skin temperature
Evaporation	Latent heat lost as sweat/skin moisture vaporises	The single most efficient mechanism in heat; becomes progressively ineffective when relative humidity > 70%
Respiration	Heat lost in expired air (and respiratory water)	Listed as a fifth mechanism in cold-injury physiology; depends on ambient temperature and humidity

- ▶ The **wet-bulb globe temperature (WBGT)** integrates air temperature, humidity, radiant heat and wind speed, and is superior to the simple “heat index” for assessing environmental heat load.

Normal core temperature and its physiological variation

- ▶ **Mean oral temperature** ≈ 36.6°C (95% CI 35.7–37.3°C); a temperature >37.7°C (99.9°F) — the 99th percentile of healthy individuals — defines fever.
- ▶ **Diurnal rhythm:** lowest around **8 a.m.**, highest around **4 p.m.**; seasonal variation (lower in summer, higher in winter).
- ▶ **Site differences:** rectal temperature is ~0.4°C (0.7°F) **higher** than oral; **lower-oesophageal** temperature best reflects core; unadjusted-mode **tympanic** readings run ~0.8°C (1.6°F) **lower than rectal**.
- ▶ **Menstrual cycle:** at ovulation temperature **rises by ~0.6°C (1°F)** and stays elevated through the luteal phase (progesterone effect).

- **Modifiers:** temperature falls slightly with age ($\sim 0.02^{\circ}\text{C}$ lower per decade), and varies with demographics and comorbidity (e.g., higher in cancer, lower in hypothyroidism).

Integrated responses to cold and heat stress; acclimatisation

Stimulus	Heat conservation/production response	Heat dissipation response
Cold exposure	Cutaneous reflex vasoconstriction (conserves heat); shivering + raised muscle tone; norepinephrine release and non-shivering thermogenesis; delayed thyroid-axis activation; behavioural warming	Suppressed
Heat exposure	Suppressed	Cutaneous vasodilation (skin blood flow up 25–30 $\times$) + diaphoresis/evaporation; splanchnic–renal vasoconstriction to defend BP; behavioural cooling

- **Heat acclimatisation** is a set of adaptations developing over 1 to several weeks of work in the heat: the sweating threshold is lowered, sweat volume increases with a lower salt concentration, plasma volume expands (better cutaneous flow), and the heart rate falls with a higher stroke volume. Sweating rates reach 1–2 L/h in acclimatised individuals. Acclimatisation is lost (“de-acclimatisation”) within weeks of leaving the hot environment.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- **Thermoregulatory negative-feedback loop (block diagram).** Labels: *Cutaneous warmth/cold receptors* and *temperature of blood* → afferent input → **Preoptic anterior hypothalamus** (set point / comparator) → efferent limbs: (1) Sympathetic — cutaneous vasoconstriction/vasodilation; (2) Sudomotor — sweating; (3) Somatic — shivering; (4) Endocrine — thyroid axis / norepinephrine; (5) Behavioural responses → effectors alter *Heat production vs Heat loss (radiation, conduction, convection, evaporation, respiration)* → **Core temperature** → feedback arrow back to hypothalamus.
- **Set-point diagram — fever vs hyperthermia.** Draw a horizontal “thermostat” line at 37°C . *Fever*: set point raised (e.g., $37 \rightarrow 39^{\circ}\text{C}$) by PGE₂ → body actively conserves/produces heat to reach it (vasoconstriction, shivering, “feels cold”). *Hyperthermia/heatstroke*: set point unchanged at 37°C but core temperature overshoots because heat load exceeds dissipation. Label the OVLT/PGE₂ input on the fever side.

Clinical / Diagnostic significance

- **Fever vs hyperthermia (a must-distinguish):**

Feature	Fever	Hyperthermia (e.g., heatstroke)
Hypothalamic set point	Raised (PGE2-mediated)	Normal / unchanged
Mechanism	Pyrogens → IL-1, IL-6, TNF, IFN → PGE2 (via EP-3 receptor, near the OVLT — organum vasculosum of lamina terminalis) → cAMP → raised set point	Heat load (exogenous + endogenous) overwhelms dissipation; no pyrogens
Skin	Often cold (vasoconstriction), shivering	Hot, dry (classic heatstroke) or sweaty (exertional)
Response to antipyretics	Responds (aspirin/acetaminophen/NSAID lower set point by ↓brain PGE2)	No response — dangerous; needs rapid physical cooling

- **Pyrogen pathway (fever):** exogenous pyrogens (e.g., lipopolysaccharide/endotoxin) → myeloid/endothelial cells release **pyrogenic cytokines** (IL-1, IL-6, TNF) → hypothalamic endothelial PGE2 → glial cAMP → set point reset upward; antipyretics (cyclooxygenase inhibitors) reverse this.
- **Hyperthermia/heatstroke:** core >40.5°C with CNS dysfunction; above 42°C thermosensitive enzymes fail and there is **uncoupling of oxidative phosphorylation**, endothelial injury, heat-shock-protein/cytokine-mediated SIRS, DIC and multiorgan failure. Antipyretics are useless and potentially harmful; treat by rapid cooling (evaporative/immersion) to ~38–39°C.
- **Hypothermia (core <35°C):** failure of heat conservation; the **autonomic** limb (vasoconstriction, shivering) is the immediate defence and the **endocrine** (thyroid) limb the delayed one. The **Osborn (J) wave**, cold diuresis, coagulopathy and “paradoxical undressing” are classic; rewarming risks **core-temperature afterdrop**.
- **Drugs/conditions that impair thermoregulation:** anticholinergics, phenothiazines, tricyclics (impair sweating, depress POAH dopamine), **beta-blockers**, **calcium-channel blockers** and **stimulants** (reduce cutaneous perfusion), and ethanol/anaesthetics (block shivering, cause vasodilation) — all raise heat- or cold-illness risk. Useful differentials of disordered thermoregulation: **malignant hyperthermia**, **neuroleptic malignant syndrome**, **serotonin syndrome**, **thyroid storm**.
- **Metabolic cost of temperature change:** oxygen consumption rises ~13% for every 1°C above 37°C, explaining why fever stresses cardiac/pulmonary/CNS-compromised patients.

High-yield exam pointers

- Central thermostat = **preoptic anterior hypothalamus**; integrates **skin thermoreceptor** input + **blood temperature**; regulated **set point** ~37°C.

- ▶ Normal core 36.5–37.5°C; mean oral 36.6°C; fever defined as >37.7°C (99th percentile).
- ▶ Four/five heat-loss routes: radiation (55–65%), conduction (10–15%), convection, evaporation (most efficient, fails if humidity >70%), respiration.
- ▶ Skin blood flow can rise 25–30×; evaporative sweating up to 1–2 L/h when acclimatised; water conducts heat 25× faster than air.
- ▶ Fever = raised set point (pyrogen→PGE2→EP-3, near OVLT); hyperthermia = normal set point overwhelmed — only fever responds to antipyretics.
- ▶ Efferent limbs: autonomic (immediate) + endocrine/thyroid (delayed) + somatic shivering + behavioural.
- ▶ Acclimatisation (1–several weeks): lower sweat threshold, more sweat with less salt, plasma-volume expansion, lower HR.
- ▶ O2 consumption ↑13% per 1°C rise; ovulation raises core by ~0.6°C; rectal is 0.4°C > oral.

SOURCE & COVERAGE

- ▶ **Harrison's Principles of Internal Medicine, 22e** — “Fever” (Dinarelllo & Surana; thermoregulatory centre, set point, normal temperatures and variation, fever vs hyperthermia, pyrogen/PGE2 pathway, antipyretic mechanism); “Heat-Related Illnesses” (Danzl; thermoregulation, heat-dissipation mechanisms, skin blood flow, acclimatisation, heatstroke); “Hypothermia and Peripheral Cold Injuries” (Danzl; five heat-loss mechanisms with percentages, autonomic vs endocrine defence of thermoneutrality).
- ▶ **Coverage note:** This is a basic-physiology (anatomy/physiology) question; the RGUHS spec lists **no dedicated specialty textbook**, and Harrison covers thermoregulation only as it is embedded within the Fever, Heat-Related-Illness and Hypothermia chapters (spec flagged as a thin/”gap” topic). The answer therefore synthesises these three chapters; the underlying control-loop framework (afferent–integrator–efferent limbs, shivering/non-shivering thermogenesis, behavioural responses) is universally accepted standard physiology and is stated only where consistent with the cited Harrison text. Cell-physiology depth (e.g., brown-adipose-tissue UCP-1 mechanism, TRP-channel thermoreceptors) is not elaborated in this corpus and has been omitted rather than fabricated.

DNA replication

Asked in: Paper I Nov 2019 — RGUHS MD General Medicine

Definition / Introduction — DNA replication is the enzymatically catalysed, **semiconservative** process by which a cell duplicates its entire double-stranded genome so that each daughter cell receives an identical copy during division. It exploits the strict **base-pair complementarity** of the double helix (A–

T, G–C): the two parental strands separate and each acts as a **template** for synthesis of a new complementary strand, so every daughter duplex contains one old (parental) and one newly made strand. In humans, ~3 billion base pairs per haploid genome are copied with extraordinary fidelity during the **S phase** of the cell cycle, the accuracy of which is essential to prevent mutation, cancer and inherited disease.

Structure of DNA — the template that makes replication possible

- ▶ DNA is a **double-stranded right-handed helix** of four bases — **adenine (A)**, **thymine (T)**, **guanine (G)**, **cytosine (C)** — with **A pairing T** (2 hydrogen bonds) and **G pairing C** (3 hydrogen bonds) across the helix.
- ▶ The two strands are **antiparallel**: one runs 5'→3', its partner 3'→5'; the sugar–phosphate (deoxyribose–phosphodiester) backbone is on the outside, bases inside.
- ▶ This **complementarity and double-stranded nature permit faithful replication during cell division** and underlie the flow of information DNA → RNA → protein.
- ▶ In the eukaryotic nucleus DNA is packaged with **histones** into **nucleosomes** (core octamer of H2A, H2B, H3, H4; H1 is the linker histone), coiled into **solenoid** fibres and **supercoiled chromatin**, ending in **centromeres** and **telomeres** — all of which must be transiently unpacked and re-assembled as the replication fork passes.

Key enzymes and proteins of the replication machinery

Protein / enzyme	Function
DNA helicase	Unwinds and separates the parental duplex at the fork (ATP-dependent)
Topoisomerase / DNA gyrase	Relieves torsional strain (positive supercoils) ahead of the fork
Single-strand binding (SSB) proteins	Coat and stabilise unwound single strands; prevent re-annealing
Primase (an RNA polymerase)	Synthesises short RNA primers providing a free 3'-OH to start synthesis
DNA polymerase	Adds dNTPs to the 3'-OH; synthesises only 5'→3', reads template 3'→5'; has 3'→5' exonuclease proofreading
Sliding clamp / clamp loader	Tethers polymerase to template for high processivity
DNA ligase	Seals nicks (phosphodiester bonds) between adjacent fragments
Telomerase	Reverse transcriptase that extends 3' chromosome ends (germ/stem/cancer cells)

- ▶ **Polymerase specialisation:** in bacteria, **Pol III** is the main replicase and **Pol I** removes RNA primers and fills the gaps; in eukaryotes, **Pol α /primase** initiates, **Pol δ** extends the lagging strand and **Pol ϵ** the leading strand, while **Pol γ** replicates mitochondrial DNA.

Stages of replication — initiation, elongation, termination

- ▶ **Initiation:** Begins at specific **origins of replication** — a single *oriC* in bacteria but **thousands of origins** along the large eukaryotic chromosomes (permitting timely S-phase completion). Origins are “licensed” once per cycle by the **origin recognition complex (ORC)** and loading of the **MCM helicase**, ensuring DNA is copied **exactly once** per cell cycle. Helicase opens the duplex to form two **replication forks** moving in opposite directions (a **replication bubble**).
- ▶ **Elongation:** Helicase unwinds; SSB and topoisomerase keep the template open and untangled. Primase lays an RNA primer; DNA polymerase extends it 5'→3', incorporating the correct complementary dNTP. Because the two template strands are antiparallel and polymerase works in only one direction, the two new strands are made differently (see below).
- ▶ **Termination:** Forks converge; in eukaryotes adjacent **replicons** merge, RNA primers are excised and replaced with DNA, and ligase joins all fragments into two continuous daughter duplexes. Histones reassemble nucleosomes on the new DNA.

Leading vs lagging strand and Okazaki fragments

Feature	Leading strand	Lagging strand
Direction relative to fork	Same as fork movement	Opposite to fork movement
Synthesis	Continuous	Discontinuous
Primers needed	One (single)	Many (one per fragment)
Product	One long strand	Short Okazaki fragments later ligated
Eukaryotic polymerase	Pol ϵ	Pol δ

- ▶ The lagging strand is built as short segments called **Okazaki fragments** (~100–200 nucleotides in eukaryotes; ~1000–2000 in bacteria), each begun with its own RNA primer; primers are then removed, gaps filled and nicks sealed by **DNA ligase**.

Fidelity, proofreading and DNA repair

- ▶ Replication is remarkably accurate (~1 error per 10^9 – 10^{10} bp) because of (1) correct base selection, (2) 3'→5' **exonuclease proofreading** by polymerase, and (3) post-replication **mismatch repair**.
- ▶ Certain sites are mutation “hot spots”: adjacent pyrimidines (T-T, C-C) form **UV-induced photoadducts/pyrimidine dimers**; methylated CpG cytosines deaminate to thymine causing recurrent C→T (G→A) transitions.

- Repair pathways correcting replication/damage errors — and the diseases caused by their failure:

Repair pathway	Corrects	Disease if defective
Nucleotide excision repair (NER)	Bulky lesions / pyrimidine dimers	Xeroderma pigmentosum
Mismatch repair (MMR) — <i>MutS/MSH2, MLH1</i>	Base mismatches & slippage from replication	HNPCC / Lynch syndrome (colon, endometrial, ovarian cancer)
Homologous recombination — <i>BRCA1/2, Fanconi pathway</i>	Double-strand breaks, inter-strand crosslinks	Hereditary breast/ovarian cancer; Fanconi anaemia

Telomeres, telomerase and the “end-replication problem”

- Because lagging-strand synthesis needs a primer, the extreme 3' end of a linear chromosome cannot be fully copied, so chromosomes **shorten with each division** (telomere attrition) — a marker of replicative ageing/senescence.
- **Telomerase**, a ribonucleoprotein **reverse transcriptase** carrying its own RNA template, adds tandem **TTAGGG** repeats to chromosome ends, counteracting shortening.
- Telomerase is active in germline, stem and most **cancer** cells (conferring replicative immortality) but largely silent in mature somatic tissue — a key link between replication biology and oncogenesis and ageing.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- **Labelled replication fork:** show parental duplex opened into a “Y”. Label — *parental DNA (3' and 5' template strands), helicase (at fork), single-strand binding proteins, topoisomerase/gyrase (ahead of fork), RNA primer, primase, leading strand (continuous, 5'→3'), lagging strand with Okazaki fragments, DNA polymerase, DNA ligase, direction of fork movement.*
- **Semiconservative replication (Meselson–Stahl) schematic:** one parental double helix → two daughter duplexes, each with one *old (parental)* strand (shaded) and one *new* strand. Label *parental strand, newly synthesised strand, origin of replication, replication bubble/two forks.*

Clinical / Diagnostic significance

- **Cancer:** loss of replication fidelity / repair drives carcinogenesis — MMR defects produce **microsatellite instability** in Lynch syndrome; **BRCA1/2** and Fanconi-pathway defects give breast/ovarian cancer; reactivated **telomerase** sustains tumour growth.
- **Pharmacology:** replication is the target of cytotoxic and antimicrobial drugs — antimetabolites and **fluoropyrimidines/cytarabine/gemcitabine** (block dNTP supply/incorporation), **topoisomerase inhibitors** (irinotecan, etoposide), **alkylating agents** and **fluoroquinolones**

(inhibit bacterial gyrase/topoisomerase) and antiretroviral/antiviral **reverse-transcriptase and polymerase inhibitors**.

- ▶ **Inherited disease:** replication-slippage at unstable repeats causes **trinucleotide-repeat expansion disorders** (e.g., Huntington, fragile X, myotonic dystrophy); unequal crossing-over of tandem repeats causes **CMT1A** (PMP22 duplication).
- ▶ **Diagnostics:** the same complementarity and polymerase chemistry underpin **PCR, next-generation sequencing** and molecular cytogenetics used across modern internal medicine.

High-yield exam pointers

- ▶ DNA replication is **semiconservative** — proven by **Meselson & Stahl**; each daughter duplex = one old + one new strand.
- ▶ DNA polymerase synthesises only **5'→3'** and **needs an RNA primer** made by primase (cannot start de novo).
- ▶ **Leading strand = continuous; lagging strand = discontinuous (Okazaki fragments)** later joined by DNA ligase.
- ▶ Fork proteins: **helicase** (unwinds), **SSB** (stabilises), **topoisomerase/gyrase** (relieves supercoils), **primase, polymerase, ligase**.
- ▶ **Bacteria = one origin (oriC); eukaryotes = many origins**; replication confined to **S phase** and licensed (**ORC/MCM**) to occur **once per cycle**.
- ▶ Fidelity = base selection + **3'→5' proofreading** + **mismatch repair**; MMR failure → **Lynch syndrome / microsatellite instability**.
- ▶ **NER defect** → **xeroderma pigmentosum**; **BRCA/Fanconi defect** → **breast/ovarian cancer, Fanconi anaemia**.
- ▶ **Telomerase** (RNP reverse transcriptase) adds **TTAGGG** repeats, solves the end-replication problem; reactivated in cancers.

SOURCE & COVERAGE

- ▶ **Harrison's Principles of Internal Medicine, 22e** — "*Principles of Human Genetics*" (DNA double-helix structure and base-pair complementarity, faithful semiconservative replication, chromatin/nucleosome/telomere organisation, the cell cycle and replication of chromosomes at mitosis, replication-error mutational hot spots, and the DNA-repair pathways with their disease correlations — nucleotide excision repair/xeroderma pigmentosum, mismatch repair/HNPCC–Lynch, BRCA1 and the Fanconi pathway, and trinucleotide-repeat expansion).

Coverage note: Harrison 22e (and the cited chapter) treat DNA structure, chromatin, the cell cycle, replication fidelity and DNA-repair/cancer correlations, but do **not** detail the enzymatic replication-fork machinery. The mechanistic specifics in this answer —

helicase/topoisomerase/SSB/primase/polymerase/ligase, leading- versus lagging-strand synthesis, Okazaki fragments, polymerase subtypes, origin licensing (ORC/MCM) and telomerase chemistry — are drawn from universally-accepted standard molecular biology and are stated to satisfy the full scope of the question; they are not unique claims of the corpus.

Down Syndrome (Trisomy 21): Genetic Mechanism, Risk Factors and Clinical Features

Asked in: Paper I Nov 2019 — RGUHS MD General Medicine

Definition / Introduction — Down syndrome is the commonest **autosomal chromosomal (aneuploidy) disorder** compatible with survival and the leading genetic cause of **intellectual disability**. It results from the presence of **three copies of chromosome 21 (trisomy 21)**, or of a rearrangement that produces three copies of the critical long-arm segment of chromosome 21. Nearly **0.5% of all human conceptions are trisomic for chromosome 21**; because of high fetal loss the birth incidence is about **1 in 700**, varying from ~1 in 1000 in young mothers to more than three-fold higher with advanced maternal age. The phenotype reflects a *gene-dosage effect* — over-expression of the genes on the supernumerary chromosome 21.

Cytogenetic basis — three genetic mechanisms

Chromosomal disorders are caused by **numerical (aneuploidy) or structural (translocation, deletion, duplication) aberrations**; such disorders occur in ~1% of the general population, ~8% of stillbirths and close to **50% of spontaneously aborted fetuses** (Harrison). Trisomy 21 arises by three distinct mechanisms:

Mechanism	Karyotype	Approx. share	Origin / key point
Free (standard) trisomy 21	47,XX,+21 or 47,XY,+21	~95%	Meiotic non-disjunction, predominantly in maternal meiosis I; <i>strongly maternal-age dependent</i> ; recurrence risk low (~1%)
Robertsonian translocation	e.g. 46,XX,der(14;21) or der(21;21) — <i>translocation Down syndrome</i>	~4%	Fusion of long arms of an acrocentric chromosome (commonly 14, or 21;21) with chromosome 21; <i>not</i> age-related; ~ $\frac{1}{3}$

Mechanism	Karyotype	Approx. share	Origin / key point
			inherited from a phenotypically normal balanced-translocation carrier parent , giving a substantial recurrence risk
Mosaicism	46,N/47,+21	~1–2%	Post-zygotic non-disjunction at an early mitotic division → two cell lines; phenotype usually milder and variable

- ▶ *Cytogenomic (karyotype/chromosomal microarray) analysis should always be performed* — even though most patients have simple trisomy — to detect **unbalanced translocations**, because such a child may have a parent carrying a **balanced translocation** with a high recurrence risk in future offspring and in that parent's relatives (CMDT).

Mechanism of non-disjunction and gene dosage

- ▶ **Non-disjunction** = failure of paired homologous chromosomes (meiosis I) or sister chromatids (meiosis II) to segregate, so one gamete receives **two copies of chromosome 21** and, after fertilisation by a normal gamete, the zygote is trisomic.
- ▶ The error occurs most often in the **maternal oocyte at meiosis I**; the oocyte pool is arrested from fetal life and only completes meiosis at ovulation, so prolonged arrest predisposes to mis-segregation — the biological basis of the maternal-age effect (rates of **aneuploidy are increased in the female germline**; by contrast new *point* mutations increase with paternal age).
- ▶ **Mosaic trisomy** reflects **mitotic non-disjunction** in the early embryo, producing a normal and a trisomic cell line.
- ▶ The phenotype is a **gene-dosage (over-expression) effect** of the *Down syndrome critical region* on the distal long arm (**21q22**); triplication of genes here (including *APP*) accounts for the major features and for the near-universal Alzheimer pathology.

Risk factors

- ▶ **Advanced maternal age** — the single most important factor. The risk rises *exponentially* and accelerates markedly after **age 35**; by **age 45 the risk is as high as ~1 in 40**, because older oocytes are predisposed to non-disjunction during meiosis (CMDT).
- ▶ **Previous child with trisomy 21** — recurrence in free trisomy is ~1% (age-related risk plus a small increment).

- ▶ **Parental balanced (Robertsonian) translocation carrier** — confers the highest recurrence risk: a *der(21;21)* carrier parent has an effectively ~100% risk, and a *der(14;21)* carrier mother ~10–15% (lower if the father is the carrier).
- ▶ **Parental germline mosaicism** for trisomy 21.
- ▶ *Paternal age does NOT increase the risk of trisomy 21 (CMDT)* — a high-yield discriminator.

Clinical features (multisystem)

Diagnosis is usually made at **birth** on the basis of typical craniofacial features, **hypotonia** and a **single transverse palmar crease (CMDT)**.

System	Features
Craniofacial / dysmorphic	Brachycephaly with flat occiput , up-slanting palpebral fissures with epicanthal folds , <i>Brushfield spots</i> (speckled iris), small ears, flat nasal bridge, large/protruding tongue (relative macroglossia), short neck
Musculoskeletal / limbs	Hypotonia , single transverse palmar (simian) crease, clinodactyly of the 5th finger , wide “sandal gap” between 1st–2nd toes, joint laxity, atlanto-axial instability
Neurodevelopment	Intellectual disability of variable degree; developmental delay; early-onset Alzheimer-type dementia in the 4th–5th decade
Cardiac	Congenital heart disease in ~50% , classically atrioventricular (endocardial) canal / AV septal defect , also VSD, ASD, tetralogy
Gastrointestinal	Duodenal atresia , Hirschsprung disease, celiac disease (immune-related)
Haematologic	Transient abnormal myelopoiesis (transient neonatal leukaemia) that usually resolves with conservative care; increased childhood acute lymphoblastic and especially myeloid leukaemia (ML-DS)
Endocrine / immune	Hypothyroidism , diabetes mellitus, immune deficiency with frequent infections

- ▶ **Leukaemia** in Down syndrome typically responds to *reduced-dose chemotherapy*, but relapse carries a poor outcome (CMDT).
- ▶ **Alzheimer disease**: adults with trisomy 21 *consistently* develop the neuropathologic hallmarks of AD if they survive beyond ~40 years; the **extra dose of the APP gene on chromosome 21 is the initiating cause, producing excess cerebral amyloid (Harrison)*. Average life expectancy of those surviving childhood who develop dementia is ~55 years*.

Diagnosis and screening

- ▶ **Prenatal screening (first/early-second trimester):** maternal serum **multiple-marker screen** (α -fetoprotein and other biomarkers), increased **nuchal translucency/thickness** and **under-development of the nasal bone** on ultrasonography.
- ▶ **Cell-free fetal DNA (cffDNA / NIPT)** in maternal blood gives high-sensitivity, high-specificity non-invasive detection.
- ▶ **Confirmatory diagnosis:** fetal **karyotype/cytogenomic analysis** by **chorionic villus sampling** or **amniocentesis** prenatally, and **postnatal karyotype** — mandatory to define the mechanism (free trisomy vs translocation) for **recurrence-risk counselling**.
- ▶ *Indications for cytogenetic analysis* (Harrison Table 479-4) include advanced maternal age, abnormal ultrasound, a positive maternal serum screen, multiple congenital anomalies, intellectual disability and developmental delay.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Non-disjunction in meiosis:** normal vs abnormal segregation of chromosome 21. Label: *homologous pair of chromosome 21, meiosis I — failure of homologue separation (non-disjunction), meiosis II, gametes — one with 2 copies of 21 and one with 0, fertilisation by normal gamete $\rightarrow$ 47,+21 trisomic zygote.*
- ▶ **Robertsonian translocation karyogram:** label *acrocentric chromosomes 14 and 21, fusion at centromere $\rightarrow$ der(14;21), balanced carrier parent (45 chromosomes, normal phenotype), unbalanced offspring with translocation Down syndrome (46 chromosomes, 3 copies of 21q).*

Clinical / Diagnostic significance

- ▶ **Always karyotype** the child (and parents if a translocation is found) — distinguishes the ~95% sporadic free trisomy (low recurrence) from translocation Down syndrome (potentially very high familial recurrence).
- ▶ **Multisystem surveillance** at diagnosis: echocardiography for AV canal/CHD, evaluation for duodenal atresia, baseline blood count for transient myelopoiesis/leukaemia, **thyroid function**, screening for **celiac disease**, hearing/vision, and caution regarding **atlanto-axial instability** (cervical-spine assessment before anaesthesia or sport).
- ▶ **Management is largely supportive:** surgical correction of duodenal atresia and congenital heart disease as in any patient; no medical therapy alters the neurodevelopmental or neurodegenerative course, and **antioxidant supplementation has shown no benefit** (CMDT).
- ▶ **Genetic counselling** for parents on recurrence risk and prenatal options in future pregnancies is essential.

High-yield exam pointers

- ▶ Commonest **autosomal aneuploidy**; birth incidence $\sim 1/700$; $\sim 0.5\%$ of conceptions are trisomic for 21.
- ▶ Three mechanisms: **free trisomy** $\sim 95\%$ (**meiotic non-disjunction**, **maternal age-dependent**), **Robertsonian translocation** $\sim 4\%$ (**familial**, **age-independent**), **mosaic** $\sim 1-2\%$.
- ▶ **Advanced maternal age** is the key risk factor; by age 45 ≈ 1 in 40; **paternal age does not increase risk**.
- ▶ **CHD** in $\sim 50\%$, classically **AV (endocardial) canal defect**; **GI: duodenal atresia** (“double-bubble”).
- ▶ **Haematology: transient abnormal myelopoiesis** in neonates; increased **ALL and AML (ML-DS)** in childhood.
- ▶ Classic signs: hypotonia, **single palmar crease**, epicanthal folds, Brushfield spots, protruding tongue, clinodactyly, sandal gap.
- ▶ **Triplicated APP gene (chromosome 21) $\rightarrow$ early Alzheimer dementia** by the 4th–5th decade; life expectancy ~ 55 years.
- ▶ **Cytogenomic/karyotype analysis is mandatory** to detect unbalanced translocation and guide recurrence-risk counselling.
- ▶ Prenatal: **multiple-marker serum screen + nuchal translucency + nasal bone**, confirmed by **cffDNA (NIPT)** and **amniocentesis/CVS karyotype**.

SOURCE & COVERAGE

- ▶ **Harrison’s Principles of Internal Medicine, 22e** — “Principles of Human Genetics” (chromosomal/cytogenetic disorders: aneuploidy, non-disjunction, Robertsonian translocation, mosaicism, indications for cytogenetic analysis); “The Integration of Inherited Genetics into Clinical Practice”; “Alzheimer’s Disease and Other Dementias” (*APP*/chromosome-21 mechanism); “Myelodysplastic Syndromes” (Down syndrome predisposition).
- ▶ **CMDT 2026** — “Genetic & Genomic Disorders: Down Syndrome” (incidence, maternal-age risk, screening, clinical features, leukaemia, dementia, karyotype/counselling, management).

Coverage note: Harrison 22e treats chromosomal-syndrome clinical detail sparingly (chromosome-disorder specifics are condensed from earlier editions), so the clinical and screening depth here is drawn mainly from CMDT 2026. The exact mechanism percentages ($\sim 95\%$ free trisomy / $\sim 4\%$ translocation / $\sim 1-2\%$ mosaic), the specific translocation recurrence-risk figures, the “21q22 Down syndrome critical region”, and several classic dysmorphic eponyms (Brushfield spots, clinodactyly, sandal gap) are universally accepted standard genetics not all stated verbatim in the available corpus; CMDT confirms the translocation/recurrence principle,

the single palmar crease, flat occiput, epicanthal folds, large tongue and 50% CHD/AV-canal figure.

Effects of Disease on Drug Concentration and Response

Asked in: Paper I Jul 2020 — RGUHS MD General Medicine

Definition / Introduction — The response to a drug is the product of two linked processes: **pharmacokinetics** (the relationship between dose and plasma/tissue concentration, governed by absorption, distribution, metabolism and excretion — ADME) and **pharmacodynamics** (the relationship between concentration and effect at the molecular target). Concurrent disease can perturb *either* arm, shifting the position of the dose–response curve relative to the **therapeutic window** and thereby causing toxicity or loss of efficacy at conventional doses. A useful unifying idea is that disease modulates drug action by altering the **expression or function of the genes whose products determine PK and PD** — the same framework underlying pharmacogenomics. The clinically dominant disease states are **renal failure, hepatic disease, heart failure/shock, altered protein-binding (acute illness)**, and the physiologically “disease-like” extremes of **age**.

Conceptual framework — why disease matters

- ▶ **The therapeutic ratio (index/window)**: the separation between the dose–concentration curve for the *desired* effect and that for *toxicity* (Fig. 71-1). Disease that raises free drug concentration or sensitises the target effectively *narrows* this window; the danger is greatest for drugs with an intrinsically **narrow therapeutic index** (digoxin, phenytoin, aminoglycosides, vancomycin, warfarin, lithium, antiarrhythmics).
- ▶ **“High-risk pharmacokinetics”**: when active drug concentration depends on a **single** elimination pathway, any disease (or genetic/drug-interaction) inhibiting that pathway produces large, often dangerous swings in concentration. Drugs cleared by **multiple** pathways are relatively protected.
- ▶ **Free vs total drug**: only **unbound** drug is pharmacologically active. Because response tracks free concentration, disease-induced changes in protein binding can dissociate the *total* (measured) level from the *active* level — pivotal for highly bound drugs.
- ▶ **Both PK and PD shift**: disease may change concentration (PK) *and* independently alter target sensitivity (PD), e.g. receptor up-/down-regulation, ion-channel modulation by ischaemia/electrolytes.

Disease → mechanism → consequence (master table)

Disease state	Dominant PK/PD change	Net effect on drug	Illustrative drugs
Renal failure	↓ renal excretion of drug/active metabolite; altered binding in uraemia	↑ levels, accumulation, ADR	Digoxin; dofetilide, sotalol (QT/arrhythmia); normeperidine (seizures); edoxaban
Hepatic disease (cirrhosis)	↓ first-pass metabolism, portacaval shunting, ↓ hepatocyte function; ↓ albumin	↑ oral bioavailability; ↑ free drug	Morphine, meperidine, midazolam, nifedipine (bioavailability ~doubled)
Heart failure / shock	Redistribution of CO; ↓ Vd; ↓ hepatic & renal perfusion; ↓ gut perfusion	↑ plasma & CNS/cardiac levels; ↓ clearance; ↓ oral absorption	Lidocaine, digoxin; orally administered drugs (reduced effect)
Acute illness (MI, infection, surgery)	↑ acute-phase reactant binding (transient)	↓ free drug → ↓ efficacy	Drugs bound to α1-acid glycoprotein
Chronic kidney/liver disease	↓ albumin → ↓ binding	↑ free drug → ↑ effect/toxicity	Phenytoin (monitor <i>free</i> level)
Elderly / children	Altered organ maturity/decline, body-compartment size, polypharmacy	Variable; ↑ ADRs	Long- $t_{1/2}$ benzodiazepines (falls/hip fracture)

Renal disease

- ▶ If a drug or its active metabolite is mainly renally excreted and high levels cause ADRs (“high-risk pharmacokinetics”), the **dose or dosing interval must be reduced** in renal dysfunction to avoid toxicity.
- ▶ **Digoxin** is the classic example. **Dofetilide** and **sotalol** undergo predominant renal excretion and risk **QT prolongation and torsades** if not dose-reduced.
- ▶ **Active/toxic metabolites accumulate** even when the parent is hepatically cleared: **meperidine** (**pethidine**) is largely metabolised by the liver, but its metabolite **normeperidine** is renally excreted and accumulates in renal failure, producing **CNS excitation** — **irritability, twitching, seizures**.
- ▶ **Anticoagulants**: at approved doses **edoxaban** appears *more* effective in mild renal dysfunction, possibly reflecting higher drug levels — a caution against assuming “lower function is always safer.”
- ▶ **Binding**: **uraemia** alters **protein binding** of some drugs (e.g. **phenytoin**), so measuring the **free concentration** is preferable.

- ▶ **Practical dose adjustment** is based on the severity of dysfunction indexed by **creatinine clearance** (estimated in standard practice by the *Cockcroft–Gault* equation); published dose/interval tables give only a **first approximation** that must be refined with plasma-level data (where available) and clinical observation.

Hepatic disease

- ▶ **Standard liver-function tests do NOT predict** the need for dose adjustment in hepatitis or cirrhosis (a key exam point) — there is no hepatic equivalent of creatinine clearance; severity tools such as the *Child–Pugh* score are used clinically but no test reliably quantifies metabolic capacity.
- ▶ **Loss of first-pass (presystemic) metabolism** is the central effect: disrupted hepatocyte function, altered liver architecture and portacaval shunts mean orally administered drug bypasses hepatic extraction.
- ▶ For **high first-pass drugs** — morphine, meperidine, midazolam, nifedipine — **oral bioavailability is almost doubled** in cirrhosis versus normal liver. Therefore the **oral dose should be reduced**.
- ▶ Reduced albumin synthesis further **lowers protein binding**, raising free drug.

Heart failure and shock (circulatory failure)

- ▶ With **reduced tissue perfusion**, cardiac output is **redistributed** to protect heart and brain at the expense of other tissues.
- ▶ Consequences: drug distributes into a **smaller volume of distribution** → **higher plasma concentrations**, and the well-perfused **brain and heart are exposed to these higher levels** → exaggerated CNS or cardiac effects (e.g. lidocaine, digoxin toxicity).
- ▶ **Reduced renal and hepatic perfusion impairs clearance**; **reduced gut perfusion impairs absorption**, so orally administered drugs may have **reduced or absent effect** — favour the IV route in shock.

Altered protein binding and acute-phase states

- ▶ Many drugs circulate **partly bound to plasma proteins**; only free drug acts.
- ▶ In **chronic kidney or liver disease**, binding falls and **drug action increases**; in MI, infection or surgery, acute-phase reactants **transiently increase binding and decrease efficacy**.
- ▶ The effect is greatest for **highly bound drugs**: a fall in binding from **99% to 98% doubles the free fraction** (1% → 2%) — a quantitative pearl. Hence for **phenytoin**, monitor **free** rather than total concentration.

Disease-modified pharmacodynamics (same concentration, different effect)

- ▶ A drug may produce **no action or a different spectrum** in disease versus health, and disease can confound interpretation of ADRs (e.g. worsening dyspnoea on **amiodarone** in chronic lung disease may be drug, disease, or intercurrent illness — favour alternative antiarrhythmics).
- ▶ The drug–receptor interaction sits in a **dynamic biologic milieu**: **ion-channel blockade** (anticonvulsant/antiarrhythmic) is modulated by **membrane potential**, itself altered by **extracellular potassium and local ischaemia**.
- ▶ **Receptors are up-/down-regulated** by disease or by the drug: chronic **β -blockade up-regulates β -receptor density**, so abrupt withdrawal can precipitate rebound hypertension/tachycardia.

Extremes of age (physiologically “disease-like”)

- ▶ **Elderly**: multiple pathologies, **polypharmacy**, and decline of disposition organs → more interactions and ADRs. **Start below the usual adult dose and titrate slowly**; minimise drug number and doses/day. Long- $t_{1/2}$ **benzodiazepines** are linked to **hip fractures** (falls from sedation plus osteoporosis).
- ▶ **Children**: metabolism and response pathways **mature at different rates**; body-compartment sizes change. With limited evidence, doses are scaled to **weight or body surface area** as a first approximation unless age-specific data exist.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Therapeutic-ratio dose–response curves** (Fig. 71-1): two panels, x-axis *Dose or concentration*, y-axis *Probability of drug response (0–100%)*; plot a *Desired effect* curve and an *Adverse effect* curve. Label **Top = wide therapeutic ratio** (well-separated curves) and **Bottom = narrow therapeutic ratio** (overlapping curves); annotate the gap as the **therapeutic window**, and show how disease “shifts the adverse curve left.”
- ▶ **Presystemic (first-pass) elimination schematic** (Fig. 71-3): *Orally administered drug* → *Intestinal lumen* → *Enterocyte* (with **P-glycoprotein efflux** back to lumen and **metabolite** formation) → *Portal vein* → *Hepatocyte* (with **biliary canaliculus/bile** excretion and **metabolism**) → *Systemic circulation*. Annotate “**cirrhosis/portacaval shunt** → **first-pass lost** → **↑ oral bioavailability**.”

Clinical / Diagnostic significance

- ▶ **Therapeutic drug monitoring (TDM)** is the practical tool when disease distorts PK — useful for **anticonvulsants, antiarrhythmics, antirejection agents, aminoglycosides/vancomycin, digoxin, lithium**; measure **trough** for efficacy/toxicity (e.g. vancomycin nephrotoxicity) and **peak** (1–2 h) when targeting a peak effect (e.g. QT on sotalol/dofetilide).
- ▶ Prefer **free-drug levels** in hypoalbuminaemia/uraemia (phenytoin).

- ▶ Recognise **reactive-metabolite toxicity** amplified by disease/co-medication: **acetaminophen** hepatotoxicity follows glutathione depletion — risk ↑ with **enzyme inducers** (**phenobarbital**, **phenytoin**) and **ethanol**; treat with **N-acetylcysteine**.
- ▶ **Classify the ADR:** *Type A* (dose-dependent extension of pharmacology — bleeding on anticoagulants) versus *Type B* (dose-independent, often immunologic — SJS/TEN, DRESS, anaphylaxis).
- ▶ In shock/HF, **give drugs IV**, reduce loading where Vd is contracted, and re-check renal/hepatic function as perfusion changes.

High-yield exam pointers

- ▶ Response tracks **free, not total drug**; **99%→98% binding doubles free drug**.
- ▶ **Renal disease:** dose-reduce renally cleared, narrow-window drugs — **digoxin**, **dofetilide**, **sotalol**; beware **normeperidine** seizures.
- ▶ **Liver disease:** LFTs don't guide dosing; first-pass falls, so oral bioavailability of **morphine/meperidine/midazolam/nifedipine ~doubles** → cut the oral dose.
- ▶ **Heart failure/shock:** ↓ Vd + ↓ clearance → **higher plasma & CNS/cardiac levels**; gut hypoperfusion blunts oral absorption.
- ▶ **Acute-phase states** (MI, infection, surgery) transiently ↑ **binding** → ↓ efficacy.
- ▶ “**High-risk pharmacokinetics**” = single-pathway elimination + narrow window = dramatic disease-related toxicity.
- ▶ **β-blocker withdrawal** rebound reflects disease/drug **receptor up-regulation** (a PD effect).
- ▶ **Elderly:** “start low, go slow”, minimise polypharmacy; long-t_{1/2} benzodiazepines → hip fractures.
- ▶ Adjust by **creatinine clearance (Cockcroft–Gault)**, then confirm with TDM and clinical response.

SOURCE & COVERAGE

- ▶ **Harrison's Principles of Internal Medicine, 22e** — “*Principles of Clinical Pharmacology*” (sections: Effects of Disease on Drug Concentration and Response — Renal disease, Liver disease, Heart failure and shock, Drug use in the elderly/children; Principles of Pharmacokinetics — protein binding, clearance, half-life, high-risk pharmacokinetics; Principles of Pharmacodynamics; Adverse Drug Reactions; Tables 71-1 and 71-2) and adjacent “*Pharmacogenomics*” for the gene-function framework.
- ▶ **Coverage note:** This is a single-chapter clinical-pharmacology topic and is covered well by Harrison 22e; the spec lists no dedicated subspecialty text and no CMDT chapter. *Cockcroft–Gault* (for creatinine-clearance estimation) and *Child–Pugh* (as the clinical hepatic-severity tool) are added as universally accepted standard internal medicine —

Harrison here specifies “creatinine clearance”-based renal dose adjustment and explicitly states that standard liver-function tests do **not** guide hepatic dose adjustment.

ELISA principle, methods and applications

Asked in: Paper I May 2022 — RGUHS MD General Medicine

Definition / Introduction — The **Enzyme-Linked Immunosorbent Assay (ELISA)** is a *solid-phase immunoassay* that detects and quantifies an antigen or antibody by exploiting the highly specific antigen–antibody reaction, using an **enzyme-labelled reagent (conjugate)** that converts a colourless **chromogenic substrate** into a coloured product. The intensity of colour, read as **optical density (OD)** in a spectrophotometer, is proportional to the quantity of analyte. First described by *Engvall and Perlmann* and independently by *Van Weemen and Schuurs* (1971), ELISA replaced radioimmunoassay (RIA) because it gives comparable sensitivity without radioactive hazard. It is the workhorse screening and quantitative assay of clinical immunology, serology and endocrinology.

Immunological basis (the principle)

- ▶ ELISA depends entirely on the **specificity of the antibody–antigen bond**. Each B cell makes a **single antibody specificity**, and the **variable regions (VL and VH) form the antigen-binding (Fab) site**; within these are *hypervariable regions* that constitute the unique antigen-combining site (the *idiotype*) — this is what confers assay specificity.
- ▶ An antigen presents distinct **antigenic determinants (epitopes)**; an antibody is directed against one such epitope. *Sandwich* assays require an antigen large enough to carry **≥2 epitopes** so that capture and detector antibodies bind simultaneously.
- ▶ High assay sensitivity reflects **high-affinity antibodies** generated in vivo by *somatic hypermutation and affinity maturation*; reagent antibodies are often **monoclonal antibodies** (hybridoma technology), which provide a single, reproducible, well-defined specificity.
- ▶ The **enzyme label amplifies the signal**: one bound enzyme molecule turns over many substrate molecules, magnifying a small number of antigen–antibody complexes into a visible/measurable colour.

Components / reagents

- ▶ **Solid phase** — 96-well polystyrene microtitre plate (also beads, membranes) that adsorbs protein.
- ▶ **Capture reagent** — antigen (to detect antibody) or antibody (to detect antigen) coated on the well.
- ▶ **Enzyme conjugate** — antibody covalently linked to an enzyme.

- ▶ **Substrate / chromogen** — converted by the enzyme into a coloured product.
- ▶ **Blocking agent** — bovine serum albumin (BSA), casein or non-fat milk to saturate free sites and prevent non-specific binding.
- ▶ **Wash buffer** — phosphate-buffered saline with Tween-20 (PBS-T) to remove unbound reagents between steps.
- ▶ **Stop solution** — e.g., dilute sulphuric acid to halt the colour reaction.
- ▶ **Read-out** — ELISA plate reader (spectrophotometer) measuring OD at a defined wavelength.

Enzyme label	Common substrate / chromogen	Colour & read wavelength
Horseradish peroxidase (HRP)	TMB (tetramethylbenzidine); OPD; ABTS	blue → yellow on acid stop, read ~450 nm
Alkaline phosphatase (ALP)	p-nitrophenyl phosphate (pNPP)	yellow, read ~405 nm
β-galactosidase	ONPG / fluorogenic substrates	yellow / fluorescent

Types of ELISA

Type	What is coated	Detection step	Main use / notes
Direct	Antigen	Enzyme-labelled <i>primary</i> antibody binds antigen directly	Fewest steps, low cross-reactivity; less sensitive, each antibody must be labelled
Indirect	Antigen	Unlabelled primary (test) antibody, then enzyme-labelled anti-Ig secondary	Detects/quantifies antibody in serum (e.g., HIV, viral serology); signal amplified, one conjugate serves many tests
Sandwich (capture)	Capture antibody	Antigen bound, then enzyme-labelled detector antibody to a second epitope	Quantifies antigen ; needs multivalent antigen (≥2 epitopes); high sensitivity & specificity
Competitive / inhibition	Antibody (or antigen)	Sample analyte competes with labelled analyte for limited binding sites	For small antigens/haptens (single epitope: drugs, steroid hormones); signal is inversely proportional to analyte

- ▶ **Related variant** — ELISPOT: detects individual cytokine-secreting cells (e.g., IFN-γ-releasing T cells); the basis of some interferon-gamma release assays for tuberculosis.

Methodology (sandwich ELISA, stepwise)

- ▶ 1. **Coating** — adsorb capture antibody onto wells; incubate.
- ▶ 2. **Wash** — remove unbound antibody.
- ▶ 3. **Block** — add BSA to saturate remaining binding sites.
- ▶ 4. **Add sample** — patient serum/plasma; target antigen is captured; incubate, then wash off unbound material.
- ▶ 5. **Add conjugate** — enzyme-labelled detector antibody binds a second epitope of the captured antigen; incubate, wash.
- ▶ 6. **Add substrate/chromogen** — enzyme generates a coloured product over a timed interval.
- ▶ 7. **Stop** — add acid stop solution.
- ▶ 8. **Read & interpret** — measure OD in a plate reader; **quantitative** assays read against a *standard curve*; **qualitative** assays compare OD against a pre-set *cut-off* (positive vs negative). Each run includes positive, negative and blank controls.

Applications

- ▶ **Infectious-disease serology / screening:** HIV (modern *4th-generation combo* assays detect **p24 antigen + anti-HIV antibody**), hepatitis B (HBsAg, anti-HBc, anti-HBs), hepatitis C antibody, dengue (NS1 antigen, IgM/IgG), leptospirosis, syphilis, *H. pylori*, SARS-CoV-2 antibody.
- ▶ **Acute vs past infection:** IgM-capture (MAC-) ELISA detects recent infection because **IgM is the first antibody of the primary response**; IgG reflects past infection or immunity (*secondary antibody response*).
- ▶ **Endocrine / hormone assays:** hCG (pregnancy test), TSH, insulin, cortisol, thyroid hormones.
- ▶ **Tumour markers:** PSA, CEA, AFP, CA-125.
- ▶ **Autoantibodies:** ANA, anti-dsDNA, anti-CCP, ANCA, anti-TPO.
- ▶ **Allergy:** allergen-specific IgE.
- ▶ **Others:** cytokines, cardiac troponin, D-dimer, therapeutic-drug and toxicology monitoring, food/veterinary testing.

Advantages and limitations

- ▶ **Advantages:** high sensitivity and specificity; **safe** (no radioisotopes, unlike RIA); inexpensive and rapid; **high-throughput and automatable** (96-well plates, plate readers); both **qualitative and quantitative**; stable reagents and long enzyme-conjugate shelf life.
- ▶ **Limitations:** **false positives** from cross-reactivity/non-specific binding (mandating confirmatory testing); **false negatives** in the pre-seroconversion *window period*; the **hook/prozone effect** in sandwich assays; sensitive to technical error (inadequate washing, pipetting, incubation timing); a positive antibody result indicates exposure but **does not by itself distinguish active from past infection** (resolved by IgM-capture format or antigen/NAT testing).

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Sandwich ELISA schematic** — labels: *microtitre well (solid phase), capture antibody, antigen (analyte), enzyme-labelled detector antibody, enzyme, chromogenic substrate, coloured product, read OD in plate reader.*
- ▶ **Indirect ELISA schematic** — labels: *well coated with antigen, patient serum antibody (primary), enzyme-conjugated anti-human Ig (secondary), substrate → colour; alongside a small bar of the 4 ELISA types (direct, indirect, sandwich, competitive).*

Clinical / Diagnostic significance

- ▶ **Screening tool:** because of its **high sensitivity**, ELISA is the first-line *screening* test (e.g., HIV); reactive results are confirmed by a more specific assay (Western blot / line immunoassay / NAT) to exclude false positives.
- ▶ **Window period:** antibody-based ELISA can be falsely negative early in infection before seroconversion; **antigen detection** (HIV p24, dengue NS1) or nucleic-acid testing covers this gap — the rationale for combined Ag/Ab assays.
- ▶ **Quantitation & monitoring:** quantitative ELISA against a standard curve allows titres/levels to be followed (hormones, tumour markers, antibody titres).
- ▶ **Hook (prozone) effect:** in sandwich assays a *very high* antigen concentration can paradoxically lower the signal and give a falsely low/negative result — suspect when the clinical picture mismatches the result; re-test with dilution.
- ▶ **Confirmation principle:** a sensitive screen (ELISA) followed by a specific confirmatory test minimises both false negatives (missed disease) and false positives (mislabelling).

High-yield exam pointers

- ▶ **ELISA = Enzyme-Linked Immunosorbent Assay**, a *solid-phase immunoassay*; Engvall & Perlmann, 1971; replaced RIA (no radioactivity).
- ▶ Principle: **antigen-antibody specificity + enzyme-amplified colorimetric read-out** ($OD \propto \text{analyte}$).
- ▶ Four types: **direct, indirect, sandwich, competitive** — *indirect = detect antibody, sandwich = detect/quantify antigen, competitive = small haptens (signal inversely proportional).*
- ▶ Common enzymes: **HRP** (substrate **TMB**, read 450 nm) and **ALP** (substrate **pNPP**, read 405 nm).
- ▶ Sandwich ELISA needs an antigen with ≥ 2 **epitopes**; reagent antibodies are often **monoclonal**.
- ▶ Classic use: **HIV screening** (4th-gen combo = p24 Ag + Ab), confirmed by Western blot.
- ▶ **IgM-capture ELISA = acute/recent infection** (IgM is the first antibody); **IgG = past/immune**.
- ▶ Pitfalls: false negative in **window period**; **hook/prozone effect** at very high antigen.

- Advantages: sensitive, specific, safe, cheap, rapid, **high-throughput/automatable**; ELISPOT detects single cytokine-secreting cells.

SOURCE & COVERAGE

Harrison 22e — Ch 360 “Introduction to the Immune System” (immunological basis: antibody–antigen specificity, Fab/variable-region antigen binding, idiotype, affinity maturation, monoclonal antibody technology, Ig structure, IgM primary vs IgG secondary antibody response). **Coverage note (gap):** Harrison Ch 360 does **not** describe the ELISA technique itself — assay formats (direct/indirect/sandwich/competitive), enzyme–substrate systems (HRP/TMB, ALP/pNPP), the stepwise methodology, the hook effect, and named clinical applications (HIV/HBV/HCV/dengue serology, hormone and tumour-marker assays) are drawn from standard, universally accepted laboratory/clinical-immunology knowledge and are not citable to the provided chapter. Only the underlying immunology is source-grounded.

Epigenetics

Asked in: Paper I Nov 2021 · Paper I May 2019 (2×) — RGUHS MD General Medicine

Definition / Introduction — The term *epigenetics* (Greek *epi-* = “over, around”), coined by *Conrad Waddington* in 1942, denotes the heritable and reversible mechanisms by which **gene expression and phenotype are altered without any change in the underlying DNA nucleotide sequence**. The *epigenome* is the constellation of covalent modifications of DNA and histones — plus non-coding RNAs — that determine chromatin structure and hence the cell’s transcriptome and proteome. Although all somatic cells carry an essentially identical genome, sex-, tissue- and environment-dependent epigenetic marks generate cell-type specificity, and their dysregulation underlies imprinting disorders, cancer, ageing and neuropsychiatric disease.

Biochemical basis — the three core mechanisms

Fundamental to epigenetic regulation is packaging of the genome into **chromatin**. The basic unit is the **nucleosome** — 147 base pairs of DNA wrapped around an octamer of 8 histones (two copies each of the core histones **H2A, H2B, H3, H4**). Compaction governs accessibility to transcription factors and repair machinery: *euchromatin* (open) is transcriptionally active, *heterochromatin* (compacted) is repressed. Three processes regulate compaction:

Mechanism	Key players	Functional output
DNA methylation	Cytosine methylation of CpG dinucleotides (5-mC); written de novo by DNMT3A/3B, maintained after replication by	Promoter CpG-island methylation → gene silencing ; CpG islands normally

Mechanism	Key players	Functional output
	DNMT1; reversed via TET1–3 oxidation (5-mC→5-hmC→5-fC→5-caC)	unmethylated to permit transcription
Histone post-translational modifications (hPTMs)	≥60 covalent marks added by writers , removed by erasers , recognised by readers	Acetylation (KATs/HATs add; HDACs + NAD ⁺ -dependent sirtuins remove) loosens chromatin → activation; lysine methylation (KMTs) gives context-specific output
Nucleosome remodelling	ATP-dependent SWI/SNF, ISWI, INO80 families; histone variants H2AZ (start sites), H3.3 (gene bodies)	Reposition/evict nucleosomes; activate or repress transcription

- ▶ **Acetylation** of H3K9ac and H3K27ac → transcriptional activation (neutralises lysine positive charge, creating a reader-binding surface); dynamic and rapidly reversed by HDACs.
- ▶ **Lysine methylation** gives a “histone code”: *activating* marks = **H3K4me3**, **H3K36me3**, **H3K79me3**; *repressive* = **H3K27me3**; *repeat/centromeric silencing* = **H3K9me3**. Methylation is more stable than acetylation and its output depends purely on effector (reader) binding.
- ▶ Other marks: phosphorylation of **H2A at Ser139 (γH2A.X)** flags DNA double-strand breaks; ubiquitination, SUMOylation (repression) and PARP-mediated ADP-ribosylation also signal on chromatin.
- ▶ **RNA epigenetics (epitranscriptomics)**: reversible **m6A** methylation of mRNA by writers METTL3/METTL14 and demethylases ALKBH5/FTO controls mRNA fate (degradation vs translation).

Physiological epigenetic phenomena

- ▶ **X-chromosome inactivation (Lyonisation)**: dosage compensation silencing one of the two X chromosomes in females, mediated by the **Xist** long non-coding RNA; the inactive X is highly methylated with low histone acetylation. Choice of X is random but then stably transmitted through cell division; ~15% of X genes escape inactivation.
- ▶ **Genomic imprinting**: monoallelic, parent-of-origin-specific expression of a small subset of autosomal genes, mediated by allele-specific DNA methylation. The imprint is **reset in the germline** in a sex-specific manner and maintained lifelong.
- ▶ **Bivalent chromatin** in embryonic stem cells: developmental genes carry both activating **H3K4me3** and repressive **H3K27me3** (“poised”), resolving to one mark on differentiation. **H3K9me3** heterochromatin (via SUV39H1) is an epigenetic barrier to reprogramming into iPSCs.

- ▶ **Environmental integration:** diet alters chromatin — acetyl-CoA (from ACLY/ACSS2/PDH) is the best predictor of histone acetylation; **S-adenosylmethionine (SAM)** is the universal methyl donor for DNA/histone methylation, linking folate/methionine status to the epigenome.

Epigenetics in disease

- ▶ **Cancer — a combined genetic + epigenetic disease.** The first epigenetic driver, the remodeller **SMARCB1**, was identified in malignant rhabdoid tumours (1998); TCGA shows **25–30% of cancer driver mutations occur in chromatin-regulatory proteins** (e.g. **MLL3/MLL4**, **EP300/CBP**, **SMARCA4**, **ARID1A** — mostly loss-of-function). **EZH2** (H3K27me3 writer) is an oncogene over-expressed in breast/prostate/melanoma. “**Oncohistones**” — **H3.3 K27M** in paediatric high-grade glioma and **K36M** in chondroblastoma. **MLL1 (KMT2A)** translocations drive AML and ~80% of infant ALL. Metabolic mutations in **IDH1/2**, **FH**, **SDH** generate 2-hydroxyglutarate/fumarate/succinate that inhibit α -KG-dependent demethylases → hypermethylation. Cancer epigenomes show global hypomethylation (genomic instability) with focal CpG-island hypermethylation silencing tumour-suppressors.
- ▶ **Imprinting / uniparental-disomy (UPD) disorders:** **Prader-Willi** (loss of paternal 15q11-13 — deletion, maternal UPD, or imprinting defect) vs **Angelman** (loss of maternal 15q11-13); **Beckwith-Wiedemann syndrome** (overactive **IGF2** / loss of **CDKN1C**; paternal UPD chr 11; overgrowth + Wilms’ tumour risk); **GNAS1** imprinting → pseudohypoparathyroidism Ia (maternal) vs pseudopseudohypoparathyroidism (paternal, *Albright hereditary osteodystrophy*). Hydatidiform mole = exclusively paternal genome; ovarian teratoma = maternal.
- ▶ **Neurodevelopmental / neuropsychiatric:** **Rett syndrome** (X-linked, **MECP2** methyl-CpG-binding protein); **Kabuki syndrome** (**MLL4/KMT2D** or **UTX/KDM6A**); **Rubinstein-Taybi syndrome** (**CBP/CREBBP** acetyltransferase); **Fragile-X** (**FMR1/FMR2** promoter hypermethylation). Hypomethylation of **SNCA** (Parkinson’s) and **APP** (Alzheimer’s), and altered histone acetylation, feature in neurodegeneration; **BDNF** and **REST** are epigenetically regulated in depression/schizophrenia.
- ▶ **Ageing:** progressive heterochromatin loss (reduced **H3K9me3/H3K27me3**), seen severely in **Hutchinson-Gilford progeria** and **Werner syndrome**; the DNA-methylation “clock” predicts chronological age better than telomere length. **NAD⁺-dependent sirtuins** (class III HDACs, e.g. **SIRT1/SIRT6**) mediate caloric-restriction longevity.
- ▶ **Immunity/inflammation:** corticosteroids recruit **HDAC2** to NF- κ B-driven inflammatory promoters in asthma; **FOXP3** and **CTLA4** hypermethylation impairs regulatory T cells in rheumatoid arthritis; “trained immunity” / inflammatory memory is epigenetically encoded.

Tools for studying the epigenome

- ▶ **ChIP-seq** — chromatin immunoprecipitation + sequencing maps genome-wide histone marks and protein-DNA binding.

- ▶ **ATAC-seq** — Tn5 transposase inserts adapters into open chromatin to map accessibility, even single-cell.
- ▶ **CUT&RUN / CUT&Tag** — antibody-tethered MNase or Tn5; fewer cells, lower background, single-cell capable.
- ▶ **Hi-C / 3C and Hi-ChIP** — 3-D genome architecture, enhancer-promoter loops and topologically associated domains (TADs).
- ▶ **CRISPR epigenome editing** — catalytically dead dCas9 fused to a writer/eraser to activate or repress a target gene without cutting DNA.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Nucleosome & chromatin modifications:** DNA double helix wound around the histone octamer (label H2A, H2B, H3, H4, “147 bp”), with N-terminal **histone tails** carrying **acetylation** (Ac, H3K27ac → active) and **methylation** (Me, H3K27me3 → repressed); mark CpG DNA methylation (5-mC); show transition **euchromatin** (open, active) ↔ **heterochromatin** (compact, silent); annotate **Writers / Erasers / Readers** and DNMT1/3A/3B, TET, HATs/HDACs, KMTs/KDMs.
- ▶ **Imprint-reset schematic** (Fig 479-8 style): maternal germline X both alleles unmethylated, paternal germline methylated → reset each generation; label **Prader-Willi** (paternal loss) vs **Angelman** (maternal loss) at 15q11-13.

Clinical / Diagnostic significance

- ▶ **Diagnosis:** methylation-specific PCR / MS-MLPA for Prader-Willi, Angelman, Beckwith-Wiedemann and Fragile-X; epigenomic “cell-of-origin” profiling identifies cancers of unknown primary better than mutation sequencing; DNA-methylation age as a biomarker of biological ageing.
- ▶ **Therapeutics (epigenetic drugs):** DNMT inhibitors *azacitidine* and *decitabine* (global hypomethylation reactivating tumour-suppressors) for MDS and AML; HDAC inhibitors (vorinostat, romidepsin, panobinostat) for cutaneous T-cell lymphoma and multiple myeloma; EZH2 inhibitors (B-cell lymphoma, sarcoma); IDH inhibitors (IDH-mutant AML/glioma); LSD1, DOT1L and MLL1 inhibitors in leukaemias; BET (bromodomain) inhibitors suppress MYC. Reversibility of epigenetic marks is the key therapeutic rationale.
- ▶ **Pearl:** epigenetic therapy is increasingly combinatorial — re-expressing tumour antigens and IFN responses to potentiate chemotherapy and immunotherapy.

High-yield exam pointers

- ▶ Epigenetics = heritable change in gene expression **without** DNA-sequence change; coined by Waddington (1942).

- ▶ Three mechanisms: DNA methylation (CpG/5-mC), histone PTMs (acetylation/methylation), nucleosome remodelling; plus RNA m6A.
- ▶ DNMT1 = maintenance; DNMT3A/3B = de novo; TET enzymes erase methylation.
- ▶ Active marks: H3K4me3, H3K36me3, acetylation; repressive: H3K27me3, H3K9me3, DNA-CpG methylation.
- ▶ X-inactivation via Xist lncRNA; imprinting reset in germline — Prader-Willi (paternal), Angelman (maternal), Beckwith-Wiedemann (IGF2).
- ▶ Cancer: 25–30% of driver mutations in chromatin regulators; EZH2 oncogene; oncohistones H3K27M/H3K36M; IDH/FH/SDH → hypermethylation.
- ▶ Epigenetic drugs: azacitidine/decitabine (DNMTi), vorinostat/romidepsin (HDACi), EZH2/IDH/BET inhibitors — exploit reversibility.
- ▶ Disease links: Rett (MECP2), Fragile-X (FMR1), Rubinstein-Taybi (CREBBP), Kabuki (KMT2D/KDM6A), ageing methylation clock, progeria H3K9me3 loss.

SOURCE & COVERAGE

- ▶ Harrison's Principles of Internal Medicine, 22e — "The Role of Epigenetics in Disease and Treatment" (biochemical bases, writers/erasers/readers, tools, cancer/ageing/brain/immunity epigenetics, epigenetic drugs).
- ▶ Harrison's Principles of Internal Medicine, 22e — "Principles of Human Genetics" (X-inactivation/Xist, genomic imprinting, imprint reset, uniparental disomy, Prader-Willi/Angelman/Beckwith-Wiedemann, GNAS1, Rett, cancer methylation).

Coverage note: This topic has no dedicated subspecialty textbook in the corpus and is not a CMDT topic; grounding is the two Harrison chapters above, which cover the ask comprehensively. Specific drug indications and disease-gene associations are taken verbatim from those chapters.

Extraocular muscles and their movements. Write a note on Superior orbital fissure syndrome

Asked in: Paper I Nov 2022 — RGUHS MD General Medicine

Definition / Introduction — Each eye is moved by **six extraocular muscles (EOMs)** — four recti (superior, inferior, medial, lateral) and two obliques (superior, inferior) — supplied by the **oculomotor (III), trochlear (IV) and abducens (VI)** cranial nerves arising from their brainstem nuclei. Their coordinated action keeps the image of a target on the fovea (*foveation*) and maintains binocular single vision. The **superior orbital fissure (SOF)** is the cleft between the greater and lesser wings of the sphenoid through which III, IV, VI and the ophthalmic division (V1) of the trigeminal nerve enter the

orbit; its compromise produces a characteristic **painful ophthalmoplegia** with **V1 sensory loss** but **preserved vision** — the *superior orbital fissure syndrome*.

Extraocular muscles — innervation and actions

Muscle	Cranial nerve	Primary action	Secondary actions
Medial rectus	III (inferior division)	Adduction	—
Lateral rectus	VI	Abduction	—
Superior rectus	III (superior division)	Elevation (in abduction)	Adduction, intorsion
Inferior rectus	III (inferior division)	Depression (in abduction)	Adduction, extorsion
Superior oblique	IV	Intorsion; depression (in adduction)	Abduction
Inferior oblique	III (inferior division)	Extorsion; elevation (in adduction)	Abduction

- ▶ Mnemonic for innervation: **LR6 SO4, rest 3** — Lateral Rectus by VI, Superior Oblique by IV, the remaining four EOMs (plus levator palpebrae superioris and the pupillary sphincter/ciliary muscle) by III.
- ▶ The **oculomotor nerve** also supplies the **levator palpebrae superioris** (lid elevation) and, via its parasympathetic component, the **iris sphincter** and **ciliary muscle** (pupil constriction, accommodation).
- ▶ The **vertical recti** act best as pure elevators/depressors when the eye is **abducted**; the **obliques** act best when the eye is **adducted** (superior oblique = main depressor in adduction; inferior oblique = main elevator in adduction). This underlies the *cardinal positions* used to isolate weak muscles.

Movements of the eye and their neural control

- ▶ **Terminology:** *ductions* are monocular movements; *versions* are conjugate (both eyes same direction); *vergences* are disjunctive (convergence/divergence). The clinician tests the six **cardinal positions of gaze** to identify a paretic muscle, aided by yoke-muscle pairing (e.g., right lateral rectus pairs with left medial rectus on right gaze).
- ▶ **Classes of movement** (Harrison): **saccades** (rapid refixation), **smooth pursuit** (tracking a moving target), and **gaze stabilization / optokinetic reflexes** during head and body movement. These are coordinated by pontine–midbrain centres under descending **supranuclear** input from frontal and parieto-occipital cortex.
- ▶ **Horizontal gaze:** the **paramedian pontine reticular formation (PPRF)** drives the ipsilateral abducens nucleus; abducens interneurons cross via the **medial longitudinal fasciculus (MLF)** to the contralateral medial rectus subnucleus, yoking abduction of one eye with adduction of the other.

- ▶ **Internuclear ophthalmoplegia (INO):** an MLF lesion causes **failure of adduction** of the ipsilateral eye on lateral gaze with nystagmus of the abducting eye; **multiple sclerosis** is the commonest cause. The **frontal eye field** generates contralateral saccades.

Ocular motor nerve palsies — clinical correlation

- ▶ **Oculomotor (III) palsy:** ptosis, a **dilated pupil**, and the eye resting “**down and out**” (unopposed lateral rectus + superior oblique). A **pupil-involving, painful III palsy** suggests a **compressive lesion (posterior communicating artery aneurysm/tumour)** — demands urgent CT/MR angiography. A **pupil-sparing III palsy** is usually **microvascular** (diabetes, hypertension) and recovers spontaneously. *Aberrant regeneration* (lid elevation/pupil constriction on adduction or downgaze) follows trauma/compression, never microvascular infarct.
- ▶ **Trochlear (IV) palsy:** **vertical diplopia** worse on reading/downgaze, with **hypertropia and excyclotorsion**; the **Bielschowsky head-tilt test** (diplopia worse on tilting toward the affected side) is the cardinal sign. The IV nerve is uniquely vulnerable to **closed head trauma**.
- ▶ **Abducens (VI) palsy:** **horizontal diplopia** worse on gaze toward the lesion (failure of abduction). A **classic false-localising sign of raised intracranial pressure**; at the petrous apex, mastoiditis causes deafness, pain and VI palsy (**Gradenigo’s syndrome**).
- ▶ **Localising clue:** multiple ocular-motor palsies should never be ascribed to chance microvascular events — neuroimaging must target the **cavernous sinus, superior orbital fissure and orbital apex**, where III, IV, V1 and VI lie in close proximity.

Superior orbital fissure syndrome — anatomy, features and causes

- ▶ **Structures traversing the SOF:** oculomotor nerve (superior and inferior divisions), trochlear (IV), abducens (VI), the three branches of the **ophthalmic division (V1)** — lacrimal, frontal and nasociliary — the **superior ophthalmic vein**, and **sympathetic fibres**. *Crucially, the optic nerve (II) and ophthalmic artery pass through the separate optic canal, not the SOF**.*
- ▶ **Clinical features (Harrison Table 452-2 — “Sphenoid fissure / superior orbital”):** involvement of III, IV, VI and first division of V (V1) producing:
 - **Total external ophthalmoplegia** — globe fixed in central position with diplopia.
 - **Ptosis** (III → levator palpebrae) and a **fixed, dilated, unreactive pupil** (parasympathetic III involvement = internal ophthalmoplegia).
 - **Proptosis** (orbital congestion / superior ophthalmic vein obstruction).
 - **V1 sensory loss** over forehead, upper eyelid and cornea with an **absent corneal reflex**; periorbital pain is common.
 - **Vision is preserved** because the optic nerve is spared — the key sign distinguishing SOF syndrome from **orbital apex syndrome**.

- **Causes (Harrison):** invasive tumours of the sphenoid bone and aneurysms. Other standard causes: trauma (sphenoid/orbital fractures), neoplasms (meningioma, nasopharyngeal carcinoma, metastases), infections (including mucormycosis in diabetics), and idiopathic **granulomatous inflammation (Tolosa-Hunt syndrome)** — the latter is a painful ophthalmoplegia that is dramatically responsive to glucocorticoids.

Superior orbital fissure vs orbital apex vs cavernous sinus syndromes

Feature	SOF syndrome	Orbital apex syndrome	Cavernous sinus syndrome
Nerves involved	III, IV, V1, VI	III, IV, V1, VI + II	III, IV, VI, V1 (± V2)
Optic nerve / vision	Spared (vision intact)	Involved → visual loss	Usually spared
Pupil / sympathetics	Fixed dilated (III)	Fixed dilated (III)	III palsy ± Horner's (oculosympathetic)
Proptosis / chemosis	Proptosis ±	Proptosis ±	Prominent (venous occlusion), may be bilateral
Typical causes (Harrison)	Sphenoid tumours; aneurysms	Invasive fungal infection, amyloidosis, granuloma	Thrombosis (orbital cellulitis/ <i>S. aureus</i> , sinusitis, mucormycosis), aneurysm, carotid-cavernous fistula, tumour, Tolosa-Hunt

- The **orbital apex syndrome** is essentially “SOF syndrome **plus optic neuropathy**” — vision loss is the discriminator.
- **Cavernous sinus syndrome** adds V2 involvement, possible **postganglionic Horner's** (sympathetic plexus on the carotid), prominent **chemosis/orbital swelling**, and may become **bilateral** via intercavernous channels; a **carotid-cavernous fistula** produces a pulsatile, bruit-positive proptosis.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- **Diagram 1** — Actions of the six EOMs (right eye, “flower” diagram): central circle for the eye with eight radiating arrows labelled Superior rectus (up & out), Inferior rectus (down & out), Medial rectus (in/adduction), Lateral rectus (out/abduction), Superior oblique (down in adduction), Inferior oblique (up in adduction); annotate innervation III / IV / VI beside each.
- **Diagram 2** — Coronal section through the superior orbital fissure / cavernous sinus: label Oculomotor (III), Trochlear (IV), Ophthalmic (V1), Maxillary (V2), Abducens (VI), Internal carotid artery, Superior ophthalmic vein, Optic nerve (II) in optic canal

(separate), Annulus of Zinn. Mark that VI and ICA lie within the sinus while III, IV, V1, V2 lie in the lateral wall.

Clinical / Diagnostic significance

- ▶ **Examination:** test the six cardinal positions, **corneal light reflex (Hirschberg)** and the **cover test** (detects deviations as small as 1°); the **red-glass / diplopia chart** localises the paretic muscle. Always check the **pupil, lid and corneal sensation** in any ophthalmoplegia.
- ▶ A **painful ophthalmoplegia with V1 numbness and intact vision** = **SOF syndrome until proven otherwise** — obtain **contrast MRI/MRA of the orbital apex, SOF and cavernous sinus**; add CT for bony sphenoid lesions/fractures and **angiography** if aneurysm/fistula suspected.
- ▶ **Emergencies to exclude:** posterior communicating artery **aneurysm** (pupil-involving III palsy), **cavernous sinus thrombosis** (fever, bilateral signs, sepsis source) and **rhino-orbital mucormycosis** in a diabetic/immunocompromised host (urgent biopsy, antifungals, surgical debridement).
- ▶ **Management** is cause-directed: glucocorticoids for **Tolosa-Hunt**, antibiotics/anticoagulation for septic cavernous sinus thrombosis, surgery/embolisation for tumour or fistula. Symptomatic diplopia relief uses **occlusion, prisms (Fresnel), or eye-muscle surgery** once the deficit stabilises.

High-yield exam pointers

- ▶ **6 EOMs; innervation** = LR6 SO4, rest III. III also supplies levator, iris sphincter and ciliary muscle.
- ▶ **III palsy** = “down and out” + ptosis + **dilated pupil**; pupil-involving + pain → **aneurysm** (emergency); pupil-sparing → **microvascular**.
- ▶ **IV palsy** = **vertical diplopia, head-tilt test positive**; commonest nerve injured in head trauma.
- ▶ **VI palsy** = **horizontal diplopia**; false-localising sign of raised ICP; Gradenigo’s at petrous apex.
- ▶ **SOF contents** = III, IV, VI, V1, superior ophthalmic vein, sympathetics — **NOT the optic nerve (optic canal)**.
- ▶ **SOF syndrome:** ophthalmoplegia + ptosis + dilated pupil + V1 loss + **vision preserved**; **orbital apex** = SOF + optic neuropathy; **cavernous sinus** = adds V2 ± Horner’s + chemosis, may be bilateral.
- ▶ **Tolosa-Hunt** = **idiopathic granulomatous painful ophthalmoplegia, steroid-responsive** (diagnosis of exclusion).
- ▶ Multiple ocular-motor palsies together → image the **cavernous sinus / SOF / orbital apex**, not “diabetic coincidence.”

SOURCE & COVERAGE

Harrison 22e — Ch 34 “Disorders of the Eye” (EOM innervation, eye-movement classes/control, III/IV/VI palsies, INO; Horton) and Ch 452 “Trigeminal Neuralgia, Bell’s Palsy, and Other Cranial Nerve Disorders” (Table 452-2 cranial-nerve syndromes — superior orbital fissure, orbital apex, cavernous sinus; cavernous sinus syndrome text). **Coverage note:** Harrison covers SOF/orbital-apex/cavernous-sinus syndromes only briefly (Table 452-2) and does not tabulate the detailed primary/secondary actions of individual EOMs or the cardinal-position testing scheme; these, the muscle-action table, the *LR6SO4* mnemonic, the precise SOF contents (superior ophthalmic vein, sympathetics) and the optic-canal-vs-SOF distinction are supplied from universally accepted standard anatomy/neuro-ophthalmology (consistent with Brazis, *Localization in Clinical Neurology*, cited in the spec but not provided as text here). The *Rochon-Duvigneaud* eponym for SOF syndrome is standard but not in the provided Harrison text.

Fabry’s disease

Asked in: Paper IV Nov 2020 — RGUHS MD General Medicine

Definition / Introduction — Fabry disease (*angiokeratoma corporis diffusum universale*) is an **X-linked lysosomal storage disease** caused by deficient activity of the lysosomal hydrolase **α -galactosidase A**, encoded by the **GLA** gene. The enzyme defect leads to progressive intralysosomal accumulation of the neutral glycosphingolipid **globotriaosylceramide (Gb3, also called ceramide trihexoside)**, predominantly within **vascular endothelium**, and in renal, cardiac, neural, corneal and cutaneous cells. It is a multisystem vasculopathy and is regarded as **likely the most prevalent lysosomal storage disease (LSD)**, with manifestations spanning a spectrum from classic early-onset disease in hemizygous males to attenuated, organ-limited late-onset variants.

Etiology, genetics and pathogenesis

- ▶ **Enzyme/substrate:** deficiency of **α -galactosidase A** (a neutral glycosphingolipidosis) → failure to cleave the terminal galactose from **globotriaosylceramide (Gb3)**, causing its lysosomal accumulation. Substrate is in part delivered to lysosomes by **LDL-receptor-mediated uptake**.
- ▶ **Gene/inheritance:** mutations in the **GLA** gene on the X chromosome (Xq22). Inheritance is **X-linked**; Harrison’s neuropathy chapter terms it *X-linked dominant* because **heterozygous females can be clinically affected** owing to **Lyonization** (random X-inactivation).
- ▶ **Epidemiology:** estimated prevalence of **hemizygous males 1 in 40,000 to 1 in 3,500** in selected populations. **Females have a higher prevalence of mutations but far more variable expression; up to 70% of heterozygous females show clinical manifestations.**

- ▶ **Threshold concept:** disease appears when residual enzyme activity falls below a tissue-specific threshold; small differences in residual activity (and substrate flux) explain the broad phenotypic spectrum, including organ-restricted variants.
- ▶ **Pathology:** progressive Gb3 deposition in **endothelial and smooth-muscle cells of small vessels** produces a generalised vasculopathy with ischaemia/infarction in kidney, heart and brain; deposition in **dorsal-root ganglia/small nerve fibres** produces a painful small-fibre neuropathy.

Clinical features (multisystem)

The **classic triad/quartet** of early disease comprises **acroparesthesias, angiokeratomas, hypohidrosis and corneal opacity**, with later renal, cardiac and cerebrovascular failure.

System	Key manifestations (faithful to source)
Skin	Angiokeratomas — punctate, dark red to blue-black, flat or slightly raised, telangiectatic lesions that do not blanch with pressure ; densest between the umbilicus and knees (“bathing-suit area”), also umbilicus, scrotum, inguinal region, perineum. Easily overlooked.
Sweat glands	Hypohidrosis (heat/exercise intolerance).
Peripheral nerve	Acroparesthesia — debilitating episodic burning/lancinating pain of the hands and feet , lasting minutes to days, precipitated by temperature change, exercise, fatigue or fever ; begins in childhood/early adult life (small-fibre neuropathy).
Eye	Corneal and lenticular opacities on slit-lamp (classic whorl-like <i>cornea verticillata</i> ; Fabry cataract) — useful diagnostic clue; usually asymptomatic.
GI	Abdominal pain (may mimic appendicitis or renal colic) and recurrent diarrhoea , often from childhood.
Kidney	Proteinuria, isosthenuria and progressive renal dysfunction in the 2nd–4th decades → end-stage renal disease. ~5% of males with “ idiopathic renal failure ” carry GLA mutations.
Heart	Hypertension, left ventricular hypertrophy, anginal chest pain and congestive heart failure in the 3rd–4th decades; a restrictive / hypertrophic cardiomyopathy picture. ~1–3% of “ idiopathic hypertrophic cardiomyopathy ” is Fabry.
CNS / vasculature	Premature cerebrovascular disease / stroke and TIA (a noninflammatory vasculopathy); ~2–5% of

System	Key manifestations (faithful to source)
	“idiopathic stroke” at 35–50 years carry GLA mutations.
Other	Leg lymphedema without hypoproteinemia.

Phenotypic variants and sex differences

- ▶ **Classic male (hemizygous) phenotype:** earliest and most severe — childhood acroparesthesias, angiokeratomas, hypohidrosis, GI pain → renal, cardiac and cerebrovascular disease; untreated, death often by the fifth decade from cardiovascular, renal or cerebrovascular disease.
- ▶ **Later-onset / residual-activity variants:** patients with some residual α -galactosidase A activity develop late, often organ-restricted disease — predominantly cardiac (mimicking hypertrophic cardiomyopathy / “cardiac variant”), or predominantly renal or CNS; some present primarily with a dilated cardiomyopathy.
- ▶ **Heterozygous females:** highly variable, from asymptomatic carrier to full classic disease; here heart disease is the most common life-threatening manifestation.
- ▶ **Cause of death / organ hierarchy:** in males, renal disease followed by cardiovascular disease; in females, cardiac disease predominates.

Investigations / Diagnosis

- ▶ **Enzyme assay (males):** markedly reduced or absent α -galactosidase A activity in plasma/leukocytes (dried blood spot) is diagnostic in hemizygous males.
- ▶ **GLA gene sequencing:** required in females, in whom enzyme activity may be normal (Lyonization), and to confirm amenable mutations for chaperone therapy.
- ▶ **Biomarkers:** elevated Gb3 (plasma/urine) and its deacylated form lyso-Gb3 (globotriaosylsphingosine) support diagnosis and monitor treatment (standard practice).
- ▶ **Slit-lamp examination:** corneal/lenticular opacities aid diagnosis.
- ▶ **Tissue biopsy:** renal/cardiac/skin biopsy shows lipid-laden cells; electron microscopy reveals characteristic lamellar (“zebra-body”/myelin-figure) lysosomal inclusions (standard).
- ▶ **Organ surveillance:** urinalysis/proteinuria and eGFR; ECG/echocardiography/cardiac MRI (LVH, late gadolinium enhancement); MRI brain for white-matter/vascular lesions.

Management / Treatment

- ▶ **Disease-specific:**
 - **Enzyme replacement therapy (ERT)** — intravenous α -galactosidase A (agalsidase) clears stored lipid from many cell types; instituted early to slow progression.
 - **Pharmacologic chaperone** — oral migalastat — stabilises and enhances the patient’s residual mutant enzyme; an oral option only for patients with “amenable” GLA mutations.

- ▶ Symptomatic / supportive:
 - Neuropathic pain (acroparesthesia): gabapentin and carbamazepine reduce chronic and episodic pain; avoid known triggers (heat, exertion, fever).
 - Renal failure: chronic haemodialysis or kidney transplantation can be life-saving.
 - Cardiac/cerebrovascular: standard heart-failure/arrhythmia care, antihypertensives, and stroke prophylaxis (antiplatelet/risk-factor control).
- ▶ Key principle: renal insufficiency, cardiac fibrosis and stroke are irreversible — therefore early institution of therapy gives the best chance to prevent or slow life-threatening complications.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ Multisystem “spoke” diagram of Fabry disease. Centre box: GLA mutation → α -galactosidase A deficiency → Gb3 (ceramide trihexoside) accumulation in vascular endothelium. Radiating labelled spokes: Skin — angiokeratomas (bathing-suit area), hypohidrosis; Eye — cornea verticillata / lenticular opacity; Peripheral nerve — acroparesthesia (burning hands/feet); GI — pain, diarrhoea; Kidney — proteinuria → ESRD; Heart — LVH / HCM-like, heart failure; Brain — premature stroke/TIA; Limbs — lymphedema.
- ▶ Metabolic pathway block. Labels: Globotriaosylceramide (Gb3) → [α -galactosidase A — BLOCKED] → lactosylceramide + galactose; show lysosomal accumulation of Gb3 and downstream lyso-Gb3 biomarker.

Clinical / Diagnostic significance

- ▶ “Hidden” cause of common idiopathic syndromes: consider Fabry in young/middle-aged “idiopathic” stroke, unexplained LVH/hypertrophic cardiomyopathy, and unexplained proteinuric renal failure, especially with a positive family history.
- ▶ Treatable LSD: one of the few LSDs with both ERT and an oral chaperone, making early recognition and family screening (X-linked pedigree, cascade GLA testing) clinically rewarding.
- ▶ Differential of cardiomyopathy: an important storage cause of restrictive/hypertrophic cardiomyopathy (with amyloidosis, haemochromatosis, sarcoidosis, glycogen storage disease).
- ▶ Pain mimicry: acroparesthetic crises and Fabry abdominal pain are frequently misdiagnosed as rheumatic “growing pains”, appendicitis or renal colic in childhood, delaying diagnosis.

High-yield exam pointers

- ▶ X-linked deficiency of α -galactosidase A (gene GLA) → accumulation of globotriaosylceramide (Gb3 / ceramide trihexoside); most prevalent LSD.
- ▶ Classic tetrad: acroparesthesias + angiokeratomas + hypohidrosis + corneal opacity (cornea verticillata).

- ▶ **Angiokeratomas:** non-blanching, dark red–blue, “bathing-suit” distribution (umbilicus to knees).
- ▶ **Organ timeline:** renal disease 2nd–4th decades, cardiac disease 3rd–4th decades, stroke at 35–50 years, untreated death ~5th decade.
- ▶ **Carrier of “idiopathic” disease:** ~5% idiopathic renal failure, ~1–3% idiopathic HCM, ~2–5% idiopathic young stroke.
- ▶ **Females affected** (Lyonization); enzyme assay may be normal in females → need GLA sequencing.
- ▶ **Treatment:** IV enzyme replacement (agalsidase) + oral migalastat (chaperone) for amenable mutations; gabapentin/carbamazepine for pain; dialysis/transplant for ESRD.
- ▶ **Mortality:** males — renal then cardiac; females — cardiac predominates.

SOURCE & COVERAGE

- ▶ **Harrison’s Principles of Internal Medicine, 22e** — “*Lysosomal Storage Diseases*” (Fabry disease: genetics, Gb3 accumulation, multisystem features, diagnosis, ERT/migalastat); “*Peripheral Neuropathy*” (Fabry small-fibre neuropathy, angiokeratoma corporis diffusum, premature atherosclerosis); “*Amyloidosis and Other Restrictive Cardiomyopathies*” (Fabry as a storage restrictive cardiomyopathy); “*Ischemic Stroke / TIA*” (Fabry as a noninflammatory vasculopathic cause of stroke).
- ▶ **CMDT 2026** — “*Heart Failure & Cardiomyopathy*” (Fabry among causes of restrictive cardiomyopathy) and “*Nervous System Disorders*” (Fabry as a vascular cause of TIA).

Coverage note: The corpus is rich on Fabry’s phenotype, genetics, organ epidemiology and therapy. A few standard add-ons not stated verbatim in these chapters but universally accepted internal-medicine facts are flagged in text — the **GLA locus (Xq22)**, the eponym **cornea verticillata**, **lyso-Gb3** biomarker, **agalsidase** as the specific ERT, and the **lamellar/zebra-body** ultrastructure; all are standard and accurate.

Factors Affecting Drug Metabolism

Asked in: Paper I Nov 2020 — RGUHS MD General Medicine

Definition / Introduction — Drug metabolism (biotransformation) is the enzymatic conversion of a drug into compounds that are usually **more polar and hence more readily excreted** than the parent drug. It occurs predominantly in the **liver**, but also in the kidney, intestinal epithelium, lung and plasma. Metabolism proceeds in two phases — **Phase I** (chemical modification, most often oxidation by the **cytochrome P450 (CYP) mono-oxygenase superfamily**) and **Phase II** (conjugation by glucuronyl-, acetyl-, sulfo- and methyl-transferases). Because metabolism is a principal determinant of plasma drug

concentration, the marked **inter-individual variability** in drug response is largely explained by genetic, physiological, pathological and environmental factors that modulate these enzyme systems.

Phases and machinery — orienting framework

- ▶ **Phase I (functionalisation):** oxidation, reduction, hydrolysis; the CYP superfamily dominates. The CYPs most important for drug disposition are CYP3A4/CYP3A5 (metabolise the greatest number of drugs), CYP2D6, CYP2C9, CYP2C19, CYP2B6, CYP1A2 and CYP2E1.
- ▶ **Phase II (conjugation):** glucuronidation (UGT), N-acetylation (NAT1/NAT2), sulfation, methylation and glutathione conjugation — usually inactivating and yielding highly polar, excretable products.
- ▶ **Nature of metabolites:** may be **inactive**, **pharmacologically active**, or **toxic/reactive**. *Prodrugs* require metabolism for activity (ACE inhibitors, the ARB *losartan*, *irinotecan*, *tamoxifen*, *codeine* → morphine, *clopidogrel*). Reactive metabolites (e.g. acetaminophen → NAPQI) can cause tissue toxicity.
- ▶ **High-risk pharmacokinetics:** when an active drug's elimination depends on a **single** metabolic pathway, any factor inhibiting that pathway produces large, clinically important swings in concentration.

Genetic / pharmacogenetic factors (the dominant source of variability)

A **multimodal** population distribution of metabolic activity indicates a single-gene effect, producing **poor (PM)**, **intermediate**, **normal/extensive (EM)** and **ultrarapid (UM)** metaboliser phenotypes (gene duplication causes UM). EMs given an inhibitor can behave like PMs — **phenocopying**.

Enzyme / gene	Variant phenotype	Substrate drug(s)	Clinical consequence
CYP2D6	PM 5–10% (Europeans/Africans; few Asians); UM (gene duplication)	codeine, metoprolol, carvedilol, timolol, propafenone, nortriptyline, tamoxifen	PM: no codeine analgesia, exaggerated β -blockade; UM: codeine→morphine toxicity (child deaths post-tonsillectomy; FDA black-box, banned <12 yr)
CYP2C19	PM ~20% Asians, 2–3% others, >50% Oceania	clopidogrel, omeprazole, mephenytoin	reduced clopidogrel bioactivation → stent thrombosis/stroke; lower ulcer-cure with omeprazole
CYP2C9 + VKORC1	loss-of-function alleles	warfarin, phenytoin, glipizide, losartan	low warfarin dose, phenytoin neurotoxicity, glipizide hypoglycaemia; the two genes explain up

Enzyme / gene	Variant phenotype	Substrate drug(s)	Clinical consequence
			to 50% of warfarin dose variance
CYP3A5	non-expresser splice variant (most Europeans/Asians)	tacrolimus, vincristine	African “expressers” eliminate tacrolimus faster (reduced efficacy)
NAT2 (acetylation)	slow acetylators ~50% of Europeans/Africans (fewer East Asians)	isoniazid, hydralazine, procainamide, some sulfonamides	INH hepatitis/neuropathy; drug-induced lupus with hydralazine/procainamide
TPMT (+ NUDT15)	homozygous inactive ~1/300	azathioprine, 6-mercaptopurine	severe, potentially fatal myelosuppression
UGT1A1	Gilbert’s promoter variant	irinotecan, atazanavir	diarrhoea/marrow depression; unconjugated hyperbilirubinaemia
DPYD	loss-of-function homozygote	5-fluorouracil, capecitabine, tegafur	severe/fatal chemotherapy toxicity
Pseudocholinesterase	atypical variant	succinylcholine	prolonged neuromuscular block / apnoea
G6PD	deficiency (African/Mediterranean/South Asian)	primaquine, rasburicase, dapsone	oxidative haemolytic anaemia

Enzyme induction and inhibition (drug interactions)

The single most modifiable factor: co-administered drugs (and chemicals) that **induce** or **inhibit** metabolising enzymes/transporters.

	Enzyme inducers (↓ effect of substrate)	Enzyme inhibitors (↑ effect/toxicity of substrate)
Agents	Rifampin, carbamazepine, phenytoin, phenobarbital, St. John’s wort, glutethimide, chronic alcohol, cigarette smoking (CYP1A2), chlorinated insecticides	Cimetidine (many CYPs), ketoconazole/itraconazole/fluconazole, erythromycin/clarithromycin, amiodarone (also P-gp), ritonavir, fluoxetine/paroxetine (CYP2D6), grapefruit juice (intestinal CYP3A4)
Affected drugs	warfarin, quinidine, cyclosporine, losartan, oral contraceptives, methadone, dabigatran	warfarin, theophylline, phenytoin, statins (myopathy), colchicine, cyclosporine, digoxin

	Enzyme inducers (↓ effect of substrate)	Enzyme inhibitors (↑ effect/toxicity of substrate)
Kinetics	Slow onset/offset (days–weeks; needs new enzyme synthesis)	Rapid onset (competition at active site)

- *Special interactions*: **allopurinol** (xanthine oxidase inhibitor) blocks azathioprine/6-MP catabolism → toxicity; **chronic alcohol/phenytoin/phenobarbital** increase acetaminophen hepatotoxicity by inducing reactive-metabolite formation and depleting glutathione.

Physiological factors

- **Age — neonates/infants**: drug-metabolising pathways **mature at different rates after birth**; immature glucuronidation underlies *chloramphenicol* “gray-baby” syndrome and prolonged neonatal jaundice. Dosing in children is approximated by **weight or body-surface area**.
- **Age — elderly**: declining hepatic mass, **reduced hepatic clearance** and reduced hepatic blood flow (plus falling GFR and altered body composition) impair metabolism; with polypharmacy and comorbidity this drives ADRs. *Rule*: start low, go slow, minimise drug number.
- **Sex, pregnancy, nutrition and circadian rhythm** also modulate enzyme activity (e.g. altered CYP activity and volume of distribution in pregnancy); protein-calorie malnutrition reduces enzyme content.

Pathological / disease factors

- **Liver disease (hepatitis, cirrhosis)**: standard liver-function tests do **not** predict dose adjustment. **First-pass metabolism falls** owing to hepatocyte dysfunction, distorted architecture and porto-caval shunting, so oral bioavailability of **high first-pass drugs (morphine, meperidine, midazolam, nifedipine)** is **almost doubled** in cirrhosis — reduce the oral dose.
- **Heart failure / shock**: redistributed cardiac output and **decreased hepatic (and renal) perfusion** **impair drug clearance**; reduced gut perfusion may also lower absorption. Highest impact on **flow-limited (high-extraction) drugs**.
- **Renal disease**: although metabolism per se is hepatic, accumulation of **active/toxic metabolites** matters — e.g. **normeperidine** accumulates in renal failure causing CNS excitation/seizures; altered protein binding (uremia) raises free drug (phenytoin).
- **Thyroid status and acute inflammatory states** alter enzyme expression and acute-phase protein binding.

Other determinants

- **First-pass (presystemic) elimination & hepatic extraction ratio**: drug crossing gut wall and liver before reaching the systemic circulation. **High-extraction (flow-limited) drugs** (nitroglycerin, verapamil, morphine, lidocaine) have clearance sensitive to **hepatic blood flow**; **low-extraction (capacity-limited) drugs** (warfarin, phenytoin) are sensitive to enzyme activity and protein

binding. Nitroglycerin is given sublingual/transdermal to bypass near-complete first-pass extraction.

- ▶ **Drug transporters:** efflux (P-glycoprotein/*ABCB1*) and uptake (OATP1B1/*SLCO1B1*) transporters control delivery of drug to metabolising enzymes; *SLCO1B1* variants raise statin myopathy risk.
- ▶ **Environmental/dietary:** smoking, chronic alcohol, industrial pollutants (induction); grapefruit juice (inhibition).

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Bimodal/multimodal population-frequency curve of CYP2D6 activity** — x-axis “enzymatic activity (lesser → greater)”, y-axis “population frequency”; label the **antimode**, **Poor metabolisers (PM, 2 loss-of-function alleles)**, **Extensive metabolisers (EM)** and **Ultrarapid metabolisers (UM, gene duplication)**.
- ▶ **Two-phase biotransformation flow diagram:** *Lipophilic parent drug* → **Phase I** (oxidation/reduction/hydrolysis, CYP450) → **Phase II** (glucuronidation / acetylation / sulfation / methylation / glutathione conjugation) → *polar conjugate* → *renal/biliary excretion*; annotate branch points for **inducers (↑)** and **inhibitors (↓)**.

Clinical / Diagnostic significance

- ▶ Explains why **fixed doses give variable effects** and is the basis for **therapeutic drug monitoring** (warfarin, phenytoin, digoxin, immunosuppressants, anticonvulsants).
- ▶ Guides **pre-emptive/point-of-care pharmacogenetic testing** (CPIC and Dutch Pharmacogenetics Working Group guidelines); e.g. TPMT/NUDT15 before thiopurines, DPYD before 5-FU, CYP2C19 before clopidogrel, **HLA-B\57:01*** before abacavir.
- ▶ Mandates **dose reduction** in hepatic disease, heart failure and the elderly, and **anticipation of interactions** when starting/stopping a known inducer or inhibitor of CYP2D6/CYP3A/P-glycoprotein.
- ▶ A 2023 7-country, 6944-patient trial showed pre-emptive **12-gene panel** genotyping cut serious ADRs by ~30%.

High-yield exam pointers

- ▶ Two phases: **Phase I = oxidation (CYP450)**; **Phase II = conjugation** (glucuronyl/acetyl/sulfo/methyl-transferase).
- ▶ **CYP3A4** metabolises the most drugs; **CYP2D6** is genetically the most polymorphic.
- ▶ **Slow acetylators (NAT2 ~50%)** → INH hepatitis/neuropathy and hydralazine/procainamide lupus.

- ▶ **TPMT** deficiency (~1/300) → fatal azathioprine/6-MP marrow toxicity; **DPYD** → 5-FU toxicity; **UGT1A1** (Gilbert) → irinotecan toxicity.
- ▶ **CYP2D6 UM + codeine** → fatal opioid toxicity (FDA black box); **CYP2D6 PM** → codeine ineffective.
- ▶ Inducers (rifampin, carbamazepine, phenytoin, St. John's wort, chronic alcohol, smoking) act slowly; inhibitors (cimetidine, azole antifungals, macrolides, amiodarone, grapefruit juice) act fast.
- ▶ **Cirrhosis doubles** oral bioavailability of high first-pass drugs (morphine, midazolam, nifedipine) → reduce dose.
- ▶ **Pseudocholinesterase** deficiency → suxamethonium apnoea; **G6PD** deficiency → primaquine/rasburicase haemolysis.

SOURCE & COVERAGE

- ▶ Harrison's Principles of Internal Medicine, 22e — "Principles of Clinical Pharmacology" (drug metabolism, first-pass effect, enzyme induction/inhibition tables, effects of renal/hepatic/cardiac disease, age) and "Pharmacogenomics" (CYP2D6/2C19/2C9/3A5, NAT2, TPMT/NUDT15, UGT1A1, DPYD, pseudocholinesterase, G6PD; PM/EM/UM phenotypes; CPIC; 12-gene trial).
- ▶ CMDT 2026 — "Geriatric Disorders" (impaired hepatic clearance and ADRs in older adults) and pharmacogenetic/therapeutic-drug-monitoring material for current management framing.
- ▶ Coverage note: the corpus is clinical-pharmacology focused; classic pharmacology specifics not separately tabulated in Harrison (Phase I reduction/hydrolysis sub-types, microsomal CYP1A2/CYP2E1 induction by smoking/alcohol, neonatal "gray-baby" glucuronidation immaturity, high- vs low-extraction/flow- vs capacity-limited classification) are included as **universally accepted standard internal-medicine pharmacology** and are consistent with the inducer/first-pass data Harrison does provide.

Falls in Elderly

Asked in: Paper I Sep 2025 — RGUHS MD General Medicine

Definition / Introduction — A **fall** is an event in which a person inadvertently comes to rest on the ground, floor, or a lower level, not as a result of a major intrinsic event (e.g., stroke, seizure) or overwhelming external force. Falls are among the most common and most consequential of the **geriatric syndromes**: **over one-third of community-dwelling people aged >65 fall each year**, rising to about **one-half of long-term-care (LTC) residents**, and the rate climbs steeply with age. They are *multifactorial* (rarely a single cause), often labelled "mechanical" yet usually concealing reversible intrinsic factors,

and they are the **leading cause of death from injury in persons over 65**. Falls therefore demand a systematic, comprehensive internal-medicine evaluation rather than dismissal as accidents.

Epidemiology and impact

- ▶ **Prevalence:** ≈ 1 in 3 community-dwellers >65 and ≈ 1 in 2 LTC residents fall annually; gait abnormality is present in 15% at >65 and approaches **40% by age ≥ 85** .
- ▶ **Morbidity:** $\sim 10\%$ of falls cause serious injury — most commonly fractures of **wrist, hip, and vertebrae**, plus **subdural haematoma** and soft-tissue trauma.
- ▶ **Mortality:** Complications (hip fracture, subdural haematoma) are the leading injury-related cause of death after 65; **hip-fracture mortality in older women is $\sim 20\%$ at 1 year**, especially if debilitated pre-fracture.
- ▶ **Functional/psychological burden:** Nearly **1 in 5 elderly voluntarily restrict activity from fear of falling**, accelerating deconditioning, loss of independence, and institutionalisation. A *long lie* on the floor risks dehydration, pressure injury, hypothermia, and **rhabdomyolysis**.

Why the elderly fall — physiology of balance

- ▶ Upright bipedal gait needs integration of **postural control + locomotion** across brainstem locomotor centres (pontine tegmentum, midbrain, subthalamic region), cerebellum, basal ganglia, and frontal cortex.
- ▶ Standing balance depends on **three sensory channels** — **visual, vestibular, and proprioceptive** (muscle-spindle/joint). There is healthy redundancy, but **loss of any two of the three** is sufficient to destabilise stance.
- ▶ With ageing: balance mechanisms degrade, reaction time slows, and **postural sway increases**, so any added insult (drug, illness, hazard) precipitates a fall.
- ▶ **Cognitive contribution:** Impaired **executive function** degrades *dual-task walking* (walking while attending to a cognitive task), predisposing demented elders to falls.

Risk factors (intrinsic, extrinsic, modifiable)

The presence of **multiple risk factors** multiplies risk. Harrison and CMDT classify them as below.

Domain	Risk factors
Intrinsic	Previous falls; gait/balance disorder ; visual deficits; muscle weakness/physical disability (incl. knee osteoarthritis); orthostatic hypotension ; cognitive impairment; depression; peripheral neuropathy; foot disorders
Medications	Polypharmacy (≥ 4 prescription drugs) ; benzodiazepines & sedative-hypnotics, antidepressants, antipsychotics, anticholinergics,

Domain	Risk factors
	antiepileptics, opioids, antihypertensives & diuretics, nitrates, antiarrhythmics, hypoglycaemics
Extrinsic / environmental	Loose rugs, electrical cords, poor lighting, unsafe stairs, slippery/wet floors, lack of grab-bars; inappropriate footwear (slippers, high heels); multifocal/bifocal lenses

- ▶ *Medication is the most common reversible cause* — meta-analysis identifies **sedative-hypnotics, antidepressants, and benzodiazepines** as the highest-risk classes.
- ▶ *Postural hypotension* includes **postprandial** hypotension (nadir 30–60 min after a meal) and is defined by a systolic drop >20 mmHg, diastolic drop >10 mmHg, or standing SBP <90 mmHg.

Classification of fall patterns (mechanism-based clues)

- ▶ **Drop attacks / collapsing falls:** sudden loss of postural tone (“legs gave out”); think syncope, orthostatic hypotension, atonic seizure, myoclonus, cataplexy (emotional trigger), or third-ventricle colloid cyst — *not* to be confused with vertebrobasilar attacks.
- ▶ **Toppling falls:** tone maintained but fall “like a tree trunk,” often a consistent direction — cerebellar/vestibular lesions, **thalamic astasia**; an *early* feature of **progressive supranuclear palsy (PSP)** and a *late* feature of Parkinson’s disease.
- ▶ **Falls due to gait freezing/festination:** feet stick while centre of mass advances → forward fall; Parkinson’s disease and related parkinsonian syndromes.
- ▶ **Falls from sensory loss:** somatosensory/visual/vestibular deficits; worse on uneven ground and in poor light.
- ▶ **Falls from weakness:** cannot rise from chair or recover after perturbation; often *cannot get up* afterwards (long lie); frequently due to treatable deconditioning.

Clinical assessment

- ▶ **Screen every older patient annually:** “Have you fallen in the past year?”, “Are you afraid of falling?”, “Do you have trouble climbing stairs or rising from chairs?”
- ▶ **Timed Up and Go (TUG) test:** time the patient rising from a chair (no hands), walking ~3 m/10 ft, turning, returning, and sitting. >12 s (**Harrison**) / ≥12.5 s (**CMDT**) indicates **high fall risk** and mandates fuller assessment.
- ▶ **Targeted history:** circumstances, provoking factors (head turn, standing, post-meal, nocturia, straining), prodrome (dizziness — lightheaded vs vertigo, palpitations, focal neurology, seizure features), and a **collateral witness** account. Crucially **distinguish syncope/seizure** from a mechanical fall (as many as half of “unexplained falls” in demented elders are near-syncope from postural hypotension).

- ▶ **Examination:** supine vs standing BP/pulse at immediate and 3 min (orthostasis); cardiac exam (arrhythmia, aortic stenosis, MR, HF); **visual acuity**; neck range of motion; lower-limb strength (hip abductors/flexors, knee, ankle), tone, **proprioception and vibration**, cerebellar heel–shin, reflexes; **monofilament screen** for neuropathy; inspection of feet (**calluses**, **hallux valgus**, **hammertoes**) and footwear; gait/balance observation.
- ▶ **Investigations (history-guided):** CBC and basic metabolic panel; fingerstick glucose; urinalysis (only if UTI symptoms); ECG ± cardiac monitoring if syncope suspected; EEG if seizure suspected; X-rays for fractures; **brain imaging for head trauma, focal signs, anticoagulation, or suspected subdural** — otherwise it is reasonable to observe 48–72 h rather than image reflexively.

Complications

- ▶ **Fractures** — wrist, hip, vertebrae (osteoporosis greatly amplifies risk and is *vastly undertreated* — the “osteoporosis care gap,” <20% of fragility-fracture patients receive treatment).
- ▶ **Chronic subdural haematoma** — easily missed; suspect in any elder with new neurological or cognitive change *even without* recalled trauma or headache.
- ▶ Hip fracture → hospitalisation, nursing-home admission, high 1-year mortality; head/spinal injury; **rhabdomyolysis/dehydration** from a long lie; and **fear of falling** with loss of confidence and independence.

Management and prevention (multifactorial)

Because causation is multifactorial, effective prevention usually needs **several simultaneous interventions** (AGS/BGS guideline; *World Falls Guidelines*, Montero-Odasso 2022).

Contributor	Intervention
Gait/balance, weakness	Exercise — Tai Chi, balance, gait & resistance/strength training (most consistently effective; benefits even in the 80s–90s); physiotherapy; assistive devices
Orthostatic/postprandial hypotension	Reduce hypotensive drugs; hydration, compression stockings; midodrine , fludrocortisone , droxidopa ; rise slowly; postprandial caution
Medications	Medication review/deprescribing (Beers & STOPP criteria); withdraw benzodiazepines, sedative-hypnotics, anticholinergics, unnecessary antihypertensives
Vision	Cataract surgery; correct refraction; avoid multifocal/bifocal lenses (extra caution in first weeks of new glasses)

Contributor	Intervention
Cardiac	Treat arrhythmia (antiarrhythmic, ablation, pacemaker); aortic-stenosis valve replacement (often transcatheter)
Bone health	Bisphosphonate (e.g., alendronate) for osteoporosis to prevent first/recurrent fracture; calcium
Vitamin D	Replacement ≥ 800 IU/day in deficiency (<i>USPSTF advises against routine vitamin D for fall prevention in community-dwellers; avoid high-dose — 60,000 IU monthly increased falls</i>)
Environment	Home-safety evaluation (occupational therapist): lighting, grab-bars, non-slip surfaces, remove rugs/cords; proper footwear
Recurrent fallers	Fall-alert/medical-alert system to prevent long lie; hip protectors in selected patients
Feet	Podiatric care; properly fitted shoes
Cognition	Supervision; cognitive/dual-task training; hazard-free environment

- ▶ **AF + high fall risk:** the stroke risk outweighs the bleeding risk — **anticoagulation is generally preferred**; consider a **left atrial appendage closure device**.
- ▶ The CDC STEADI programme (*Stopping Elderly Accidents, Deaths and Injuries*) provides screening/assessment/intervention tools.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Multifactorial model of falls (Venn / converging-arrows):** three overlapping circles labelled *Intrinsic factors* (gait/balance disorder, weakness, orthostatic hypotension, visual/sensory loss, cognitive impairment), *Medications* (polypharmacy ≥ 4 , benzodiazepines, sedative-hypnotics, antihypertensives), *Extrinsic/environmental* (poor lighting, loose rugs, footwear, multifocal lenses) — overlap zone labelled **FALL**, with outcome arrows to *Fracture (hip/wrist/vertebra)*, *Subdural haematoma*, *Fear of falling*, *Loss of independence*.
- ▶ **Three-channel balance triangle:** apex **Postural control / Balance**, three feeding inputs labelled **Visual, Vestibular, Proprioceptive**, with a note “loss of any 2 of 3 → imbalance,” integrated at **Brainstem–Cerebellum–Frontal cortex**.

Clinical / Diagnostic significance

- ▶ Falls are a **sentinel marker** of occult disease (sepsis, MI, stroke, arrhythmia, dehydration) and of frailty — a presenting “atypical” complaint in the elderly.

- ▶ The single most useful bedside discriminator is **syncopal vs non-syncopal** fall, because it diverts the work-up toward cardiac/neurological evaluation.
- ▶ **TUG ≥ 12 s**, prior falls, and polypharmacy reliably flag the high-risk patient for prospective intervention *before* injury.
- ▶ Every fragility fracture should trigger **osteoporosis assessment and treatment** (closing the care gap) and a multifactorial falls work-up.

High-yield exam pointers

- ▶ **>1/3 of community elders and ~1/2 of LTC residents fall yearly; ~10% cause serious injury;** falls are the leading injury-death cause after 65.
- ▶ **TUG > 12 s (≥ 12.5 s CMDT) = high fall risk.** Always measure **postural BP** (drop SBP > 20 / DBP > 10 mmHg).
- ▶ **Polypharmacy = ≥ 4 prescription drugs;** highest-risk classes are **benzodiazepines, sedative-hypnotics, antidepressants**.
- ▶ **Fall patterns:** drop attack (loss of tone), toppling fall (early PSP, late PD), freezing fall (parkinsonism), sensory-loss fall, weakness fall.
- ▶ **Exercise (Tai Chi, balance + strength training)** is the most consistently effective single intervention; multifactorial intervention adds modest benefit.
- ▶ **Chronic subdural haematoma** — overlooked; suspect with new cognitive/neurological change even without recalled trauma.
- ▶ **Hip fracture** $\rightarrow$ **~20% 1-year mortality** in older women; **osteoporosis care gap** ($< 20\%$ treated).
- ▶ Use **Beers** and **STOPP** criteria for deprescribing; **CDC STEADI** for screening.
- ▶ In **AF + high fall risk**, anticoagulate (stroke risk $>$ bleed risk); consider **LAA closure**.

SOURCE & COVERAGE

- ▶ **Harrison's Principles of Internal Medicine, 22e** — “Gait Disorders, Imbalance, and Falls” (epidemiology, balance physiology, gait-disorder classification, fall patterns, TUG, risk-factor table, STEADI, treatment) and “Caring for the Geriatric Patient” (geriatric-syndrome framing, AGS/BGS algorithm, immediate post-fall evaluation Table, management-by-cause Table, vitamin D, anticoagulation/AF, Beers/STOPP deprescribing).
- ▶ **CMDT 2026** — “Geriatric Disorders” (current management: fall-risk-factor/intervention table, TUG ≥ 12.5 s, postprandial hypotension, complications, USPSTF vitamin D stance, bisphosphonate/alendronate, assistive devices, World Falls Guidelines 2022).
- ▶ *Coverage note:* No dedicated geriatrics subspecialty text was provided in the spec; the answer is fully grounded in the above Harrison chapters and CMDT, which cover the topic comprehensively.

Gene and Cell-Based Therapy in Clinical Medicine (Gene Therapy in Medicine)

Asked in: Paper III May 2019 — RGUHS MD General Medicine

Definition / Introduction — **Gene therapy** is a class of therapeutics in which the *active agent* is a *nucleic-acid sequence* (DNA or RNA) rather than a protein or small molecule, used to treat or prevent disease by replacing, adding, silencing or **editing** a gene in a physiologically relevant target cell. Because delivery of naked DNA/RNA into cells is inefficient, most gene therapy uses a **vector** (delivery vehicle) — usually a virus stripped of its own genes and re-loaded with the therapeutic **transgene** under a suitable promoter, or a non-viral carrier such as a **lipid nanoparticle** (LNP). Clinical trials began in 1990; the first licensed product appeared in 2012, and gene/cell therapy is now the fastest-growing sector of medicine, spanning inherited diseases, haemoglobinopathies, haemophilia and cancer (**CAR-T cells**).

Essential elements & basic strategy

- ▶ Every gene-therapy approach has **three components**: (1) a **gene delivery vehicle (vector)**; (2) the **gene to be delivered (transgene)**; and (3) a relevant **target cell**. The whole process by which the vector enters the cell and expresses the transgene is called **transduction**.
- ▶ **Route of delivery**:
 - ***In vivo*** — vector injected directly into the patient (e.g., subretinal, intramuscular, intravenous to liver/CNS).
 - ***Ex vivo*** — *target cells (haematopoietic stem cells [HSCs], T cells, etc.) are removed, gene-modified in the laboratory, and the autologous cells re-infused; this combines gene transfer with cellular therapy**.
- ▶ **Durable expression** is achieved either by (a) transducing **stem cells with an integrating vector** (all progeny carry the gene) or (b) transducing **long-lived post-mitotic cells** (neuron, skeletal muscle, hepatocyte) where the DNA persists *episomally* for the life of the cell — avoiding the risks of integration.
- ▶ **Therapeutic designs**: replace the missing gene; supply a **truncated/functional surrogate** (B-domain-deleted *FVIII*, **microdystrophin** or *utrophin* for Duchenne muscular dystrophy); achieve a similar effect via an alternative pathway; or **knock down** a harmful gene using *siRNA/shRNA*.

Gene delivery vehicles (vectors)

Feature	Retroviral / Lentiviral	Adenoviral	AAV (adeno-associated virus)	Lipid nanoparticle (non-viral)
Genome	RNA	DNA	DNA	RNA

Feature	Retroviral / Lentiviral	Adenoviral	AAV (adeno-associated virus)	Lipid nanoparticle (non-viral)
Packaging limit	~8 kb	8–30 kb	~5 kb (wild-type genome ~4.7 kb)	10 kb or more
Dividing cells needed?	Retroviral <i>yes</i> ; lentiviral transduces non-dividing cells	No	No	No
Genome integration	Yes	No	No (mainly episomal)	No
Long-term expression	Yes	Poor	Yes (in non-dividing cells)	Transient (RNA)
Main advantage	Persistent gene transfer in transduced tissues	Highly effective in transducing many tissues	Few inflammatory responses, non-pathogenic	Can package RNA or DNA; rapid manufacture
Main disadvantage	Insertional mutagenesis/oncogenesis; used only <i>ex vivo</i>	Capsid elicits strong immune response; short-lived	Limited packaging (~5 kb); pre-existing neutralising antibodies	Immunogenic; predominantly targets the liver

- ▶ AAV is the dominant *in vivo* vector for genetic disease — non-pathogenic, transduces long-lived tissues, but limited to inserts <5 kb and constrained by **pre-existing anti-capsid neutralising antibodies** (screen before dosing) and anti-capsid **memory T-cell** responses.
- ▶ **Lentiviral** vectors largely replaced first-generation **retroviral** vectors for *ex vivo* HSC work because their *safer integration pattern* lowers insertional-oncogenesis risk.

Gene editing — CRISPR/Cas9

- ▶ Differs from gene *transfer*: a bacterial **Cas9** nuclease + a **guide RNA** (delivered as a ribonucleoprotein [RNP] or as mRNA + gRNA in an LNP) introduces a **double-strand break** (DSB) at a precise genomic locus.
- ▶ **Repair pathways**:
 - **Non-homologous end joining (NHEJ)** — error-prone; causes small insertions/deletions that **disrupt (knock out)** a gene. *All currently approved/most advanced editing products use this cleavage-only step* (more efficient).
 - **Homology-directed repair (HDR)** — needs a co-delivered targeting (donor) template (e.g., AAV6) for precise **gene correction/replacement**; less efficient.
- ▶ Editing is **heritable to all daughter cells**, so it persists even in a growing organ (e.g., child's liver) — a key advantage.

Applications — genetic disease (selected approved products)

Product (generic)	Disease	Vector / approach	Transgene / target	Target tissue
Strimvelis	ADA-SCID	Retroviral, <i>ex vivo</i>	ADA (adenosine deaminase)	Autologous HSCs
Luxturna (voretigene neparvovec)	Biallelic RPE65 retinal dystrophy	AAV2, <i>in vivo</i>	RPE65	Retinal pigment epithelium (subretinal)
Zolgensma (onasemnogene abeparvovec)	Spinal muscular atrophy type 1 (<2 yr)	AAV9, single IV	SMN1	Spinal motor neurons
Zynteglo / Lyfgenia (betibeglogene autotemcel)	Transfusion-dependent β -thalassaemia; sickle cell disease	Lentiviral, <i>ex vivo</i>	β^A -T87Q anti-sickling globin	Autologous HSCs
Skysona (elivaldogene autotemcel)	Cerebral adrenoleukodystrophy	Lentiviral, <i>ex vivo</i>	ABCD1	Autologous HSCs
Roctavian (valoctocogene roxaparvovec)	Severe haemophilia A	AAV5, single IV	B-domain-deleted FVIII	Hepatocytes
Hemgenix / Beqvez	Haemophilia B	AAV5 / AAVrh74, single IV	Factor IX-Padua	Hepatocytes
Elevidys (delandistrogene moxeparvovec)	Duchenne muscular dystrophy	AAVrh74	micro-dystrophin	Skeletal muscle
Casgevy (exagamglogene autotemcel)	Sickle cell disease; β -thalassaemia	CRISPR/Cas9 editing, <i>ex vivo</i>	Inactivates BCL11A $\rightarrow$ $\uparrow$ HbF	Autologous HSCs

- **Proof of principle — X-linked SCID:** *IL2RG* mutation (γ c chain). Retroviral correction of autologous CD34+ cells gave durable immune reconstitution **but 5 of 20 children developed T-ALL** from vector integration near **LMO-2** (insertional mutagenesis) — the landmark safety lesson driving the shift to lentiviral vectors and mandatory **15-year insertion-site monitoring**.
- **Haemoglobinopathies:** lentiviral β^A -T87Q globin or CRISPR knock-down of **BCL11A** (de-represses γ -globin $\rightarrow$ HbF) abolished vaso-occlusive crises / transfusion dependence in the large majority of treated patients (mean Hb rose from $\sim$ 7.5 to $\sim$ 13 g/dL in the Casgevy editing trial).
- **Haemophilia B** illustrated the human anti-AAV immune response; the high-specific-activity **factor IX-Padua** variant allowed lower vector doses and durable mild-range factor levels.

- ▶ **In vivo editing** (LNP-delivered Cas9 mRNA + gRNA to hepatocytes) is reducing transthyretin in ATTR amyloidosis, plasma kallikrein in hereditary angioedema (KLKB1), and (in trials) PCSK9 / Lp(a) / ANGPTL3 for cardiovascular risk.

Applications — cancer

- ▶ **Modifying the tumour:** intratumoral adenoviral *p53* restoration; **suicide/prodrug genes** (HSV-thymidine kinase + ganciclovir → toxic phosphorylated nucleoside with bystander killing).
- ▶ **Modifying the host (immune): CAR-T cells** — autologous T cells engineered with a **chimeric antigen receptor** (antibody-derived scFv + CD3ζ + a **costimulatory domain**, CD28 or 4-1BB) that recognise antigen **independent of MHC**. Targets: **CD19** (B-ALL, large B-cell/mantle-cell lymphoma) and **BCMA** (multiple myeloma); >80% complete-response rates in refractory B-ALL with long remissions.
- ▶ **Oncolytic immuno-virotherapy:** talimogene laherparepvec, a GM-CSF-armed oncolytic herpesvirus approved for melanoma, replicates selectively in tumour and triggers systemic antitumour immunity.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **CAR vs native T-cell receptor (Fig. 483-1):** draw a tumour/target cell presenting antigen; alongside, a native TCR (αβ chains recognising peptide on MHC class I, signalling via the CD3 (γε, εδ, ζζ) complex) and a CAR T cell. Label the CAR: **extracellular scFv** (VH + VL from a monoclonal antibody), **spacer/hinge**, **transmembrane domain**, **costimulatory domain** (CD28 or 4-1BB), and **CD3ζ signalling chain**. Add the note “MHC-independent recognition”.
- ▶ **Ex vivo vs in vivo gene therapy schematic:** Label — *Ex vivo*: harvest autologous CD34+ HSC / T cells → lentiviral or CRISPR modification in lab → myeloablation/lymphodepletion → re-infuse; *In vivo*: AAV or LNP injected directly → target tissue (liver / retina / motor neuron / muscle).

Clinical / Diagnostic significance

- ▶ **Potential complications (mechanistic classes):** gene silencing (promoter repression); **genotoxicity** (insertional mutagenesis/oncogenesis); **phenotoxicity** (over-/ectopic transgene expression); **immunotoxicity** (to vector or transgene); **horizontal transmission** (viral shedding) and **vertical/germline transmission**.
- ▶ **Vector-specific adverse events & mitigation:**
 - Retroviral/lentiviral → **secondary malignancy** from insertional mutagenesis; mitigate with lentiviral vectors, insulators, suicide genes, lifelong monitoring.
 - AAV (systemic) → asymptomatic **transaminitis with loss of expression** (anti-capsid T cells; treat with **glucocorticoids/reduce dose**) and **complement-mediated thrombotic**

microangiopathy (thrombocytopenia + MAHA + AKI; responds to **eculizumab**); barrier contraception until semen clears of vector DNA.

- CRISPR → **off-target cleavage** (pre-clinical screening; long-term follow-up).
- CAR-T → **cytokine release syndrome** (fever, hypotension, hypoxia, multi-organ failure; treat **tocilizumab ± corticosteroids**); **ICANS/neurotoxicity** (cerebral oedema, encephalopathy; early **dexamethasone**); **B-cell aplasia/hypogammaglobulinaemia** (Ig replacement, PJP/VZV prophylaxis ≥1 year); rare **secondary T-cell malignancy** (FDA boxed warning, 2024; lifelong monitoring).
- ▶ **History from a gene-therapy recipient (Table 483-5):** know the **vector** (integrating vs non-integrating), **dose/route**, **target tissue**, **which gene** was transferred, and any adverse events; on follow-up screen for new **malignancy**, **neuro/ophthalmic**, **autoimmune** or **haematologic** disorders.

High-yield exam pointers

- ▶ Three pillars: **vector + transgene + target cell**; the process = **transduction**; delivery is **in vivo** or **ex vivo (autologous)**.
- ▶ *AAV = *dominant in vivo vector (episomal, non-integrating, ~5 kb limit)*; *lentivirus = workhorse for ex vivo HSC/T-cell** integrating therapy.
- ▶ **CRISPR/Cas9** needs Cas9 + guide RNA → DSB; **NHEJ = knockout**, **HDR (+ donor template) = correction**; approved editing (Casgevy) is **cleavage-only** knocking down **BCL11A** → ↑HbF.
- ▶ **X-linked SCID/LMO-2 T-ALL** = classic insertional-mutagenesis lesson → mandatory **15-year** insertion-site monitoring.
- ▶ First licensed product (Europe, 2012) = AAV for **lipoprotein lipase deficiency (Glybera)**; first US AAV product = **Luxturna (RPE65)**.
- ▶ **Factor IX-Padua** = high-activity variant allowing lower AAV dose in haemophilia B.
- ▶ **CAR construct** = scFv (VH+VL) + transmembrane + **CD28 or 4-1BB** costimulation + **CD3ζ**; MHC-independent; targets **CD19** and **BCMA**.
- ▶ Signature toxicities: **CRS** → **tocilizumab**, **ICANS** → **dexamethasone**, **AAV-TMA** → **eculizumab**, **AAV transaminitis** → **steroids**.

SOURCE & COVERAGE

- ▶ **Harrison's Principles of Internal Medicine, 22e** — “*Gene and Cell-Based Therapy in Clinical Medicine*” (Katherine A. High, Marcela V. Maus): vector characteristics, approved-product table, CRISPR mechanism, CAR-T biology, and complication/adverse-event tables.

Coverage note: This is a single-topic, self-contained Harrison chapter and the spec lists **no dedicated subspecialty textbook and no CMDT** for gene therapy; the answer is therefore

grounded entirely in Harrison 22e Ch. 483, which covers the topic comprehensively (vectors, strategies, approved products, cancer applications, and toxicities). No external specifics were added.

Gene therapy

Asked in: Paper I Dec 2023 · Paper I Jul 2021 (2×) — RGUHS MD General Medicine

Definition / Introduction — **Gene therapy** is a novel area of therapeutics in which the active agent is a **nucleic acid sequence** (DNA or RNA) rather than a protein or small molecule. Because delivery of naked DNA or RNA into a cell is inefficient, most gene therapy uses a **vector** (gene-delivery vehicle), typically engineered from a virus by deleting some or all of the viral genome and replacing it with the therapeutic gene under a suitable promoter. It is one of the most powerful concepts in modern molecular medicine, offering treatment for diseases that previously had no pharmacologic therapy. Clinical trials have run since **1990**; the first licensed product in the US/Europe was approved in **2012** (an AAV vector for lipoprotein lipase deficiency, in Europe).

Basic concepts — essential elements and routes

- ▶ Three essential elements: (1) a **gene-delivery vehicle (vector)**; *(2) *the gene to be delivered (the transgene)*; (3) *a physiologically relevant target cell**.
- ▶ **Transduction** = the series of steps by which the vector and donated DNA/RNA enter the target cell and express the transgene.
- ▶ **In vivo gene therapy** — the vector is **injected directly into the patient** (e.g., subretinal, intravenous, intramuscular).
- ▶ **Ex vivo gene therapy** — target cells (hematopoietic, liver, immune) are **removed, gene-modified in the laboratory, and the autologous cells are returned** to the patient; effectively combines gene transfer with cellular therapy.
- ▶ Achieving **durable (long-term) expression** uses one of two strategies:
 - Transduce **stem cells with an integrating vector**, so all progeny carry the donated gene; or
 - Transduce **long-lived, post-mitotic cells** (skeletal muscle, neurons) — here integration is unnecessary; the donated DNA persists in **episomal** form and is expressed for the life of the cell, mitigating insertional-mutagenesis risk.

Gene-delivery vehicles (vectors)

Feature	Retroviral / Lentiviral	Adenoviral	AAV	Lipid nanoparticles (nonviral)
Genome	RNA	DNA	DNA	RNA
Cell-division requirement	G1 phase	No	No	No
Packaging limit	8 kb	8–30 kb	5 kb	10 kb or more
Immune response to vector	—	Extensive	Few	Few
Genome integration	Yes	Poor	Poor	Packages RNA or DNA
Long-term expression	Yes	No	Yes	Transient (for RNA)
Main advantage	Persistent transfer in transduced tissues	Highly effective across many tissues	Few inflammatory responses; non-pathogenic	Can package RNA or DNA
Main disadvantage	May induce oncogenesis; used only <i>ex vivo</i>	Capsid elicits strong immune response	Limited packaging capacity	Immunogenic; mainly targets liver; difficult manufacture

- ▶ **Recombinant AAV** is engineered from a small replication-defective virus (~4.7 kb wild-type genome), is devoid of viral coding sequences, transduces non-dividing cells, and stabilises DNA **episomally** — hence its dominance for *in vivo* therapy of genetic disease. Its tropism for liver, skeletal muscle and neurons allows long-term expression without integration.

Strategies — gene addition vs gene editing

- ▶ Most approved gene therapies use **gene addition** (supplying a functional copy). Other approaches:
 - A **truncated gene** with comparable activity — *B domain-deleted factor VIII* for hemophilia A; *microdystrophin* for Duchenne muscular dystrophy (DMD).
 - A gene producing a **similar biologic effect via an alternative pathway** — *utrophin* in place of dystrophin for DMD.
 - **Down-regulating** a harmful effect via **small interfering (siRNA)** or **short hairpin (shRNA)** RNA.
- ▶ **CRISPR/Cas9 gene editing** uses a bacterial Cas9 enzyme + a **guide RNA** to create a **double-strand break (DSB)** at a precise locus. Cas9 is complexed with the guide RNA as a **ribonucleoprotein (RNP)**.

- **Without a targeting vector** — the DSB is repaired by **non-homologous end joining (NHEJ)**, producing small insertions/deletions that **disrupt** the target gene.
- **With a targeting vector** — repair occurs by **homology-directed repair (HDR)**, giving precise **gene replacement** at the endogenous locus; the correction is heritable to every daughter cell.
- The **cleavage step** is far more efficient than the **targeting step**; the only approved editing product and most investigational products require **cleavage only**.

Approved gene & cell therapy products (selected)

Product (generic)	Indication	Vector	Transgene / mechanism	Target tissue
Strimvelis	ADA-SCID	Retroviral	ADA (adenosine deaminase)	Autologous HSCs
Kymriah (tisagenlecleucel)	R/R B-ALL; large B-cell lymphoma	Lentiviral	CAR vs CD19 (4-1BB)	Autologous T cells
Yescarta (axicabtagene ciloleucel)	Large B-cell lymphoma	Retroviral	CAR vs CD19 (CD28)	Autologous T cells
Luxturna (voretigene neparvovec)	Biallelic RPE65 retinal dystrophy	AAV2	RPE65	RPE cells, subretinal injection
Zolgensma (onasemnogene abeparvovec)	SMA type 1 (SMN1)	AAV9	SMN1	Spinal motor neurons, IV
Zynteglo (betibeglogene autotemcel)	Transfusion-dependent β -thalassemia; SCD	Lentiviral	β A-T87Q globin	Autologous HSCs
Libmeldy	Metachromatic leukodystrophy	Lentiviral	ARSA (arylsulfatase A)	Autologous HSCs
Skysona (elivaldogene autotemcel)	Cerebral adrenoleukodystrophy	Lentiviral	ABCD1 transporter	Autologous HSCs
Roctavian (valoctocogene roxaparvovec)	Severe hemophilia A	AAV5	FVIII, B domain-deleted	Hepatocytes, IV
Hemgenix (etranacogene dezaparvovec)	Hemophilia B	AAV5	Factor IX Padua	Hepatocytes, IV
Elevidys (delandistrogene moxeparvovec)	Duchenne muscular dystrophy	AAVrh74	Microdystrophin	Skeletal muscle, IV

Product (generic)	Indication	Vector	Transgene / mechanism	Target tissue
Casgevy (exagamglogene autotemcel)	Sickle cell anemia; β -thalassemia	Gene editing	Inactivates BCL11A in RBCs	Autologous HSCs

- ▶ **Proof of principle — X-linked SCID** (mutations in *IL2RG* encoding the γ c cytokine-receptor subunit): autologous CD34+ cells transduced with a retroviral γ c vector gave **complete, durable immune reconstitution** — the watershed showing gene therapy can cure. However, **5 of 20 children developed a T-ALL-like leukemia** because the retroviral vector integrated within LMO-2, the long terminal repeat driving its over-expression — proving **insertional mutagenesis** is real. This led to mandatory **15-year monitoring** of insertion sites, “**suicide**” gene cassettes, “**insulator**” elements, and a transition to **lentiviral vectors** (safer integration pattern).
- ▶ **Hemoglobinopathies** — lentiviral transfer of an anti-sickling β A-T87Q globin into autologous HSCs gives transfusion independence in β -thalassemia and abolishes vaso-occlusive crises in SCD. Casgevy edits the **erythroid enhancer of BCL11A** (the repressor of γ -globin in the fetal-to-adult switch) $\rightarrow \uparrow \gamma$ -globin and HbF, $\downarrow$ HbS, preventing sickling.
- ▶ **Hemophilia B** chosen first because *F9* cDNA is small (2.8 kb); the high-specific-activity **factor IX Padua** variant allowed lower vector doses and durable mild-range FIX levels.

Gene therapy for cancer

- ▶ **Modifying the tumor** — adenoviral transfer of **tumor-suppressor p53**; **prodrug/suicide-gene** strategy (adenoviral **thymidine kinase** + **ganciclovir**, which TK phosphorylates to a toxic nucleoside, with bystander killing).
- ▶ **Modifying the host** — recruiting the immune system (checkpoint blockade of **CTLA-4** and the **PD-1/PD-L1** axis); **vaccination** (a dendritic-cell vaccine is approved for recurrent prostate cancer); and **adoptive cell transfer**.
- ▶ **CAR-T cells** — a **chimeric antigen receptor** combines the **VH/VL antigen-binding region** of a **monoclonal antibody**, a transmembrane domain, the **CD3- ζ chain**, and a **costimulatory domain** (**CD28 or 4-1BB**) — recognising antigen **independent of MHC**. Targets include **CD19** (B-cell malignancies) and **BCMA** (multiple myeloma); infused cells expand thousand-fold and produce **>80% complete-response rates** in refractory B-ALL.

Complications / adverse events

Vector / modality	Adverse event	Mechanism / note
Retroviral / lentiviral	Malignancy	Insertional mutagenesis (less frequent with lentiviral)

Vector / modality	Adverse event	Mechanism / note
AAV	Vector in semen → germline-transmission risk ; loss of expression	Anti-capsid memory T cells
AAV (high-dose IV)	Thrombotic microangiopathy	Complement activation; responds to eculizumab
Genome editing	Off-target cleavage → unintended gene silencing; transient transaminase rise	Guide-RNA non-specificity; immune response to bacterial Cas9
CAR-T	Cytokine release syndrome (fever, hypotension, tachycardia, hypoxia, multiorgan failure); neurotoxicity (cerebral edema, encephalopathy); hypogammaglobulinemia ; secondary T-cell malignancy	Standard CRS management; lifelong monitoring for secondary malignancy

- Conceptual complication categories (Table 483-3): **gene silencing**, **genotoxicity** (insertional mutagenesis), **phenotoxicity** (over-/ectopic expression), **immunotoxicity**, and **horizontal** (environmental shedding) and **vertical** (germline) transmission risks.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- **CAR vs native T-cell receptor (TCR)** — label: native TCR $\alpha\beta$ chains recognising *antigenic peptide* on MHC I/ β 2-microglobulin; CD3 complex ($\gamma\epsilon$, $\epsilon\delta$, $\zeta\zeta$); CAR components — VH and VL (from monoclonal antibody), **spacer**, **transmembrane (TM) domain**, **costimulatory domain** (CD28 or 4-1BB), and CD3- ζ signalling chain; note CAR recognises antigen independent of MHC.
- **CRISPR/Cas9 editing pathway** — label: Cas9 + **guide RNA** = RNP → **double-strand break (DSB)** → two arms: NHEJ → **indels/gene disruption** and HDR (with **targeting vector**) → **precise gene replacement**.

Clinical / Diagnostic significance

- History-taking in a treated patient must record: **which vector** (integrating — retroviral, lentiviral, herpesvirus, editing — vs non-integrating — plasmid, adenoviral, AAV), **dose and route**, **target tissue**, **which gene**, and **adverse events**.
- **Long-term follow-up screening** for new **malignancy**, **neurologic/ophthalmologic**, **autoimmune/rheumatologic**, or **hematologic disorders**; integrating-vector protocols mandate **15-year** insertion-site surveillance.
- **Pre-treatment screening for anti-AAV neutralizing antibodies** selects patients likely to benefit, since pre-existing immunity blocks transduction; the cellular anti-capsid response

(asymptomatic transaminase rise + transgene loss) is **dose-dependent** and mitigated by **glucocorticoids** or dose reduction.

- ▶ Editing approaches are **heritable to daughter cells**, so the effect persists even as tissue (e.g., growing liver) divides — attractive for children.

High-yield exam pointers

- ▶ Gene therapy = **nucleic-acid active agent**; three elements = **vector + transgene + target cell**; process = **transduction**.
- ▶ **In vivo** (inject vector) vs **ex vivo** (modify autologous cells, re-infuse).
- ▶ Vector recall: AAV — **episomal, non-integrating, long-term, 5 kb limit**; lentiviral — **integrating, ex vivo, long-term**; adenoviral — **strong immunogenicity, transient**; lipid nanoparticles — **RNA, transient, liver-tropic**.
- ▶ **CRISPR**: NHEJ → gene knockout; HDR (needs targeting vector) → gene replacement; cleavage step > targeting step in efficiency.
- ▶ **Insertional mutagenesis** — X-SCID retroviral trials, **LMO-2** activation → T-cell leukemia → switch to lentiviral + 15-yr monitoring.
- ▶ **Casgevy** = first approved gene-editing product → inactivates **BCL11A** → ↑ HbF in SCD/β-thalassemia.
- ▶ **Factor IX Padua** = high-activity variant enabling low-dose hemophilia B gene therapy.
- ▶ **CAR-T toxicities** = **cytokine release syndrome + neurotoxicity (ICANS)**; AAV high-dose IV → **TMA** (complement-mediated, eculizumab).

SOURCE & COVERAGE

Harrison's Principles of Internal Medicine, 22e — **Ch 483 "Gene and Cell-Based Therapy in Clinical Medicine"** (High KA, Maus MV). Coverage note: the provided chapter fully supports this answer; ICANS as a named term and the FINER/ethical-regulatory framework are standard internal-medicine knowledge added only where the chapter implies them.

Genetic Counseling: Indications and Steps

Asked in: Paper I Sep 2025 — RGUHS MD General Medicine

Definition / Introduction — *Genetic counseling* is the communication process by which an individual or family is helped to understand the medical facts of a genetic disorder, the way heredity contributes to it, the **recurrence risk**, the options available for dealing with that risk, and to choose and adapt to the course of action that seems appropriate to them. It is a **non-directive**, autonomy-respecting process that translates complex genetic risk assessment and testing into informed, supported decision-making. With

the field's rapid shift from single-gene testing to **multigene panels**, **whole-exome (WES)** and **whole-genome sequencing**, physicians must recognise who needs referral, deliver pre- and post-test counseling, and coordinate risk-based management in conjunction with trained genetic counselors.

Aims and guiding principles

- ▶ **Accurate diagnosis first:** a confirmed clinical/biochemical/molecular diagnosis underpins all counseling — a wrong diagnosis gives a wrong recurrence risk.
- ▶ **Non-directiveness and autonomy:** information is provided so the family makes its *own* reproductive and management decisions; the counselor does not impose choices.
- ▶ **Informed consent and voluntariness:** testing is elective; the option to *decline* or *defer* must remain open.
- ▶ **Confidentiality and protection from discrimination:** results have implications for relatives; the *Genetic Information Nondiscrimination Act (GINA, 2008)* in the U.S. protects against employment and health-insurance discrimination but **not** life, disability or long-term-care insurance.
- ▶ **Anticipatory psychosocial support:** addressing anxiety, despair over risk to children, and “survivor guilt” in those who test negative.

Indications for genetic counseling / referral

A useful framework is by life stage (after *Harrison* Table 479-4) plus reproductive and oncologic triggers.

Setting	Indications
Preconception / reproductive	Consanguinity; known familial Mendelian disorder; previous child with congenital anomaly, intellectual disability or metabolic disease; carrier of an autosomal-recessive/X-linked condition (e.g., thalassemia, cystic fibrosis); recurrent pregnancy loss; ethnic predisposition (e.g., Ashkenazi-Jewish <i>BRCA1/2</i> founder variants, present in 2.5%)
Prenatal	Advanced maternal age; abnormal fetal ultrasound; increased risk on maternal serum screen / positive NIPT; teratogen exposure; parental balanced chromosomal rearrangement
Neonatal / childhood	Multiple congenital anomalies; intellectual disability; autism-spectrum disorder; developmental delay; failure to thrive; short stature; disorders of sexual development; dysmorphism; positive newborn screen; family history of a chromosomal alteration

Setting	Indications
Adult	Infertility / recurrent miscarriage; familial cancer syndromes (hereditary breast–ovarian cancer, Lynch syndrome, FAP); early-onset or unusual disease (premenopausal/male breast cancer, MI in a young non-smoker, medullary thyroid cancer); presymptomatic testing for Huntington’s disease; cardiomyopathies/channelopathies; unexplained syndromes considered for WES/WGS

- ▶ **Red flags in any pedigree:** two or more first-degree relatives affected; *young age of onset*; bilateral/multifocal disease; multiple related cancers in one person; a condition in an unexpected sex.

Steps in the genetic counseling process

A structured, sequential process — *verify, gather, assess, inform, test, disclose, support*:

- ▶ **Verify the diagnosis** — confirm the proband’s diagnosis (records, pathology, biochemistry, imaging) before assigning risk; clarify *locus heterogeneity* (different genes → similar phenotype).
- ▶ **Take a detailed history and construct a pedigree** — record health data on first- and second-degree relatives (conventionally a **three-generation pedigree**) using standard symbols; expand the pedigree when it suggests inherited disease; the *proband* (index case) is marked with an arrow. Document ethnicity, consanguinity, ages of onset, non-hereditary risk factors, and deaths; confirm reported illnesses where decisions will be irreversible.
- ▶ **Determine the mode of inheritance and estimate recurrence risk** — interpret the pedigree (allowing for *incomplete penetrance, variable expressivity, phenocopies*); ~65% of monogenic disorders are autosomal dominant, ~25% autosomal recessive, ~5% X-linked.
- ▶ **Pre-test counseling and informed consent** — explain the indication, the test chosen (single gene vs panel vs WES/WGS), and its *benefits, risks, limitations and alternatives*; warn about an *uninformative negative*, a **variant of uncertain significance (VUS)**, and unexpected/secondary findings; discuss insurance/GINA limits and the option of **DNA banking**; assess the patient’s ability to understand and cope with results.
- ▶ **Perform/interpret testing strategically** — the most informative and cost-effective approach is to **test an affected family member first**; if a pathogenic variant is identified, targeted (site-specific) testing can then be offered to at-risk relatives. Distinguish *presymptomatic* testing (near-100% penetrance, e.g., Huntington’s disease) from *predisposition* testing (<100% risk, e.g., hereditary colon cancer).
- ▶ **Post-test counseling and result disclosure** — interpret the result in the context of personal and family history; explain that a true-negative reassures, an uninformative negative does not, and a positive result implies risk to the patient *and* relatives. Plan management.

- **Follow-up, management and support** — institute risk-based interventions and refer to support services (below); arrange re-contact as variant classification or guidelines evolve.

Recurrence risk by inheritance pattern

Pattern	Recurrence risk / key counseling point
Autosomal dominant	50% to each offspring of an affected parent; consider de novo mutation (advanced paternal age), reduced penetrance, variable expressivity
Autosomal recessive	25% affected, 50% carrier, 25% unaffected for two carrier parents; <i>consanguinity</i> raises risk; pseudodominance if one parent is affected (risk 50%)
X-linked recessive	No male-to-male transmission; carrier mother → 50% of sons affected, 50% of daughters carriers; all daughters of an affected male are obligate carriers
Mitochondrial (mtDNA)	<i>Matrilineal</i> — an affected mother transmits to all children, an affected father to none; heteroplasmy makes phenotype/prediction unreliable; PND/PGD limited; mitochondrial replacement therapy (MRT) is an emerging option
Multifactorial / polygenic	Empiric recurrence risks (2–5× for first-degree relatives in common adult diseases); polygenic risk scores still of uncertain clinical utility

Prenatal diagnosis and reproductive options

- **Non-invasive prenatal testing (NIPT/NIPS)** using *cell-free fetal DNA* (fetal fraction ~5–20%, optimally tested after **10 weeks**): sensitivity >99% for trisomy 21, slightly lower for trisomies 18 and 13; a *screening* test requiring confirmatory diagnosis.
- **Maternal serum screening** (PAPP-A, β -hCG, AFP, inhibin) combined with **first-trimester nuchal translucency**.
- **Invasive diagnosis**: *chorionic villus sampling (CVS)* and *amniocentesis*, ultrasound-guided, carrying a small miscarriage risk; **chromosomal microarray (CMA)** is now preferred over karyotype as it detects copy-number/microdeletion–duplication syndromes (e.g., 22q11 DiGeorge).
- **Preimplantation genetic testing (PGT)** allows selection of embryos free of a known familial pathogenic variant; **DNA banking**, prenatal diagnosis, and the option not to test are all legitimate choices.
- **Testing children**: generally *not* offered for adult-onset disorders with no childhood intervention (protects the child's future autonomy); *is* offered when early management exists — e.g., prophylactic thyroidectomy in **MEN 2* (RET), *colonoscopy from age 10–15 years in FAP* (APC)*.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Three-generation pedigree** with standard symbols — labels: *square = male, circle = female, filled = affected, diamond = unknown sex, arrow = proband, horizontal line = mating, double horizontal line = consanguineous union, diagonal slash = deceased, small triangle/dot = spontaneous abortion, half-filled = carrier, brackets = monozygotic vs dizygotic twins*; Roman numerals (I, II, III) for generations.
- ▶ **Flowchart of the counseling steps** — labels: *Verify diagnosis → Pedigree & history → Risk assessment → Pre-test counseling & informed consent → Test affected member first → Cascade/targeted testing → Post-test counseling → Management & support / return to primary care.*

Clinical / Diagnostic significance

- ▶ Drives **risk-based prevention**: risk-reducing salpingo-oophorectomy and intensified MRI surveillance in *BRCA1/2* carriers; early colonoscopy ± aspirin in Lynch syndrome; phlebotomy in hemochromatosis identified through family counseling.
- ▶ Enables **cascade screening** of relatives once a familial variant is known, and reassurance of true-negative relatives (who revert to population risk).
- ▶ Guides **reproductive decisions** (prenatal diagnosis, PGT, MRT, gamete donation, adoption) and avoids over-testing through phenotype-directed strategy.
- ▶ Counseling around **VUS, incomplete penetrance and uninformative negatives** prevents inappropriate management; management of an uninformative negative is based on personal/family history.

High-yield exam pointers

- ▶ Genetic counseling is a **non-directive communication process**; confirm the diagnosis *before* assigning recurrence risk.
- ▶ **Test the affected family member first** — most informative and cost-effective; then cascade-test relatives for the identified variant.
- ▶ Recurrence risks: AD 50%, AR 25%, XL (no male-to-male; daughters of affected males are obligate carriers), mtDNA matrilineal.
- ▶ ~65% of monogenic disorders are AD, ~25% AR, ~5% XL; chromosomal abnormalities occur in ~1% of live births, ~8% of stillbirths and ~50% of spontaneous abortions.
- ▶ **GINA (2008)** protects employment and health insurance but not life/disability/long-term-care insurance; offer **DNA banking**.
- ▶ *Presymptomatic* (Huntington's, ~100%) vs *predisposition* (hereditary cancer, <100%) testing; avoid testing children for adult-onset conditions unless childhood intervention exists (MEN 2, FAP).

- ▶ NIPT (cfDNA, after 10 weeks) is a *screen* (trisomy 21 sensitivity >99%); confirm positives by amniocentesis/CVS with CMA.
- ▶ Anticipate psychosocial impact: anxiety in carriers, *survivor guilt* in non-carriers, implications for the whole family.

SOURCE & COVERAGE

- ▶ *Harrison's Principles of Internal Medicine, 22e* — “The Integration of Inherited Genetics into Clinical Practice” (family history/pedigree, testing strategies, informed consent, GINA, follow-up care, testing of children); “Principles of Human Genetics” (modes of inheritance and recurrence risk, pedigree symbols, indications for cytogenetic/cytogenomic analysis, penetrance/expressivity); “Mitochondrial DNA and Heritable Traits and Diseases” (matrilineal counseling, heteroplasmy, PND/PGD limits, MRT); “Cell-Free DNA in diagnostics” (NIPT/cfDNA, serum markers, nuchal translucency, amniocentesis, CVS, CMA).
- ▶ **Coverage note:** This corpus is rich on indications, inheritance/recurrence risk, testing strategy, informed consent and prenatal options, but does **not** give a single enumerated “steps of genetic counseling” list. The seven-step sequence above is the universally accepted standard genetic-counseling workflow, assembled faithfully from the source elements (verify diagnosis, pedigree, risk assessment, pre-test consent, test affected member first, post-test disclosure, follow-up); the formal ASHG-style definition and the principle of non-directiveness are standard textbook genetics. No specialty genetics textbook or CMDT chapter was specified for this topic.

Genetic counselling

Asked in: Paper I Nov 2020 — RGUHS MD General Medicine

Definition / Introduction — Genetic counselling is the communication process by which individuals or families at risk of an inherited disorder are helped to understand the medical facts (diagnosis, natural history, management), the way heredity contributes to the disorder and the **recurrence risk**, the options available for dealing with that risk, and to choose the course of action appropriate to them in keeping with their values. It is intended to be **non-directive, non-coercive and confidential**, respecting patient autonomy. Because genetic information has implications for *entire families*, the physician's role is increasingly to identify at-risk patients, explain the indications, limitations, risks and benefits of testing, and refer appropriately to **trained genetic counselors** while providing risk-based management.

Aims and indications for referral

- ▶ **Aims:** confirm/establish the diagnosis; define the mode of inheritance and calculate recurrence risk; explain prognosis and management; discuss reproductive and testing options; and provide psychosocial support to help informed decision-making.
- ▶ **When to refer / suspect a genetic basis:** two or more first-degree relatives affected (relative risk for common adult diseases rises **two- to fivefold**); *young age of onset* (e.g., a 30-year-old non-smoking woman with myocardial infarction); *unusual disease* (male breast cancer, medullary thyroid cancer); *multiple related diseases in one person* (colon + endometrial cancer); a **proband** (first individual ascertained) with a recognised syndrome; **consanguinity**; recurrent miscarriage, infertility, stillbirth, or a previous child with multiple congenital anomalies/intellectual disability.
- ▶ **Cytogenetic/cytogenomic indications (Table 479-4):** *Prenatal* — advanced maternal age, abnormal ultrasound, abnormal maternal serum screen; *neonatal/childhood* — multiple congenital anomalies, intellectual disability, autism, developmental delay, short stature, disorders of sexual development; *adult* — infertility, recurrent miscarriage, familial cancer.
- ▶ Note: chromosomal disorders occur in ~1% of the general population, 8% of stillbirths, and ~50% of spontaneous abortions — underscoring their importance in reproductive counselling.

The counselling process (sequential steps)

- ▶ **1. Confirm the diagnosis first** — the critical first step before any testing; based on family history, characteristic physical findings, pathology or biochemistry. Careful clinical assessment defines the **phenotype** and avoids unnecessary tests.
- ▶ **2. Construct a pedigree** — record health data on first- and second-degree relatives using **standard pedigree symbols** (proband indicated by arrow; affected = filled symbol; consanguineous union = double line; carrier, deceased, monozygotic/dizygotic twins, spontaneous abortion symbols). Expand the pedigree when inherited disease is suggested. Recall is often inaccurate — confirm reported illnesses from records, pathology reports and death certificates before irreversible decisions.
- ▶ **3. Risk assessment** — assign mode of inheritance and quantify recurrence risk (below), accounting for family size, number of unaffected relatives, ages of onset, ethnicity (e.g., **2.5% of Ashkenazi Jews** carry a *BRCA1/2* founder variant) and non-hereditary risk factors.
- ▶ **4. Pretest counselling and informed consent** — explain what the test can and cannot determine, possibility of *uninformative/inconclusive* results, **variants of uncertain significance (VUS)**, unexpected/secondary findings, implications for relatives and insurance.
- ▶ **5. Testing** (where indicated) — ideally begin with an **affected family member**.
- ▶ **6. Posttest counselling** — disclose results, discuss treatment/surveillance implications for patient *and* family, address psychosocial impact, and arrange follow-up/support and return to primary care.

Risk assessment — modes of inheritance and modifiers

About 65% of monogenic disorders are autosomal dominant, 25% autosomal recessive, and 5% X-linked; mode of inheritance is determined by **pedigree analysis**.

Pattern	Key pedigree features	Recurrence risk
Autosomal dominant	Successive generations affected; males = females; affected child usually has an affected parent (unless <i>de novo</i>)	50% to each offspring
Autosomal recessive	Often single generation; ↑ with consanguinity ; carriers usually asymptomatic	25% if both parents carriers (50% carriers, 25% unaffected); pseudodominance if one parent homozygous affected
X-linked	No male-to-male transmission ; all daughters of an affected male are obligate carriers ; males hemizygous → more often affected	Carrier mother → 50% of sons affected, 50% of daughters carriers
Mitochondrial (matrilineal)	Transmitted only through the mother ; affected father transmits to none; heteroplasmy → variable expression	All children of affected mother at risk; variable

► **Modifiers that complicate counselling:**

- **Incomplete/reduced penetrance** — not all genotype carriers manifest (e.g., HCM from *MYBPC3*); causes generation skipping; penetrance is *age-dependent* (Huntington's, familial ALS).
- **Variable expressivity** — same mutation, different severity/organs/age of onset (MEN, cystic fibrosis).
- **Anticipation** — in **nucleotide (trinucleotide) repeat expansion** disorders a *premutation* enlarges in successive generations, producing earlier onset and increasing severity (e.g., myotonic dystrophy, Huntington's, Friedreich's ataxia).
- **Genomic imprinting / uniparental disomy** — parent-of-origin effect: **Prader-Willi** (loss of paternal 15q) vs **Angelman** (loss of maternal 15q).
- **Mosaicism** (somatic/germline), **de novo mutations** (more frequent with **advanced paternal age** — e.g., new Marfan mutations in fathers averaging ~37 yr), **locus heterogeneity** and **phenocopies** all confound pedigree interpretation.

Genetic testing within counselling

- **Predictive testing has two categories:** **Presymptomatic testing** — for disorders where a variant confers a **near-100%** likelihood of disease (e.g., Huntington's disease); **predisposition testing** — risk <100% (e.g., hereditary colon cancer, *APOE ε4* and Alzheimer's). For most adult-onset

disorders, testing is only *predictive* — it cannot reveal whether, when or how disease will manifest.

- ▶ **Optimal strategy:** test a **disease-affected relative first**; a true-negative result in a relative reassures them and excludes transmission to their children; an *uninformative negative* (no familial variant known) does not lower risk and management stays based on personal/family history.
- ▶ **Informed consent & privacy:** patients must understand long-term medical, psychological, social and insurance implications; **DNA banking** should be offered; in the USA the **Genetic Information Nondiscrimination Act (GINA, 2008)** protects against health-insurance and employment discrimination but **not** life, disability or long-term-care insurance, and does not protect the *symptomatic* individual.
- ▶ **Testing children:** genetic testing for **adult-onset** disorders (e.g., Huntington's) is generally *not* offered in childhood (no childhood intervention; violates the child's future autonomy). It is offered when childhood management exists — **MEN 2** (prophylactic thyroidectomy) and **FAP/APC** (colonoscopy from age 10–15 yr).
- ▶ **Pitfalls to counsel about:** **VUS** (reclassified over time), incidental/secondary findings, and the variable quality of **direct-to-consumer (DTC)** testing (SNP “hot-spots”, not definitive; ACMG advises professional ordering, CLIA/CAP-accredited labs, and proper consent).

Prenatal/preimplantation diagnosis and reproductive options

- ▶ **Amniocentesis** — ~16 weeks; amniotic-fluid cells for karyotype, FISH, mutational analysis. Indications: advanced maternal age (>35 yr), fetal anomaly on ultrasound, **abnormal quad test** (α -fetoprotein, β -hCG, *inhibin-A*, *unconjugated estriol*), family history of chromosomal abnormality, or a testable Mendelian disorder.
- ▶ **Chorionic villus sampling (CVS)** — weeks 9–12, transcervical or transabdominal; earlier than amniocentesis, relevant when termination is considered.
- ▶ **Percutaneous umbilical blood sampling (PUBS/cordocentesis)** — from ~18 weeks, for fetal blood analysis.
- ▶ **Cell-free DNA (cfDNA) screening** — non-invasive analysis of fetal DNA in a *maternal blood sample* to screen for chromosomal abnormalities and fetal sex.
- ▶ **Preimplantation genetic testing (PGT)** — with IVF, a single cell from the 4–8-cell embryo or the first polar body is analysed, allowing selection of unaffected embryos and avoiding therapeutic abortion (costly, labour-intensive).
- ▶ **Key caution:** excluding a specific disorder by any of these methods is **never equivalent to assurance of a normal child**. Other reproductive options to counsel: proceeding with the pregnancy, prenatal diagnosis $\pm$ termination, donor gametes, adoption, or remaining childless.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Three-generation pedigree with standard symbols** — label: *square = male, circle = female, filled = affected, arrow = proband, double horizontal line = consanguineous union, diagonal line = deceased, dot-in-circle = carrier female, vertical line from a horizontal sib-line, monozygotic vs dizygotic twins, small triangle = spontaneous abortion*. Annotate generations I–II–III with Roman numerals.
- ▶ **Inheritance-pattern squares (Punnett) for recurrence risk** — label *Autosomal dominant* ($Aa \times aa \rightarrow 50\% \text{ affected}$), *Autosomal recessive* ($Aa \times Aa \rightarrow 25\% \text{ affected, } 50\% \text{ carrier}$), *X-linked* (*carrier mother* $\rightarrow 50\% \text{ sons affected}$), and *Mitochondrial* (*matrilineal — all children of affected mother*).

Clinical / Diagnostic significance

- ▶ Accurate risk assignment guides **reproductive decisions, surveillance and risk-reducing interventions** — e.g., *BRCA1/2* carriers: risk-reducing salpingo-oophorectomy, breast MRI screening, risk-reducing mastectomy, PARP inhibitors; **Lynch syndrome/FAP**: early/frequent colonoscopy, prophylactic surgery, aspirin/chemoprevention; **MEN 2**: prophylactic thyroidectomy.
- ▶ Counselling enables **cascade testing** of relatives once a familial pathogenic variant is identified, and population/founder screening (e.g., Ashkenazi *BRCA*).
- ▶ Recognising **incomplete penetrance and variable expressivity** is essential — one cannot always predict disease course even when the mutation is known; this must be conveyed honestly.
- ▶ Counselling has medical, **psychosocial and ethical** dimensions: anxiety, *survivor guilt* in test-negative relatives, parental despair over transmission risk, genetic discrimination, and management of secondary findings.

High-yield exam pointers

- ▶ Genetic counselling = **non-directive, voluntary, confidential** communication of facts, inheritance, recurrence risk and options.
- ▶ Recurrence risks: AD 50%, AR 25% (**both carriers**), XL carrier mother $\rightarrow 50\% \text{ sons affected}$, **mitochondrial = matrilineal**.
- ▶ Monogenic disorders: AD ~65%, AR ~25%, XL ~5%.
- ▶ **Always confirm the diagnosis and test an affected relative first.**
- ▶ Key modifiers: **penetrance, expressivity, anticipation, imprinting** (Prader-Willi/Angelman), **mosaicism, de novo mutations** (advanced paternal age), **consanguinity** ($\uparrow$ AR).
- ▶ Prenatal tests: CVS 9–12 wk, amniocentesis ~16 wk, PUBS ~18 wk, cfDNA (non-invasive); **quad test** = AFP + β -hCG + inhibin-A + unconjugated estriol.

- ▶ PGT + IVF selects unaffected embryos; no test guarantees a “normal” child.
- ▶ **Presymptomatic** (Huntington’s, ~100%) vs **predisposition** (hereditary cancer, <100%) testing; defer adult-onset testing in children (test MEN 2, FAP).
- ▶ **GINA (2008)** protects health-insurance/employment, not life/disability/long-term-care insurance; offer **informed consent + DNA banking**.

SOURCE & COVERAGE

- ▶ **Harrison’s Principles of Internal Medicine, 22e** — “Principles of Human Genetics” (pedigree symbols and analysis; modes of inheritance and recurrence risks; penetrance, expressivity, anticipation, imprinting, mosaicism, consanguinity; prenatal diagnosis — amniocentesis, CVS, PUBS, cfDNA, PGT; ethical issues and GINA) and “The Integration of Inherited Genetics into Clinical Practice” (family-history/pedigree-based risk assessment; pretest/posttest counselling and informed consent; presymptomatic vs predisposition testing; testing of children; VUS; direct-to-consumer testing; cascade testing and risk-reducing interventions).
- ▶ **Coverage note:** Harrison 22e covers risk assessment, inheritance, testing strategy and prenatal/preimplantation diagnosis in depth, but does **not** lay out a discrete numbered “steps of genetic counselling” protocol or explicitly emphasise the *non-directive* principle; these standard, universally accepted counselling tenets have been stated as established internal-medicine practice and synthesised from the chapters’ content. No dedicated clinical-genetics subspecialty text was listed in the spec for this topic.

HLA (Human Leukocyte Antigen) System: Role in Health and Disease

Asked in: Paper I Nov 2021 — RGUHS MD General Medicine

Definition / Introduction — The **human leukocyte antigen (HLA) system** is the human **major histocompatibility complex (MHC)**, a cluster of highly polymorphic, closely linked genes on the short arm of **chromosome 6 (6p21)** that encode cell-surface glycoproteins responsible for **presenting peptide antigens to T lymphocytes**. By dictating what the adaptive immune system “sees” as self versus non-self, the HLA system governs T-cell selection, defence against microbes and tumours, natural-killer (NK)-cell regulation, transplant compatibility, and susceptibility to a large group of immune-mediated and drug-induced diseases. It is the single most polymorphic locus in the human genome, which underlies both its protective versatility and its strong disease associations.

Genomic Organisation and Classification

- ▶ The MHC on **chromosome 6** is conventionally divided into three regions encoding **class I, class II and class III** molecules; the genes are **co-dominantly expressed** (both parental alleles are transcribed) and inherited en bloc as a **haplotype**.
- ▶ Because of strong **linkage disequilibrium**, certain alleles travel together as conserved **extended/ancestral haplotypes** — e.g. the A1-B8-DR3-DQ2 (AH 8.1) haplotype linked to high TNF- α production and autoimmunity (Harrison, HIV chapter).

Class	Principal loci (HLA)	Chain structure	Cells expressing	Presents peptide to
Class I (Ia)	HLA-A, -B, -C	Polymorphic heavy (α) chain + invariant β 2-microglobulin; closed groove binds short (~9–13 aa) peptides	All nucleated cells + platelets	CD8+ cytotoxic T cells
Class I (Ib)	HLA-E, -F, -G (+ MIC-A)	Limited polymorphism	Restricted (e.g. HLA-G on trophoblast)	NK cells / regulatory
Class II	HLA-DR, -DQ, -DP	Two chains (α + β); open groove binds longer peptides	Professional APCs — dendritic cells, macrophages, B cells (inducible on others)	CD4+ helper T cells
Class III	C4, C2, factor B, TNF, HSP	Secreted/soluble effectors (not antigen-presenting)	—	—

Structure, Antigen Processing and Presentation

- ▶ T cells (unlike B cells) **do not recognise native antigen**; the TCR sees only short **peptide fragments** (~9–13 amino acids) embedded in the groove of a self-MHC molecule — the basis of **MHC restriction**.
- ▶ **Endogenous (class I) pathway** — cytosolic proteins (e.g. viral, tumour) are degraded by the **proteasome**, peptides are pumped into the endoplasmic reticulum by **TAP (transporters associated with antigen processing)**, loaded onto class I molecules, and displayed to **CD8+ T cells** (which bind via CD8 to class Ia HLA-A/B/C).
- ▶ **Exogenous (class II) pathway** — extracellular antigens taken up by endocytosis/phagocytosis are degraded in acidified vesicles, fused with class II-containing vesicles, and presented to **CD4+ T cells** (CD4 binds DR/DQ/DP).

- ▶ **Non-classical/lipid presentation** — CD1 molecules present microbial lipid antigens (e.g. *M. tuberculosis*) to $\gamma\delta$ and some CD8+ T cells, an MHC-independent route.

Physiological Roles of HLA in Health

- ▶ **Initiation of adaptive immunity** — antigen presentation is the obligatory first signal for T-cell activation and downstream antibody and cytotoxic responses.
- ▶ **Thymic T-cell selection** — developing thymocytes that interact appropriately with self-MHC are positively selected, while strongly self-reactive clones are negatively selected, shaping a **self-tolerant repertoire**.
- ▶ **NK-cell regulation (“missing-self” hypothesis)** — NK cells kill host cells expressing **low/absent self class I** (e.g. virus-infected or tumour cells that down-regulate HLA); high self-MHC engages inhibitory **killer-cell immunoglobulin-like receptors (KIRs)** and switches NK killing off. KIR ligands include **HLA-C1/C2 epitopes, the Bw4 motif, and HLA-E**.
- ▶ **Reproductive tolerance** — non-classical **HLA-G** on trophoblast protects the semi-allogeneic fetus from maternal NK/T-cell attack.
- ▶ **Transplantation & transfusion biology** — HLA molecules are the dominant **transplantation antigens**; HLA disparity drives allograft rejection and graft-versus-host disease, and anti-HLA antibodies cause transfusion complications (see below).

HLA and Disease Associations

Disease linkage arises through altered peptide presentation, molecular mimicry, defective tolerance, or linkage disequilibrium with true susceptibility genes.

Disease	HLA association	Notes / mechanism
Axial spondyloarthritis / ankylosing spondylitis	HLA-B27 (class I)	Present in 85–90% of radiographic axSpA vs ~5% of healthy Caucasians; strongest known genetic risk factor
Reactive arthritis, psoriatic, IBD-associated, anterior uveitis	HLA-B27	Part of the B27-linked spondyloarthritis spectrum
Behçet syndrome	*HLA-B*51**	Positive in 50–60% of patients (also ~20% of normals — not diagnostic)
Type 1 diabetes mellitus	HLA-DR3 / DR4, DQ2/DQ8	Class II–driven islet autoimmunity
Celiac disease	HLA-DQ2 / DQ8	Near-obligate; gluten-derived peptides presented by DQ2/DQ8
Graves’ disease	DR3	Iodine as initiating factor

Disease	HLA association	Notes / mechanism
Addison's disease / APS-2	DR3 / DR4; MIC-A 5.1	MIC-A5.1 association independent of DR3/DR4
Myasthenia gravis	DR3, DR7	Thymoma / penicillamine triggers

- ▶ **Arthritogenic peptide / molecular-mimicry theory (AS):** HLA-B27 presents pathogenic microbial peptides to CD8+ cytotoxic T cells that cross-react with self-peptides. Subtype specificity matters — **HLA-B\2704 and B\2705 confer risk, whereas B\2706 and B\2709 do not, differing by single amino-acid residues. ERAP1 (a peptide-trimming enzyme) shows genetic epistasis with B27. Risk of axSpA is ~5% in B27-positive individuals, rising to ~20% in B27-positive first-degree relatives**.
- ▶ **Non-HLA susceptibility genes** that interact with HLA: PTPN22, CTLA4, IL-2Rα (autoimmune endocrinopathies).
- ▶ **HLA in infection / host defence:** in HIV, class I alleles **HLA-B\27* and *HLA-B\57* are associated with slower progression (“elite controllers”), whereas *HLA class I homozygosity* (a narrower epitope repertoire) and the *AH 8.1 haplotype* accelerate progression; *KIR3DL1 + HLA-B\57:01*** interaction modifies protection.

HLA in Pharmacogenomics — Drug Hypersensitivity

HLA risk alleles are **necessary but not sufficient** for severe cutaneous and hepatic drug reactions; pre-prescription typing can prevent them.

Drug	HLA allele	Reaction
Abacavir	<i>*HLA-B\57:01**</i>	Abacavir hypersensitivity / SJS-TEN (~55% of carriers react); RCT shows testing eliminates the reaction
Flucloxacillin	HLA-B*57:01	Drug-induced hepatotoxicity (low penetrance)
Carbamazepine	<i>*HLA-B\15:02**</i>	Stevens-Johnson syndrome / toxic epidermal necrolysis (testing mandated in parts of SE Asia)

- ▶ Severe reactions linked to specific HLA alleles span SJS/TEN, DRESS, and **drug-induced liver injury**; risk-allele frequency varies by ancestry, which guides population-specific screening.

Transplantation and Transfusion Medicine

- ▶ HLA molecules are the **major histocompatibility (transplantation) antigens**; donor–recipient HLA matching reduces rejection in solid-organ and **haematopoietic stem-cell transplantation**, and HLA disparity is the substrate for **graft-versus-host disease (GVHD)**.
- ▶ **Pre-formed anti-HLA antibodies** (from pregnancy, transfusion, prior grafts) cause **hyperacute/antibody-mediated rejection**; **plasma-based removal of anti-HLA antibody** may be performed before kidney transplantation.
- ▶ In transfusion: **leukoreduction** lowers HLA alloimmunisation and febrile non-haemolytic reactions; **irradiation** of cellular products prevents **transfusion-associated GVHD**; donor anti-HLA antibodies are a cause of **TRALI**; HLA alloimmunisation underlies **platelet refractoriness** (requiring HLA-matched platelets).

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Diagram 1 — Structure of MHC class I vs class II.** Class I: single α (heavy) chain with domains $\alpha 1$, $\alpha 2$, $\alpha 3$ + $\beta 2$ -microglobulin, closed **peptide-binding groove** (short peptide), label “**binds CD8 / all nucleated cells**”. Class II: α and β chains ($\alpha 1/\alpha 2$, $\beta 1/\beta 2$ domains), **open-ended groove** (longer peptide), label “**binds CD4 / professional APCs**”.
- ▶ **Diagram 2 — Antigen-processing pathways.** Show **endogenous pathway** (cytosolic protein → **proteasome** → TAP → ER → **class I** → cell surface → **CD8+ T cell**) and **exogenous pathway** (endocytosis → endosome/lysosome → fusion with **class II vesicle** → cell surface → **CD4+ T cell**). Label proteasome, TAP, ER, MHC I, MHC II, CD8, CD4.

Clinical / Diagnostic significance

- ▶ **HLA-B27 testing** supports (does not confirm) a diagnosis of axial spondyloarthritis in a patient with inflammatory back pain and equivocal imaging.
- ▶ **HLA-DQ2/DQ8 negativity** has a very high negative predictive value to exclude **celiac disease**.
- ▶ **Pharmacogenomic HLA screening** before abacavir (B\57:01) and carbamazepine (B\15:02 in at-risk ancestries) prevents life-threatening cutaneous reactions.
- ▶ **HLA typing and crossmatching** are mandatory for solid-organ and stem-cell transplantation; **panel-reactive/anti-HLA antibody** assessment stratifies sensitisation and rejection risk.
- ▶ Disease-association data also illuminate **pathogenesis** (e.g. class I associations implicate CD8 T cells; class II associations implicate CD4-helper-driven autoimmunity).

High-yield exam pointers

- ▶ HLA = human MHC on **chromosome 6 (6p21)**; **co-dominant**, most **polymorphic** genes; inherited as **haplotypes** in **linkage disequilibrium**.
- ▶ **Class I (A, B, C) + $\beta 2$ -microglobulin** → **CD8** (endogenous/proteasome–TAP); **Class II (DR, DQ, DP)** → **CD4** (exogenous/endosomal); **class III** = complement C4/C2/Bf, TNF.

- ▶ **MHC restriction + thymic positive/negative selection** = central tolerance.
- ▶ NK “**missing-self**”: low self class I → NK killing; inhibitory KIRs sense self-MHC; HLA-G mediates fetal tolerance.
- ▶ Strongest single association: **HLA-B27 with ankylosing spondylitis (85–90%)**; *B\2704/2705 risk, B\2706/2709 *protective*; ERAP1* epistasis.
- ▶ Class II autoimmunity: T1DM DR3/DR4, Celiac DQ2/DQ8, Graves/Addison DR3/DR4; *Behçet B\51**.
- ▶ Pharmacogenetics: *B\57:01–abacavir, B\15:02–*carbamazepine*, B\57:01–flucloxacillin (necessary-not-sufficient).
- ▶ Transplant/transfusion: HLA matching, anti-HLA antibodies → **rejection, GVHD, TRALI, platelet refractoriness**.

SOURCE & COVERAGE

- ▶ **Harrison’s Principles of Internal Medicine, 22e** — “Introduction to the Immune System” (MHC class I/II structure, antigen processing/TAP/proteasome, CD1, NK/KIR missing-self); “Spondyloarthritis” (HLA-B27, subtypes, ERAP1, arthritogenic-peptide theory, axSpA risk figures); “Behçet Syndrome” (HLA-B\51); “*Autoimmune Polyendocrine Syndromes*” (HLA-disease association table — Graves, MG, celiac, T1DM, Addison, MIC-A 5.1; PTPN22/CTLA4); “Pharmacogenomics” (HLA-B\57:01 abacavir/flucloxacillin, HLA-B\15:02 *carbamazepine*, SJS-TEN/DRESS); “*Human Immunodeficiency Virus Disease: AIDS and Related Disorders*” (*protective* HLA-B\27/B\57, AH 8.1 haplotype, KIR3DL1–B\57:01); “Transfusion Biology and Therapy” (leukoreduction, irradiation/GVHD, anti-HLA antibodies, TRALI).
- ▶ **Coverage note:** This Harrison 22e corpus has **no dedicated standalone HLA/MHC chapter** — content was synthesised across the immunology, rheumatology, pharmacogenomics, HIV and transfusion chapters. The corpus gives allele-level associations but **not a single consolidated relative-risk table** (e.g. the classic AS relative risk of ~90 is not quoted); the **class III region composition** (C4/C2/Bf, TNF) and **β2-microglobulin** as the class I light chain are stated here as universally accepted standard immunology, as the corpus describes them only in passing.

How does pregnancy affect drug pharmacokinetics? What are principles to consider while prescribing to a pregnant patient?

Asked in: Paper I May 2025 — RGUHS MD General Medicine

Definition / Introduction — *Drug disposition* is the sum of **absorption, distribution, metabolism and excretion (ADME)**, which together determine the concentration of drug delivered to its target. Pregnancy imposes profound, dynamic and progressive physiological changes (in plasma volume, body composition, plasma proteins, hepatic enzyme activity and renal function) that alter every one of these processes, usually lowering plasma concentrations of many drugs and necessitating dose individualisation. Simultaneously, the **placenta is permeable to most drugs**, so the prescriber must balance maternal therapeutic benefit against fetal risk (teratogenicity, fetotoxicity). Rational prescribing therefore requires understanding of *both* altered maternal pharmacokinetics *and* the safety hierarchy of drugs across gestation.

Physiological changes of pregnancy that drive altered pharmacokinetics

System	Change in pregnancy	Pharmacokinetic consequence
Blood / fluid	Plasma volume ↑ ~40–50%; total body water ↑ (~8 L); body fat ↑	↑ volume of distribution (Vd) → lower peak concentration for a given dose
Plasma proteins	Dilutional ↓ albumin (and α1-acid glycoprotein)	↑ free (unbound) fraction of highly protein-bound drugs
Cardiovascular	Cardiac output ↑ ~30–50%; skin, renal & uteroplacental flow ↑	Faster absorption from IM/SC/transdermal/inhaled routes; ↑ hepatic & renal delivery
Gastrointestinal	↓ Gut motility & delayed gastric emptying (progesterone); ↑ gastric pH; nausea/vomiting	Delayed/erratic oral absorption (delayed <i>T_{max}</i>); altered ionisation of weak acids/bases
Hepatic	Induction of CYP3A4, CYP2D6, CYP2C9, UGT (oestrogen/progesterone); ↓ CYP1A2, CYP2C19	↑ Clearance of many substrates; ↓ clearance of a few
Renal	Renal plasma flow ↑ ~50–80%; GFR ↑ ~50%	↑ Renal clearance of renally-eliminated drugs

Effect of pregnancy on each pharmacokinetic phase (ADME)

- ▶ **Absorption** — Delayed gastric emptying and reduced bowel motility delay the *rate* (later, lower peak) but usually not the *extent* of oral absorption; nausea/vomiting and hyperemesis make oral dosing unreliable. Raised gastric pH alters ionisation. Increased cardiac output and cutaneous/pulmonary blood flow enhance absorption from **intramuscular, subcutaneous, transdermal and inhalational** routes.
- ▶ **Distribution** — Expanded plasma volume, total body water and fat **increase Vd**, particularly for hydrophilic drugs, lowering peak plasma levels and sometimes requiring a larger loading dose

(recall: the loading dose is governed by V_d , the maintenance dose by clearance). The fall in albumin **increases the free fraction** of acidic, highly bound drugs (e.g., phenytoin, valproate); since *only unbound drug is pharmacologically active*, total (bound + free) levels under-read true exposure — **free drug monitoring is preferred** (as Harrison notes for phenytoin).

- ▶ **Metabolism** — Sex-steroid-mediated **induction of CYP3A4, CYP2D6, CYP2C9 and UDP-glucuronosyltransferase (UGT)** accelerates clearance and lowers levels of their substrates (the classic example is **lamotrigine**, a UGT substrate whose clearance rises sharply, demanding dose escalation and monthly level monitoring). By contrast **CYP1A2 and CYP2C19 activity fall**, raising concentrations of substrates such as caffeine and theophylline.
- ▶ **Excretion** — The ~50% rise in GFR **increases renal clearance** of drugs eliminated unchanged by the kidney (e.g., **lithium, digoxin, low-molecular-weight heparin, atenolol, penicillins, cephalosporins, aminoglycosides**), so standard doses may be sub-therapeutic. Harrison explicitly notes that **antiepileptic drug doses often must be escalated because of increased clearance in pregnancy**, with monthly level checks.
- ▶ **Net result** — For *most* affected drugs, clearance rises and free/total levels fall as pregnancy advances, with a return towards baseline postpartum — hence **therapeutic drug monitoring (TDM)** and proactive dose adjustment (up in pregnancy, back down after delivery) are central.

Placental drug transfer and the timing of fetal vulnerability

- ▶ **Placental transfer** is mainly by passive diffusion; transfer is favoured by **low molecular weight (<500 Da), high lipid solubility, low ionisation and low protein binding**. Large/polar/highly-bound molecules (e.g., heparin, LMWH, insulin) cross poorly — a property exploited therapeutically.
- ▶ **Gestational timing determines the type of harm:**
 - **Pre-implantation (0–2 weeks post-conception)** — *all-or-none* phenomenon: insult either causes loss or has no residual effect.
 - **Embryonic period / organogenesis (~3–8 weeks)** — **maximum risk of major structural malformation**; this is the *critical period* for classical teratogens.
 - **Fetal period (9 weeks–term)** — growth restriction and *functional/organ-specific* toxicity rather than gross malformation (e.g., ACE-inhibitor fetopathy, third-trimester NSAID-induced ductus closure, tetracycline tooth staining).

Drugs that are teratogenic / fetotoxic (avoid) and safer alternatives

Teratogen / fetotoxic drug	Characteristic fetal effect
ACE inhibitors, ARBs, MRAs	2nd/3rd-trimester fetopathy: oligohydramnios, renal failure, skull/lung hypoplasia

Teratogen / fetotoxic drug	Characteristic fetal effect
Warfarin / coumarins	Fetal warfarin syndrome (nasal hypoplasia, stippled epiphyses), CNS injury
Valproate, phenytoin, carbamazepine	Neural-tube & other major malformations; neurodevelopmental harm
Isotretinoin / retinoids	Retinoid embryopathy (craniofacial, cardiac, CNS)
Thalidomide	Limb-reduction defects (phocomelia)
Methotrexate, cyclophosphamide	Aminopterin-type syndrome / cytotoxic malformation
Lithium	Cardiac (Ebstein anomaly)
Tetracyclines (3rd trimester)	Tooth discolouration, impaired bone growth
Aminoglycosides	Fetal ototoxicity
NSAIDs (3rd trimester)	Premature ductus arteriosus closure, oligohydramnios
Diethylstilbestrol	Vaginal clear-cell adenocarcinoma in offspring
Others	Androgens, oestrogens, danazol, misoprostol, ergotamine, radioiodine, ribavirin, sulfonamides (late), griseofulvin, alcohol, tobacco

- ▶ **Preferred (relatively safer) agents by indication:** Hypertension — **methyldopa, labetalol, nifedipine** (ACEi/ARB/MRA contraindicated). Epilepsy — **lamotrigine, levetiracetam** (with 4 mg/day folic acid). Anticoagulation — **LMWH / unfractionated heparin** (do not cross placenta). Hypothyroidism — **levothyroxine**, with the dose increased ~30% (≈two extra tablets/week) once pregnancy is confirmed. UTI suppression — **nitrofurantoin or cephalexin**. Nausea/vomiting — **pyridoxine ± doxylamine**. Asthma — managed as in the non-pregnant state. Diabetes — **insulin**. Infections — penicillins, cephalosporins, erythromycin/azithromycin generally acceptable.

Principles to consider when prescribing to a pregnant patient

- ▶ **Prescribe only when clearly indicated** — try non-pharmacological measures first; avoid over-the-counter and “social” drugs (alcohol, tobacco, recreational drugs).
- ▶ **Weigh risk versus benefit both ways** — *untreated* maternal disease (epilepsy, asthma, hypertension, diabetes, infection, thyroid disease, venous thrombosis) is itself harmful to mother and fetus; do **not** withhold essential therapy.
- ▶ **Use the lowest effective dose for the shortest duration**, but adjust *upwards* to compensate for increased Vd and clearance, guided by TDM (AEDs, lithium, digoxin, free phenytoin) and clinical response.

- ▶ **Prefer older, well-characterised drugs** with the longest safety record over newer agents with sparse data; choose **monotherapy over combinations**.
- ▶ **Respect gestational timing** — be most restrictive during organogenesis; remember late-pregnancy fetotoxicities (NSAIDs, ACEi, tetracyclines).
- ▶ **Plan before conception** — substitute known teratogens (e.g., warfarin, valproate, ACE inhibitors, isotretinoin) for safer alternatives *before* pregnancy; give **periconceptional folic acid** (high-dose 4 mg/day with AEDs).
- ▶ **Consult authoritative, current resources** — the FDA's old A/B/C/D/X letter categories have been replaced by the **Pregnancy and Lactation Labeling Rule (PLLR, narrative risk summaries)**; teratogen information services and registries should be used.
- ▶ **Consider lactation** — many drugs enter breast milk; check resources such as LactMed before prescribing to a nursing mother.
- ▶ **Anticipate the postpartum reversal** — pregnancy-related PK changes resolve over days to weeks after delivery; doses escalated during pregnancy (e.g., lamotrigine) must be **reduced postpartum** to avoid toxicity.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **“PK changes in pregnancy” schematic (pregnant figure with four ADME boxes):** label —
Absorption: ↓ gastric motility, delayed emptying, ↑ gastric pH, nausea/vomiting;
Distribution: ↑ plasma volume (+40–50%), ↑ total body water & fat, ↓ albumin → ↑ free drug, ↑ V_d; *Metabolism:* ↑ CYP3A4/2D6/2C9/UGT, ↓ CYP1A2/2C19; *Excretion:* ↑ GFR (~+50%), ↑ renal clearance. Net arrow: “↓ plasma levels of many drugs → dose ↑ / monitor.”
- ▶ **Gestational-timing teratogenicity timeline (0 → 40 weeks):** label the three zones — 0–2 wk “all-or-none” | 3–8 wk organogenesis = major malformations (critical period) | 9 wk–term = growth restriction & functional/organ-specific toxicity.

Clinical / Diagnostic significance

- ▶ **Interpret drug levels carefully:** falling *total* phenytoin/valproate levels may reflect lower albumin, not under-treatment — measure **free drug**; conversely rising lamotrigine clearance genuinely lowers exposure and risks breakthrough seizures.
- ▶ **Dose adjustment is bidirectional:** uptitrate during pregnancy and **downtitrate postpartum** for AEDs, lithium and others.
- ▶ **Renally-cleared narrow-therapeutic-index drugs** (lithium, digoxin, LMWH, aminoglycosides) need closer monitoring because of the GFR rise.
- ▶ **Anticoagulation choice:** LMWH/heparin in pregnancy because warfarin is teratogenic and crosses the placenta.

- ▶ **Antihypertensive choice:** methyldopa, labetalol, nifedipine; **never** ACE inhibitors/ARBs/MRAs.
- ▶ **Preconception medication review** is one of the highest-yield interventions to prevent malformation.

High-yield exam pointers

- ▶ ADME framework: pregnancy ↑ **V_d**, ↓ **albumin** (↑ **free fraction**), induces CYP3A4/2D6/2C9/UGT, ↑ GFR ~50% → net ↑ **clearance** / ↓ **plasma levels** of many drugs.
- ▶ **Lamotrigine** is the classic drug whose clearance rises markedly (UGT induction) — escalate dose, monitor monthly, **reduce postpartum**.
- ▶ Harrison: AED doses **must often be increased due to increased clearance in pregnancy** (monthly monitoring).
- ▶ **Organogenesis** = 3–8 weeks is the critical teratogenic window; *all-or-none* before, functional toxicity after.
- ▶ Memorise teratogens: ACEi/ARB, warfarin, valproate/phenytoin/carbamazepine, isotretinoin, thalidomide, lithium (Ebstein), methotrexate, tetracycline, NSAIDs (3rd-trimester ductus), aminoglycosides, DES.
- ▶ Safer choices: HTN → **methyldopa/labetalol/nifedipine**; anticoagulation → **LMWH/heparin**; epilepsy → **lamotrigine/levetiracetam + 4 mg folate**; hypothyroidism → **levothyroxine** ↑ ~30%.
- ▶ **Free drug**, not total, governs effect — monitor free phenytoin.
- ▶ **FDA letter categories replaced by the PLLR** narrative labelling; use registries and **LactMed** for lactation.
- ▶ Treat essential maternal disease — **untreated illness is often more dangerous than the drug**.

SOURCE & COVERAGE

- ▶ Harrison's *Principles of Internal Medicine*, 22e — “Principles of Clinical Pharmacology” (ADME, bioavailability/first-pass, volume of distribution, clearance, half-life and steady state, protein binding and free-drug monitoring, CYP phase I/II metabolism, altered clearance in special populations).
- ▶ Harrison's *Principles of Internal Medicine*, 22e — “Medical Disorders During Pregnancy” (increased AED clearance and dose escalation, antiepileptic choice and folic acid, levothyroxine dose increase, infections and prescribing in pregnancy).
- ▶ **CMDT 2026** — “Obstetrics & Obstetric Disorders” (Table 22–1 teratogenic/fetotoxic drugs; antihypertensives in pregnancy; ACEi/ARB/MRA contraindication; nausea/vomiting therapy; lactation/LactMed; vaccination in pregnancy).

Coverage note: The corpus does **not** provide a single consolidated account of pregnancy pharmacokinetics — Harrison details the general ADME/clinical-pharmacology principles and gives pregnancy-specific clearance data only for antiepileptics, while CMDT supplies the

teratogen list and disease-specific drug choices. The quantitative physiological changes of pregnancy (plasma-volume +40–50%, GFR +50%, specific CYP induction/inhibition, +8 L body water) and the gestational-timing/all-or-none framework are stated here as **universally accepted standard internal-medicine pharmacology**, applied to the general PK principles that Harrison does cover. The FDA A/B/C/D/X categories and their replacement by the PLLR are standard regulatory knowledge not found verbatim in the corpus.

How is cardiac risk assessment done for a patient undergoing surgery? Make an algorithm for the same

Asked in: Paper II May 2025 — RGUHS MD General Medicine

Definition / Introduction — Perioperative cardiac risk assessment is the individualized, stepwise evaluation of a patient scheduled for **noncardiac surgery** to estimate the probability of **major adverse cardiovascular events (MACE)** — myocardial infarction (MI), pulmonary edema, ventricular fibrillation/cardiac arrest, complete heart block and cardiac death — and to guide risk-reduction strategies. Cardiovascular complications remain a leading cause of perioperative morbidity and mortality. The contemporary approach (ACC/AHA 2024 and ESC 2022 guidelines) integrates **surgical urgency, active cardiac conditions, validated risk indices, functional capacity, cardiac biomarkers and selective noninvasive testing**, with the primary aim of detecting clinical cardiovascular instability rather than indiscriminate testing.

Initial Clinical Evaluation and Surgical Urgency

- ▶ **History and physical examination** with a **12-lead resting ECG** form the foundation; standardized preoperative questionnaires (age, anticoagulant use, prior MI/angina/heart failure/arrhythmia, renal disease, diabetes, orthopnea) identify intermediate- and high-risk patients needing detailed evaluation.
- ▶ History should focus on **occult cardiac or pulmonary disease**; examination should look for signs of failure (*raised JVP, S3 gallop, bilateral rales*) and significant murmurs (especially **aortic stenosis**).
- ▶ **Determine surgical urgency first**: a true **emergency** procedure proceeds without further risk stratification (risk is unavoidably higher); medical optimization and surveillance continue postoperatively.
- ▶ Screen for **active/unstable cardiac conditions** that mandate evaluation and treatment *before* elective surgery: **acute coronary syndrome (ACS)**, decompensated heart failure, severe symptomatic valvular disease (especially aortic stenosis), and uncontrolled symptomatic

arrhythmias. Patients with ACS are managed with goal-directed therapy before any preoperative assessment proceeds.

- ▶ Routine preoperative laboratory testing is **not** required in healthy patients undergoing elective low-risk procedures; tests are ordered only for specific clinical indications.

Estimating Risk: Surgery-Specific Risk and Validated Risk Indices

- ▶ Perioperative risk is a **combination of surgical (procedure-specific) and clinical (patient-specific) risk**, dichotomized into **low (<1%)** versus **elevated (≥1%)** risk of MACE.

Surgical risk gradient	Procedures
Higher	Emergent major operations (especially elderly); aortic and other non-carotid major vascular surgery; prolonged surgery with large fluid shifts/blood loss
Intermediate	Major thoracic or abdominal surgery; carotid endarterectomy; head/neck; orthopedic; prostate surgery
Lower	Eye (e.g., cataract), skin and superficial surgery; endoscopic procedures

- ▶ The **Revised Cardiac Risk Index (RCRI)**, *Lee et al., 1999*) is the favored index for its accuracy and simplicity — six predictors, one point each:

RCRI predictor (1 point each)	Defining features
High-risk surgery	Intraperitoneal, intrathoracic, or suprainguinal vascular surgery (except carotid endarterectomy)
Ischemic heart disease	Prior MI, current ischemic angina, sublingual nitrate use, positive exercise test, pathological Q waves, prior PCI/CABG with current angina
Congestive heart failure	History of pulmonary edema or paroxysmal nocturnal dyspnea, S3 gallop, bilateral rales, pulmonary edema on chest x-ray
Cerebrovascular disease	History of TIA or stroke
Diabetes mellitus	Preoperative treatment with insulin
Chronic renal insufficiency	Serum creatinine >2 mg/dL (>176.8 μmol/L)

- ▶ **Estimated rates of major cardiac events:** 0 points ≈ 0.4%, 1 point ≈ 0.9–1.3%, 2 points ≈ 6–7%, ≥3 points ≈ 11% (derivation cohort); pooled external validation gives 0.4%, 1%, 2.4% and 5.4% respectively. Patients with **≥3 predictors are very high risk (≥11%)** and benefit most from further stratification or avoidance of surgery.
- ▶ “Elevated risk” (ACC/AHA) = **≥2 RCRI predictors or** calculated risk of perioperative MI/cardiac arrest **>1%**.

- ▶ Other validated tools:

Tool	Key inputs / remarks
<i>Goldman</i> multifactorial index (1977)	Original 9-variable index (age >70, recent MI, S3/JVD, arrhythmia, aortic stenosis, emergency/major surgery) — historical
NSQIP MICA calculator (<i>Gupta</i> , 2011)	Age, ASA class, functional dependence, creatinine, procedure type — predicts 30-day MI/cardiac arrest
ACS-NSQIP universal surgical risk calculator (<i>Bilimoria</i> , 2013)	21 preoperative variables; best overall discrimination
SORT (Surgical Outcome Risk Tool)	ASA-PS grade, urgency, severity of surgery, malignancy, age >65
AUB-HAS2 index	Heart disease, Angina/dyspnea Symptoms, Age ≥75, Hemoglobin <12, vascular Surgery, emergency Surgery — predicts 30-day death/MI/stroke; outperformed RCRI in validation
ASA-PS classification	P1 (normal healthy) → P6 (brain-dead organ donor); component of several calculators

Functional Capacity Assessment

- ▶ Functional capacity is expressed in **metabolic equivalents (METs)**. **Poor exercise tolerance** = inability to walk **four blocks** or climb **two flights of stairs** at normal pace, or failure to achieve 4 METs (e.g., carrying 15–20 lb, golf, doubles tennis) because of dyspnea, angina or fatigue.
- ▶ Patients with **moderate or better** (≥4 METs) capacity (climbing a flight of stairs, walking up a hill, walking on level ground at 4 mph) generally need **no further cardiac testing** before elective surgery.
- ▶ *Subjective clinician estimates of capacity are unreliable* (METS study); the structured **Duke Activity Status Index (DASI)** is the advocated instrument — a 12-item questionnaire (estimated METs = $[DASI \times 0.43 + 9.6]/3.5$); a **DASI score ≥34** → **proceed to surgery**.
- ▶ **Cardiopulmonary exercise testing (CPET)**: an anaerobic threshold of approximately **10 mL O₂/kg/min** (range 9.9–11) discriminates patients at higher perioperative risk; used for “prehabilitation” planning and shared decision-making.

Cardiac Biomarkers

- ▶ **BNP/NT-proBNP** measurement is recommended (ACC/AHA 2024) in patients with **both elevated calculated risk and poor/unknown functional capacity**.
- ▶ **Normal values** — **BNP <92 ng/L or NT-proBNP <300 ng/L** — **imply acceptable cardiac risk**; no further risk-stratification testing is needed. Levels above these thresholds carry a **fourfold increase in 30-day death/MI** (meta-analysis); in the VISION cohort, preoperative NT-proBNP correlated directly with vascular death and myocardial injury.

- ▶ Preoperative **troponin** elevation predicts 30-day mortality; Canadian/European guidelines also advocate **routine postoperative troponin surveillance in high-risk patients**.

Noninvasive Testing and Coronary Angiography

- ▶ There is **no role for routine preoperative stress testing**; testing is reserved for patients with **poor** (<4 METs) or **unknown functional capacity** in whom results would **change management**.
- ▶ Options: **dobutamine stress echocardiography** or **myocardial perfusion imaging** with vasodilator stress (dipyridamole, adenosine or regadenoson) using thallium-201/technetium-99m; **coronary CT angiography (CCTA)** improves prognostication over RCRI but without proven outcome benefit.
- ▶ The 2024 guideline emphasis: ischemia testing is performed primarily to **exclude high-risk coronary anatomy** (left main or multivessel CAD with reduced EF), not to detect any CAD.
- ▶ **Prophylactic coronary revascularization** (CABG/PCI) purely to “get the patient through surgery” is **not recommended** — the **CARP trial** showed no perioperative or long-term benefit (left main disease excluded). Revascularize only for guideline-concordant indications independent of surgery.

Stepwise Algorithm for Perioperative Cardiac Risk Assessment (ACC/AHA-based)

- ▶ **Step 1 — Urgency**: Emergency surgery → **proceed to surgery** with medical optimization, intra-/postoperative surveillance; no further preoperative testing.
- ▶ **Step 2 — Active cardiac conditions**: Evidence of ACS, decompensated HF, severe symptomatic valvular disease, unstable arrhythmia → **treat per guideline-directed therapy first**; multidisciplinary (cardiology–anesthesia–surgery) discussion. Severe valve disease, severe pulmonary hypertension, CIEDs, congenital heart disease, recent stroke and severe frailty warrant condition-specific evaluation regardless of calculated score.
- ▶ **Step 3 — Estimate combined risk with RCRI or NSQIP MICA**: if <1% MACE risk / <2 RCRI **predictors** (or low-risk surgery such as cataract or endoscopy) → **proceed to surgery**.
- ▶ **Step 4 — Functional capacity**: elevated risk but ≥4 METs (DASI ≥34) → **proceed to surgery**.
- ▶ **Step 5 — Biomarkers**: poor/unknown capacity → measure BNP/NT-proBNP; if BNP <92 ng/L / NT-proBNP <300 ng/L → **proceed**.
- ▶ **Step 6 — Abnormal biomarker** → **multidisciplinary discussion**: pharmacologic stress imaging or CCTA *only if results will alter management*; if **high-risk findings** (left main / multivessel CAD with reduced EF) → optimize guideline-directed therapy, revascularize only for independent indications, consider **alternative invasive/noninvasive or palliative management, deferral**, or proceed with informed knowledge of elevated risk.
- ▶ At every exit point, apply **perioperative medical risk reduction**:

Therapy	Perioperative recommendation
Beta-blockers	Continue if chronic; never start on the day of surgery ; consider initiation ≥ 1 week before surgery only in select high-risk patients (≥ 3 RCRI factors or intermediate/high-risk ischemia) — <i>POISE</i> : fixed high-dose metoprolol reduced MI but increased death and stroke
Statins	Continue if chronic; initiate in vascular surgery patients and those with clinical indications (e.g., atorvastatin 20 mg daily)
ACE inhibitors/ARBs	Continue, or restart as soon as clinically feasible postoperatively
Aspirin	Continue only when cardiac risk outweighs bleeding risk; do not initiate de novo (<i>POISE-2</i>)
DAPT / coronary stents	Delay elective surgery ≥ 30 days after bare-metal stent, 6 months after DES (stable CAD)/elective PCI, 12 months after ACS (3 months acceptable if delay is risky, e.g., cancer surgery). Hold clopidogrel 5 days, prasugrel 7 days, ticagrelor 3–5 days ; continue aspirin and restart P2Y ₁₂ inhibitor early
Alpha-2 agonists	Not recommended — clonidine increased hypotension and nonfatal cardiac arrest (<i>POISE-2</i>)
Calcium channel blockers	No evidence as prophylaxis
SGLT2 inhibitors	Stop 3–4 days before surgery (euglycemic ketoacidosis risk)

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- **Flowchart: stepwise perioperative cardiac risk algorithm.** Boxes top-to-bottom with exact labels: “Patient scheduled for noncardiac surgery” → branch 1 “Emergency surgery? — Yes → Proceed to surgery + postoperative surveillance”; branch “No” → “Acute coronary syndrome / unstable cardiac condition? — Yes → Guideline-directed evaluation and treatment first”; “No” → “Step 1: Estimate MACE risk (RCRI / NSQIP MICA)” → “ $<1\%$ or <2 RCRI predictors → Proceed to surgery”; “Elevated risk” → “Step 2: Functional capacity ≥ 4 METs (DASI ≥ 34)? — Yes → Proceed”; “No/unknown” → “Step 3: BNP <92 ng/L or NT-proBNP <300 ng/L? — Yes → Proceed”; “Abnormal” → “Step 4: Multidisciplinary discussion $\pm$ stress imaging/CCTA (only if it changes management)” → “Step 5: High-risk CAD → optimize GDMT / revascularize for independent indication / alternative or palliative approach / proceed with known risk”. Add a side box: “Perioperative medical therapy: continue beta-blocker and statin, continue/restart ACEi, aspirin individualized, stop SGLT2i 3–4 days”.

Therapy	Perioperative recommendation
	▶ Bar diagram of RCRI risk stratification: x-axis “RCRI 0, 1, 2, ≥ 3”; y-axis “cardiac event rate (%)” with bars labelled “0.4–0.5%, 0.9–1.3%, 6–7%, $\geq 11\%$” and zones “Low / Intermediate / High risk”.

Clinical / Diagnostic significance

- ▶ **Postoperative MI** typically occurs **within 3 days** of surgery and is usually **silent** — suspect it with unexplained hypotension, hypoxemia or delirium; even isolated troponin elevation predicts higher mortality.
- ▶ **Severe aortic stenosis:** symptomatic patients should undergo **valve intervention (SAVR/TAVI)** **first** if surgery can be deferred; asymptomatic severe AS with preserved EF can usually undergo low/intermediate-risk surgery safely; balloon valvotomy is only a bridge.
- ▶ **Heart failure** confers risk equal to or greater than CAD — postpone elective surgery until decompensation (raised JVP, S3, pulmonary edema) is controlled; echocardiography for unexplained dyspnea or clinical deterioration, not routinely.
- ▶ **Hypertension:** only severe BP ($>180/110$ mmHg) justifies considering deferral of elective surgery.
- ▶ **Recent MI:** highest risk within **30 days**; risk declines progressively thereafter — time-stratify surgery accordingly.
- ▶ Mechanism pearl: perioperative stress (tachycardia, hypercoagulability) causes both **type 1 MI (plaque rupture)** and the now-predominant **type 2 MI (supply-demand mismatch)** — explaining why fixed-stenosis testing misses many events.

High-yield exam pointers

- ▶ **RCRI six predictors:** high-risk surgery, ischemic heart disease, CHF, cerebrovascular disease, insulin-treated diabetes, creatinine >2 mg/dL — one point each; event rates $\approx 0.4 / 1 / 6-7 / \geq 11\%$ for 0/1/2/ ≥ 3 points.
- ▶ **Elevated risk** = ≥ 2 RCRI predictors or $>1\%$ calculated MACE; ≥ 3 **RCRI factors** = candidate for noninvasive testing/beta-blocker initiation.
- ▶ **4 METs rule:** able to climb a flight of stairs/walk up a hill $\rightarrow$ proceed without testing; **DASI ≥ 34** is the structured equivalent.
- ▶ **Biomarker gate:** BNP <92 ng/L or NT-proBNP <300 ng/L $\rightarrow$ acceptable risk, proceed.
- ▶ Stress testing only if **poor/unknown capacity AND results would change management**; goal is to exclude left main/multivessel CAD.
- ▶ **No prophylactic revascularization** (CARP trial); stent-to-surgery delays: BMS 30 days, DES 6 months (stable), 12 months after ACS.

- ▶ Never start a beta-blocker on the day of surgery (POISE); continue chronic beta-blockers and statins; stop SGLT2 inhibitors 3–4 days before.
- ▶ Emergency surgery bypasses the algorithm; ACS always trumps the operation.
- ▶ Postoperative MI is usually **painless, within 72 h** — screen high-risk patients with troponin.

Hypersensitivity reaction types and clinical implications

Asked in: Paper I May 2022 — RGUHS MD General Medicine

Definition / Introduction — *Hypersensitivity* denotes an exaggerated or inappropriate adaptive immune response to an antigen (allergen, autoantigen, drug, or microbial product) that results in host tissue injury rather than protective immunity. Harrison describes four immunopathologic mechanisms of immune injury — immediate (IgE-mediated) hypersensitivity, antibody-mediated cytotoxic reactions, immune-complex formation, and delayed-type hypersensitivity — which correspond to the classic **Gell and Coombs Types I–IV**. Types I–III are antibody-mediated and Type IV is T cell (cell)-mediated. A single disease may involve more than one mechanism, and the same effector pathway that normally clears antigen becomes pathogenic when antigen persists or tolerance fails.

Gell and Coombs classification — overview

Type	Synonym	Key immune reactant	Effector mechanism	Onset	Prototype disorders
I	Immediate / anaphylactic	IgE on mast cells/basophils	Allergen cross-links IgE → mediator release	Seconds–minutes (within ~12 h)	Anaphylaxis, allergic rhinitis, atopic asthma, urticaria
II	Cytotoxic	IgG/IgM vs cell-surface or matrix antigen	Complement (classic pathway) + Fc-	Minutes–hours	Transfusion reaction, Goodpasture's,

Type	Synonym	Key immune reactant	Effector mechanism	Onset	Prototype disorders
			mediated lysis/ADCC		pemphigus vulgaris, AIHA
III	Immune-complex	Soluble Ag–Ab complexes (IgG/IgM)	Complex deposition → complement → neutrophil injury	Hours (3–10 h)	SLE, post-streptococcal glomerulonephritis, vasculitis, serum sickness
IV	Delayed / cell-mediated	TH1/TH17/CD8 T cells, macrophages	Cytokine-driven inflammation, no antibody	48–72 h	Tuberculin reaction, contact dermatitis, granulomatous disease

Type I — Immediate (IgE-mediated) hypersensitivity

- ▶ **Sensitisation:** *TH2*-type helper cells (and the *TFH13* subset) secreting IL-4, IL-5, IL-6, IL-10 (and IL-13) drive B-cell class-switching to IgE on first allergen exposure.
- ▶ **Effector cells:** Mast cells and basophils bear **high-affinity Fc receptors for IgE (FcεRI)**; cell-bound antiallergen IgE effectively “arms” these cells.
- ▶ **Trigger:** Re-exposure → allergen cross-links surface IgE → degranulation and mediator release.
- ▶ **Mediators** released fall into three functional groups (Harrison):
 - *Increase vascular permeability and contract smooth muscle:* **histamine**, **platelet-activating factor (PAF)**, **SRS-A** (slow-reacting substance of anaphylaxis = leukotrienes), bradykinin.
 - *Chemotactic/activating for other inflammatory cells:* **ECF-A** (eosinophil chemotactic factor of anaphylaxis), **NCF** (neutrophil chemotactic factor), **leukotriene B4**.
 - *Modulate release of other mediators:* PAF, BK-A.
- ▶ **Clinical spectrum:** systemic **anaphylaxis** (hypotension, bronchospasm, angioedema), allergic rhinitis/conjunctivitis, atopic (extrinsic) asthma, urticaria–angioedema, food and drug allergy.
- ▶ A *late-phase* reaction (4–12 h) driven by recruited eosinophils and TH2 cells follows the immediate wheal-and-flare in many patients.

Type II — Antibody-mediated cytotoxic hypersensitivity

- ▶ **Mechanism:** Complement-fixing (C1-binding) antibodies — IgM, IgG1, IgG2, IgG3 — directed against antigens on *normal or foreign cells/tissues* bind complement via the **classic pathway**, initiating a cascade (analogous to immune-complex injury) that culminates in **cell lysis or tissue injury** (membrane-attack complex) and Fc-mediated opsonophagocytosis/ADCC.

- ▶ **Three sub-patterns** (standard immunology): (a) *complement/cell lysis*, (b) *opsonisation–phagocytosis*, (c) *antibody alters cell function* without destruction (receptor stimulation or blockade).
- ▶ **Examples cited in Harrison:**
 - **Red-cell lysis in transfusion reactions** (and autoimmune haemolytic anaemia, haemolytic disease of the newborn).
 - **Goodpasture’s syndrome** — anti-glomerular basement membrane antibody against the **type IV collagen $\alpha 3$ chain**.
 - **Pemphigus vulgaris** — anti-epidermal (desmoglein) antibody inducing blistering skin disease.
- ▶ **Receptor-directed (functional) variants** — Graves’ disease (stimulating anti-TSH-receptor Ab) and myasthenia gravis (blocking anti-AChR Ab) — are the classic “Type V/Type II functional” examples.

Type III — Immune-complex-mediated hypersensitivity

- ▶ **Mechanism:** After antigen exposure, soluble **antigen–antibody (immune) complexes** circulate; if **not cleared by the reticuloendothelial system**, they deposit in **blood-vessel walls** and in tissues such as **renal glomeruli**, activate complement, and recruit neutrophils → **vasculitis or glomerulonephritis**.
- ▶ **Determinants of injury:** the quantity and physicochemical properties (size, charge, antigen:antibody ratio) of complexes determine whether they are pathogenic; complexes formed in slight antigen excess deposit most readily.
- ▶ **Complement link:** deficiencies of early classic-pathway components (C1q, C1r/s, C4, C2) cause *inefficient clearance of immune complexes*, predisposing to immune-complex–mediated autoimmune syndromes — **SLE and SLE-like syndromes, glomerulonephritis, and vasculitis** (Harrison Table 360-12).
- ▶ **Clinical examples:** systemic lupus erythematosus, post-streptococcal/membranoproliferative glomerulonephritis, cryoglobulinaemic and other small-vessel vasculitides, serum sickness, and the local *Arthus reaction*.

Type IV — Delayed-type (cell-mediated) hypersensitivity

- ▶ **Definition (Harrison):** inflammatory reactions **initiated by mononuclear leukocytes, not by antibody alone**; “delayed” because the secondary cellular response appears **48–72 h** after antigen exposure, versus the **<12 h** immediate response.
- ▶ **Effector axis:** antigen processed by DCs → presented to CD4⁺ T cells; **IL-12 from APCs induces IFN- γ (TH1 response)**. Classic DTH is centred on **IFN- γ –, IL-2–, and TNF- α –secreting TH1 cells and macrophages**; **NK cells** contribute to contact hypersensitivity.

- ▶ **Granuloma formation:** under sustained IFN- γ , macrophages undergo **epithelioid transformation** and fuse into **multinucleated giant cells** → **granulomatous inflammation**.
- ▶ **Prototype test:** intradermal **tuberculin purified protein derivative (PPD)** in a previously *M. tuberculosis*-exposed host produces an **indurated area** at **48–72 h**.
- ▶ **DTH-driven diseases (Harrison):** fungal (histoplasmosis), mycobacterial (**tuberculosis, leprosy**), chlamydial (lymphogranuloma venereum), helminthic (schistosomiasis), toxin (berylliosis), and **hypersensitivity pneumonitis** (organic dusts); DTH also drives tissue damage in **rheumatoid arthritis, temporal arteritis, and granulomatosis with polyangiitis**, and underlies **allergic contact dermatitis**.

Type IV subtype	Dominant T cell / effector	Example
IVa	TH1 + macrophage (IFN- γ)	Tuberculin reaction, granuloma, contact dermatitis
IVb	TH2 + eosinophil	Chronic asthma, DRESS
IVc	Cytotoxic CD8 ⁺ T cell	Stevens-Johnson syndrome / TEN, contact dermatitis
IVd	T cell + neutrophil	Acute generalised exanthematous pustulosis (AGEP), Behçet

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Four-panel Gell-Coombs schematic** (one box per type). Labels: *Type I* — allergen, IgE, Fc ϵ RI, mast cell, granules (histamine/leukotrienes/PAF); *Type II* — target cell-surface antigen, IgG/IgM, complement (C1→MAC), phagocyte (Fc receptor); *Type III* — soluble antigen + antibody → immune complex, deposition in vessel wall/glomerulus, complement, neutrophil; *Type IV* — antigen-presenting cell, CD4⁺ TH1 cell, IFN- γ /IL-2/TNF- α , macrophage → epithelioid/giant cell granuloma.
- ▶ **Time-course line graph** of skin reaction: x-axis = hours after challenge; label *immediate wheal-and-flare* (minutes, *Type I*), *late-phase* (4–12 h), and *delayed induration* (48–72 h, *Type IV / tuberculin*).

Clinical / Diagnostic significance

- ▶ **Mechanism guides diagnosis:** serum tryptase and skin-prick/specific-IgE testing for *Type I*; direct/indirect Coombs (antiglobulin) test and tissue immunofluorescence for *Type II*; complement (low C3/C4), ANA/anti-dsDNA, cryoglobulins and immune-complex glomerular deposits for *Type III*; **patch testing** and the **tuberculin/IGRA** read at 48–72 h for *Type IV*.
- ▶ **Mechanism guides therapy:** *Type I* — adrenaline (first-line for anaphylaxis), H1-antihistamines, glucocorticoids, allergen avoidance/immunotherapy, anti-IgE (omalizumab); *Types II/III* — glucocorticoids, plasma exchange, rituximab/cytotoxic agents, IVIg for selected immune-

complex disease; Type IV — topical/systemic glucocorticoids, calcineurin inhibitors, and avoidance of the contact/drug allergen.

- ▶ **Tolerance failure is the upstream lesion:** breakdown of **central (AIRE-dependent thymic) and peripheral (Treg/anergy) tolerance** converts physiologic responses into autoimmune Type II/III/IV disease (Harrison Ch 361). Environmental triggers — drugs (**procainamide, phenytoin** → **drug-induced lupus**), infections (EBV), and loss of Treg cells — precipitate disease in genetically susceptible hosts (e.g., **HLA-B27**).
- ▶ **Severe cutaneous adverse reactions** (SJS/TEN, DRESS, AGEP) are T cell-mediated (Type IV) drug hypersensitivities and demand immediate drug withdrawal.

High-yield exam pointers

- ▶ **Types I–III are antibody-mediated; Type IV is T cell-mediated** — the single most testable contrast.
- ▶ **Type I onset within ~12 h vs Type IV induration at 48–72 h** — memorise the tuberculin timing.
- ▶ Type I effector = **mast cell + FcεRI + IgE**; key mediators histamine, SRS-A (**leukotrienes**), PAF, ECF-A.
- ▶ Type II antibodies that fix complement = **IgM, IgG1, IgG2, IgG3**; triad of examples — **transfusion reaction, Goodpasture's (anti-type IV collagen α3), pemphigus vulgaris**.
- ▶ Type III injury site = **vessel walls and renal glomeruli**; **early complement deficiency (C1q, C4, C2) → poor clearance → SLE/immune-complex disease**.
- ▶ Type IV hallmark = **granulomatous inflammation** (epithelioid + multinucleated giant cells, IFN-γ-driven); seen in TB, leprosy, sarcoid-type reactions, contact dermatitis.
- ▶ **Adrenaline is the first-line drug for Type I anaphylaxis** — not antihistamines.
- ▶ **Procainamide and phenytoin** are classic causes of drug-induced lupus (immune-complex/Type III autoimmunity).

SOURCE & COVERAGE

Harrison 22e — Ch 360 “Introduction to the Immune System” (Immediate-Type Hypersensitivity, Cytotoxic Reactions of Antibody, Immune-Complex Formation, Delayed-Type Hypersensitivity Reactions; Table 360-12) + Ch 361 “Mechanisms of Regulation and Dysregulation of the Immune System” (tolerance, Treg, autoimmunity). **Coverage note (spec gap = true):** Harrison describes the four immune-injury mechanisms but does **not** use the eponym “*Gell and Coombs*” nor the explicit numbered labels *Type I–IV*; this universally accepted immunology framework has been mapped onto Harrison's named mechanisms. The **Type IV sub-classification (IVa–d)**, the **Type II sub-patterns / functional “Type V”** (Graves', myasthenia gravis), the **Arthus/serum-sickness** examples, and specific **diagnostic test and drug-dose** details

are standard textbook internal medicine added for completeness and are not verbatim in the provided chapters.

Inherited Mitochondrial Disorders in Adults

Asked in: Paper I Jul 2021 — RGUHS MD General Medicine

Definition / Introduction — Mitochondrial disorders are a clinically and genetically heterogeneous group of multisystem diseases caused by defective **oxidative phosphorylation (OXPHOS)**, arising from mutations in either the **mitochondrial genome (mtDNA)** or the **nuclear genome (nDNA)**. Because mitochondria generate ATP in virtually every nucleated cell, any organ can be affected, but high-energy tissues — brain, eye, skeletal and cardiac muscle, endocrine glands, kidney and liver — dominate the picture. The term *inherited mitochondrial disorders* in adults principally denotes the **maternally transmitted mtDNA diseases** (e.g., LHON, MELAS, MERRF) plus nuclear-encoded disorders that secondarily destabilise mtDNA (e.g., POLG-related PEO, MNGIE). Many present for the first time in adolescence/adulthood, or are childhood diseases surviving into adult life.

Mitochondrial genome and unique genetic principles

- ▶ **mtDNA structure:** a circular, double-stranded molecule of **16,569 nucleotides** containing **37 genes** — **13** encode protein subunits of the ETC, **22** encode tRNAs and **2** encode rRNAs (12S, 16S). The non-coding **control region (D-loop)** governs replication/transcription.
- ▶ **Division of labour:** mtDNA encodes only 13 of the ~89 respiratory-chain subunits — **Complex I** (7: ND1, 2, 3, 4, 4L, 5, 6), **Complex III** (1: cytochrome *b*), **Complex IV/COX** (3: COX1, 2, 3) and **Complex V** (2: ATPase 6, 8). **Complex II (SDH), CoQ10 and cytochrome c are entirely nuclear-encoded** — hence SDH staining serves as an internal control. ~1500 nuclear genes support mitochondrial biogenesis; mtDNA is replicated by nuclear-encoded **polymerase-γ (POLG)**.
- ▶ **Maternal inheritance:** mtDNA is transmitted exclusively through the **ovum**; sperm mitochondria are degraded. Affected **mothers transmit to all offspring of both sexes, but only daughters transmit onward**; an affected father never transmits — paternal transmission virtually excludes an mtDNA disorder.
- ▶ **Heteroplasmy & homoplasmy:** each cell carries hundreds–thousands of mtDNA copies. Coexistence of mutant and wild-type mtDNA = **heteroplasmy**; uniformity = **homoplasmy**. Pathogenic mutations are usually heteroplasmic (LHON and m.1555A>G deafness are homoplasmic exceptions).
- ▶ **Threshold effect:** disease appears only when mutant load exceeds a critical level (typically **70–90%**), and the threshold is lower in oxidative-dependent tissues (brain, eye, heart, muscle).

- ▶ **Mitotic segregation & the bottleneck:** random partition of mtDNA at cell division shifts heteroplasmy across tissues and with age (clonal expansion), explaining variable, age-dependent penetrance and intrafamilial variability. A **germline bottleneck** during oogenesis produces large, unpredictable shifts in mutant load between mother and child.
- ▶ **Nuclear (Mendelian) mtDNA disorders:** mutations in nuclear maintenance genes (POLG, Twinkle/PEO1, ANT1, TYMP) cause **multiple mtDNA deletions or depletion**, inherited autosomal dominant/recessive.

Classic mtDNA syndromes affecting adults

Syndrome	Cardinal features	Commonest mutation (gene)	Genetics
LHON (Leber hereditary optic neuropathy)	Subacute, painless, sequential central visual loss in young men	m.11778G>A (<i>ND4</i> , ~69%), m.14484T>C (<i>ND6</i>), m.3460G>A (<i>ND1</i>) — Complex I	Homoplasmic, maternal; M:F ≈ 8:1
MELAS	Stroke-like episodes <40 y, encephalopathy (seizures/dementia), lactic acidosis, migraine, short stature, deafness, diabetes	m.3243A>G (<i>MT-TL1</i> , tRNA-Leu, ~80%); m.3271T>C (~10%)	Heteroplasmic, maternal
MERRF	Myoclonus , epilepsy, cerebellar ataxia , myopathy with ragged-red fibres , deafness, lipomas	m.8344A>G (<i>MT-TK1</i> , tRNA-Lys, ~80–90%)	Heteroplasmic, maternal
NARP / MILS	Neuropathy, ataxia, retinitis pigmentosa ; >90% load → maternally inherited Leigh syndrome	m.8993T>G (<i>MT-ATP6</i> , Complex V)	Heteroplasmic, maternal
CPEO	Late bilateral ptosis + ophthalmoplegia , proximal myopathy, exercise intolerance	Single large-scale deletion/duplication	Mostly sporadic (somatic)
Kearns-Sayre syndrome	Triad: PEO + onset <20 y + pigmentary retinopathy ; plus cardiac conduction block , ataxia, CSF protein >100 mg/dL, short stature, diabetes	Single large deletion (4977-bp “ common deletion ”)	Sporadic

Syndrome	Cardinal features	Commonest mutation (gene)	Genetics
Pearson syndrome	Infantile sideroblastic anaemia + pancytopenia + exocrine pancreatic insufficiency + lactic acidosis; survivors evolve to KSS	Large single deletion	Sporadic
MIDD	Maternally inherited diabetes + sensorineural deafness	m.3243A>G	Maternal
Aminoglycoside / non-syndromic deafness	Sensorineural hearing loss, precipitated by aminoglycosides (<i>ecogenetic</i>)	m.1555A>G (12S rRNA)	Homoplasmic, maternal (1:500)

- ▶ **MNGIE** (mitochondrial neurogastrointestinal encephalomyopathy): an **autosomal-recessive** (nuclear) disorder of the **thymidine phosphorylase gene** (TYMP/ECGF1) causing secondary multiple mtDNA deletions/depletion — ptosis, PEO, severe **GI dysmotility with pseudo-obstruction**, cachexia, peripheral neuropathy and **leukoencephalopathy**; onset in late teens, death usually before 40. Diagnosed by low leukocyte thymidine phosphorylase and raised **plasma thymidine and deoxyuridine**.
- ▶ **POLG-related disease**: adPEO/arPEO, **SANDO** (sensory ataxic neuropathy, dysarthria, ophthalmoplegia), parkinsonism and Alpers syndrome — **valproate is contraindicated** (risk of fatal hepatic failure).
- ▶ **Other nuclear “dynamics” genes**: *MFN2* → Charcot-Marie-Tooth type 2; *OPA1* → dominant optic atrophy with deafness/neuropathy.

Clinical features by organ system

- ▶ **CNS**: stroke-like episodes, seizures, myoclonus, migraine, cerebellar ataxia, dystonia, parkinsonism, cognitive decline/dementia, sensorineural deafness, optic atrophy.
- ▶ **Peripheral nerve**: length-dependent sensorimotor or autonomic polyneuropathy.
- ▶ **Skeletal muscle (mitochondrial myopathy)**: ptosis, external ophthalmoplegia, exercise intolerance, myalgia, proximal weakness, rhabdomyolysis/myoglobinuria.
- ▶ **Cardiac**: **conduction block** (especially KSS — may need pacemaker), hypertrophic then dilated cardiomyopathy, Wolff-Parkinson-White pre-excitation (with m.3243A>G).
- ▶ **Endocrine**: diabetes mellitus, short stature, hypothyroidism, hypoparathyroidism, hypogonadism, premature ovarian failure.

- ▶ **Ophthalmic:** pigmentary (“salt-and-pepper”) retinopathy, cataract, optic atrophy, ophthalmoplegia.
- ▶ **GI / hepatic / renal:** dysphagia, gastroparesis, pseudo-obstruction, pancreatitis; hepatopathy; renal tubular acidosis / **Fanconi syndrome**.

Investigation of suspected mtDNA disease

- ▶ **Biochemistry:** blood and CSF **lactate** (CSF lactate more specific with CNS disease), **lactate-to-pyruvate ratio** (>20 suggests an OXPHOS defect; <20 suggests pyruvate dehydrogenase defect), CK (often normal/mildly raised), plasma/urine amino acids, urinary organic acids (TCA intermediates), plasma acylcarnitines, and **GDF-15** (sensitive/specific serum marker of mitochondrial myopathy).
- ▶ **Neuroimaging:** MRI — MELAS shows cortical stroke-like lesions in **posterior cerebrum that do not respect vascular territories**, sparing white matter; Leigh syndrome shows symmetrical T2/FLAIR signal in **basal ganglia (putamen), globus pallidus and brainstem**; basal-ganglia calcification on CT; **MR spectroscopy** detects a lactate peak.
- ▶ **Cardiac/other:** ECG and echocardiography (conduction defects, cardiomyopathy); EMG/NCS; audiometry; ophthalmology/ERG.
- ▶ **Muscle biopsy:** **ragged-red fibres** on modified Gomori trichrome (subsarcolemmal mitochondrial accumulation), intensely “**ragged-blue**” fibres on SDH stain, scattered **COX-negative fibres**, and **paracrystalline “parking-lot” inclusions** on electron microscopy. RRFs are absent in NARP/MILS and LHON.
- ▶ **Molecular genetics (now first-line):** targeted PCR/RFLP for common point mutations (3243, 8344, 8993, 11778/14484/3460); whole **mtDNA next-generation sequencing**; **long-range PCR / Southern blot** for deletions; nuclear gene panels and WES/WGS. Because heteroplasmy varies between tissues, a **negative blood test (e.g., m.3243A>G load falls in blood with age)** should **prompt urine sediment or skeletal-muscle testing**; deletions are best detected in muscle.

Management

- ▶ **General:** no curative therapy — multidisciplinary, largely **supportive and surveillance-based**. Aggressively treat seizures (recognise subtle/subclinical seizures in MELAS), cardiac conduction disease (**pacemaker/ICD in KSS**), diabetes, endocrinopathy, dysphagia/PEG feeding, ptosis (props/surgery), cataract, and hearing loss (aids, **cochlear implant**).
- ▶ **Cofactors/vitamins (limited evidence):** **CoQ10** (up to ~200 mg three times daily; clearly beneficial in primary CoQ10 deficiency), riboflavin, **L-carnitine**, creatine, α-lipoic acid, vitamins C/E; **idebenone** (a CoQ analogue) is approved (EMA) for LHON.
- ▶ **Disease-specific:** **L-arginine / L-citrulline** (NO precursors) for MELAS stroke-like episodes (acute and prophylactic); **folinic acid** for CSF folate deficiency; **dichloroacetate (DCA)** lowers

lactate but causes peripheral neuropathy; **allogeneic haematopoietic stem-cell / bone-marrow transplantation** to restore thymidine phosphorylase in MNGIE.

- ▶ **Drugs to avoid:** valproate (especially with *POLG* mutations), **aminoglycosides** in m.1555A>G carriers, propofol/barbiturates, and **metformin/statins** caution (lactic acidosis); strongly advise **LHON carriers to avoid tobacco and alcohol** (penetrance reaches ~93% in male smokers).
- ▶ **Reproductive options:** genetic counselling is difficult because the bottleneck makes transmitted load unpredictable; **prenatal/preimplantation diagnosis is reliable only for NARP m.8993T>G**. Options include **oocyte donation**, PGD, and **mitochondrial replacement therapy (MRT)** — *maternal spindle transfer* or *pronuclear transfer* into a donor egg (licensed in the UK).

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Diagram 1 — Circular mtDNA map (16,569 bp):** draw the circle showing the **D-loop / control region**, the two rRNAs (12S, 16S), and the disease-linked loci — *ND1/ND4/ND6* (LHON), *MT-TL1/tRNA-Leu* position 3243 (MELAS), *MT-TK1/tRNA-Lys* position 8344 (MERRF), *MT-ATP6* position 8993 (NARP/MILS), 12S rRNA 1555 (aminoglycoside deafness) and the “**common deletion**” (4977 bp) region. Label: heavy/light strands, OXPHOS complexes I, III, IV, V encoded.
- ▶ **Diagram 2 — Respiratory chain & heteroplasmy threshold:** Complexes I→II→CoQ10→III→cytochrome c→IV→V across the inner membrane with H⁺ pumping and ATP synthesis; alongside, a bar showing **wild-type vs mutant mtDNA** with a marked “**threshold (70–90%)**” above which disease is expressed.

Clinical / Diagnostic significance

- ▶ Consider mitochondrial disease in any **unexplained progressive multisystem disorder**, particularly combinations that “don’t fit” a single nuclear gene — e.g., diabetes + deafness, stroke + lactic acidosis, ptosis + cardiac block + retinopathy.
- ▶ A **stroke not conforming to a vascular territory** in a young adult with lactic acidosis is MELAS until proven otherwise.
- ▶ **Ragged-red fibres are neither universal nor specific** (also seen in inclusion-body myositis, ageing, zidovudine myopathy) — interpret with COX/SDH histochemistry and genetics.
- ▶ Genetic diagnosis directs **counselling, cascade testing and reproductive planning**, and flags **drug avoidances** (valproate, aminoglycosides).

High-yield exam pointers

- ▶ mtDNA = 16,569 bp, 37 genes (13 protein, 22 tRNA, 2 rRNA); **strict maternal inheritance, no recombination, heteroplasmy, threshold effect**.
- ▶ **LHON** = homoplasmic Complex I point mutations (11778/14484/3460), young men, painless central vision loss; idebenone; avoid tobacco/alcohol.

- ▶ **MELAS** = m.3243A>G (tRNA-Leu); diagnostic triad: stroke-like episode <40 y + encephalopathy + lactic acidosis/RRF; treat with **L-arginine**.
- ▶ **MERRF** = m.8344A>G (tRNA-Lys); myoclonus + epilepsy + ataxia + RRF + lipomas.
- ▶ **NARP/MILS** = m.8993T>G (ATPase 6); >90% load → Leigh syndrome; the **one mutation with reliable prenatal diagnosis**.
- ▶ **KSS** = single large mtDNA deletion (**4977-bp common deletion**); PEO + onset <20 + retinopathy + heart block (**pacemaker**); CSF protein >100.
- ▶ **MNGIE** = autosomal-recessive **TYMP** defect; PEO + GI pseudo-obstruction + neuropathy + leukoencephalopathy; ↑ plasma thymidine; allogeneic SCT.
- ▶ **m.1555A>G 12S-rRNA** = aminoglycoside-induced ototoxic deafness (**ecogenetic** — avoid aminoglycosides).
- ▶ **Lactate:pyruvate >20** = OXPHOS defect; muscle = **ragged-red** (Gomori), **ragged-blue** (SDH), **COX-negative fibres, paracrystalline inclusions**.
- ▶ **Avoid valproate in POLG disease**; therapy is supportive; **MRT (spindle/pronuclear transfer)** prevents transmission.

SOURCE & COVERAGE

- ▶ **Harrison's Principles of Internal Medicine, 22e** — “Mitochondrial DNA and Heritable Traits and Diseases” (Skorecki & Cohen).
- ▶ **Bradley and Daroff's Neurology in Clinical Practice, 8e** — Chapter “Mitochondrial Disorders” (Turner, Pitceathly & Schapira), used for the adult syndrome spectrum (CPEO/KSS, MNGIE, POLG/SANDO), muscle-biopsy histochemistry, the diagnostic algorithm and management.
- ▶ *Coverage note:* CMDT has no dedicated chapter on inherited mitochondrial disease; current-management details (CoQ10/idebenone doses, L-arginine, MRT, allogeneic SCT for MNGIE) are drawn from the two texts above and reflect universally accepted internal-medicine practice.

Limbic system

Asked in: Paper I Jul 2020 — RGUHS MD General Medicine

Definition / Introduction — The **limbic system** is a phylogenetically ancient, ring-like (“limbus” = border) network of cortical and subcortical structures encircling the corpus callosum and upper brainstem, formed of **limbic cortex** (hippocampus, amygdala, entorhinal cortex), **paralimbic cortex** (cingulate gyrus, insula, temporopolar and orbitofrontal cortex), the **anterior and medial thalamic nuclei**, the **medial/basal striatum and basal forebrain**, and the **hypothalamus**. It integrates emotion,

motivation, autonomic and endocrine tone, olfaction, and declarative (explicit) memory, and is the substrate of amnesia, temporal-lobe epilepsy and limbic encephalitis.

Components and gross anatomy

- ▶ **Limbic cortex (core)** — *hippocampal formation* (archicortex: hippocampus proper/cornu ammonis, dentate gyrus, subiculum), *amygdala* (housed in the **uncus** of the medial temporal lobe), and *entorhinal cortex* — the gateway for cortical input into the hippocampus.
- ▶ **Paralimbic (mesocortical) belt** — *cingulate gyrus*, *parahippocampal gyrus*, *insula*, *temporopolar* and *orbitofrontal* cortex. The cingulate gyrus sweeps around the splenium of the corpus callosum and **blends into the parahippocampal gyrus**, forming a continuous limbic lobe (pericallosal + mesial-temporal + insular + orbital cortex of Broca).
- ▶ **Olfactory structures** — olfactory bulb/tract, anterior perforated substance and primary olfactory (paleo)cortex; olfaction is the only sensory modality reaching cortex without an obligatory thalamic relay.
- ▶ **Subcortical relays** — *fornix* (efferent hippocampal tract), *mammillary bodies* (hypothalamus), *anterior* and *mediodorsal thalamic nuclei*, *septal nuclei* and *nucleus basalis of Meynert* (basal forebrain, cholinergic), *retrosplenial cortex* and the *cingulum* bundle.
- ▶ **Diencephalic hub** — the *hypothalamus* links the system to homeostasis, the autonomic nervous system and the pituitary (neuroendocrine output).

The Papez circuit (memory loop)

- ▶ Originally proposed by **James Papez (1937)** as the anatomical substrate of *emotion*; in modern usage it is the **posterior limbic circuit for explicit (declarative) memory**.
- ▶ Closed reverberating loop:

Hippocampus → fornix → mammillary body → mammillothalamic tract (of Vicq d'Azyr) → anterior thalamic nucleus → cingulate gyrus (via internal capsule) → cingulum → parahippocampal/entorhinal cortex → back to hippocampus.

- ▶ The *mediodorsal thalamic nucleus*, *retrosplenial cortex* (an alternative hippocampo-thalamic route) and *basal forebrain* are functionally integral; bilateral damage to **any node** of this circuit produces amnesia.

Functional organisation

Functional division	Key structures	Behaviour subserved	Disease correlate
Anterior (emotional-affiliative)	Amygdala, anterior paralimbic/orbitofrontal cortex (overlaps <i>salience network</i>)	Emotion, motivation, fear, autonomic tone, endocrine drive	Temporal-lobe epilepsy; behavioural-variant FTD

Functional division	Key structures	Behaviour subserved	Disease correlate
Posterior (mnemonic) = Papez circuit	Hippocampus, entorhinal cortex, posterior paralimbic cortex, limbic thalamic nuclei	Declarative memory for recent episodes/experiences	Amnesic state; Alzheimer's disease
Olfactory	Olfactory bulb/tract, piriform cortex, amygdala, entorhinal cortex	Smell perception and its emotional/memory linkage	Uncinate fits (olfactory hallucinations)
Homeostatic	Hypothalamus, mammillary bodies, septal nuclei	Autonomic, neuroendocrine, feeding, sexual, rage/defence	Wernicke-Korsakoff; septal rage

- ▶ **Amygdala** — assigns emotional (especially *fearful*) salience to stimuli and tags emotionally charged events for stronger memory; bilateral lesions impair recognition of fear in faces.
- ▶ **Anterior cingulate cortex** — modulates autonomic activity, emotional response selection and the affective component of pain; part of the *rostral limbic system* (with periaqueductal grey, ventral striatum, orbitofrontal and anterior insular cortex). Bilateral lesions cause **akinetetic mutism**; cingulotomy is used for intractable pain/OCD.
- ▶ **Hippocampus** — encodes new declarative memories and spatial maps (*place cells*); damage spares previously consolidated remote memories and **implicit/procedural learning**.

Major connections and neurochemistry

- ▶ **Afferents** — all sensory association cortices funnel into limbic cortex via the entorhinal cortex; the *perirhinal cortex* relays visual/object information and the *parahippocampal cortex* relays spatial (dorsal-stream) information to the hippocampus.
- ▶ **Principal efferent tracts** — the **fornix** (hippocampus → mammillary body/septum), the **mammillothalamic tract** (mammillary body → anterior thalamus), the **stria terminalis** and **ventral amygdalofugal pathway** (amygdala → hypothalamus/septum/brainstem), and the **medial forebrain bundle** (septum/hypothalamus ↔ brainstem).
- ▶ **Cholinergic supply** — the **basal forebrain** (*nucleus basalis of Meynert, medial septal nucleus*) provides the major cholinergic input to hippocampus and neocortex; its degeneration underlies the memory deficit of AD and the rationale for **cholinesterase inhibitors**.
- ▶ **Other modulators** — *mesolimbic dopamine* (ventral tegmental area → nucleus accumbens/amygdala) underlies reward and motivation; serotonergic and noradrenergic projections modulate limbic affective tone; the hippocampus is densely glutamatergic and

selectively vulnerable to hypoxia, hypoglycaemia and seizure-induced excitotoxicity (hippocampal sclerosis).

The amnestic syndrome (clinical hallmark of limbic damage)

- ▶ Defined as a disturbance of **explicit memory** in the absence of deficits of attention, language or visuospatial function; *always implies bilateral limbic injury* (hippocampo-entorhinal complex or thalamus). Unilateral left hippocampal lesions cause only transient amnesia.
- ▶ Components: prominent **anterograde amnesia** (cannot store new information) > **retrograde amnesia** (recent memories more vulnerable than remote — *Ribot's gradient*).
- ▶ **Confabulation** (filling gaps with implausible information) occurs when the lesion also disrupts the frontothalamic network, as in **Wernicke-Korsakoff syndrome** and head trauma.
- ▶ **Implicit/procedural memory is preserved** — patients acquire new motor/perceptual skills without conscious recollection.
- ▶ Bedside test: 4–5 word list registration, then delayed recall at 5–10 min; amnestics fail recall and may forget that a list was given. Recognition better than recall suggests a milder, retrieval-stage defect.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Medial sagittal view of the limbic system** — label: *cingulate gyrus, parahippocampal gyrus, uncus (amygdala), hippocampus, fornix, mammillary body, anterior thalamic nucleus, septal nuclei, olfactory bulb/tract, hypothalamus, corpus callosum*.
- ▶ **Papez circuit loop** — draw the closed loop with labelled arrows: *Hippocampus → Fornix → Mammillary body → Mammillothalamic tract → Anterior thalamic nucleus → Cingulate gyrus → Cingulum → Entorhinal/parahippocampal cortex → Hippocampus*.

Clinical / Diagnostic significance

- ▶ **Alzheimer's disease (AD)** — neurofibrillary degeneration begins in the **entorhinal cortex and hippocampus**, explaining the early selective episodic-memory loss; spreads to limbic then neocortical areas. Prodrome = **amnestic mild cognitive impairment (aMCI)**; MRI shows hippocampal/medial-temporal atrophy; FDG-PET shows posterior-cingulate/precuneus hypometabolism.
- ▶ **Wernicke-Korsakoff syndrome** — thiamine deficiency damages the **mammillary bodies** and medial thalamus; Korsakoff psychosis = persistent recent-memory loss with confabulation.
- ▶ **Herpes simplex encephalitis** — necrotising involvement of medial temporal/limbic cortex causes amnesia and a **Klüver-Bucy-type picture** (hyperorality, hypermetamorphosis, inappropriate sexual displays, emotional blunting, visual agnosia/"psychic blindness") — classically from bilateral anterior-temporal/amygdala damage.

- ▶ **Autoimmune & paraneoplastic limbic encephalitis** — subacute confusion, depression/agitation, severe short-term-memory deficit and temporal-lobe seizures with **bilateral mesial-temporal T2/FLAIR hyperintensity**. Antibodies: **anti-LGI1** (faciobrachial dystonic seizures + hyponatremia), **anti-NMDAR** (young women, psychosis, dyskinesias, ovarian teratoma), **anti-AMPA**, **anti-GABA-B** (seizures, SCLC), **anti-Ma2** (testicular tumour), **anti-Hu** (SCLC).
- ▶ **Temporal-lobe (limbic) epilepsy** — aura of fear, déjà vu, **uncinate fits** (olfactory/gustatory hallucinations); interictal *Geschwind syndrome* (hyposexuality, hypergraphia, hyperreligiosity).
- ▶ **Transient global amnesia** — acute, self-limited (24–48 h) isolated anterograde amnesia with repetitive questioning; ~20% recur.
- ▶ **Other amnestic causes** — PCA/ACA territory infarcts, fornix/septal lesions (colloid cyst, anterior communicating artery aneurysm rupture), thalamic and medial-temporal tumours, head trauma, anoxia, Pick's disease/FTLD, LATE (limbic-predominant age-related TDP-43 encephalopathy).

High-yield exam pointers

- ▶ Limbic system = **emotion + memory + olfaction + autonomic/endocrine homeostasis**; “limbus” = border ring around the corpus callosum.
- ▶ **Papez circuit mnemonic**: *Hippocampus–Fornix–Mammillary body–Mammillothalamic tract–Anterior thalamus–Cingulate–back to Hippocampus*.
- ▶ **Bilateral** limbic lesions are required to produce a *persistent* amnestic state.
- ▶ **Anterograde amnesia > retrograde**; **confabulation** = added frontothalamic involvement (Wernicke-Korsakoff).
- ▶ **Implicit/procedural memory is spared** in pure amnesia.
- ▶ **Mammillary bodies** = Wernicke-Korsakoff; **hippocampus/entorhinal cortex** = early Alzheimer's disease.
- ▶ **Klüver-Bucy syndrome** = bilateral anterior temporal/amygdala damage → placidity, hyperorality, hypersexuality, hypermetamorphosis, visual agnosia.
- ▶ **Limbic encephalitis** = subacute amnesia + seizures + psychiatric change + bilateral mesial-temporal FLAIR signal → screen for **LGI1, NMDAR, AMPAR, GABA-B, Ma2, Hu** antibodies and occult malignancy.
- ▶ **Anterior cingulate** lesion → akinetic mutism; **septal** lesion → rage/irritability.

- ▶ Coverage note: The corpus covers limbic *function, circuitry and clinical correlates* in depth; the **Klüver-Bucy** eponym and its component features are universally accepted standard neurology (the feature-set is described in Brazis under herpes-encephalitis/temporal-lobe damage) and are included as such.

Monoclonal Antibodies: Clinical Pharmacology

Asked in: Paper I May 2022 — RGUHS MD General Medicine

Definition / Introduction — **Monoclonal antibodies (mAbs)** are laboratory-engineered immunoglobulins of a single specificity, directed against one defined epitope (antigen) and produced in large, high-affinity quantities. In therapeutics, animal-derived antigen-combining sequences are grafted into human immunoglobulin genes (**chimerized** or **humanized** products) or generated *de novo* from mice carrying human immunoglobulin gene loci (**fully human** antibodies). They form the backbone of modern targeted and immunologic cancer therapy and of immunomodulation in inflammatory disease, acting with precision but carrying a distinctive class toxicity profile (infusion reactions, immune-related adverse events, cytokine release). The generic suffix **-mab** denotes a monoclonal antibody.

Structure, Nomenclature and Production

- ▶ **Basic unit** is an IgG immunoglobulin: two **Fab** arms carry the antigen-binding *variable regions* (the complementarity-determining regions, CDRs, confer specificity); the **Fc** stem recruits effector functions (complement, Fc-receptor-bearing immune cells).
- ▶ **Production**: very large quantities of high-affinity mAbs against specific tumor/cell antigens are produced, then the rodent antigen-combining sequences are grafted into human Ig genes, or the antibody is derived from mice bearing human Ig gene loci — progressively reducing immunogenicity.
- ▶ **Nomenclature by source** (WHO stem system — standard, see Coverage note):

Type	Suffix	Sequence origin	Examples
Murine	-omab	100% mouse (highly immunogenic)	(largely obsolete)

Type	Suffix	Sequence origin	Examples
Chimeric	-ximab	mouse variable + human constant	Rituximab, Cetuximab, Infliximab
Humanized	-zumab	only CDRs murine	Trastuzumab, Pertuzumab, Bevacizumab, Alemtuzumab, Obinutuzumab
Fully human	-umab	entirely human	Panitumumab, Ofatumumab, Ipilimumab, Nivolumab, Durvalumab

- ▶ Less immunogenic constructs allow repeated dosing with lower risk of anti-drug antibodies and hypersensitivity.

Mechanisms of Action

- ▶ **Direct signal blockade / antiproliferative effect** — binding a growth-driving surface receptor interrupts intracellular signalling (e.g., *trastuzumab* interrupts HER2/neu signals; *pertuzumab* blocks HER2 dimerization; anti-CD20 agents interrupt signals driving lymphomagenesis).
- ▶ **Antibody-dependent cell-mediated cytotoxicity (ADCC)** — Fc engages NK/effector cells; *obinutuzumab* has altered glycosylation that enhances killer-cell activation.
- ▶ **Complement-dependent cytotoxicity (CDC)** — *alemtuzumab* (anti-CD52) activates complement against the target cell.
- ▶ **Immune-response activation** — anti-tumor mAbs both kill tumor cells and stimulate host anti-tumor immune mechanisms.
- ▶ **Checkpoint release** — immunoregulatory mAbs bind antigens on *host* immune cells (not tumor) to reactivate suppressed cytotoxic T cells (anti-PD-1/PD-L1, anti-CTLA4, anti-LAG3).
- ▶ **Bridging (bispecific)** — *BiTe* antibodies physically tether a T cell to a tumor cell, forcing immune killing.
- ▶ **Targeted delivery** — *antibody-drug conjugates (ADCs)* and radio-/toxin-conjugates ferry a cytotoxic “warhead” selectively to the antigen-bearing tumor cell.

Pharmacokinetics and Administration

- ▶ **Large proteins** — not orally bioavailable (digested in the gut); given **intravenously** or **subcutaneously**.
- ▶ **Slow elimination** — therapeutic antibodies are eliminated *very slowly*, probably by **lysosomal uptake and degradation**, giving a long half-life that permits **infrequent dosing** (e.g., **monthly injections**).

- ▶ **Not metabolized by cytochrome P450** and not renally excreted as intact protein — hence few classical pharmacokinetic drug interactions, though pharmacodynamic immune interactions occur.
- ▶ Distribution is largely confined to plasma and interstitial fluid; placental transfer (IgG) is relevant in pregnancy, and all conjugated cytotoxic mAbs carry embryofetal toxicity warranting contraception.

Therapeutic Strategies and Target Classification

Four general antibody strategies are recognised, plus a stroma-directed group:

Strategy	Mechanism	Representative targets and agents
Anti-tumor cell antibodies	Bind tumor surface antigen → block signalling, recruit immune/complement attack	CD20 — Rituximab, Ofatumumab, Obinutuzumab; CD52 — Alemtuzumab; EGFR — Cetuximab, Panitumumab; HER2/neu — Trastuzumab, Pertuzumab; CD38 — Daratumumab, Isatuximab
Bispecific T-cell engagers (BiTe)	One arm binds tumor antigen, other binds CD3 → drags T cell onto tumor	CD19×CD3 — Blinatumomab
Immunoregulatory (checkpoint) antibodies	Target host immune-cell receptors to release the brakes on T cells	CTLA4 — Ipilimumab; PD-1 — Nivolumab, Pembrolizumab, Cemiplimab; PD-L1 — Atezolizumab, Avelumab, Durvalumab; LAG3 — Relatlimab
Antibody conjugates (ADC / radio / toxin)	Antibody delivers a cytotoxic “warhead” to the tumor	See ADC table below
Stroma-directed antibodies	Target tumor-supporting vasculature	VEGF — Bevacizumab; VEGFR2 — Ramucirumab

Major Classes and Antibody-Drug Conjugates

- ▶ **Anti-CD20 (rituximab, ofatumumab):** B-cell lymphomas — used alone and with chemotherapy/radiation; *obinutuzumab* (enhanced ADCC) is valuable in **chronic lymphocytic leukemia**.
- ▶ **Anti-CD52 (alemtuzumab):** complement-activating; chronic lymphoid leukemia and T-cell malignancies; **tumor lysis syndrome prophylaxis** may be needed.
- ▶ **Anti-EGFR (cetuximab, panitumumab):** chemorefractory colorectal cancer and head-and-neck cancer with radiation; cause an **acneiform rash** (topical antibiotic + steroid cream) and photosensitivity.

- ▶ **Anti-HER2 (trastuzumab, pertuzumab):** HER2-overexpressing breast and certain GI cancers; pertuzumab blocks HER2 dimerization and augments trastuzumab; both are **cardiotoxic**, especially after anthracyclines — check and monitor LV function.
- ▶ **BiTe (blinatumomab):** anti-CD19 × anti-CD3; active in B-cell acute lymphocytic leukemia; toxicities are **cytokine release syndrome** (fever, hypotension, tachycardia) and neurologic deterioration (early sign: deteriorating handwriting → cortical dysfunction) needing dose-pausing ± glucocorticoids.
- ▶ **Checkpoint inhibitors:** *ipilimumab* (anti-CTLA4) was the first proof that purely immunoregulatory antibodies are safe and effective; *nivolumab/pembrolizumab* (anti-PD-1) and *atezolizumab* (anti-PD-L1) benefit many cancers; *pembrolizumab* first-line in PD-L1-expressing metastatic NSCLC (a milestone replacing chemotherapy); *relatlimab* (anti-LAG3) augments nivolumab in melanoma. **Tissue-agnostic** approval applies to MSI-high / mismatch-repair-deficient tumors and high **tumor mutational burden** (≥ 10 mutations/megabase).

Antibody-drug conjugates (humanized mAb + linker + cytotoxic payload; linker controls intracellular vs extracellular “bystander” release):

Payload class	ADC	Target	Indication / key toxicity
DNA disruptor (calicheamicin)	Gemtuzumab ozogamicin	CD33	AML; hepatic veno-occlusive disease
	Inotuzumab ozogamicin	CD22	ALL; VOD, myelosuppression
	Loncastuximab tesirine	CD19	Refractory DLBCL; vascular leak
Microtubule (maytansine/auristatin)	Ado-trastuzumab emtansine	HER2	Breast (trastuzumab-resistant); cardiac/pulmonary
	Brentuximab vedotin	CD30	Hodgkin lymphoma; neuropathy
	Enfortumab vedotin	Nectin-4	Urothelial cancer
	Belantamab mafodotin	BCMA	Myeloma; ocular keratopathy
Topoisomerase I	Fam-trastuzumab deruxtecan	HER2	Breast/gastric/NSCLC; interstitial lung disease
	Sacituzumab govitecan	Trop2	Triple-negative breast; diarrhea (UGT1A1*28)

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

Payload class	ADC	Target	Indication / key toxicity
▶ IgG monoclonal antibody structure: label <i>Fab region</i>, <i>Fc region</i>, <i>antigen-binding site</i> (<i>variable region V_H / V_L</i>), <i>complementarity-determining regions (CDRs)</i>, <i>heavy chain</i>, <i>light chain</i>, <i>hinge region</i>, <i>disulfide bonds</i>; shade murine vs human portions to contrast <i>chimeric vs humanized vs fully human</i>. ▶ Four therapeutic strategies schematic (after Fig. 78-4): central <i>tumor cell</i> bearing surface <i>tumor antigen (T-Ag)</i>; label (1) <i>anti-tumor-cell antibody</i> → ADCC/CDC/signal block; (2) <i>BiTe</i> bridging a <i>T cell (CD3)</i> to <i>tumor (CD19)</i>; (3) <i>checkpoint axis</i> — <i>PD-1 / PD-L1</i> and <i>CTLA4</i> with <i>immunoregulatory antibody</i>; (4) <i>antibody-drug conjugate</i> (<i>antibody-linker-warhead</i>); and <i>anti-VEGF antibody</i> on a <i>tumor blood vessel</i>.			

Clinical / Diagnostic significance

- ▶ **Biomarker-guided use:** HER2 overexpression, EGFR/RAS status, CD-antigen expression, MSI/mismatch-repair status and tumor mutational burden select responders — molecular/liquid biopsy is integral to prescribing.
- ▶ **Pre-treatment screening:** assess **hepatitis B and C status** before anti-B-cell antibodies (risk of reactivation and opportunistic infection); baseline **echocardiography/LVEF** before anti-HER2 agents; ophthalmologic exam before ocular-toxic ADCs.
- ▶ **Beyond oncology:** the same biology underlies *infliximab* (anti-TNF, chimeric), *rituximab* and *abatacept* used to treat severe immune-mediated disease — including, per Harrison, severe immunologically-mediated **adverse drug reactions** refractory to steroids.
- ▶ **Immune-related adverse events (irAEs)** from checkpoint inhibitors are unpredictable, can appear late even during sustained tumor control, and demand a low threshold for high-dose glucocorticoids; **myocarditis**, though rare, can be rapidly fatal.

High-yield exam pointers

- ▶ Suffix **-mab** = monoclonal antibody; **-ximab** chimeric, **-zumab** humanized, **-umab** fully human (decreasing immunogenicity).
- ▶ Effector mechanisms: **signal blockade**, **ADCC**, **CDC**, **immune activation**; conjugates add targeted cytotoxic delivery.
- ▶ PK: **not oral**, IV/SC, **no CYP metabolism**, slow lysosomal degradation → long half-life → **monthly dosing**.
- ▶ **Trastuzumab/pertuzumab** → **cardiotoxicity** (worse post-anthracycline); **cetuximab** → **acneiform rash**; **bevacizumab** → **hypertension**, **proteinuria**, **thrombosis**, **bleeding**, **GI perforation**.
- ▶ **Blinatumomab (BiTe)** → **cytokine release syndrome + neurotoxicity**; checkpoint inhibitors → **immune-related AEs** (colitis, thyroiditis, hepatitis, myocarditis).

- ▶ Gemtuzumab/inotuzumab ozogamicin → veno-occlusive disease; belantamab → keratopathy; trastuzumab deruxtecan → interstitial lung disease.
- ▶ Checkpoint biomarkers: MSI-high / mismatch-repair deficient / TMB ≥ 10 mut/megabase = tissue-agnostic indication.
- ▶ First-line: **infusion-reaction prophylaxis** (glucocorticoid $\pm$ antihistamine, slow infusion); severe irAEs → **high-dose steroids**, then rituximab/infliximab/abatacept/mycophenolate/plasmapheresis.

SOURCE & COVERAGE

Harrison 22e — Ch 78 “Principles of Cancer Treatment” (antibody-mediated therapeutic approaches, BiTe, immunoregulatory/checkpoint antibodies, stroma-directed antibodies, antibody-drug conjugates; Fig. 78-4; Tables 78-4 and 78-6) and Ch 71 “Principles of Clinical Pharmacology” (antibody pharmacokinetics — slow lysosomal elimination/monthly dosing; immune-checkpoint-related ADRs and their management with steroids/rituximab/infliximab/abatacept/mycophenolate/plasmapheresis).

Coverage note: Harrison does not provide a dedicated mAb-pharmacology chapter (spec gap = true). Antibody **structure detail** (Fab/Fc/CDR domains) and the **WHO -omab/-ximab/-zumab/-umab stem nomenclature** are universally accepted standard immunology/pharmacology added for completeness — they are not stated verbatim in the provided chapters (Harrison uses the broader terms “chimerized,” “humanized,” and “fully human,” and loosely labels some agents “humanized”). The statements that mAbs are non-oral, lack CYP metabolism, and undergo placental transfer are standard pharmacology; only “slow lysosomal elimination with monthly dosing” is given explicitly in Ch 71. Non-oncology examples (infliximab, abatacept use) and individual ADC/checkpoint indications are grounded in the cited tables/figure.

Neurotransmitters

Asked in: Paper I Dec 2023 — RGUHS MD General Medicine

Definition / Introduction — **Neurotransmitters** are endogenous chemical messengers synthesised by neurons, stored in synaptic vesicles, released into the synaptic cleft in a calcium-dependent manner on depolarisation, and acting on specific pre- or post-synaptic receptors to alter the excitability of the target cell. They are the molecular currency of **chemical synaptic transmission** and the principal targets of nearly every centrally acting drug — antidepressants, antipsychotics, anxiolytics, anti-parkinsonian agents, analgesics and drugs of abuse all act by modulating neurotransmitter synthesis, release, receptor signalling, reuptake or degradation. Harrison frames their clinical relevance through the **monoamine**

hypothesis of mood disorders, the dopaminergic reward circuit of addiction, and the GABA/glutamate excitatory-inhibitory balance.

Defining criteria and classification

A substance qualifies as a neurotransmitter if it is synthesised in the neuron, stored and released on stimulation, mimics the effect of nerve stimulation when applied exogenously, binds specific receptors, and has a defined mechanism of inactivation (reuptake or enzymatic degradation).

Class	Members	Key biosynthetic point
Amino acids	Glutamate (principal excitatory); GABA (principal inhibitory); glycine (inhibitory)	GABA synthesised from glutamate by glutamic acid decarboxylase (GAD1)
Biogenic amines (monoamines) — catecholamines	Dopamine, norepinephrine, epinephrine	Derived from tyrosine; tyrosine hydroxylase = rate-limiting enzyme of catecholamine biosynthesis
Biogenic amines — indoleamine / imidazole	Serotonin (5-HT, from tryptophan); histamine	Monoamine reuptake/oxidation governs synaptic levels
Acetylcholine	ACh	Synthesised from choline + acetyl-CoA; terminated by acetylcholinesterase
Neuropeptides	Endorphins, enkephalins; orexin (hypocretin); β -endorphin, melanocortin; CRF	Co-released with classical transmitters
Endocannabinoids	Anandamide, 2-arachidonoylglycerol	Retrograde messengers acting on CB1
Gaseous / unconventional	Nitric oxide, carbon monoxide; purines (ATP, adenosine)	Not vesicular; freely diffusible (NO/CO)

Major neurotransmitter systems and their CNS pathways

Harrison's circuit diagram of mood and reward (Fig. 462-3) maps each monoamine to a discrete brainstem/midbrain source nucleus projecting diffusely to the limbic system.

Transmitter	Source / projection	Main receptors	Principal action	Disease correlation
Dopamine	Ventral tegmental area (VTA), substantia nigra → nucleus accumbens, cortex	D1–D5 (metabotropic)	Reward “rheostat”, motor control, cognition	Parkinson disease, schizophrenia, addiction
Norepinephrine	Locus coeruleus (LC) → widespread	α - and β -adrenergic	Arousal, vigilance, mood, stress	Depression, anxiety

Transmitter	Source / projection	Main receptors	Principal action	Disease correlation
Serotonin (5-HT)	Dorsal raphe / raphe nuclei → widespread	5-HT ₁₋₇ (5-HT ₃ is ionotropic)	Mood, sleep, appetite, impulse control	Depression, OCD, anxiety
Glutamate	Cortical/limbic glutamatergic neurons	NMDA, AMPA, kainate, mGluR	Principal excitatory; long-term potentiation/synaptic plasticity	Excitotoxicity, schizophrenia
GABA	Interneurons (GAD1)	GABA-A (ionotropic Cl ⁻), GABA-B (metabotropic)	Principal inhibitory transmitter	Epilepsy, anxiety, spasticity
Acetylcholine	Basal forebrain, brainstem	Nicotinic (ionotropic), muscarinic	Arousal, memory, autonomic control	Alzheimer disease, myasthenia
Endogenous opioids	Arcuate/hypothalamic peptidergic neurons	μ, δ, κ opioid (Gi/o)	Analgesia, reward, mood	Addiction, pain
Endocannabinoids	Post-synaptic, retrograde	CB1	Retrograde dampening of release	Addiction

Life cycle of chemical synaptic transmission

- **Synthesis** — precursor amino acids/choline converted by rate-limiting enzymes (e.g., tyrosine hydroxylase for catecholamines, GAD for GABA).
- **Storage** — packaging into synaptic vesicles by vesicular transporters.
- **Release** — action potential opens voltage-gated **Ca²⁺ channels** at the terminal; Ca²⁺ influx triggers exocytotic, quantal release into the cleft.
- **Receptor activation** — binding to **ionotropic** (ligand-gated ion channel, fast) or **metabotropic** (G-protein-coupled, slow/modulatory) receptors on the post-synaptic membrane.
- **Termination** — (1) **reuptake** by membrane transporters (e.g., the **dopamine transporter, DAT**; serotonin and norepinephrine transporters); (2) **enzymatic degradation** (monoamine oxidase, catechol-O-methyltransferase, acetylcholinesterase).
- **Plasticity** — repeated activity alters **synaptic strength** (long-term potentiation/depression) and **gene expression** via second messengers and transcription factors (**cAMP-CREB, ΔFosB**), the molecular basis of learning and of addiction.

Receptor types and signal transduction

- **Ionotropic receptors** — ligand-gated channels giving rapid responses: **NMDA / AMPA / kainate** (glutamate), **GABA-A (Cl⁻)**, **nicotinic ACh**, **5-HT₃**.

- ▶ **Metabotropic receptors** — G-protein-coupled, modulatory: dopaminergic, adrenergic, most serotonergic, GABA-B, muscarinic, opioid and cannabinoid receptors.
- ▶ **Example (opioid signalling, Fig. 462-2)** — μ -opioid agonists couple to **Gi/o**, **inhibit adenylyl cyclase** $\rightarrow$ $\downarrow$ cAMP $\rightarrow$ $\downarrow$ PKA, activate K^+ channels and inhibit Ca^{2+} channels, hyperpolarising the neuron; chronic exposure **upregulates the cAMP-CREB pathway**, underlying tolerance, dependence and withdrawal.
- ▶ **Second-messenger relevance** — lithium (mood stabiliser) competes with magnesium to inhibit **GSK3 β** and phosphoinositide-signalling enzymes, illustrating how transmitter-downstream cascades are themselves drug targets.

Neurotransmitters and drugs of abuse / reward circuitry

All addictive drugs converge on promoting **dopamine neurotransmission in the nucleus accumbens** (VTA target), though their initial molecular targets differ (Harrison Table 462-1):

Drug	Transmitter affected	Target (action)
Opioids	Endorphins, enkephalins	μ - and δ -opioid receptors (agonist)
Psychostimulants (cocaine, amphetamine, methamphetamine)	Dopamine	DAT (cocaine = antagonist; amphetamine/methamphetamine = reverse transport)
Nicotine	Acetylcholine	Nicotinic cholinergic receptors (agonist)
Ethanol	GABA / glutamate / 5-HT / ACh	GABA-A (positive allosteric modulator); NMDA glutamate (antagonist); 5-HT ₃ (positive allosteric modulator)
Marijuana	Endocannabinoids (anandamide, 2-AG)	CB1 receptor (agonist)
Phencyclidine, ketamine	Glutamate	NMDA receptor (antagonist)

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Chemical synapse / transmitter life cycle** — label: pre-synaptic terminal, mitochondrion, synaptic vesicles, voltage-gated Ca^{2+} channel, synaptic cleft, **transmitter molecules**, post-synaptic **ionotropic and metabotropic receptors**, **reuptake transporter** (e.g., DAT), degrading enzyme (MAO/acetylcholinesterase), post-synaptic density.
- ▶ **Monoamine source-nuclei map** (after Fig. 462-3) — label: **VTA (dopaminergic)**, **locus coeruleus (noradrenergic)**, **dorsal raphe (serotonergic)**, **nucleus accumbens**, amygdala, hippocampus, prefrontal cortex, hypothalamus; arrows for glutamatergic, GABAergic, dopaminergic and peptidergic projections.

Clinical / Diagnostic significance

- ▶ **Mood disorders** — tricyclics (imipramine) block serotonin/norepinephrine reuptake and MAO inhibitors (tranylcypromine) raise monoamines, giving rise to the **monoamine deficiency hypothesis** of depression; the delayed (weeks) clinical response shows efficacy depends on downstream **neuroplastic/BDNF-mediated adaptation**, not the acute rise in transmitter.
- ▶ **Rapid-acting antidepressants** — **ketamine**, a non-competitive NMDA **glutamate-receptor antagonist**, produces antidepressant effects within hours in treatment-resistant depression, redirecting focus to **glutamatergic transmission and synaptic plasticity**.
- ▶ **Psychedelics / MDMA** — 5-HT_{2A} partial agonism (psychedelics) and serotonin-releasing action (MDMA) are under study for depression and PTSD.
- ▶ **Parkinson disease** — degeneration of **midbrain dopaminergic neurons**; basis for dopamine-replacement therapy and experimental fetal/stem-cell-derived dopamine-neuron grafts.
- ▶ **Addiction** — convergence on the **VTA–nucleus accumbens dopamine reward pathway**; cAMP–CREB and ΔFosB adaptations drive tolerance, dependence and relapse.
- ▶ **Gut–brain axis** — gut bacteria synthesise **GABA and serotonin** and signal to the CNS via the vagus nerve, modulating anxiety- and depression-like behaviour (Ch. 435).

High-yield exam pointers

- ▶ **Glutamate** = principal excitatory; **GABA** = principal inhibitory transmitter of the CNS.
- ▶ **Tyrosine hydroxylase** = rate-limiting enzyme of catecholamine synthesis; **GAD (GAD1)** synthesises GABA from glutamate.
- ▶ Source nuclei: **dopamine** — **VTA/substantia nigra**; **norepinephrine** — **locus coeruleus**; **serotonin** — **raphe nuclei**.
- ▶ **Ionotropic** (NMDA, AMPA, GABA-A, nicotinic, 5-HT₃) = fast; **metabotropic** (GPCR: dopaminergic, adrenergic, GABA-B, opioid, muscarinic) = slow/modulatory.
- ▶ Transmitter action terminated by **reuptake (DAT, SERT, NET)** or **enzymatic degradation (MAO, COMT, acetylcholinesterase)**.
- ▶ **Ketamine** = **NMDA antagonist**, a rapid-acting antidepressant; **lithium** acts on GSK3β / phosphoinositide signalling.
- ▶ Drugs of abuse converge on **dopamine release in the nucleus accumbens** (Table 462-1).
- ▶ Opioids → Gi/o → ↓cAMP/PKA, with chronic cAMP–CREB upregulation underlying dependence.

SOURCE & COVERAGE

Harrison 22e — Ch 462 “Biology of Psychiatric Disorders” (monoamine hypothesis, signal transduction, Fig. 462-2 opioid/LC signalling, Fig. 462-3 mood–reward circuitry, Table 462-1)

drugs of abuse) and Ch 435 “Pathobiology of Neurologic Diseases” (GABA/serotonin and the gut–brain axis; dopaminergic-neuron degeneration).

Coverage note (spec gap = true): Harrison covers neurotransmitters *through disease biology*, not as a basic-physiology topic — the defining criteria, the systematic chemical classification (amino-acid / monoamine / cholinergic / peptide / endocannabinoid / gaseous-purinergic), the stepwise synaptic-transmission cycle, the ionotropic-vs-metabotropic receptor framework, and individual receptor subtype lists (D1–D5, α/β -adrenergic, 5-HT1–7, κ -opioid, glycine, histamine, muscarinic) are supplied here as **universally-accepted standard internal-medicine/neuroscience** scaffolding, not verbatim from the two provided chapters. All transmitter-source nuclei, enzymes, receptor mechanisms, drug-of-abuse targets and clinical correlations stated are grounded in Ch 462/435.

Newer Anticoagulant Drugs

Asked in: Paper I May 2019 — RGUHS MD General Medicine

Definition / Introduction — *Newer anticoagulants* are agents developed to overcome the limitations of the classical drugs (unfractionated heparin and vitamin K antagonists such as warfarin) — namely the need for parenteral administration or routine laboratory monitoring, the slow onset/offset, the narrow therapeutic window, and numerous food/drug interactions. The term encompasses the synthetic pentasaccharide **fondaparinux**, the parenteral **direct thrombin inhibitors** (argatroban, bivalirudin, desirudin), and, most importantly for current practice, the oral **direct-acting oral anticoagulants** (DOACs) — the direct thrombin inhibitor *dabigatran* and the direct factor Xa inhibitors *rivaroxaban*, *apixaban* and *edoxaban*. DOACs target a single activated clotting factor, have rapid onset, predictable pharmacokinetics, and are given in fixed doses without routine coagulation monitoring.

Classification of newer anticoagulants

Class	Target	Drugs	Route
Synthetic pentasaccharide	Factor Xa (via antithrombin)	Fondaparinux	SC
Parenteral direct thrombin (IIa) inhibitors	Thrombin active site $\pm$ exosite 1	Argatroban, Bivalirudin, Desirudin (lepirudin withdrawn)	IV/SC
Oral direct thrombin inhibitor	Thrombin (IIa)	Dabigatran etexilate	Oral
Oral direct factor Xa inhibitors (“-xabans”)	Factor Xa	Rivaroxaban, Apixaban, Edoxaban	Oral

- ▶ The DOACs are **small molecules that bind reversibly to the active site** of their target enzyme, inhibiting *free and clot-bound* factor (unlike heparin, which acts only on circulating factors and cannot inhibit fibrin-bound thrombin).
- ▶ Mnemonic for Xa inhibitors: the “-**xa-bans**” (riv-a-ROXA-ban) all *ban factor Xa*; *dabigatran* is the lone direct thrombin inhibitor.

Direct oral anticoagulants — comparative pharmacology

Characteristic	Rivaroxaban	Apixaban	Edoxaban	Dabigatran
Target	Factor Xa	Factor Xa	Factor Xa	Thrombin (IIa)
Prodrug	No	No	No	Yes (etexilate)
Bioavailability	80%	60%	50%	6%
Usual dosing	once daily (bid)	twice daily	once daily	twice daily
Half-life	7–11 h	12 h	9–11 h	12–17 h
Renal excretion	33%	25%	35%	80%
Key interactions	CYP3A4 + P-gp	CYP3A4 + P-gp	P-gp	P-gp

- ▶ **Dabigatran** is the only prodrug (absorbed as dabigatran etexilate, converted by esterases); its very low bioavailability explains *dyspepsia* (the capsule contains tartaric acid) and the need for an intact capsule.
- ▶ **Renal clearance is the critical safety pivot**: dabigatran (80% renal) is the most dialysable and the most affected by chronic kidney disease; factor Xa inhibitors are less renally dependent. All require dose reduction or avoidance in significant renal impairment.
- ▶ Potent **dual P-gp + CYP3A4 inhibitors** (e.g., azole antifungals, ritonavir) raise drug levels; strong inducers (rifampicin, carbamazepine, phenytoin, St John’s wort) lower them — these are the main interactions to avoid.

Indications and dosing

Licensed indications (all four DOACs unless stated):

- ▶ **Non-valvular atrial fibrillation** — stroke prevention (NOT in mechanical heart valves or moderate–severe rheumatic mitral stenosis).
- ▶ **Treatment of venous thromboembolism (VTE)** — DVT and PE, and secondary prevention.
- ▶ **Thromboprophylaxis after elective hip or knee arthroplasty** — dabigatran, rivaroxaban, apixaban (edoxaban only in Japan).
- ▶ **Secondary prevention in coronary/peripheral artery disease** — low-dose rivaroxaban with aspirin (*COMPASS* regimen).

Indication	Rivaroxaban	Apixaban	Dabigatran	Edoxaban
AF stroke prevention	20 mg OD (15 mg if CrCl 15–49)	5 mg BD (2.5 mg BD if ≥ 2 ABC)	150 mg BD (75 mg BD if CrCl 15–30)	60 mg OD (30 mg if CrCl 15–50, wt ≤ 60 kg, or potent P-gp inhibitor)
Acute VTE	15 mg BD $\times 21$ d $\rightarrow$ 20 mg OD	10 mg BD $\times 7$ d $\rightarrow$ 5 mg BD	150 mg BD <i>after</i> ≥ 5 d parenteral	60 mg OD <i>after</i> ≥ 5 d parenteral
VTE — extended (after 6 mo)	10 mg OD	2.5 mg BD	—	—
Hip/knee prophylaxis	10 mg OD	2.5 mg BD	220 mg OD	—
CAD/PAD (with aspirin)	2.5 mg BD	—	—	—

- ▶ **ABC dose-reduction criteria for apixaban in AF** = Age > 80 y, Body weight < 60 kg, serum Creatinine ≥ 1.5 mg/dL — reduce to 2.5 mg BD if *any two* are present.
- ▶ **Single-drug (“all-oral”) regimens:** only *rivaroxaban* and *apixaban* can be started without a heparin lead-in for VTE; *dabigatran* and *edoxaban* require ≥ 5 days of parenteral anticoagulant (LMWH) first.
- ▶ Rivaroxaban 15/20 mg **must be taken with food** to ensure absorption; apixaban and edoxaban are food-independent.
- ▶ Landmark non-inferiority trials vs warfarin in AF: *RE-LY* (dabigatran), *ROCKET AF* (rivaroxaban), *ARISTOTLE* (apixaban), *ENGAGE AF-TIMI 48* (edoxaban).

Parenteral newer agents

- ▶ **Fondaparinux** — synthetic analogue of the antithrombin-binding pentasaccharide (MW 1728). It binds only to antithrombin and is *too short to bridge thrombin*, so it catalyses **factor Xa inhibition only**. Given SC once daily; 100% bioavailable; plasma half-life **17 h**; cleared **unchanged renally** (contraindicated if CrCl < 30 mL/min). Dose: **2.5 mg OD** (prophylaxis/ACS), 5–10 mg OD by weight for VTE treatment. It **does not cause HIT** (no PF4 binding, no cross-reactivity) and so is useful in HIT, but **has no antidote** (protamine ineffective).
- ▶ **Parenteral direct thrombin inhibitors** — used chiefly in *heparin-induced thrombocytopenia (HIT)* and PCI:
 - *Argatroban* — univalent active-site inhibitor, **hepatically metabolised**, half-life ~ 45 min, monitored by aPTT; drug of choice in **HIT with renal failure**.
 - *Bivalirudin* — bivalent (active site + exosite 1) 20-amino-acid hirudin analogue, shortest half-life (~ 25 min), partly renally cleared; an alternative to heparin in PCI and HIT.
 - *Desirudin* — recombinant hirudin; renally cleared.

Monitoring, reversal and management of bleeding

- ▶ **Routine monitoring is not required.** When assessment is needed (adherence, overdose, pre-urgent surgery, suspected accumulation): a *normal PT* largely excludes clinically relevant levels of factor Xa inhibitors and a *normal aPTT/thrombin time* excludes dabigatran. Quantitative assays = **chromogenic anti-Xa assay** (calibrated) for the xabans; **dilute thrombin time / ecarin clot time** for dabigatran. Apixaban has minimal effect on PT, so anti-Xa assay is needed.
- ▶ **Bleeding — general measures:** hold the drug, local haemostasis, fluids/blood products; **activated charcoal** if ingested within ~2–4 h; *vitamin K is of no value*. Calculate residual effect from last dose and renal function.
- ▶ **Specific reversal agents:**
 - **Idarucizumab** — humanised monoclonal antibody *fragment* that binds dabigatran with very high affinity; **5 g IV** (two 2.5 g vials); rapidly normalises aPTT/dilute thrombin time. If unavailable, **activated PCC 50 units/kg**.
 - **Andexanet alfa** — recombinant, catalytically inactive **decoy factor Xa** that sequesters the xabans (and also heparin/LMWH). *Low dose* = 400 mg bolus + 4 mg/min infusion (≤120 min); *high dose* = 800 mg bolus + 8 mg/min. High dose if last dose was large (rivaroxaban >10 mg / apixaban >5 mg) and taken <8 h ago. If unavailable, **four-factor PCC 25–50 units/kg** (≈2000 units).
 - Fondaparinux and argatroban/bivalirudin have **no licensed antidote**.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Coagulation cascade with drug targets:** draw the common pathway — *Factor X* → *Xa* → (*prothrombinase*) → *Prothrombin (II)* → *Thrombin (IIa)* → *Fibrinogen* → *Fibrin*. Label arrows blocking **Factor Xa**: Rivaroxaban, Apixaban, Edoxaban, Fondaparinux (via antithrombin) and blocking **Thrombin (IIa)**: Dabigatran, Argatroban, Bivalirudin. Show Warfarin acting upstream on synthesis of factors *II, VII, IX, X* (and *proteins C, S*). Mark Idarucizumab → dabigatran and Andexanet alfa → Xa inhibitors as reversal arrows.
- ▶ **Antithrombin-mediated inhibition schematic:** antithrombin bridging unit — heparin neutralises both *Xa* and *IIa*; LMWH mainly *Xa*; **fondaparinux only Xa** (pentasaccharide too short to bridge thrombin).

Clinical / Diagnostic significance

- ▶ **Advantages over warfarin:** fixed oral dosing, rapid onset/offset, predictable response, no routine INR monitoring, few food and fewer drug interactions, and **significantly less intracranial haemorrhage**.

- ▶ **Disadvantages/cautions:** higher-dose dabigatran, rivaroxaban and edoxaban cause **more GI bleeding**; renal clearance limits use in advanced CKD; cost; short half-life means missed doses rapidly lose protection.
- ▶ **Contraindications / avoid:** mechanical prosthetic valves and moderate–severe rheumatic mitral stenosis (warfarin superior — *RE-ALIGN* showed harm with dabigatran); **pregnancy and lactation** (cross placenta/breast milk — use LMWH); triple-positive **antiphospholipid syndrome** (DOACs inferior to warfarin); severe renal/hepatic impairment.
- ▶ **Peri-procedural:** stop DOAC 1–2 days before moderate/high-risk procedures (longer if renal impairment); unlike warfarin, **no heparin “bridging” is needed** because of rapid offset.
- ▶ **Special populations:** in cancer-associated VTE, apixaban/edoxaban/rivaroxaban are acceptable alternatives to LMWH but are **avoided in GI/genitourinary tumours** (bleeding) and where chemotherapy interactions exist.

High-yield exam pointers

- ▶ DOACs = **dabigatran (anti-IIa) + rivaroxaban / apixaban / edoxaban (anti-Xa)**; only dabigatran is a *prodrug*.
- ▶ **Dabigatran is 80% renally excreted** → most affected by CKD and the only DOAC removed by dialysis.
- ▶ **Apixaban** has the least GI bleeding and is often preferred in CKD; remember the **ABC** reduction rule (Age>80, Body wt<60, Creatinine≥1.5).
- ▶ **Dabigatran & edoxaban need a ≥5-day parenteral lead-in** for VTE; rivaroxaban & apixaban are all-oral.
- ▶ **Idarucizumab** → **dabigatran**; **Andexanet alfa** → **factor Xa inhibitors**; 4-factor PCC is the fallback for both.
- ▶ **Fondaparinux** = pure anti-Xa pentasaccharide, $t_{1/2}$ 17 h, no HIT, no antidote.
- ▶ DOACs are **contraindicated in mechanical valves, rheumatic MS, pregnancy and antiphospholipid syndrome** — these patients need warfarin.
- ▶ DOACs cause **less intracranial bleeding than warfarin** but sometimes **more GI bleeding**.
- ▶ Qualitative tests: **PT** for xabans, **aPTT/TT** for dabigatran; quantitative = **anti-Xa assay** and **dilute thrombin/ecarin clot time** respectively.

SOURCE & COVERAGE

- ▶ Harrison’s Principles of Internal Medicine, 22e — “Antiplatelet, Anticoagulant, and Fibrinolytic Drugs” (parenteral anticoagulants, fondaparinux, parenteral direct thrombin inhibitors, warfarin, and the Direct Oral Anticoagulants section incl. Table 123-9 pharmacology comparison, dosing, monitoring and reversal).

- ▶ CMDT 2026 — “Disorders of Hemostasis, Thrombosis, & Antithrombotic Therapy” (Tables 16-9/16-10: DOAC dosing, transitions; DOAC-associated major-bleeding reversal guidance with idarucizumab and low/high-dose andexanet alfa; cancer-associated VTE and APS cautions).
- ▶ Trial names (RE-LY, ROCKET AF, ARISTOTLE, ENGAGE AF-TIMI 48, COMPASS, RE-ALIGN) are universally accepted landmark internal-medicine references; COMPASS appears in Harrison’s further reading.

Pharmacogenomics

Asked in: Paper I Sep 2025 — RGUHS MD General Medicine

Definition / Introduction — **Pharmacogenetics** is the study of how *single* inherited genetic variants determine unusual (beneficial or adverse) responses to a drug in an individual or family; **pharmacogenomics** extends this to *multiple* variants across whole genomes and populations to explain variability in drug efficacy and toxicity. The genes involved — those governing drug metabolism, transport, targets, and immune recognition — are collectively termed **pharmacogenes**. The discipline aims to choose effective drugs and doses, avoid adverse drug reactions (ADRs) in high-risk individuals, guide drug development, and serves as a cornerstone of **precision (personalised) medicine**.

Core concepts and metabolizer phenotypes

- ▶ The commonest variant is a **single nucleotide polymorphism (SNP)**; *non-synonymous* (amino-acid-changing) SNPs are a frequent cause of altered pharmacogene function. Other variants: small insertions/deletions, splice and promoter variants, **copy-number variation** (gene deletion or duplication). SNP assays may miss large duplications, and the highly polymorphic **HLA locus** on chromosome 6 is best characterised by sequencing.
- ▶ The frequency of pharmacogene variants **varies strikingly by ancestry**, so specific ethnic groups can be at unusually high risk of aberrant drug response.
- ▶ A **multimodal (non-unimodal)** distribution of plasma drug concentration signals that one gene predominates in that drug’s metabolism, classically yielding four phenotypes (illustrated by CYP2D6):

Phenotype	Genotype	Enzyme activity	Consequence for a substrate
Poor metabolizer (PM)	2 loss-of-function alleles	Absent/very low	↑ steady-state level, longer time to steady state; toxicity (or no effect if prodrug)

Phenotype	Genotype	Enzyme activity	Consequence for a substrate
Intermediate metabolizer (IM)	1 functional / 2 reduced-function alleles	Reduced	Modestly altered handling
Normal / extensive metabolizer (EM)	1–2 functional alleles	Normal	Expected response
Ultrarapid metabolizer (UM)	Gene duplication (2–12 copies)	Very high	↓ parent-drug level (drug failure), or toxicity if active metabolite formed

- ▶ The combination of alleles on the two chromosomes (the **diplotype**) determines the phenotype. **Phenocopying** occurs when a co-prescribed inhibitor converts a genetic EM into a functional PM.

Genetic variants affecting pharmacokinetics (PK)

- ▶ Discovery uses **candidate-gene** approaches (knowing the metabolic pathway) and unbiased **genome-wide association (GWA)** studies; results require replication.

Gene / product	Drug(s)	Clinical effect of variant
CYP3A4 / CYP3A5	Tacrolimus, vincristine	CYP3A5 splice variant in Europeans/Asians → low activity; African “expressers” eliminate tacrolimus faster (↓ efficacy), lower vincristine-neuropathy risk
CYP2D6	Codeine, metoprolol/carvedilol, propafenone, nortriptyline, tamoxifen	PM 5–10% of Europeans/Africans (few Asians); codeine→morphine fails in PMs and is dangerous in UMs
CYP2C19	Clopidogrel, omeprazole	PM ~20% Asians, 2–3% others, >50% Oceania; LOF → clopidogrel failure (stent thrombosis/stroke); **2C1917** UM → ↑ bleeding
CYP2C9 (+ VKORC1)	Warfarin, phenytoin, glipizide, losartan	↑ phenytoin neurotoxicity, glipizide hypoglycaemia; ↓ warfarin dose; losartan (prodrug) fails
DPYD (dihydropyrimidine dehydrogenase)	5-fluorouracil, capecitabine, tegafur	LOF (2A, 13, rs67376798) → severe/fatal toxicity; dose-reduce IMs
TPMT	Azathioprine, 6-mercaptopurine	Inactive homozygote (~1/300) → fatal pancytopenia (2, 3A, 3B, 3C)

Gene / product	Drug(s)	Clinical effect of variant
NUDT15	Thiopurines	LOF → excess myelosuppression (esp. East Asians)
NAT2	Isoniazid, procainamide, hydralazine	“Slow acetylators” (~50% Europeans/Africans) → INH hepatitis, drug-induced lupus
UGT1A1	Irinotecan, atazanavir	Gilbert’s promoter variant → irinotecan diarrhoea/marrow suppression, unconjugated hyperbilirubinaemia
SLCO1B1 (OATP1B1)	Simvastatin	Noncoding SNP → ↑ myopathy (accounts for ~60% of risk)
MDR1 (P-glycoprotein) / MATE1, MATE2	Digoxin / metformin	Altered efflux (digoxin toxicity) / uptake (metformin glucose-lowering)

- ▶ For **warfarin**, polymorphisms in **CYP2C9** (PK) plus the **VKORC1** promoter (PD target) account for up to ~50% of dose variability, with a smaller contribution from **CYP4F2** (vitamin K metabolism).

Genetic variants affecting pharmacodynamics (PD) and disease-pathway interactions

- ▶ **VKORC1 promoter** (–1639G>A) variant (common in Asians) lowers transcription and warfarin dose requirement (~30% of variability alone).
- ▶ **β₂- and β₁-adrenergic receptor** polymorphisms modulate response to β-agonists in asthma and β-blocker heart-rate/BP lowering in heart failure/hypertension.
- ▶ **Drug–disease gene interactions**: CYP inducers precipitate attacks in the **porphyrias**; **G6PD** deficiency (African, Mediterranean, South-Asian descent) → haemolysis with **primaquine** and **rasburicase**; **RYR1** (ryanodine receptor) variants → **malignant hyperthermia** with volatile anaesthetics/succinylcholine; subclinical **congenital long-QT** unmasked by QT-prolonging drugs (torsades); **ACKR1** variant → benign ethnic neutropenia.

Immunogenetics — HLA and severe cutaneous/hepatic ADRs

HLA risk alleles are **necessary but not sufficient** (a third, unidentified factor is needed); frequencies vary by ancestry, underpinning population-specific screening.

HLA allele	Drug	Reaction
* <i>HLA-B57:01</i> **	Abacavir	Hypersensitivity (55% of carriers react); also flucloxacillin hepatotoxicity

HLA allele	Drug	Reaction
*HLA-B15:02**	Carbamazepine	SJS/TEN (Han Chinese, SE Asians)
*HLA-A31:01**	Carbamazepine	SJS/TEN, DRESS (Europeans)
*HLA-B58:01**	Allopurinol	SJS/TEN (Korean, Han Chinese, Japanese, Thai)

- ▶ These manifest as Stevens-Johnson syndrome / toxic epidermal necrolysis (SJS/TEN), DRESS, and drug-induced liver injury.

Pharmacogenomics of tumour and pathogen genomes (somatic / targeted therapy)

- ▶ Tumour genotyping selects targeted agents and spares non-responders: **Trastuzumab** for **HER2 (Herceptin-receptor)**-positive breast cancer (and potentiates anthracycline cardiotoxicity); **Imatinib** targets **BCR-ABL1** (Philadelphia chromosome, CML) and **c-KIT** (GIST); **Vemurafenib** inhibits **BRAF V600E** ($\approx 40\%$ of melanomas, not wild-type BRAF); **Crizotinib** for **ALK-rearranged NSCLC**. Rapid emergence of resistance often necessitates combinations (e.g., BRAF + MEK inhibitors).

Pharmacogenomics in drug development

- ▶ Human genetics validates and de-risks targets: rare **gain-of-function PCSK9** variants cause familial hypercholesterolaemia, while **loss-of-function PCSK9** SNPs (2.5% of African-Americans) lower LDL and coronary risk without harm — directly spawning **PCSK9 monoclonal antibodies**. Other genetics-driven targets: **HSD17B13** (chronic liver disease), **ANGPTL3** (hyperlipidaemia). Large biobanks (**UK Biobank**, **All of Us**) and **polygenic risk scores** extend this approach to drug “repurposing”.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Population distribution of CYP2D6 activity (Fig 72-1A)**: x-axis “Enzymatic activity (lesser $\rightarrow$ greater)”, y-axis “Population frequency”; three labelled humps — **Poor metabolizers (PM, 2 mutant alleles)**, **Extensive metabolizers (EM, 1–2 wild-type alleles)**, **Ultrarapid metabolizers (UM, gene duplication >2 copies)**; mark the antimode separating PMs from EMs.
- ▶ **Gene-dose effect on drug concentration (Fig 72-1B)**: plot Concentration vs Time for a single dose then chronic therapy; curves labelled **PM (highest AUC, longest $t_{1/2}$)**, **EM**, **UM (lowest AUC, fastest clearance)** — show higher and later steady state in PMs.

Clinical / Diagnostic significance

- ▶ **Implementation models:** *Point-of-care* (variant assay ordered at prescription, result in 1–2 h) vs *preemptive* genotyping (panel tested in advance, stored in the EHR with real-time clinical decision support [CDS]).
- ▶ **Guidelines:** the Clinical Pharmacogenetics Implementation Consortium (CPIC) and the Dutch Pharmacogenetics Working Group publish drug–gene dosing recommendations; the FDA embeds pharmacogenetic data in package inserts (e.g., codeine black-box warning forbidding use in children <12 y).
- ▶ **Evidence base:** an RCT showed **HLA-B57:01* testing eliminates abacavir SJS/TEN — the strongest case for mandatory testing. HLA-B15:02 screening was mandated before carbamazepine in parts of SE Asia (though some prescribers simply switched to phenytoin, also an SJS/TEN risk). Warfarin pharmacogenetic dosing trials showed no/modest benefit. A 2023 European trial (Sven et al., 6944 patients, 7 countries) of a 12-gene/50-variant preemptive panel reduced clinically relevant ADRs (across 42 drugs) by 30%***, supporting preemptive screening.
- ▶ **Decision to test** depends on the magnitude/clinical importance of the genetic effect, strength of evidence (anecdote → post-hoc → RCT), availability of alternative therapy or therapeutic drug monitoring, and cost-benefit.

High-yield exam pointers

- ▶ Define and distinguish pharmacogenetics (single variant/individual) from pharmacogenomics (genome-wide/population).
- ▶ Memorise the PM/IM/EM/UM scheme with CYP2D6 and the codeine story (PM = no analgesia; UM = fatal respiratory depression, FDA ban <12 y after tonsillectomy).
- ▶ TPMT/NUDT15 → thiopurine myelosuppression; DPYD → 5-FU/capecitabine toxicity; UGT1A1 → irinotecan; CYP2C19 → clopidogrel failure; SLCO1B1 → simvastatin myopathy.
- ▶ Warfarin = CYP2C9 + VKORC1 (up to 50% of dose variability).
- ▶ **HLA-B57:01–abacavir, HLA-B15:02–carbamazepine, HLA-B58:01–allopurinol*** (necessary-but-not-sufficient).
- ▶ G6PD–primaquine/rasburicase haemolysis; RYR1–malignant hyperthermia; NAT2 slow acetylators–INH hepatitis/drug-induced lupus.
- ▶ Oncology targets: HER2–trastuzumab, BCR–ABL1/c-KIT–imatinib, BRAF V600E–vemurafenib, ALK–crizotinib.
- ▶ Implementation: CPIC guidelines, FDA labels, preemptive EHR + CDS; Sven 2023 panel cut ADRs by 30%.
- ▶ PCSK9 loss-of-function → PCSK9 inhibitors: genetics validating drug targets.

SOURCE & COVERAGE

- ▶ **Harrison's Principles of Internal Medicine, 22e** — “Pharmacogenomics” (Dan Roden) and “Principles of Clinical Pharmacology” (PK/PD variability framework: metabolizer phenotypes, steady state, loading doses).
- ▶ **CMDT 2026** — Appendix “Therapeutic Drug Monitoring, Pharmacogenetic Tests...” (TPMT 2/3A/3B/3C, DPYD 2A/13/rs67376798, CYP2C1917, *VKORC1* -1639G>A, *HLA-B57:01* abacavir, *HLA-B15:02* carbamazepine, *HLA-B58:01* allopurinol screening).
- ▶ *HLA-B58:01-allopurinol* and *HLA-A31:01*-carbamazepine associations cross-checked in CMDT 2026 and *Bologna, Dermatology* (severe cutaneous adverse reactions).
- ▶ Coverage note: The corpus covers this topic richly via a dedicated Harrison chapter; the online Harrison tables (e72-1/e72-2) listing exhaustive allele frequencies are referenced but not reproduced in the text — allele-level detail above is drawn from the CMDT pharmacogenetic appendix.

Plasma enzymes in clinical medicine

Asked in: Paper I Dec 2023 — RGUHS MD General Medicine

Definition / Introduction — Plasma (serum) enzymes are protein catalysts measurable in circulating blood. A small group are *functional* enzymes that act within plasma (e.g., coagulation factors), but most have no physiological role in serum and, in Harrison's words, “have no known function in the serum and behave like other serum proteins.” Because individual enzymes are concentrated in specific tissues, the **pattern, magnitude and isoenzyme composition** of an enzyme elevation localise the organ injured, gauge its severity, and track response to treatment — the basis of “enzyme diagnosis.” No single enzyme measures total organ function, so enzymes are interpreted together as a *battery*.

Classification of plasma enzymes

Category	Behaviour in disease	Representative enzymes
Functional (plasma-specific)	Synthesised mainly by hepatocytes, act <i>in</i> plasma; levels fall when synthesis fails	Coagulation factors (II, VII, IX, X), pseudocholinesterase, lipoprotein lipase, ceruloplasmin, renin
Non-functional — secretory	Normally secreted by exocrine glands; spill into blood when gland/duct injured	Amylase, lipase (pancreas), prostatic acid phosphatase
Non-functional — cellular (cytosolic / organelle)	Leak from damaged cells; levels rise with tissue injury	AST, ALT, LDH, CK, GGT, 5'-nucleotidase, aldolase

- ▶ Harrison frames hepatic enzymes pragmatically into those whose serum rise reflects (1) **damage to hepatocytes** and (2) **cholestasis** — a clinically useful subdivision of the “cellular” group.

Mechanisms of altered plasma enzyme activity

- ▶ **Increased entry from damaged cells** — the dominant mechanism. Enzymes are “released into the blood in greater amounts when there is damage to the liver cell membrane, resulting in increased permeability.” *Cell necrosis is not required* — increased membrane permeability suffices, and there is a **poor correlation** between enzyme level and degree of damage. Hence the absolute aminotransferase value has **no prognostic significance** in acute hepatocellular injury.
- ▶ **Increased synthesis / enzyme induction** — alkaline phosphatase synthesis is induced in cholestasis and rapid bone turnover; GGT is induced by alcohol and enzyme-inducing drugs.
- ▶ **Decreased clearance** — serum enzymes are probably cleared by the reticuloendothelial system; each has a characteristic **half-life (measured in days)** that determines how long it stays elevated.
- ▶ **Reduced production** — *functional* enzymes (clotting factors) fall when hepatic synthetic capacity fails.

Hepatic plasma enzymes (grounded in Harrison Ch 348)

Hepatocellular (“leakage”) enzymes — the aminotransferases

- ▶ **AST** is present (decreasing order of concentration) in liver, cardiac muscle, skeletal muscle, kidney, brain, pancreas, lung, leukocytes and erythrocytes — so it is **non-specific**. **ALT** is found primarily in liver and is therefore the **more liver-specific** indicator.
- ▶ Normal range $\approx 10\text{--}40$ IU/L. Levels up to **300 IU/L** are non-specific and seen in any liver disorder (commonest cause of minimal elevation = fatty liver disease).
- ▶ **Striking elevation >1000 IU/L** occurs almost exclusively with extensive hepatocellular injury: (1) **viral hepatitis**, (2) **ischemic liver injury** (prolonged hypotension / acute heart failure), (3) **toxin- or drug-induced injury**. A gallstone passing into the common bile duct can transiently push them to **1000–2000 IU/L**, after which they fall quickly into a cholestatic pattern.
- ▶ **AST:ALT ratio** — $\text{ALT} \geq \text{AST}$ in most acute hepatocellular disease; ratio <1 in chronic viral hepatitis and NAFLD, rising >1 as cirrhosis develops. A ratio **$>2:1$ is suggestive** and **$>3:1$ highly suggestive** of alcohol-related liver disease (AST rarely >300 IU/L, ALT often normal because of alcohol-induced **pyridoxal-phosphate [vitamin B6] deficiency**).

Cholestatic enzymes — alkaline phosphatase, 5'-nucleotidase, GGT

- ▶ ALP and 5'-nucleotidase lie *in or near the bile canalicular membrane*; GGT is in the endoplasmic reticulum and bile-duct epithelium — its more diffuse location makes it **less specific** for cholestasis.
- ▶ **ALP isoenzymes** arise from liver, bone, placenta and (less often) small intestine. Physiological rises: age >60 ($1\text{--}1.5\times$), blood groups **O and B** after a fatty meal (intestinal ALP), childhood/adolescent bone growth, and late pregnancy (placental ALP).
- ▶ A **$<3\text{-fold}$** rise is non-specific (almost any liver disease); **$>4\text{-fold}$** points to cholestasis, infiltrative disease (cancer, amyloidosis) or high-turnover bone disease (**Paget's**).

- To confirm a raised ALP is hepatic: **fractionate by electrophoresis**, or measure **GGT / 5'-nucleotidase** (both rise with hepatic ALP but are normal in bone disease). GGT is also a marker of occult alcohol use.

Feature	Hepatocellular pattern	Cholestatic pattern
Dominant enzymes	AST, ALT	ALP, GGT, 5'-NT
Typical magnitude	AST/ALT often very high (may be >1000)	ALP >4× normal
Classic causes	Viral / ischemic / toxic hepatitis	Biliary obstruction, PBC, infiltration, drugs
Confirmatory step	AST:ALT ratio; viral & autoimmune serology	GGT/5'-NT to confirm hepatic ALP; ultrasound for ducts

Extra-hepatic organ-specific enzymes (standard internal medicine)

Organ / system	Enzyme(s)	Principal clinical use
Heart	CK-MB, AST, LDH (LDH-1)	Myocardial infarction — but troponin (a regulatory protein, <i>not</i> an enzyme) is now the preferred marker
Skeletal muscle	Total CK (CK-MM), aldolase	Rhabdomyolysis, inflammatory myopathy, very high CK in Duchenne dystrophy
Pancreas	Amylase, lipase	Acute pancreatitis ($\geq 3\times$ ULN); lipase more specific and longer-lasting
Bone	ALP (bone isoenzyme)	Paget's disease, osteomalacia, rickets, bone metastases
Prostate	Acid phosphatase	Carcinoma prostate (historical; replaced by PSA)
Blood / marrow	LDH	Intravascular hemolysis, megaloblastic anaemia, tumour lysis, lymphoma
Lung / granuloma	Angiotensin-converting enzyme (ACE)	Sarcoidosis disease activity
Serous cavities	Adenosine deaminase (ADA)	Tuberculous pleural / pericardial / peritoneal effusion, TB meningitis
Toxicology	Pseudocholinesterase, RBC acetylcholinesterase	Fall in organophosphate poisoning; deficiency $\rightarrow$ scoline (suxamethonium) apnoea

Organ / system	Enzyme(s)	Principal clinical use
RBC	Glucose-6-phosphate dehydrogenase	Deficiency → drug/infection-triggered hemolysis

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Hepatocyte enzyme-leak schematic** — draw a hepatocyte abutting a sinusoid and a bile canaliculus. Label: *cytosol* → AST / ALT (leakage enzymes); *bile canaliculus membrane* → ALP and 5'-nucleotidase; *endoplasmic reticulum & bile-duct epithelium* → GGT; add an arrow “cell-membrane damage → ↑ permeability → enzyme leak into sinusoid → ↑ serum level.”
- ▶ **Serum cardiac-enzyme time-activity curve after acute MI** — x-axis “Days after onset of chest pain,” y-axis “Serum activity (× upper normal),” plotting CK-MB (peak ~24 h), AST (peak ~48 h) and LDH (peak 3–6 days), with **Troponin** overlaid and labelled “not an enzyme.” (*standard medicine*)

Clinical / Diagnostic significance

- ▶ **Use as a battery** — aminotransferases + ALP + bilirubin + albumin + prothrombin time. Multiple or persistently abnormal tests make liver disease likely; all-normal results make occult disease unlikely.
- ▶ **Pattern recognition** directs the work-up: hepatocellular (AST/ALT dominant) vs cholestatic (ALP/GGT dominant) steers imaging and the chronically-abnormal-liver-tests algorithm (Fig. 348-1).
- ▶ **Isoenzymes / second enzymes localise the source** — GGT or 5'-NT confirm that a raised ALP is hepatic; CK-MB confirms myocardial origin of a raised total CK.
- ▶ **Synthetic-function tests gauge severity** — albumin (synthesised exclusively by hepatocytes, half-life 18–20 days, ~4%/day turnover) reflects *chronic* disease, whereas the PT/INR reflects clotting factors with short half-lives (6 h for factor VII to 5 days for fibrinogen) and is the single best *acute* index of hepatic synthesis. PT prolonged >5 s above control and uncorrected by parenteral vitamin K is a poor prognostic sign; INR + bilirubin feed the MELD score.
- ▶ **Caveats** — enzymes lack sensitivity and specificity: they can be normal in serious liver disease and abnormal in disease that does not affect the liver, and their magnitude does not equal prognosis in acute hepatocellular injury.

High-yield exam pointers

- ▶ **Functional enzymes** (clotting factors, pseudocholinesterase) **fall** in disease; **cellular leakage enzymes** (AST, ALT, CK, LDH) **rise**.
- ▶ **ALT is more liver-specific than AST**; aminotransferases >1000 IU/L = viral, ischemic or toxic hepatitis.

- ▶ **AST:ALT >2:1** → alcoholic; <1 → viral/NAFLD; flips to >1 as cirrhosis develops.
- ▶ **ALP >4× normal** = cholestasis / infiltration / Paget's; confirm hepatic origin with **GGT** or **5'-nucleotidase**.
- ▶ **Factor VIII** is the only clotting factor *not* made solely by hepatocytes (vascular endothelium) — so it stays normal in liver failure.
- ▶ **Vitamin-K-dependent factors** = II, VII, IX, X; the PT measures factors II, V, VII, X.
- ▶ **Lipase > amylase** for specificity in acute pancreatitis; **troponin > CK-MB** for MI (troponin is *not* an enzyme).
- ▶ **Pseudocholinesterase** ↓ in organophosphate poisoning and underlies scoline apnoea; **ADA** ↑ in tuberculous effusions; **ACE** ↑ in sarcoidosis; **LDH** ↑ in hemolysis and tumour lysis.

SOURCE & COVERAGE

Harrison's Principles of Internal Medicine, 22e — Ch 348 "Evaluation of Liver Function" (hepatocellular leakage vs cholestatic enzymes; AST/ALT tissue distribution, normal ranges, >1000 IU/L causes and AST:ALT ratio; ALP isoenzymes, GGT and 5'-nucleotidase; albumin and coagulation-factor synthetic function). **Coverage note:** Harrison 22e has no dedicated "plasma enzymes" chapter. Ch 348 fully grounds the hepatic and synthetic-function enzymes and *all numerical values, ratios and tissue distributions* stated above. The general functional-vs-non-functional classification and the extra-hepatic enzymes (CK/CK-MB, LDH isoenzymes, amylase/lipase, aldolase, acid phosphatase/PSA, ACE, pseudocholinesterase, ADA, G6PD) and the cardiac-enzyme time-activity curve are *universally accepted standard internal-medicine/biochemistry* that Harrison covers within the respective disease chapters (acute MI, acute pancreatitis, the myopathies) — not the supplied chapter — and are flagged as such.

Polymerase chain reaction technique and application

Asked in: Paper I May 2022 — RGUHS MD General Medicine

Definition / Introduction — The **polymerase chain reaction (PCR)** is a type of **nucleic acid amplification test (NAAT)** that uses specific **oligonucleotide primers** and a **DNA polymerase** to amplify a defined target region of DNA *in vitro*, generating millions of copies from a minute starting template. Because each cycle theoretically doubles the target, amplification is **exponential**, conferring extraordinary analytical sensitivity. PCR underpins modern molecular diagnostics in internal medicine — from genetic mutation analysis to pathogen detection and antimicrobial-resistance genotyping — and permits testing on vanishingly small amounts of DNA (leukocytes, buccal cells, single cells, or even a hair root).

Reaction components (“ingredients”)

Component	Role
Template DNA	The double-stranded DNA containing the target sequence to be amplified
Primer pair (forward + reverse)	Short specific oligonucleotides flanking the target; define the region amplified and provide the free 3'-OH for polymerase extension
Thermostable DNA polymerase (<i>Taq</i> , from <i>Thermus aquaticus</i>)	Heat-stable enzyme that synthesizes the new strand and survives repeated denaturation temperatures
dNTPs (dATP, dGTP, dCTP, dTTP)	Building blocks incorporated into the nascent strand
Mg ²⁺ + buffer	Cofactor essential for polymerase activity; buffer maintains optimal pH/ionic conditions
Thermal cycler	Programmable instrument that rapidly raises and lowers temperature through each cycle

- ▶ **Primer specificity is critical:** highly sensitive amplification methods require a high degree of sequence identity between primer pairs and their short target; even a **single base-pair mismatch** — particularly near the 3' end of the primer — may interfere with detection (Harrison Ch 126). This is the basis of “diagnostic escape” when a pathogen acquires a deletion/mutation at the primer site.

Steps of one PCR cycle (thermal cycling)

- ▶ **1. Denaturation (~94–95 °C):** heat separates the double-stranded template into two single strands by breaking hydrogen bonds.
- ▶ **2. Annealing (~50–65 °C):** temperature is lowered so the forward and reverse primers hybridize to their complementary single-stranded targets.
- ▶ **3. Extension / elongation (~72 °C):** *Taq* polymerase adds dNTPs to the 3' end of each primer, synthesizing a new complementary strand in the 5'→3' direction.
- ▶ These three steps constitute **one cycle**; the cycle is repeated typically **25–40 times**, and because product of one cycle is template for the next, copy number rises **exponentially** ($\approx 2^n$), yielding millions–billions of copies.
- ▶ The amplified product (“**amplicon**”) is then detected — classically by **agarose gel electrophoresis**, or read in real time (see below). **DNA sequencing can be performed directly on PCR products** (Harrison Ch 479).

Major variants / modifications of PCR

Variant	Key principle	Representative use
Reverse-transcriptase PCR (RT-PCR)	RNA first converted to cDNA by reverse transcriptase, then amplified	Detection of RNA viruses — SARS-CoV-2 (core acute-phase assay), HIV, HCV, influenza, RSV (Harrison Ch 126)
Real-time / quantitative PCR (qPCR)	Amplicon accumulation measured cycle-by-cycle via fluorescence, allowing quantification of starting copies	Viral load quantification (HIV PCR can detect as few as 20 copies/mL of blood) and treatment monitoring
Multiplex PCR	Several primer sets in one reaction detect multiple targets simultaneously	Syndromic panels — e.g., respiratory viral panel (influenza, parainfluenza, RSV, adenovirus, rhinovirus, enterovirus, metapneumovirus, coronaviruses)
Nested PCR	Two sequential amplifications with inner primers boost specificity/sensitivity	Detection of low-copy targets (<i>standard molecular biology</i> — see <i>Coverage note</i>)
Isothermal amplification	Amplifies at a single constant temperature, avoiding thermal-cycling hardware	Point-of-care / field testing in resource-limited settings; pairs with CRISPR Cas12a/Cas13a nucleic-acid sensors (Harrison Ch 126)
Digital / droplet PCR	Partitioning enables absolute quantification	Low-abundance targets, minimal residual disease (<i>standard</i> — see <i>Coverage note</i>)

- ▶ A related NAAT chemistry, the **ligase chain reaction**, is also used to amplify/detect nucleic acids (Harrison Ch 126).

Applications in internal medicine

- ▶ Infectious disease — pathogen detection (Harrison Ch 126):
 - **Viral diagnosis and monitoring:** HIV, HBV, HCV, SARS-CoV-2, influenza, RSV — for initial diagnosis, response to therapy, and (in some cases) genotypic prediction of drug resistance. RT-PCR for SARS-CoV-2 was the largest molecular-diagnostic deployment to date.
 - **Tuberculosis:** amplification of the **rpoB** gene for species-specific identification of *M. tuberculosis*.
 - **Fastidious/unculturable bacteria:** *Neisseria gonorrhoeae*, *Chlamydia trachomatis*, *Ehrlichia chaffeensis*, *Anaplasma phagocytophilum*, *Clostridioides difficile*.
 - **16S ribosomal RNA gene PCR:** broad-range amplification/sequencing of the conserved 16S rRNA gene to identify bacteria in culture-negative infections.

- **Toxin-gene detection:** *C. difficile* toxins A and B, Shiga toxin — distinguishes pathogens from colonizers.
- **Antimicrobial-resistance genotyping (Harrison Ch 126):**

Target gene(s)	Resistance detected
<i>mecA</i>	Methicillin resistance in <i>S. aureus</i> (MRSA)
<i>vanA</i> / <i>vanB</i>	Vancomycin resistance in enterococci (VRE)
<i>rpoB</i> polymorphisms	Rifampin resistance in <i>M. tuberculosis</i> ($\approx 95\%$ of rifampin resistance); probes for <i>inhA</i> and <i>katG</i> detect up to 85% of isoniazid resistance
KPC, NDM, OXA-48, IMP, VIM	Carbapenemase production in Enterobacteriaceae

- **Human genetics (Harrison Ch 479):**
 - **Mutational analysis** of discrete sequence alterations from small DNA amounts (leukocytes, single cells, buccal cells, hair roots).
 - **Direct sequencing of PCR products** to characterize specific mutations and predict disease spectrum.
 - **Genotyping of short tandem repeats (STRs / polymorphic microsatellite markers)** — di-, tri-, tetranucleotide repeats characterized readily by PCR — for **linkage and association studies**.
 - **Preimplantation/prenatal genetic diagnosis:** with IVF, PCR-based diagnosis on a **single cell** from the four- to eight-cell embryo or the first polar body.
- **Oncology (Harrison Ch 479):** somatic (tumor-biopsy) versus germline (peripheral-cell) mutational analysis to guide therapy integrating genetic/genomic information.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- **Diagram 1 — “One PCR cycle”:** a double-stranded template, with three labelled arrows/boxes: (1) Denaturation 94–95 °C → single strands; (2) Annealing 50–65 °C → forward & reverse primers bind; (3) Extension 72 °C → Taq polymerase + dNTPs synthesize new strands. Add a side note “repeat $\times 25\text{--}40$ cycles → exponential 2^n amplification.” Label: *template DNA, forward primer, reverse primer, Taq polymerase, dNTPs, new strand, amplicon*.
- **Diagram 2 — “Exponential amplification curve”:** copy number (y-axis, log scale) versus cycle number (x-axis), showing geometric doubling. Labels: $1 \rightarrow 2 \rightarrow 4 \rightarrow 8 \dots$ copies, *exponential phase, plateau*.

Clinical / Diagnostic significance

- ▶ **Sensitivity:** detects minute pathogen loads (e.g., HIV down to ~20 copies/mL), enabling earlier diagnosis and treatment than antigen detection or serology — the progression from antigen detection to PCR transformed understanding of HIV natural history.
- ▶ **Speed and real-time management:** NAATs supply etiologic diagnosis far faster than culture/serology, informing triage, antibiotic stewardship, and infection control (pivotal in the COVID-19 response).
- ▶ **Resistance prediction:** genotypic detection (e.g., *rpoB* for MDR-TB, carbapenemase genes) guides directed therapy when phenotypic susceptibility is slow or impossible.
- ▶ **Limitations / pitfalls:** technical complexity and reagent/instrument needs; risk of **false negatives** from primer-site mutation/deletion (“diagnostic escape”); risk of **false positives** from contamination — necessitating careful sample processing and standardized pipelines; targets only **known, prespecified** sequences (unlike unbiased metagenomic sequencing).
- ▶ **Emerging deployability:** isothermal amplification, lyophilized reagents (no cold chain), and CRISPR-Cas12a/Cas13a readouts are extending NAATs to point-of-care and field settings.

High-yield exam pointers

- ▶ PCR = a NAAT: amplifies a specific DNA region using **specific oligonucleotide primers + DNA polymerase** (Harrison’s exact definition).
- ▶ **Three steps per cycle:** denaturation → annealing → extension; **25–40 cycles** → **exponential 2ⁿ amplification**.
- ▶ **Taq polymerase** (thermostable, from *Thermus aquaticus*) is the workhorse enzyme; **thermal cycler** drives the temperature changes.
- ▶ RT-PCR converts RNA→cDNA — used for **SARS-CoV-2, HIV, HCV**; **qPCR/real-time PCR** quantifies viral load.
- ▶ **Multiplex PCR = syndromic panels** (respiratory, GI, meningoencephalitis).
- ▶ Resistance genes to remember: **mecA** (MRSA), **vanA/vanB** (VRE), **rpoB** (rifampin/MDR-TB, ~95%), **inhA/katG** (isoniazid, up to 85%), carbapenemases **KPC/NDM/OXA-48/IMP/VIM**.
- ▶ **16S rRNA gene PCR** identifies culture-negative bacteria; **STR/microsatellite PCR** is used in genetic linkage studies.
- ▶ A **single base-pair primer mismatch near the 3’ end** can abolish detection — basis of “diagnostic escape.”
- ▶ PCR enables testing from a **single cell** (preimplantation diagnosis) and **direct sequencing of PCR products**.

SOURCE & COVERAGE

Harrison 22e — Ch 126 “Microbial Genomics and Infectious Disease” (PCR/NAAT definition, RT-PCR, multiplex syndromic panels, 16S rRNA, resistance-gene targets and numbers, primer-

mismatch specificity, isothermal/CRISPR methods); Ch 479 “Principles of Human Genetics” (PCR for mutational analysis from small DNA amounts, direct sequencing of PCR products, STR genotyping, single-cell preimplantation diagnosis). **Coverage note (spec gap = true):** Harrison covers PCR only thinly within these chapters — it gives the formal definition and applications but does **not** spell out the stepwise thermal-cycling temperatures, the *Taq/Thermus aquaticus* enzyme detail, the dNTP/Mg²⁺ reaction mix, the 2ⁿ kinetics, or Kary Mullis’s invention (1983; Nobel Prize 1993). These, together with **nested PCR** and **digital/droplet PCR**, are included here as universally-accepted standard molecular biology to satisfy the “technique” portion of the ask and are flagged as outside the verbatim Harrison text. All organism names, gene targets, percentage figures (95% rpoB, 85% inhA/katG), the 20-copies/mL HIV figure, and the primer 3'-mismatch point are taken directly from Harrison Ch 126.

Pregnancy-Induced Hypertension (Hypertensive Disorders of Pregnancy)

Asked in: Paper II Sep 2025 — RGUHS MD General Medicine

Definition / Introduction — Pregnancy-induced hypertension (PIH) is the development of a blood pressure (BP) ≥ 140 mmHg systolic and/or ≥ 90 mmHg diastolic, recorded on two occasions ≥ 4 h apart, *after 20 weeks’ gestation* in a previously normotensive woman. It is the clinical anchor of the broader **hypertensive disorders of pregnancy (HDP)** — a spectrum spanning **gestational hypertension, preeclampsia, eclampsia and the HELLP syndrome** — and is a leading cause of maternal and perinatal morbidity and mortality worldwide. The CDC estimated that 16% of US deliveries in 2019 were complicated by an HDP, and the prevalence is rising. The only definitive cure is **delivery of the fetus and placenta**.

Classification of hypertensive disorders of pregnancy

- ▶ **Gestational hypertension** — new-onset BP $\geq 140/90$ after 20 weeks, *without* proteinuria or other end-organ features; BP normalises postpartum. With severe features it is reclassified as preeclampsia.
- ▶ **Preeclampsia** — new-onset hypertension ($\geq 140/90$) *plus* proteinuria, or end-organ dysfunction, after 20 weeks (may occur up to 6 weeks postpartum).
- ▶ **Eclampsia** — new-onset generalised tonic-clonic seizures in a woman with preeclampsia.
- ▶ **Chronic hypertension** — hypertension predating pregnancy or evident before 20 weeks.
- ▶ **Chronic hypertension with superimposed preeclampsia** — new proteinuria/end-organ features arising on a background of chronic hypertension.

Disorder	Onset	Proteinuria / end-organ features
Chronic hypertension	Pre-pregnancy or <20 weeks	Variable
Gestational hypertension	>20 weeks	Absent
Preeclampsia	>20 weeks (up to 6 wks postpartum)	Present (proteinuria <i>or</i> end-organ damage)
Eclampsia	Preeclampsia + seizures	Present

Diagnostic criteria (preeclampsia)

- ▶ **Hypertension:** BP $\geq 140/90$ mmHg on two occasions ≥ 4 h apart after 20 weeks.
- ▶ **Proteinuria:** ≥ 300 mg/24 h, or urine protein/creatinine ratio ≥ 0.3 . *Edema is no longer a diagnostic criterion.*
- ▶ **Preeclampsia without proteinuria** may still be diagnosed when hypertension is accompanied by end-organ involvement (thrombocytopenia, renal/hepatic impairment, pulmonary edema, or cerebral/visual symptoms).
- ▶ **Severe features** (any one qualifies as “preeclampsia with severe features”):
 - Severe hypertension: BP $\geq 160/110$ mmHg.
 - CNS: new headache unresponsive to medication, visual disturbance (scotomas, blurring), clonus, hyperreflexia.
 - Unrelenting severe **epigastric / right-upper-quadrant pain** (hepatic capsule stretch).
 - **Pulmonary edema.**
 - **Thrombocytopenia** platelets $<100 \times 10^9/L$.
 - **Renal insufficiency** creatinine >1.1 mg/dL.
 - **Hepatic impairment** transaminases $\geq 2\times$ normal.
- ▶ **HELLP syndrome** — *Hemolysis, Elevated Liver enzymes, Low Platelets* — a severe subtype of preeclampsia and a major cause of maternal morbidity/mortality; additional complications include coagulopathy/DIC, cerebrovascular accident, hepatic capsular rupture and placental abruption.

Pathophysiology

- ▶ Precise cause unknown; central mechanism is **abnormal placentation** with failed remodelling of spiral arteries $\rightarrow$ **chronic uteroplacental ischaemia**.
- ▶ **Angiogenic imbalance:** excess of the anti-angiogenic factor **soluble fms-like tyrosine kinase-1 (sFlt-1)** and reduced **placental growth factor (PlGF)**. A circulating sFlt-1/PlGF ratio ≥ 40 predicts development of preeclampsia with severe features within the next 2 weeks.

- ▶ **Exaggerated maternal systemic inflammatory response** and generalised endothelial dysfunction → vasoconstriction, raised peripheral resistance, capillary leak and a procoagulant state.
- ▶ **Impaired cerebral autoregulation** explains neurological features and the risk of stroke / seizures even at modestly elevated BP; headache may reflect **posterior reversible encephalopathy syndrome (PRES)** within the reversible cerebral vasoconstriction syndrome spectrum.
- ▶ New-onset hypertension of pregnancy arises from reduced placental perfusion and elevated peripheral resistance, which typically resolves after delivery.

Risk factors

- ▶ Nulliparity (primigravida), previous preeclampsia, multifetal gestation.
- ▶ Chronic hypertension, chronic kidney disease, pregestational and gestational diabetes.
- ▶ SLE, antiphospholipid antibody syndrome, thrombophilia.
- ▶ Maternal age ≥ 35 years, pre-pregnancy BMI >30 (obesity), obstructive sleep apnoea.
- ▶ Assisted reproductive technology / in-vitro fertilisation; low socioeconomic status; family history.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Angiogenic-imbalance pathway of preeclampsia (flow diagram)**. Labels: *Abnormal placentation* → *failed spiral-artery remodelling* → *uteroplacental ischaemia* → $\uparrow$ sFlt-1 and $\downarrow$ PlGF (sFlt-1/PlGF ratio ≥ 40) → *maternal endothelial dysfunction* → *vasoconstriction + capillary leak + procoagulant state* → *Hypertension, Proteinuria, end-organ injury (CNS/PRES, Liver/HELLP, Kidney, Haematological)*.
- ▶ **Target-organ involvement of preeclampsia-eclampsia (labelled body map)**. Labels: *Brain (seizures/eclampsia, PRES, stroke)*, *Eye (retinal haemorrhage, scotomas)*, *Lungs (pulmonary edema)*, *Liver (epigastric pain, HELLP, capsular rupture)*, *Kidney (proteinuria, oliguria, $\uparrow$ creatinine)*, *Blood (thrombocytopenia, haemolysis, DIC)*, *Placenta (abruption, fetal growth restriction, oligohydramnios)*.

Clinical / Diagnostic significance

- ▶ **Investigations:** serial BP; urine dipstick + protein/creatinine ratio or 24-h urinary protein; CBC with platelets; peripheral smear/LDH/haptoglobin/bilirubin (haemolysis); AST/ALT; serum creatinine and uric acid; coagulation profile if HELLP/DIC suspected; fetal surveillance (ultrasound for growth restriction, oligohydramnios, umbilical Doppler, non-stress test). sFlt-1/PlGF ratio aids risk prediction where available.
- ▶ **Differential diagnosis:** chronic hypertension, CKD, primary seizure disorder, immune thrombocytopenia, TTP, haemolytic-uraemic syndrome, acute fatty liver of pregnancy, gallbladder/pancreatic disease.

- ▶ **Prevention: low-dose aspirin (81 mg/day orally)** for women at increased risk, started between **12–28 weeks (optimally before 16 weeks)** and continued until delivery (Harrison: initiated 12–14 weeks in high-risk women). Calcium, antioxidants (vitamins C/E), salt restriction and diuretics are *not* proven effective.

Management

- ▶ **Definitive treatment = delivery** of fetus and placenta; timing balances maternal risk against fetal prematurity.
 - Preeclampsia *without* severe features: expectant management with close maternal–fetal monitoring; **deliver at 37 weeks**.
 - Preeclampsia *with* severe features: **deliver**, unless <34 weeks and eligible for expectant management in a tertiary unit; deliver before 34 weeks for unremitting symptoms, worsening labs, refractory severe hypertension, or fetal compromise.
- ▶ **Acute severe hypertension (BP $\geq$ 160/110):** treat promptly (within 60 min) to reduce stroke risk; target BP **140–150/90–100 mmHg** (avoid over-correction → placental hypoperfusion). First-line IV agents:
 - **Labetalol** 10–20 mg IV every 20 min as needed.
 - **Hydralazine** 5–10 mg IV every 20 min.
 - **Immediate-release nifedipine** 10–20 mg orally, repeat at 20 min, then 10–20 mg every 4–6 h (max 180 mg/day) — useful when no IV access.
- ▶ **Seizure prophylaxis & treatment — magnesium sulfate (drug of choice):**
 - Loading **4–6 g IV** (over 15–20 min for prophylaxis; over ~4 min to abort an eclamptic seizure), then maintenance **2–3 g/hour**; continue **24 h postpartum**.
 - Therapeutic level **4–7 mEq/L**; reduce dose/withhold if serum creatinine >1.0 mg/dL or oliguria.
 - **Monitor for toxicity** — loss of deep tendon reflexes, respiratory depression, oliguria; **antidote = calcium gluconate 1 g IV over 2 min**. Phenytoin/benzodiazepines only if magnesium unavailable.
- ▶ **Fetal lung maturity:** if <34 weeks, give antenatal corticosteroids — **betamethasone 12 mg IM every 24 h $\times$ 2 doses**, or **dexamethasone 6 mg IM every 12 h $\times$ 4 doses** (do not delay delivery in unstable severe disease).
- ▶ **Eclampsia:** turn patient to the side (prevent aspiration), secure airway/oxygenation, control seizures with magnesium sulfate, control BP, stabilise the mother, then deliver (vaginal delivery preferred; caesarean for obstetric indications).
- ▶ **Chronic hypertension in pregnancy:** preferred agents **labetalol** and **extended-release nifedipine**; **methyldopa** has a good safety record. Target BP **<140/90 mmHg** (CHAP trial — treating mild chronic hypertension to <140/90 reduces preeclampsia and preterm birth). **ACE inhibitors**,

ARBs and mineralocorticoid-receptor antagonists are contraindicated (stillbirth, fetal renal/congenital anomalies).

- ▶ **Postpartum:** continue magnesium 24 h; remain vigilant for late-onset (postpartum) preeclampsia/eclampsia — treat as antepartum with hydralazine and magnesium.

Long-term significance

- ▶ Women with gestational hypertension or preeclampsia carry an increased lifelong risk of **chronic hypertension, cardiovascular disease, chronic kidney disease and diabetes mellitus**; preeclampsia is a recognised female-specific cardiovascular risk marker warranting risk-factor modification at postnatal visits.

High-yield exam pointers

- ▶ PIH/HDP = BP $\geq 140/90$ after **20 weeks**; classified into gestational HTN, preeclampsia, eclampsia, chronic HTN, and superimposed preeclampsia.
- ▶ **Preeclampsia = hypertension + proteinuria (or end-organ damage) after 20 weeks**; edema is no longer required.
- ▶ **Severe features:** BP $\geq 160/110$, platelets $<100 \times 10^9/L$, creatinine >1.1 mg/dL, transaminases $\geq 2\times$ normal, pulmonary edema, cerebral/visual symptoms, epigastric pain.
- ▶ **HELLP** = Hemolysis, Elevated Liver enzymes, Low Platelets — severe-subtype preeclampsia.
- ▶ Pathophysiology: $\uparrow$ sFlt-1, $\downarrow$ PlGF; **sFlt-1/PlGF ratio ≥ 40** predicts severe disease.
- ▶ **Magnesium sulfate** is the drug of choice for seizure prophylaxis/treatment; **calcium gluconate** is the antidote.
- ▶ Acute severe BP: **IV labetalol or hydralazine** (target 140–150/90–100); **ACEI/ARB contraindicated** throughout pregnancy.
- ▶ **Low-dose aspirin 81 mg** from 12–16 weeks for prevention in high-risk women.
- ▶ **Delivery is the only cure** — at 37 weeks (no severe features) or earlier for severe disease; corticosteroids if <34 weeks.

SOURCE & COVERAGE

- ▶ Harrison's *Principles of Internal Medicine*, 22e — “Medical Disorders During Pregnancy” (preeclampsia, gestational hypertension, eclampsia/HELLP, pathophysiology, treatment) and “Hypertension” (hypertensive disorders of pregnancy, antihypertensive choice).
- ▶ CMDT 2026 — “Obstetrics & Obstetric Disorders” (diagnostic criteria, severity table, magnesium sulfate protocol, antihypertensive doses, corticosteroids, aspirin prophylaxis, eclampsia management) and “Systemic Hypertension” (chronic hypertension agents, methyldopa safety; CHAP trial).

Coverage note: No dedicated subspecialty obstetrics text was provided in the spec (specialty_books empty); grounding therefore rests on Harrison 22e plus CMDT 2026, which together cover the topic at exam depth.

Pyrogenic cytokines and their role in pathogenesis of fever

Asked in: Paper I Nov 2022 — RGUHS MD General Medicine

Definition / Introduction — A **pyrogen** (Greek *pyro*, “fire”) is any substance that causes fever. **Fever** is an elevation of body temperature that exceeds the normal daily variation and occurs *in conjunction with a raised hypothalamic set point* (e.g., from 37°C to 39°C) — fundamentally distinct from hyperthermia, in which the set point is unchanged and no pyrogenic molecules are involved. **Pyrogenic cytokines** are small host-derived proteins (formerly called *endogenous pyrogens*) — chiefly **IL-1, IL-6 and TNF** — that act as the central molecular link translating an infectious or inflammatory stimulus into a rise in the hypothalamic thermostat. They are the obligatory intermediaries between exogenous pyrogens and the prostaglandin E2 (PGE2)-driven elevation of the set point that produces fever.

Classification of pyrogens

- ▶ **Exogenous pyrogens** — derived from *outside* the host; mostly microbial products, microbial toxins, or whole microorganisms (including viruses).
 - Classic example: **lipopolysaccharide (endotoxin)** of all gram-negative bacteria — a highly pyrogenic molecule. An IV dose of just **2–3 ng/kg** in human volunteers produces fever, leukocytosis, acute-phase proteins, and malaise.
 - Cell-wall components of **gram-positive** organisms are less pyrogenic, but these organisms elaborate **superantigen toxins** that induce fever — *Staphylococcus aureus* toxic shock syndrome toxin-1 (TSST-1), staphylococcal enterotoxins, and streptococcal pyrogenic exotoxins — pyrogenic in animals at **1–10 µg/kg**.
- ▶ **Endogenous pyrogens = pyrogenic cytokines** — host proteins produced in response to exogenous pyrogens *or* to sterile inflammation. Fever can therefore arise **without microbial infection** (e.g., pericarditis, trauma, stroke, routine immunizations all induce IL-1, TNF and/or IL-6).

Feature	Exogenous pyrogens	Pyrogenic (endogenous) cytokines
Origin	Outside host (microbes/toxins)	Host myeloid & endothelial cells
Prototype	Endotoxin (LPS)	IL-1, IL-6, TNF

Feature	Exogenous pyrogens	Pyrogenic (endogenous) cytokines
Pyrogenic IV dose	LPS 2–3 ng/kg; superantigens 1–10 µg/kg	IL-1, TNF 10–100 ng/kg; IL-6 1–10 µg/kg
Acts via	Inducing cytokine synthesis (and TLRs)	Inducing PGE ₂ → raises set point
Needs microbe?	Yes	No (also sterile inflammation)

The pyrogenic cytokines

- ▶ Cytokines are small proteins (**molecular mass 10,000–20,000 Da**) that regulate immune, inflammatory and hematopoietic processes; IL-1 and IL-6 also drive the **neutrophilic leukocytosis** of infection.
- ▶ Each pyrogenic cytokine is encoded by a separate gene, and each independently causes fever in laboratory animals and in humans.
- ▶ A wide spectrum of bacterial and fungal products induces their synthesis and release.

Cytokine	Key features in fever
IL-1	Prototype pyrogen; fever at low IV dose 10–100 ng/kg ; shares signalling pathway with Toll-like receptors
TNF	Pyrogenic at 10–100 ng/kg ; central to sterile and septic fever
IL-6	Induced by IL-1/TNF; less potent — fever needs 1–10 µg/kg ; induces hepatic C-reactive protein (CRP)
IFN (esp. interferon-α)	Fever is a <i>prominent side effect of interferon-α therapy</i>
Ciliary neurotrophic factor (CNTF)	A member of the IL-6 family; also pyrogenic

Pathogenesis: how pyrogenic cytokines raise the hypothalamic set point

- ▶ **Source cells:** *Myeloid cells (monocytes/macrophages) and endothelial cells* are the primary producers. On encountering an exogenous pyrogen they release **IL-1, IL-6 and TNF** into the systemic circulation.
- ▶ **Site of action — the circumventricular organs:** During fever, PGE₂ is elevated in hypothalamic tissue and the third cerebral ventricle, with the highest concentrations near the **organum vasculosum of the lamina terminalis (OVLT)** — networks of enlarged (“leaky”) capillaries surrounding the hypothalamic regulatory centres. Destruction of these organs abolishes the febrile response to pyrogens.

- ▶ **Cytokines do NOT enter the brain parenchyma:** Most animal studies show pyrogenic cytokines do *not* cross from the circulation into the brain itself. Instead, circulating exogenous pyrogens and pyrogenic cytokines **interact with the endothelium of these capillaries** — this interaction is the *first step* in raising the set point.
- ▶ **PGE2 is the final common mediator:** Cytokine–endothelium interaction induces PGE2 synthesis. The enzyme **cyclooxygenase** acts on **arachidonic acid** (released from membrane phospholipid — the *rate-limiting step*) to form PGE2. Of the **four PGE2 receptors**, the **EP-3 receptor is essential for fever**: deleting the EP-3 gene in mice abolishes fever after IL-1 or endotoxin, whereas deleting the other receptor genes leaves fever intact.
- ▶ **PGE2 → cAMP → set point:** PGE2 is *not itself a neurotransmitter*. PGE2 released from the brain side of the hypothalamic endothelium triggers **PGE2 receptors on glial cells**, causing rapid release of **cyclic AMP (cAMP)** — the actual neurotransmitter. cAMP activates neuronal endings of the thermoregulatory centre, and this elevation of cAMP **raises the hypothalamic set point** (directly or by inducing other neurotransmitters).
- ▶ **Toll-like receptors (TLRs):** Distinct receptors for microbial products on the hypothalamic endothelium — **Toll-like receptors** — closely resemble **IL-1 receptors** and *share the same signal-transducing mechanism*; direct activation of either TLRs or IL-1 receptors yields **PGE2 production and fever**.
- ▶ **Peripheral PGE2 and constitutional symptoms:** Circulating cytokines also induce PGE2 in peripheral tissues, accounting for the **myalgias and arthralgias** of fever. Some systemic PGE2 escapes pulmonary destruction and reaches the hypothalamus via the **internal carotid**, but it is the rise in *brain* PGE2 that initiates the set-point change.
- ▶ **Effector limb:** Once the set point is raised, the vasomotor centre triggers **vasoconstriction** (heat conservation — cold hands/feet, the patient “feels cold”), **shivering** and **non-shivering thermogenesis** (heat production), plus behavioural adjustments, until blood temperature matches the new febrile setting.

Production of cytokines within the CNS

- ▶ Cytokines made *inside the brain* account for the **hyperpyrexia of CNS haemorrhage, trauma or infection**.
- ▶ Viral CNS infections induce **microglial (and possibly neuronal) production of IL-1, TNF and IL-6**.
- ▶ The cytokine concentration needed to cause fever is **several orders of magnitude lower** with direct intracerebral/intraventricular injection than with systemic injection; thus CNS-generated cytokines raise the set point while **bypassing the circumventricular organs**.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- **Fig. 20-1 — “Chronology of events required for the induction of fever”** (vertical flow chart). Labels, top to bottom:
- Infection, microbial toxins, mediators of inflammation, immune reactions
 - → Monocytes/macrophages, endothelial cells, others
 - → Pyrogenic cytokines: IL-1, IL-6, TNF, IFN (entering Circulation)
 - → Hypothalamic endothelium
 - → PGE2 → Cyclic AMP (cAMP)
 - → Elevated thermoregulatory set point → Heat conservation, heat production → FEVER
 - Include a side arrow labelled “Microbial toxins” acting directly on the hypothalamic endothelium (via Toll-like receptors).
- **Optional inset — hypothalamic set-point thermostat:** label OVLT (*organum vasculosum lamina terminalis*), EP-3 receptor on glial cell, thermoregulatory neuron, normothermic set point 37°C → febrile set point 39°C.

Clinical / Diagnostic significance

- **Measuring circulating cytokines is NOT useful** — IL-1 and TNF are often below assay detection limits or do not coincide with fever. For occult/low-grade fever the most valuable markers are CRP and ESR; IL-6 (which induces CRP) can be informative, but IL-6 levels fluctuate during a febrile illness whereas CRP stays elevated.
- **Anticytokine therapy blunts fever and raises infection risk:** Agents blocking IL-1, IL-6, IL-12/23, IL-17 or TNF (used in Crohn disease, rheumatoid arthritis, psoriasis) lower host defences — e.g., **latent M. tuberculosis can disseminate on anti-TNF therapy**, and anti-IL-17 raises systemic candidiasis risk. Low-grade fever in such patients warrants early, rigorous evaluation.
- **Therapeutic blockade reduces fever in autoinflammatory disease:** Fevers of familial Mediterranean fever, hyper-IgD syndrome, adult/juvenile Still disease (IL-1 β -mediated, often via NLRP3/pyrin inflammasomes) are dramatically reduced by **anakinra** or **canakinumab**.
- **Antipyretics target the PGE2 limb:** Cyclooxygenase inhibitors are potent antipyretics; antipyretic potency correlates with **inhibition of brain cyclooxygenase**. **Aspirin and acetaminophen are equally effective**; acetaminophen is a poor peripheral COX inhibitor but is oxidised by brain P450 (and inhibits COX-3, found only in the CNS). **Glucocorticoids act at two levels** — inhibiting phospholipase A2 ($\downarrow$ arachidonic acid $\rightarrow$ $\downarrow$ PGE2) and blocking transcription of pyrogenic-cytokine mRNA.
- **Blunted febrile response** is expected in newborns, the elderly, chronic hepatic/renal failure, and patients on glucocorticoids/NSAIDs/anticytokines — active disease may exist without fever; septic shock may even cause hypothermia.

High-yield exam pointers

- ▶ Pyrogenic cytokines = the *renamed* endogenous pyrogens: IL-1, IL-6, TNF, IFN, and CNTF (IL-6 family).
- ▶ PGE2 is the final mediator; EP-3 receptor is *essential* for fever (knockout abolishes it).
- ▶ cAMP — not PGE2 — is the neurotransmitter that resets the hypothalamic thermostat.
- ▶ Pyrogenic doses: LPS 2–3 ng/kg; IL-1/TNF 10–100 ng/kg; IL-6 1–10 µg/kg; superantigens 1–10 µg/kg.
- ▶ Cytokines act at the OVLT/circumventricular organs and do *not* cross into brain parenchyma.
- ▶ TLRs and IL-1 receptors share the same signalling pathway → PGE2 → fever.
- ▶ Fever (raised set point, cytokine/PGE2-mediated, *responds* to antipyretics) vs **hyperthermia** (set point unchanged, no pyrogens, *does not* respond to antipyretics).
- ▶ IL-6 induces CRP; CRP is a more stable marker than IL-6 for monitoring occult fever.
- ▶ CNS-generated IL-1/TNF/IL-6 explain **hyperpyrexia of CNS haemorrhage, trauma, infection**.

SOURCE & COVERAGE

Harrison 22e — Ch 20 “Fever” (Dinarello & Surana). Full coverage of pyrogens, pyrogenic cytokines and the PGE2/EP-3/cAMP pathogenesis of fever; spec.gap = false and no fabrication required. All doses, the four-receptor/EP-3 point, OVLT, TLR–IL-1R sharing, and CNS cytokine production are taken verbatim from this chapter. (Inflammasome detail, e.g., NLRP3/pyrin, is referenced by Ch 20 but elaborated in Chaps 360/381, cited only in passing here.)

Recombinant DNA Technology: Principles and Applications

Asked in: Paper I Nov 2021 — RGUHS MD General Medicine

Definition / Introduction — *Recombinant DNA (rDNA) technology* is the set of laboratory techniques by which DNA segments from two or more different sources are joined *in vitro* to create a novel **recombinant (chimeric) DNA molecule**, which is then introduced into a living host cell where it can be propagated (cloned) and/or expressed. It is the foundational enabling technology of modern molecular medicine: as Harrison emphasises, peptide hormones, growth factors, cytokines and vaccines can now be manufactured in large quantities using recombinant DNA and RNA technology, and the same toolkit underpins molecular diagnostics, gene therapy and gene editing. The three essential operations are: **cut** (a specific gene), **paste** (into a vector), and **clone/express** (in a host cell).

Molecular toolkit (key enzymes and reagents)

Tool	Function	Note
Restriction endonucleases	Cleave double-stranded DNA at specific palindromic recognition sequences; the “ <i>molecular scissors</i> ”	Generate cohesive (<i>sticky</i>) or blunt ends; <i>e.g.</i> EcoRI, BamHI, HindIII
DNA ligase	Forms phosphodiester bonds joining vector and insert; the “ <i>molecular glue</i> ”	Seals the recombinant molecule
Reverse transcriptase	Synthesises complementary DNA (cDNA) from an mRNA template	Source of intron-free coding sequence for expression
DNA polymerase (<i>thermostable</i> , Taq)	Template-directed synthesis of new DNA strands	Engine of PCR
Modifying enzymes	Alkaline phosphatase, polynucleotide kinase, terminal transferase	Prevent self-ligation, add/label ends
Vector	Self-replicating DNA vehicle that carries the foreign gene into the host	Plasmid, phage, viral, artificial chromosome
Host cell	Site of replication/expression	<i>E. coli</i> , yeast, mammalian or insect cells

Principle — steps of gene cloning

- ▶ **1. Isolation of the gene/DNA of interest.** The target sequence is obtained by (a) restriction digestion of genomic DNA, (b) reverse transcription of mRNA into **cDNA** (yields the coding sequence without introns — preferred for protein expression in bacteria), or (c) direct amplification by **PCR**.
- ▶ **2. Insertion into a vector (“recombination”).** Vector and insert are cut with the *same* restriction enzyme so that complementary sticky ends anneal; **DNA ligase** then covalently joins them to form the **recombinant (chimeric) DNA molecule**.
- ▶ **3. Introduction into a host cell.** The recombinant vector is taken up by competent bacteria (**transformation**), or by mammalian cells (**transfection**), or delivered by a **viral vector** (**transduction**).
- ▶ **4. Selection and screening of recombinant clones.** Host cells carrying the construct are identified using **selectable markers** (e.g., antibiotic-resistance genes), **blue–white (lacZ / β -galactosidase)** screening with X-gal, and **colony/nucleic-acid hybridisation** with labelled probes.
- ▶ **5. Amplification and expression.** The positive clone is propagated to generate millions of identical copies (a *clone/gene library*); an **expression vector** with a suitable promoter drives synthesis of the encoded protein, which is then harvested and purified.

Vectors — cloning vehicles

Vector	Approx. insert capacity	Host / use
Plasmid	up to ~10 kb	<i>E. coli</i> ; routine cloning, expression
Bacteriophage λ	~15–20 kb	Genomic libraries
Cosmid	~35–45 kb	Larger inserts
BAC (bacterial artificial chromosome)	up to ~300 kb	Large fragments, genome projects
YAC (yeast artificial chromosome)	up to ~1–2 Mb	Very large fragments
Viral vectors — retro-/lentiviral, adenoviral, adeno-associated virus (AAV)	retro/lenti ~8 kb; adeno 8–30 kb; AAV ~5 kb	<i>In vivo/ex vivo</i> gene therapy (see below)

Core analytical & amplification techniques

- ▶ **Polymerase Chain Reaction (PCR):** cyclical *in vitro* amplification — **denaturation** (~94–95 °C) → **primer annealing** (~50–65 °C) → **extension** (~72 °C, *Taq* polymerase); each cycle doubles the target, giving exponential (2^n) amplification. Enables testing from minute amounts of DNA (leukocytes, single cells, buccal cells, hair roots). **RT-PCR** converts RNA → cDNA before amplification (e.g., SARS-CoV-2, HIV viral-load); **quantitative/real-time PCR** measures copy number.
- ▶ **Hybridisation/blotting:** **Southern blot** (DNA), **Northern blot** (RNA), **Western blot** (protein); **FISH** (fluorescence *in situ* hybridisation) and array/bead-based methods detect deletions/duplications and chromosomal rearrangements.
- ▶ **DNA sequencing:** Sanger (dideoxy) sequencing of PCR products, now largely superseded by **next-generation sequencing (NGS)** — whole-exome (WES), whole-genome (WGS) and targeted gene panels — allowing unbiased, cost-effective mutational analysis.
- ▶ **Genome editing:** **CRISPR/Cas9** uses a bacterial Cas9 nuclease complexed with a **guide RNA** (ribonucleoprotein) to introduce a site-specific double-strand break; repair by non-homologous end-joining disrupts a gene, or homology-directed repair with a donor template corrects it.

Applications in clinical medicine

- ▶ **1. Recombinant therapeutic proteins** — produced in microbial/mammalian cells: **human insulin** (the first licensed recombinant drug, 1982) and modified **insulin analogues** with favourable kinetics; **GLP-1 receptor agonists**; growth hormone, erythropoietin, granulocyte colony-stimulating factor, interferons, clotting **factor VIII/IX**, and tissue plasminogen activator. Targeted modification of the recombinant peptide yields improved therapeutics (Harrison's

explicit examples: insulin analogues, GLP-1 agonists for type 2 diabetes and weight management).

- ▶ **2. Vaccines** — recombinant subunit vaccines (e.g., hepatitis B surface antigen, HPV) and, most recently, **mRNA vaccines against SARS-CoV-2**.
- ▶ **3. RNA-based therapeutics** — **small interfering RNA (siRNA)** to treat hypercholesterolaemia; antisense oligonucleotides; guide RNAs/mRNAs delivered by **lipid nanoparticles**.
- ▶ **4. Gene transfer & gene editing therapy** — a nucleic acid is the active agent, delivered by an engineered **vector**; strategies are *gene addition* (supply a missing gene) or *gene editing* (correct the endogenous locus). Approved products include:

Product	Indication	Vector / approach
Strimvelis	ADA-SCID	Retroviral, autologous HSCs (<i>ex vivo</i>)
Luxturna (voretigene neparvovec)	Biallelic <i>RPE65</i> retinal dystrophy (Leber congenital amaurosis)	AAV2, subretinal injection
Zolgensma (onasemnogene abeparvovec)	Spinal muscular atrophy type 1 (<i>SMN1</i>)	AAV9, single IV infusion
Zynteglo (betibeglogene autotemcel)	Transfusion-dependent β -thalassaemia	Lentiviral β^A -T87Q globin gene, autologous HSCs
Kymriah / Yescarta (CAR-T)	R/R B-cell leukaemia/lymphoma	Lenti-/retroviral anti-CD19 CAR, autologous T cells
CRISPR gene-editing therapy	Sickle cell disease, β -thalassaemia	CRISPR/Cas9 (FDA-approved 2023)

- ▶ **5. Molecular diagnosis** — PCR-based detection and identification of pathogens difficult to culture (mycobacteria, viruses, parasites) and tracking of outbreaks; carrier detection and mutational analysis of monogenic disease (e.g., CFTR $\Delta F508$ in cystic fibrosis); **prenatal diagnosis** (amniocentesis, chorionic villus sampling) and **non-invasive prenatal testing/liquid biopsy** using cell-free DNA (cfDNA); tumour genotyping to select **actionable, targeted therapies**.
- ▶ **6. Pharmacogenomics** — genotype-guided drug selection and dosing to optimise efficacy and minimise adverse effects.
- ▶ **7. Research tools** — gene mapping/linkage studies, transgenic and knockout animal models, and functional genomics.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Gene-cloning flowchart (label clearly):** *Gene of interest* (source DNA) and *Plasmid vector* (showing origin of replication, selectable marker / ampR, lacZ) → both cut by the Restriction endonuclease (EcoRI) producing **sticky ends** → joined by DNA ligase →

Recombinant (chimeric) plasmid → **Transformation into E. coli host* → *Selection (antibiotic resistance + blue-white screening)* → *Recombinant colony* → *Cloning / Protein expression**.

- ▶ **PCR cycle:** three boxes — **Denaturation (94–95 °C)** → **Annealing of forward & reverse primers (50–65 °C)** → **Extension (72 °C, Taq polymerase, dNTPs), with an arrow showing exponential amplification (2^n); label template DNA, primers, dNTPs, thermal cycler**.

Clinical / Diagnostic significance

- ▶ Enables manufacture of pure, abundant, non-immunogenic human proteins (insulin, clotting factors), eliminating the infection risk and supply limits of animal/cadaveric/pooled-plasma sources.
- ▶ Permits diagnosis from minute samples and at the molecular level — carrier testing, prenatal/preimplantation diagnosis, infectious-disease detection and viral-load monitoring.
- ▶ Drives **precision/personalized medicine**: tumour mutational profiling guides targeted therapy; pharmacogenomic genotyping individualises prescribing.
- ▶ Provides definitive (potentially curative) therapy for previously untreatable genetic diseases via gene transfer and CRISPR gene editing.

High-yield exam pointers

- ▶ rDNA = joining DNA from two sources *in vitro*; three steps — **cut (restriction enzyme)** → **paste (ligase)** → **clone/express (vector + host)**.
- ▶ **Restriction endonucleases = molecular scissors; DNA ligase = molecular glue.**
- ▶ **Sticky (cohesive) ends** allow vector–insert annealing; same enzyme must cut both.
- ▶ Recombinant selection: **antibiotic-resistance markers + blue-white (lacZ) screening + colony hybridisation.**
- ▶ **PCR:** denature 94–95 °C → anneal 50–65 °C → extend 72 °C (*Taq*); RT-PCR for RNA targets.
- ▶ Blotting mnemonic: Southern–DNA, Northern–RNA, Western–protein.
- ▶ **Human insulin (1982)** = first licensed recombinant therapeutic protein; mRNA SARS-CoV-2 vaccines and siRNA for hypercholesterolaemia are modern rDNA/RNA products.
- ▶ Gene-therapy vectors: **retro/lentiviral (integrating, ex vivo), adenoviral, AAV (non-integrating), lipid nanoparticles**; FDA approved the first CRISPR therapy (sickle cell disease/ β -thalassaemia) in 2023.

SOURCE & COVERAGE

- ▶ **Harrison's Principles of Internal Medicine, 22e** — “Principles of Human Genetics” (recombinant DNA/RNA technology for therapeutic proteins, vaccines, siRNA; PCR,

FISH, NGS, mutational and prenatal analysis; CFTR/ Δ F508) and “Gene and Cell-Based Therapy in Clinical Medicine” (gene delivery vehicles/vectors, transduction, CRISPR/Cas9, approved gene/cell-therapy products including Strimvelis, Luxturna, Zolgensma, Zynteglo, Kymriah/Yescarta).

- **Coverage note:** Harrison 22e covers the *applications* of rDNA technology in depth but treats the **wet-lab cloning methodology only thinly** — the chapter explicitly states the detailed mutation-detection/molecular techniques were “discussed in previous versions of this chapter.” Accordingly, the enzyme toolkit, the step-wise cloning protocol, the cloning-vector capacity figures (plasmid/phage/cosmid/BAC/YAC), blue–white screening and the blotting/Sanger details are presented as **standard, universally accepted molecular biology** rather than verbatim Harrison content; the spec flags this topic as a known thin-coverage (gap) area. The viral-vector packaging limits and all gene-therapy product details are taken directly from Harrison 22e.

Stem Cell Therapy in Clinical Medicine

Asked in: Paper I Jul 2020 — RGUHS MD General Medicine

Definition / Introduction — A **stem cell** is an undifferentiated cell defined by two cardinal properties: *self-renewal* (the ability to divide while preserving an undifferentiated state) and *differentiation* (the capacity to generate the mature effector cells of a tissue). **Stem cell therapy** is the therapeutic exploitation of these properties to regenerate, replace, or genetically correct a diseased lymphohematopoietic or other tissue. In clinical practice today it spans three overlapping domains: (1) **hematopoietic cell transplantation (HCT)** — the dominant, well-established modality; (2) **gene-modified autologous stem-cell products** (ex vivo gene addition or gene editing); and (3) engineered immune effector cells (**CAR-T therapy**). Tens of thousands of lives are saved annually by stem-cell-based therapies.

Stem cell — properties and classification

- **Two cardinal functions** (Harrison, *Hematopoietic Stem Cells*): self-renewal sustains the stem-cell pool; differentiation produces mature cells. A dividing stem cell yields one of three outcomes — two stem cells, two differentiating cells (both *symmetric*), or one of each (*asymmetric division*).
- Self-renewal is regulated by **intrinsic factors** (Bmi-1, Gfi-1, PTEN, STAT5, p21, p18, HoxB4) and **extrinsic niche signals** (Notch, Wnt, Sonic hedgehog, angiogenin, Tie2/Ang-1).
- **Classification by potency**: *totipotent* (zygote → whole organism + placenta); *pluripotent* (embryonic stem cells, induced pluripotent stem cells [iPSC] → all three germ layers);

multipotent/adult (somatic) stem cells — e.g., hematopoietic stem cells (HSC), mesenchymal stem cells (MSC).

Stem-cell type	Source	Potency	Principal clinical role
Hematopoietic (HSC)	Marrow, mobilised blood, cord blood	Multipotent	Established — HCT, gene therapy vehicle
Embryonic (ESC)	Inner cell mass	Pluripotent	Investigational
Induced pluripotent (iPSC)	Reprogrammed somatic cells	Pluripotent	Investigational/disease modelling
Mesenchymal (MSC)	Marrow stroma, fat, cord	Multipotent	Investigational (immunomodulation)
Cancer stem-like cells	Tumours	—	Relapse source; therapeutic target

The hematopoietic stem cell — markers, niche and mobilisation

- ▶ The HSC sustains all blood and immune lineages plus tissue-fixed macrophages (Kupffer cells, alveolar macrophages, osteoclasts, microglia, Langerhans cells). The estimated stem-cell pool of **20,000–200,000 cells** produces hundreds of billions of blood cells daily.
- ▶ **Surface phenotype (mainly murine-derived):** CD34, Thy-1 (CD90), c-Kit (CD117), CD133, CD164, and c-Mpl (CD110, the thrombopoietin receptor).
- ▶ **Niche:** for most of life the HSC resides in the **bone-marrow perivascular/endosteal niche**, regulated by mesenchymal and endothelial cells producing **kit ligand** and **CXCL12 (SDF-1)**, plus sympathetic neurons, Schwann cells, osteoblasts and osteoclasts. The niche both nurtures and constrains stem-cell number.
- ▶ **Homing & mobilisation:** circulating HSCs roll on endothelial **P-/E-selectins** (via CD162/CD44), firmly adhere through **VLA-4/VCAM-1** integrins, and home via **CXCL12–CXCR4** signalling. Clinically, **G-CSF** and **plerixafor** (a CXCR4 antagonist) disrupt this retention to release stem cells into blood, enabling harvest by **leukapheresis** rather than marrow puncture.
- ▶ **Clonal dynamics:** HSCs acquire ~17 somatic mutations per year; expansion of clones bearing **DNMT3A**, **TET2**, or **ASXL1** mutations underlies **clonal hematopoiesis of indeterminate potential (CHIP)**, predisposing to myeloid malignancy and adverse inflammatory outcomes.

SOURCE & COVERAGE

- ▶ Sources of stem cells (Harrison, *Hematopoietic Cell Transplantation*):

Source	Collection	Engraftment	GVHD	Notes
Bone marrow	Iliac-crest aspiration (10–15)	Reference	Lowest with unrelated donors	Original source

	mL/kg); $1.5-5 \times 10^8$ nucleated cells/kg			
Peripheral blood (PBSC)	Leukapheresis after G-CSF $\pm$ plerixafor; aim $>2.5 \times 10^6$ CD34 ⁺ /kg	Fastest (~ 1 wk earlier)	More chronic GVHD (T-cell content)	Most commonly used
Umbilical cord blood	Cryopreserved units	~ 1 wk slower	Lowest (few T cells)	Tolerates HLA mismatch; double-cord units for adults

► **Categories by donor relationship:**

- **Autologous** — patient's own stored stem cells re-infused after high-dose therapy; **no** GVHD/rejection but **no graft-versus-tumour (GVT) effect** and risk of tumour-cell contamination.
- **Syngeneic** — identical twin ($\sim 1\%$ of cases); no GVHD, no tumour contamination.
- **Allogeneic** — genetically non-identical donor; provides a **GVT effect** but risks GVHD and graft rejection.

- **HLA matching** (genes HLA-A, -B, -C, -D): odds that a full sibling matches = $\frac{1}{4}$; probability of an HLA-identical sibling = $1 - (0.75)^n$ (n = number of siblings). Matched unrelated donors are found for $\sim 60\%$ of patients via registries (>40 million donors). With HLA-identical siblings, graft rejection is $1-3\%$ and severe acute GVHD $\sim 15\%$. **Post-transplant high-dose cyclophosphamide** now permits **haploidentical** (single-haplotype-shared) transplantation.

Conditioning regimens and the transplant procedure

- The **preparative (conditioning) regimen** eradicates underlying disease and immunosuppresses the host to prevent graft rejection.
- **Myeloablative:** combinations of busulfan, cyclophosphamide, melphalan, thiotepa, carmustine, etoposide, total-body irradiation (TBI).
 - **Reduced-intensity:** e.g., fludarabine + melphalan — significant but non-lethal myelosuppression; favoured in older/comorbid patients.
 - **Nonmyeloablative:** e.g., fludarabine + 200 cGy TBI — relies on the GVT effect.
- Disease-specific examples: SCID with a matched sibling needs **no conditioning**; aplastic anaemia — cyclophosphamide + antithymocyte globulin (ATG); thalassaemia/sickle cell — busulfan + cyclophosphamide.

- **Engraftment:** marrow grafts reach 500 granulocytes/ μL by **~day 22** (PBSC ~1 week faster, cord blood ~1 week slower). Innate immunity recovers in weeks; **adaptive (T- and B-cell) immunity takes 1–2 years**. Donor chimerism is documented by sex-chromosome FISH or short-tandem-repeat analysis.

Clinical indications for stem cell transplantation

- **Non-malignant:** severe combined immunodeficiency (cure >90%), aplastic anaemia, β -thalassaemia major and sickle cell anaemia (HLA-identical sibling cure 80–90%), congenital marrow-failure and phagocyte disorders (Kostmann, chronic granulomatous disease, Wiskott-Aldrich, Chédiak-Higashi), osteopetrosis, selected storage diseases (Hurler, Gaucher), and increasingly **severe autoimmune disease** (a randomised trial showed survival benefit of HCT in severe scleroderma; trials ongoing in multiple sclerosis).
- **Malignant:** acute leukaemias (AML/ALL — allogeneic, guided by remission status and measurable residual disease), CML failing ≥ 2 tyrosine-kinase inhibitors, myelodysplasia (IPSS Int-2/high), myelofibrosis, lymphomas and Hodgkin disease (usually **autologous**), **multiple myeloma** (autologous as part of initial therapy), and **relapsed testicular germ-cell tumour** (autologous high-dose chemotherapy).

Disease	Allogeneic 3-yr survival	Autologous
Severe combined immunodeficiency	95%	—
Aplastic anaemia	98%	—
Thalassaemia	95%	—
AML (first remission)	57%	—
Multiple myeloma (initial)	—	80%
Hodgkin disease (2nd remission)	68%	89%

Complications of transplantation

- **Acute GVHD** (first ~3 months; peak ~4 weeks): triad of **maculopapular skin rash**, **cholestatic liver injury** (rising bilirubin), and **secretory diarrhoea**, graded I–IV. Prophylaxis = **calcineurin inhibitor** (cyclosporine/tacrolimus) + **methotrexate**, often with a third agent (mycophenolate, abatacept, or post-transplant cyclophosphamide). Treatment = **prednisone 1–2 mg/kg**; steroid-refractory disease responds to the JAK inhibitor **ruxolitinib**.
- **Chronic GVHD** (3 months–2 years; 20–50%): autoimmune-like — malar rash, sicca, arthritis, obliterative bronchiolitis, cholestasis. Steroid-resistant disease: **ibrutinib**, **ruxolitinib**, **belumosudil** (kinase inhibitors).
- **Regimen-related toxicity:** mucositis, **sinusoidal obstruction syndrome (SOS / veno-occlusive disease)** — tender hepatomegaly, ascites, jaundice; treated with **defibrotide**; haemorrhagic

cystitis (prevent with MESNA); transplant-associated thrombotic microangiopathy (responds to **eculizumab**); late bronchiolitis obliterans, cataracts, infertility, hypothyroidism.

- ▶ **Infection** by phase: early neutropenic bacterial/Candida; intermediate **CMV**, **Aspergillus** (CMV prophylaxis with **letermovir** or pre-emptive ganciclovir); late encapsulated bacteria/VZV. Standard prophylaxis: levofloxacin, fluconazole/mould-active azole, **co-trimoxazole** for **Pneumocystis**, acyclovir.
- ▶ **Graft failure** and disease relapse — relapse after allograft may respond to **donor lymphocyte infusions** (CML response up to 75%).

Gene- and cell-based stem cell therapies (the modern frontier)

- ▶ **Why HSCs are the ideal gene-therapy target** (Harrison, *Gene and Cell-Based Therapy*): they persist for life, so genetic modification of autologous HSCs gives a durable, **HLA-matching-free**, **GVHD-free** cure. Transgene must integrate (lentiviral) or the target locus be edited; myeloablative conditioning is still needed.
- ▶ **Ex vivo gene-addition products (autologous HSCs)**: *Strimvelis* (retroviral, ADA-SCID), *Zynteglo* (lentiviral β^A -T87Q globin, transfusion-dependent β -thalassaemia/sickle cell disease), *Skysona* (cerebral adrenoleukodystrophy, ABCD1), *Libmeldy* (metachromatic leukodystrophy, ARSA). The **X-linked SCID** trials proved gene therapy could cure but revealed **insertional mutagenesis** (LMO-2 activation $\rightarrow$ T-ALL in 5/20 children), prompting the shift to safer **lentiviral vectors**.
- ▶ **Ex vivo gene editing**: *Casgevy* (exagamglogene autotemcel) — CRISPR/Cas9 inactivation of the **BCL11A** erythroid enhancer in autologous CD34⁺ cells, de-repressing **γ -globin/HbF** to treat sickle cell disease and β -thalassaemia ($\approx$ 29/31 patients free of vaso-occlusive crises).
- ▶ **CAR-T cell therapy**: autologous T cells engineered with a **chimeric antigen receptor** (antibody scFv + transmembrane + costimulatory **CD28 or 4-1BB** + CD3 ζ). Approved anti-**CD19** products (Kymriah, Yescarta, Tecartus, Breyanzi) for B-ALL and large-cell/mantle-cell lymphoma, and anti-**BCMA** products (Abecma, Carvykti) for myeloma — >80% complete-response rates in refractory B-ALL. Key toxicities: **cytokine release syndrome** (treat with **tocilizumab** $\pm$ steroids), **ICANS/neurotoxicity** (dexamethasone), B-cell aplasia/hypogammaglobulinaemia, and a boxed-warning risk of secondary T-cell malignancy.
- ▶ **Other cell therapies**: oncolytic virus *talimogene laherparepvec* (melanoma) and dendritic-cell vaccine (sipuleucel-T) for prostate cancer.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Hematopoietic hierarchy**: central Hematopoietic stem cell with a curved *self-renewal* arrow $\rightarrow$ **Multipotent progenitor** branching into **Common lymphoid progenitor** ($\rightarrow$ B cell, T cell, NK cell) and **Common myeloid progenitor** ($\rightarrow$ Granulocyte-monocyte progenitor

→ monocyte/granulocyte; → **Megakaryocyte-erythroid progenitor** → platelets, RBCs).

Annotate decreasing self-renewal and increasing proliferation/differentiation along the axis.

- ▶ **CAR vs native T-cell receptor:** label VH and VL (scFv antigen-binding domain), spacer, transmembrane (TM) domain, costimulatory domain (CD28 or 4-1BB), CD3ζ signalling chain; alongside a native TCR αβ chains recognising antigenic peptide–MHC I through the CD3 complex.

Clinical / Diagnostic significance

- ▶ Determine **HLA type early** in candidates (e.g., all AML patients) to enable timely donor search.
- ▶ **Autologous** transplant/gene therapy avoids GVHD and donor matching but lacks a GVT effect; **allogeneic** offers GVT at the cost of GVHD — the central therapeutic trade-off.
- ▶ Recognise and grade **GVHD** (skin/liver/gut) and monitor for **SOS, TMA, CMV reactivation, and PJP** — each has specific therapy (defibrotide, eculizumab, letermovir/ganciclovir, co-trimoxazole).
- ▶ Gene-edited and CAR-T recipients require **long-term surveillance** — lifelong monitoring for secondary malignancy after CAR-T, and 15-year insertion-site monitoring for integrating-vector HSC products.

High-yield exam pointers

- ▶ Two cardinal stem-cell properties: **self-renewal + differentiation**; achieved by **asymmetric division**.
- ▶ HSC markers: **CD34, CD90 (Thy-1), CD117 (c-Kit), CD133, CD110 (c-Mpl)**.
- ▶ Mobilisation = **G-CSF + plerixafor (CXCR4 antagonist)**; target autologous dose $>2.5 \times 10^6$ **CD34⁺ cells/kg**.
- ▶ HLA-identical sibling probability = $1 - (0.75)^n$; **post-transplant cyclophosphamide** enables **haploidentical** transplant.
- ▶ Conditioning intensity: myeloablative > reduced-intensity (**fludarabine + melphalan**) > nonmyeloablative (**fludarabine + 200 cGy TBI**).
- ▶ Acute GVHD = **skin + liver + gut**; first-line **prednisone**, steroid-refractory **ruxolitinib**. Chronic GVHD steroid-refractory: **ibrutinib/ruxolitinib/belumosudil**.
- ▶ **SOS** → **defibrotide**; **TMA** → **eculizumab**; **CMV** → **letermovir/ganciclovir**.
- ▶ **Casgevy** edits **BCL11A** to raise HbF in sickle cell disease/β-thalassaemia; X-linked SCID trial caused **LMO-2 insertional T-ALL**.
- ▶ CAR-T costimulatory domains = **CD28 or 4-1BB**; CRS treated with **tocilizumab**.

SOURCE & COVERAGE

- ▶ Harrison's Principles of Internal Medicine, 22e — "Hematopoietic Stem Cells" (David T. Scadden, Dan L. Longo); "Hematopoietic Cell Transplantation" (Frederick R. Appelbaum); "Gene and Cell-Based Therapy in Clinical Medicine" (Katherine A. High, Marcela V. Maus).
- ▶ *Coverage note:* The Harrison corpus covers HSC biology, hematopoietic cell transplantation, and gene-/cell-based (CAR-T, gene-editing) therapy in depth. Coverage of **embryonic stem cell, iPSC, and mesenchymal stem cell** therapeutics is limited, as these remain largely investigational; the classification of stem cells by potency given above is standard, universally accepted textbook medicine. No dedicated specialty text or CMDT chapter was specified for this topic.

Steps of practicing evidence-based medicine

Asked in: Paper I May 2019 — RGUHS MD General Medicine

Definition / Introduction — Evidence-based medicine (EBM) is the conscientious, explicit and judicious integration of the **best available external clinical research evidence** with **individual clinical expertise** and the **patient's values and preferences** to make decisions about the care of individual patients. It updates the traditional model of clinical medicine (knowledge + intuition + judgement) by placing far greater emphasis on the *processes* by which clinicians obtain the most up-to-date and relevant research to determine for themselves whether an intervention alters disease course or improves length/quality of life. As described by its founding proponents at *McMaster University* in the early 1990s, EBM is practised as a structured, repeatable cycle of well-defined steps — classically summarised as the "5 A's" (Ask, Acquire, Appraise, Apply, Assess).

The EBM cycle — the five steps ("5 A's")

Step	"A"	Core task	Key tools
1	Ask	Convert the clinical problem into a focused, answerable question	PICO / PICOT framework
2	Acquire	Search the literature/online databases efficiently for the best external evidence	MEDLINE, EMBASE, Cochrane Library, DARE
3	Appraise	Critically appraise the evidence for validity ,	Risk-of-bias checks, AMSTAR2, levels of evidence

Step	“A”	Core task	Key tools
		importance (magnitude) and applicability	
4	Apply	Integrate the appraisal with clinical expertise and the patient’s unique features and preferences	Shared decision-making, NNT/ARR
5	Assess	Evaluate one’s own performance/outcome and record for future use (audit)	Audit, reflective record-keeping

- ▶ Harrison frames the cycle as **four key steps** (formulate the question → search literature/databases → appraise validity & relevance → integrate with the unique patient and their preferences); the widely taught **fifth step** (self-audit / “Assess” / recording for future use) completes the loop. Both framings are reproduced below.

Step 1 — ASK: frame an answerable clinical question

- ▶ Asking a **well-built clinical question** generated from a real patient encounter is arguably the **single most important step** — a sharp question makes searching and appraisal far easier and forces the clinician to define the patient, intervention and outcomes precisely.
- ▶ Use the **PICO** acronym (a fifth element, *Time-frame*, gives **PICOT**):
 - **P** — *Patient / Problem* (e.g., immunocompetent child with cutaneous warts).
 - **I** — *Intervention* (the test, drug or exposure of interest).
 - **C** — *Comparator* (placebo/vehicle or an alternative; optional).
 - **O** — *Outcome* (a clinically important, patient-relevant endpoint).
 - **T** — *Time-frame* over which the outcome is judged.
- ▶ Questions are categorised by domain — **therapy, diagnosis, prognosis, aetiology/harm, and prevention** — because the question type dictates which study design is the “best evidence.”

Step 2 — ACQUIRE: search for the best external evidence

- ▶ Conduct a **predefined, reproducible, explicit search** of the literature and online databases (MEDLINE, EMBASE, the **Cochrane Database of Systematic Reviews**, DARE) rather than relying on memory or a single textbook.
- ▶ Searching the world’s literature and appraising it is time-consuming and demands skills most busy clinicians lack; hence the pragmatic shortcut of seeking a recent, high-quality **systematic review** that has already synthesised the primary studies (the *Cochrane* reviews are the prototype).

- Pre-appraised, pre-synthesised resources (systematic reviews, guidelines, evidence summaries) sit at the top of the practical search strategy.

Step 3 — APPRAISE: critically appraise the evidence

Appraisal asks three questions: **Are the results valid?** **What are the results (importance/magnitude)?** **Will they help my patient (applicability)?** This rests on the **hierarchy of evidence**, where the strength of evidence depends on the *type of question* asked.

Level	Therapy / harm question — best evidence
1a	Systematic review of multiple RCTs with homogeneity
1b	Individual RCT with narrow confidence intervals
1c	“ All-or-none ” effect (e.g., streptomycin for TB meningitis, insulin for diabetes)
2a/2b	Cohort studies (with homogeneity / individual cohort or low-quality RCT)
2c	“ Outcomes ” research (cost–benefit, cost–effectiveness, cost–utility)
3a/3b	Case–control studies
4	Case series (and poor-quality cohort/case–control studies)
5	Expert opinion without explicit appraisal; bench research; logical deduction

- (*Oxford Centre for Evidence-Based Medicine levels.*) For **diagnosis** questions, the best evidence is an **independent, blind comparison** of an appropriate spectrum of consecutive patients against a reference (“gold”) standard; for **rare harms**, cohort/case–control studies, post-marketing surveillance and pharmacovigilance are most useful.
- **Study quality outranks design label**: a well-conducted cohort study can be more reliable than a small, poorly conducted RCT. The best therapeutic evidence comes from large, fully masked RCTs with **concealed allocation** and **intention-to-treat** analysis.
- **Systematic reviews & meta-analysis** are regarded by many as the apex of the hierarchy because they comprehensively and reproducibly summarise the evidence; meta-analysis can reveal a true benefit that individually underpowered trials missed (classically, the benefit of **streptokinase/thrombolysis in acute MI** was evident by cumulative meta-analysis a decade before large trials/guidelines confirmed it). They are *not* infallible — they cannot remedy deficient primary data and should include **unpublished trials** to avoid **publication bias**; tools such as **AMSTAR2** appraise their quality.

Tools of appraisal — quantifying test performance and treatment effect

- ▶ **Diagnostic test metrics** — *sensitivity* (detection of diseased), *specificity* (detection of non-diseased), and ROC curves illustrating their trade-off.
- ▶ **Bayes' rule / post-test probability** — the post-test probability of disease is derived from the **pre-test probability** (prevalence/clinical context), **sensitivity** and **specificity**, summarised by the **likelihood ratio (LR)**:
 - $\text{LR positive} = \text{sensitivity} / (1 - \text{specificity})$; $\text{LR negative} = (1 - \text{sensitivity}) / \text{specificity}$.
 - An $\text{LR+} > 10$ markedly raises (rules *in*) the probability of disease; a very low LR- rules it *out*. The **Bayes nomogram** (Fig. 4-2) connects pre-test probability + LR to read off post-test probability.
- ▶ **Treatment-effect metrics** (essential for the “Apply” step):
 - **Absolute Risk Reduction (ARR)** = control event rate – treatment event rate.
 - **Relative Risk Reduction (RRR)** = $\text{ARR} \div \text{control event rate}$.
 - **Number Needed to Treat (NNT)** = $1 / \text{ARR}$ — e.g., a therapy cutting 5-year mortality from 12% → 8% gives $\text{ARR} = 4\%$ and $\text{NNT} = 25$. The same relative benefit applied to a lower-risk group (6% → 4%) gives $\text{ARR} 2\%$ and $\text{NNT} 50$ — illustrating that absolute benefit falls as baseline risk falls.
 - **Odds ratio / relative risk** are the usual summary measures of relative benefit; clinicians must always also examine the *absolute* benefit and harms.

Step 4 — APPLY: integrate evidence with expertise and patient values

- ▶ Integrate the appraised evidence with the **clinician's own expertise** and the **individual patient's circumstances, comorbidities and preferences** — the “average” trial patient may not resemble the patient in front of you (external validity/generalisability).
- ▶ Ask: *Can these results be applied to my patient? Were all clinically important outcomes considered? Do the benefits outweigh the harms and costs?*
- ▶ **Clinical practice guidelines** (Institute of Medicine 1990: “systematically developed statements to assist practitioner and patient decisions about appropriate health care for specific clinical circumstances”) operationalise EBM but are meant to **assist, not dictate** — guideline-level evidence alone is never sufficient for an individual decision (notably, <15% of cardiovascular guideline recommendations rest on the highest level of trial evidence). This is the locus of **shared decision-making**.

Step 5 — ASSESS: audit and record

- ▶ **Evaluate your own performance** in executing steps 1–4 and the patient's outcome; **record the information for future use** so the appraised answer can be reused efficiently. This closes the loop and underpins clinical **audit and quality improvement** — guideline-derived “best practices”

become **quality indicators** (e.g., proportion of acute-MI patients given aspirin on admission; proportion of HFrEF patients on an ACE inhibitor).

Limitations and threats to EBM (examiner favourites)

- ▶ **Limitations:** publication bias; poor methodological quality of many trials; lack of evidence in many areas; reliance on **summary (group) statistics** that mask individual responses.
- ▶ **Threats:** data-driven and sponsor-funded systematic reviews, selective outcome reporting, non-publication of negative trials, “spin,” ghost-writing.
- ▶ EBM is an **ideal, not a finished tool**: most clinical problems will never be tested in an RCT, so excellent clinical reasoning plus respect for patient preferences remain paramount.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Evidence pyramid (hierarchy of evidence):** a triangle, broad base to narrow apex labelled bottom-to-top — *In-vitro/bench research* → *Animal research* → *Ideas/editorials/expert opinion* → *Case reports* → *Case series* → *Case-control studies* → *Cohort studies* → *Randomised controlled trials* → *Systematic reviews & meta-analyses (apex)*.
- ▶ **The EBM cycle (5 A's):** a circular loop of five boxes with arrows returning to the start — *Ask (PICO)* → *Acquire (search)* → *Appraise (validity, importance, applicability)* → *Apply (integrate with expertise + patient values)* → *Assess (audit/record)* → *back to Ask*.

Clinical / Diagnostic significance

- ▶ Provides a **reproducible, teachable framework** for translating a bedside problem into an evidence-supported decision, reducing reliance on anecdote and cognitive bias (anchoring, premature closure).
- ▶ Quantitative outputs (LR, post-test probability, NNT/ARR) let clinicians **calibrate testing and treatment thresholds** to an individual's baseline risk and to weigh benefit against harm and cost.
- ▶ Anchors **guideline development, clinical audit and quality indicators**, and frames **shared decision-making** by making the strength and limits of evidence explicit to the patient.

High-yield exam pointers

- ▶ EBM = **best external evidence + clinical expertise + patient values/preferences**; originated at *McMaster University*, early 1990s.
- ▶ Remember the 5 A's: **Ask** → **Acquire** → **Appraise** → **Apply** → **Assess** (Harrison lists the first four; the fifth is self-audit/recording).
- ▶ Step 1 question structured as **PICO(T)**; categorise by therapy/diagnosis/prognosis/harm/prevention.
- ▶ Hierarchy/best design by question: **therapy** → **RCT**; **diagnosis** → **cross-sectional study vs gold standard**; **prognosis** → **cohort**; **rare harm** → **case-control / pharmacovigilance**.

- ▶ **Systematic review/meta-analysis** = **apex**; *Cochrane* is the prototype; beware **publication bias** (include unpublished/negative trials); appraise with **AMSTAR2**.
- ▶ **NNT** = $1/ARR$; **LR+** = $\text{sensitivity}/(1 - \text{specificity})$, **LR+** >10 strongly rules in disease; use the **Bayes nomogram** for post-test probability.
- ▶ Quality can trump design: a good cohort study may beat a poor RCT; demand **concealed allocation + intention-to-treat**.
- ▶ Guidelines (IOM 1990 definition) **assist, not dictate**; <15% of CV recommendations rest on top-level evidence — individualise.

SOURCE & COVERAGE

- ▶ **Harrison's Principles of Internal Medicine, 22e** — “Decision-Making in Clinical Medicine” (the four key EBM steps; sources of evidence — clinical trials, registries, RCTs, meta-analysis; Bayes' rule, sensitivity/specificity, likelihood ratios, post-test probability; ARR/NNT; clinical practice guidelines and quality indicators).
- ▶ **Rook's Textbook of Dermatology, 10e** — “Principles of Evidence-based Dermatology” (used for the general EBM framework: the explicit **five-step cycle**, **PICO/PICOT**, the **hierarchy/levels of evidence** (Oxford CEBM), **NNT**, **AMSTAR2**, and the limitations/threats to EBM — these principles are generic to internal medicine).
- ▶ **Coverage note:** The RGUHS-suggested Harrison chapter covers the **content** of EBM richly but presents the cycle as **four steps** rather than the canonical **five-step** “5 A's”; the five-step structure and PICO/levels-of-evidence detail were grounded in Rook's general EBM chapter. The “5 A's” labelling (Ask/Acquire/Appraise/Apply/Assess) and **GRADE-style certainty rating** are universally accepted standard EBM terminology used here to organise the answer.

Structure of Internal Capsule and its blood supply

Asked in: Paper I Nov 2020 — RGUHS MD General Medicine

Definition / Introduction — The **internal capsule** is a thick, compact, V-shaped (boomerang-shaped) sheet of **projection white matter** that carries virtually all the afferent (thalamocortical) and efferent (corticofugal) fibres travelling between the cerebral cortex and the brainstem/spinal cord. On a horizontal section it lies wedged between the **caudate nucleus and thalamus medially** and the **lentiform nucleus (putamen + globus pallidus) laterally**, with its apex (genu) pointing medially. Superiorly it fans out into the **corona radiata**; inferiorly it condenses into the **crus cerebri (cerebral peduncle)**. Because an enormous volume of motor and sensory traffic is funnelled through a small territory fed by tiny perforating end-arteries, a lesion barely a few millimetres across (a *lacune*) can produce a dense contralateral hemiplegia — making this anatomy of major clinical importance.

Gross anatomy, relations and subdivisions

- ▶ **Course:** continuous above with the **corona radiata** (subcortical white matter) and below with the **crus cerebri**; medially it borders the diencephalon, laterally the basal ganglia.
- ▶ On a horizontal (axial) section the capsule has five named parts; on a sagittal view the retrolenticular and sublenticular components are best appreciated:
 - **Anterior limb** — lies between the **head of the caudate** (medially) and the **lentiform nucleus** (laterally).
 - **Genu** — the bend/apex; relates to the lateral wall of the third ventricle; abuts the ICA-derived perforators.
 - **Posterior limb** — lies between the **thalamus** (medially) and the **lentiform nucleus** (laterally); the largest and clinically most important segment.
 - **Retrolenticular part** — fibres lying *behind* the lentiform nucleus.
 - **Sublenticular part** — fibres passing *beneath* the lentiform nucleus toward the temporal lobe.

Fibre content of each part

Part	Principal fibre tracts	Functional traffic
Anterior limb	Anterior (frontal) thalamic radiation; frontopontine fibres	Prefrontal–dorsomedial/anterior thalamic loops; frontal → pontine relay
Genu	Corticobulbar (corticonuclear) fibres; corticopontine fibres to facial & hypoglossal nuclei	Supranuclear control of bulbar/cranial-nerve motor nuclei
Posterior limb	Corticospinal (pyramidal) fibres, somatotopically arranged; superior thalamic radiation (sensory); corticorubral, corticoreticular fibres	Voluntary limb movement; thalamocortical somatosensory relay
Retrolenticular part	Optic radiation (geniculocalcarine fibres); posterior thalamic radiation	Vision (LGB → calcarine cortex)
Sublenticular part	Auditory (acoustic) radiation ; temporopontine fibres	Hearing (MGB → Heschl's gyrus)

- ▶ *Brazis* confirms the corpus-derived correlates: **corticospinal fibres run in the posterior limb**, the **corticobulbar/corticopontine fibres to facial and hypoglossal nuclei are concentrated in the genu**, the **superior thalamic radiation** (light-touch/pin sensation) travels in the posterior limb, and the **geniculocalcarine (optic) fibres lie in the retrolenticular white matter**.

Blood supply

The capsule is perfused almost entirely by small, deep **perforating (penetrating) end-arteries** with little collateral overlap — hence its vulnerability to lacunar infarction in hypertension and small-vessel disease.

Part of capsule	Arterial supply (parent vessel)
Anterior limb	Medial lenticulostriate branches / recurrent artery of Heubner from the A1 (precommunal) segment of the ACA; deep A1 perforators
Genu	Penetrating lenticulostriate perforators (single-vessel occlusion → <i>capsular genu syndrome</i>); classically also direct small branches of the internal carotid artery
Posterior limb	Superior part — lateral lenticulostriate arteries from the M1 segment of the MCA; inferior/main part — anterior choroidal artery (branch of the ICA)
Retrolenticular part	Anterior choroidal artery (with contribution from the posterior choroidal artery of the PCA)
Sublenticular part	Anterior choroidal artery

- ▶ **Recurrent artery of Heubner (medial striate artery):** arises from the lateral aspect of the ACA (A1/proximal A2) and supplies the **anteroinferior limb of the internal capsule, anterior putamen and caudate, and the tip of the outer globus pallidus**. (Harrison: A1 deep penetrators supply the anterior limb, anterior perforated substance, amygdala, anterior hypothalamus and inferior head of caudate.)
- ▶ **Lateral lenticulostriate arteries:** penetrating branches of the proximal MCA (M1) supply the putamen, outer globus pallidus, posterior limb of the internal capsule, adjacent corona radiata and most of the caudate; *Brazis* adds that they feed the superior portion of both the anterior and posterior limbs.
- ▶ **Anterior choroidal artery (AChA):** arises from the internal carotid artery distal to the posterior communicating artery; supplies the posterior limb of the internal capsule, the retrolenticular white matter (through which the geniculocalcarine fibres pass), the optic tract, lateral geniculate body, midbrain and choroid plexus of the temporal horn. It is vulnerable to iatrogenic occlusion during clipping of ICA aneurysms.

Somatotopic organisation (high-yield)

- ▶ Corticospinal fibres in the **posterior limb** are arranged **antero-posteriorly: face → arm → trunk → leg**.
- ▶ *Harrison*: ischaemia at the **genu** causes **facial weakness first**, then arm, then leg, as the infarct extends **posteriorly** within the capsule.

- ▶ *Brazis*: at superior capsular levels the **face/bulbar muscles** are affected by lesions of the **genu** or **anterior posterior limb**, whereas **more posterior lesions** cause **arm and leg weakness**.
- ▶ A “**parathalamic rim**” of the posterior limb carries the sensory tracts; small lacunes that spare this rim produce a **pure motor** deficit.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Diagram 1 — Horizontal (axial) section of internal capsule** (lentiform nucleus, caudate head, thalamus drawn around a V-shaped capsule). Label: *Anterior limb, Genu, Posterior limb, Retrolenticular part, Sublenticular part; Head of caudate nucleus, Putamen, Globus pallidus (lentiform), Thalamus; fibre content — frontopontine/anterior thalamic radiation (anterior limb), corticobulbar (genu), corticospinal + superior thalamic radiation (posterior limb), optic radiation (retrolenticular), auditory radiation (sublenticular); somatotopy face→arm→leg in posterior limb.*
- ▶ **Diagram 2 — Blood supply / coronal vascular territory**. Label: *Anterior limb → recurrent artery of Heubner (ACA-A1) + medial lenticulostriates; Genu → lenticulostriates/ICA branches; Posterior limb (superior) → lateral lenticulostriates (MCA-M1); Posterior limb (inferior) + retrolenticular → anterior choroidal artery (ICA).*

Clinical / Diagnostic significance

- ▶ **Pure motor hemiparesis** — the commonest lacunar syndrome; infarct in the **posterior limb of the internal capsule** (or corona radiata/basis pontis) → contralateral face-arm-leg weakness with little/no sensory loss (*Harrison, Brazis*).
- ▶ **Ataxic hemiparesis and dysarthria-clumsy hand syndrome** — lacunes of the **posterior limb** or **genu/anterior limb** (or basis pontis) respectively.
- ▶ **Sensorimotor stroke** — posteroventral thalamus + adjacent **posterior limb**.
- ▶ **Capsular genu syndrome** — contralateral facial and lingual paresis with dysarthria, mastication-palatal-pharyngeal weakness; bilateral genu lesions may cause cognitive/behavioural change.
- ▶ **Capsular warning syndrome** — clustering TIAs affecting face, arm and leg from threatened occlusion of a **single lenticulostriate artery**, heralding a completed capsular infarct.
- ▶ **Anterior choroidal artery syndrome (Foix)** — the classic triad of contralateral **hemiplegia** (posterior-limb corticospinal interruption), **hemianaesthesia** (superior thalamic radiation), and **homonymous hemianopia** (optic tract/LGB/optic radiation), often with macular/horizontal-meridian sparing.
- ▶ **Artery of Heubner infarction** — contralateral **face and arm weakness without sensory loss** (anterior-limb + anterior putamen).

- ▶ **Investigation:** MRI with diffusion-weighted imaging (DWI) is the most sensitive for acute lacunes; perforators are too small to be seen on CT/CT-angiography. Hypertension and age are the principal risk factors (lipohyalinosis/microatheroma of penetrators).

High-yield exam pointers

- ▶ Internal capsule = compact **projection fibres**, continuous above with **corona radiata**, below with **crus cerebri**; five parts — anterior limb, **genu**, posterior limb, retrolenticular, sublenticular.
- ▶ Corticospinal fibres → posterior limb; corticobulbar → genu; optic radiation → retrolenticular; auditory radiation → sublenticular.
- ▶ Somatotopy of posterior limb: face (anterior) → arm → leg (posterior).
- ▶ Blood supply summary: Anterior limb = recurrent artery of Heubner (ACA); Posterior limb = lateral lenticulostriates (MCA) + anterior choroidal artery (ICA); Retrolenticular/sublenticular = anterior choroidal artery.
- ▶ A tiny lacune in the posterior limb can cause a **dense hemiplegia** — disproportionate deficit for lesion size.
- ▶ **Pure motor hemiparesis** = the signature capsular lacunar syndrome; lenticulostriate occlusion.
- ▶ **Anterior choroidal artery triad** = **hemiplegia** + **hemianaesthesia** + **hemianopia**; high risk of iatrogenic occlusion during ICA aneurysm clipping.
- ▶ These are **perforating end-arteries** with poor collaterals → **hypertension/age** drive lacunar disease; DWI-MRI is the key test.

SOURCE & COVERAGE

- ▶ **Harrison's Principles of Internal Medicine, 22e** — “Introduction to Cerebrovascular Diseases” (lenticulostriate territory; ACA-A1, MCA-M1 and anterior choroidal artery supply of the internal-capsule limbs) and “Ischemic Stroke” (lacunar/small-vessel syndromes; posterior-limb and genu correlations).
- ▶ **Brazis, Masdeu & Biller — Localization in Clinical Neurology**** — “Vascular Syndromes of the Forebrain, Brainstem, and Cerebellum” (recurrent artery of Heubner, anterior choroidal artery, lenticulostriate territories, capsular genu and anterior-choroidal syndromes, lacunar-infarction table) and “Localization of Lesions Affecting the Cerebral Hemispheres” (capsular somatotopy, parathalamic sensory rim, corticobulbar/corticospinal fibre course).

Coverage note: The corpus (Harrison + Brazis) covers the **blood supply, fibre correlates and lacunar/clinical syndromes** in depth and is the primary grounding here. The fine **descriptive neuroanatomy of fibre content** (anterior thalamic radiation, frontopontine, auditory radiation in the sublenticular part) is given as **universally accepted standard neuroanatomy** (Gray's/Snell), consistent with and partly confirmed by the Brazis text; no specifics have been fabricated.

Temperature regulation

Asked in: Paper I Dec 2023 — RGUHS MD General Medicine

Definition / Introduction — Thermoregulation is the homeostatic process by which the body maintains its **core temperature** within a narrow physiological range (36.5–37.5°C / 97.7–99.5°F) despite wide swings in environmental temperature and metabolic activity. It is governed by the **hypothalamus**, which acts as a biological thermostat with a defined “**set point**,” balancing **heat production** against **heat loss**. A regulated upward shift of this set point produces **fever**, whereas failure of heat dissipation with an *unchanged* set point produces **hyperthermia** — a distinction that is clinically and therapeutically pivotal.

Normal body temperature, variation and measurement

- ▶ **Normal core range:** 36.5–37.5°C; mean oral temperature 36.6°C (95% CI 35.7–37.3°C) in a study of >35,000 adults. A temperature >37.7°C (>99.9°F) — the 99th percentile for healthy individuals — defines **fever**.
- ▶ **Diurnal rhythm:** lowest at 8 a.m., highest at 4 p.m.; also lower in summer, higher in winter.
- ▶ **Physiological modifiers:** temperature falls ~0.02°C per 10-year increase in age; African-American women run 0.052°C **higher** than white men; cancer raises baseline ~0.02°C, hypothyroidism lowers it ~0.01°C.
- ▶ **Menstrual cycle:** a.m. temperature is low for the 2 weeks before ovulation, then rises ~0.6°C (1°F) at **ovulation** and stays elevated through the luteal phase until menses.
- ▶ **Site corrections (high-yield):**

Site	Relationship to oral / core
Oral	Reference; lower if mouth-breathing (tachypnoea)
Rectal	~0.4°C (0.7°F) higher than oral
Lower oesophageal	Closely reflects true core temperature
Tympanic membrane (unadjusted mode)	~0.8°C (1.6°F) lower than rectal; more variable

Hypothalamic control and the “set-point” model

- ▶ The **preoptic anterior hypothalamus** and **posterior hypothalamus** integrate two afferent inputs: (1) **peripheral** signals from cutaneous **warmth/cold receptors** via peripheral nerves, and (2) **central** signals from the **temperature of blood** bathing the hypothalamic neurons.
- ▶ The **thermoregulatory centre** compares these inputs against the **set point** and drives efferent responses to keep blood temperature matched to that setting — analogous to a **home thermostat**.

- ▶ In a thermoneutral environment, basal **metabolism produces more heat than is needed**; the hypothalamus continuously balances this excess heat production (muscle, liver) against dissipation (skin, lungs).
- ▶ A standing concept: a natural “**thermal ceiling**” (~106°F) appears to be defended by central **antipyretic neuropeptides**, so most infective fevers rarely exceed this without CNS involvement.

Heat balance — production vs loss (effector mechanisms)

- ▶ **Heat-gain / conservation effectors** (triggered when actual temperature is *below* set point, i.e., the chill/rigor phase of rising fever):
 - **Cutaneous vasoconstriction** — vasomotor-centre neurons shunt blood from skin of hands/feet to the core, reducing radiant loss; the patient *feels cold*.
 - **Shivering thermogenesis** — increased heat production from skeletal muscle.
 - **Non-shivering thermogenesis** — increased metabolic heat from the **liver** (and, in standard physiology, brown adipose tissue — see Coverage note).
 - **Behavioural** — putting on clothing/bedding to reduce heat loss.
- ▶ **Heat-loss effectors** (triggered when actual temperature is *above* set point — e.g., when the set point is reset downward by antipyretics, the defervescence/flush phase):
 - **Cutaneous vasodilation and sweating** (evaporative loss).
 - **Behavioural** — removal of clothing.
- ▶ During fever, body temperature typically rises by 1–2°C; these conservation and production processes continue until blood temperature reaches the new febrile “thermostat setting,” then are held there by normal afebrile balance mechanisms.

Fever versus hyperthermia (must distinguish)

Feature	Fever	Hyperthermia
Hypothalamic set point	Raised (e.g., 37→39°C)	Unchanged / normal
Mechanism	Pyrogen-driven; regulated rise	Uncontrolled rise exceeding heat-loss capacity
Pyrogenic molecules	Present (cytokines, PGE2)	Absent
Typical cause	Infection, inflammation, malignancy	Exogenous heat exposure / excess endogenous heat production (exertion, drugs blocking sweating, heat stroke)
Skin	May be cold (vasoconstriction)	Hot but characteristically dry (in heat stroke / anhidrotic drugs)
Response to antipyretics	Responds (aspirin/acetaminophen lower it)	Does NOT respond

Feature	Fever	Hyperthermia
Urgency	Usually benign, self-limited	Can be rapidly fatal

- ▶ **Hyperpyrexia:** fever $>41.5^{\circ}\text{C}$ ($>106.7^{\circ}\text{F}$) — seen in severe infection and especially CNS haemorrhage.
- ▶ **Hypothalamic fever:** rare regulated set-point elevation from local **trauma, haemorrhage, tumour, or intrinsic hypothalamic malfunction** — but most patients with hypothalamic damage are paradoxically **subnormal**, not supranormal.

Pathogenesis of fever — resetting the set point upward

- ▶ **Exogenous pyrogens:** microbial products/toxins. Classic example is **lipopolysaccharide (endotoxin)** of gram-negative bacteria (fever at 2–3 ng/kg IV in humans). Gram-positive toxins act as **superantigens** (e.g., TSST-1, staphylococcal enterotoxins, streptococcal pyrogenic exotoxins; fever at 1–10 µg/kg).
- ▶ **Pyrogenic cytokines** (formerly “endogenous pyrogens”): small proteins (10–20 kDa) — IL-1, IL-6, TNF, interferons, ciliary neurotropic factor — released from **monocytes/macrophages and endothelial cells**. IL-1 and TNF produce fever at 10–100 ng/kg; IL-6 requires 1–10 µg/kg. Fever can also arise *without* infection (pericarditis, trauma, stroke, immunisation).
- ▶ **Final common pathway** — PGE₂: cytokines (and direct **Toll-like receptor/IL-1 receptor** activation) act on the **hypothalamic endothelium** near the **circumventricular organ — organum vasculosum of the lamina terminalis** — raising **prostaglandin E₂ (PGE₂)**. PGE₂ (chiefly via the **EP-3 receptor**, essential for fever) stimulates glial release of **cyclic AMP**, which acts as the neurotransmitter that **elevates the thermoregulatory set point**.
- ▶ Peripheral PGE₂ induced in tissues accounts for the **myalgias and arthralgias** of fever.

Antipyresis — restoring the set point downward

- ▶ Fever is reduced by lowering the elevated set point, achieved by **reducing hypothalamic PGE₂**.
- ▶ **Cyclooxygenase (COX) inhibitors** are the principal antipyretics; potency correlates with inhibition of **brain COX**. **Aspirin and acetaminophen** are equally effective; NSAIDs (**ibuprofen**) and COX-2 inhibitors are also excellent antipyretics.
- ▶ **Acetaminophen** is a poor peripheral COX inhibitor (minimal anti-inflammatory action) but in the brain is oxidised by **cytochrome P450** to an active COX-inhibiting form (with proposed **COX-3 inhibition**); it is the **preferred** antipyretic given the platelet/GI effects of aspirin and NSAIDs.
- ▶ **In children**, use **acetaminophen or ibuprofen** — aspirin risks **Reye syndrome** with certain viral infections.
- ▶ **Glucocorticoids** act at two levels: inhibit **phospholipase A₂** (less arachidonic-acid substrate for PGE₂) and block **transcription of pyrogenic cytokine mRNA**.

- ▶ Chronic high-dose antipyretics do **not** lower *normal* core temperature — confirming PGE2 has no role in normal thermoregulation.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Diagram 1 — “Chronology of fever induction”** (Harrison Fig 20-1): vertical flow with labels — *Infection, microbial toxins, mediators of inflammation, immune reactions* → *Monocytes/macrophages, endothelial cells* → *Pyrogenic cytokines (IL-1, IL-6, TNF, IFN)* → *Circulation* → *Hypothalamic endothelium* → *PGE2* → *cyclic AMP* → *Elevated thermoregulatory set point* → *Heat conservation, heat production* → *Fever*.
- ▶ **Diagram 2 — Hypothalamic “thermostat” balance:** central box *Hypothalamic set point* with afferents labelled *Skin warmth/cold receptors* and *Temperature of blood*; left arm *Heat production / conservation* (labels: *vasoconstriction, shivering, non-shivering thermogenesis, behaviour*); right arm *Heat loss* (labels: *vasodilation, sweating, behaviour*). Show set point shifting up = **fever**, set point normal but load > loss = **hyperthermia**.

Clinical / Diagnostic significance

- ▶ **Therapeutic crux:** confirm fever vs hyperthermia — hyperthermia (heat stroke, neuroleptic malignant/serotonin syndrome, malignant hyperthermia) is an emergency, does **not** respond to antipyretics, and needs **physical/external cooling** rather than COX inhibitors.
- ▶ **Metabolic cost:** every 1°C above 37°C raises **oxygen consumption** by ~13% — hence the rationale to treat fever in cardiac, pulmonary or neurologically compromised patients.
- ▶ **Temperature–pulse dissociation (relative bradycardia):** typhoid, brucellosis, leptospirosis, drug fever, factitious fever.
- ▶ **Blunted febrile response** (may have serious infection *without* fever): neonates, elderly, chronic liver/renal failure, and patients on **glucocorticoids or anticytokine therapy** — septic shock may even cause **hypothermia**.
- ▶ **Investigations:** CBC with manual differential (band forms, toxic granulations, Döhle bodies suggest bacterial infection), CRP and ESR for occult inflammation; circulating cytokine levels are not clinically useful.

High-yield exam pointers

- ▶ Control centre = **hypothalamus**: preoptic anterior (heat-loss) + posterior hypothalamus integrating **skin receptor** and **blood-temperature** inputs against a **set point**.
- ▶ Normal core 36.5–37.5°C; fever >37.7°C; hyperpyrexia >41.5°C.
- ▶ Rectal +0.4°C over oral; tympanic (unadjusted) –0.8°C below rectal; oesophageal ≈ core.
- ▶ Fever = **raised set point**; hyperthermia = **normal set point, failed heat loss** — only fever responds to antipyretics.

- ▶ Final mediator of fever = **PGE2** acting via **EP-3 receptor** near the **OVL**T; COX inhibitors are antipyretic.
- ▶ Rising fever = **vasoconstriction + shivering** (feels cold); defervescence = **vasodilation + sweating** (flush).
- ▶ **Acetaminophen preferred**; aspirin avoided in children (**Reye syndrome**); glucocorticoids inhibit **PLA2** + cytokine transcription.
- ▶ **+13% O₂ consumption per 1°C**; relative bradycardia in typhoid/brucellosis/leptospirosis.

SOURCE & COVERAGE

Harrison's Principles of Internal Medicine, 22e — **Ch 20 "Fever"** (Dinarello & Surana): thermoregulation, hypothalamic set-point, normal temperatures and measurement, fever vs hyperthermia, pyrogen/cytokine/PGE2 pathogenesis, and antipyretic pharmacology.

Coverage note (gap flagged): Ch 20 is fever-centric; *pure thermoregulatory physiology* is covered only insofar as it underlies fever. The four physical mechanisms of heat exchange (**radiation, conduction, convection, evaporation**) and **brown adipose tissue** as the dedicated organ of non-shivering thermogenesis are universally accepted standard physiology but are **not detailed in Ch 20** (which cites skin/lung dissipation and hepatic non-shivering thermogenesis) — included here only as standard textbook physiology. Detailed hyperthermia syndromes and heat-stroke management belong to Harrison Ch 478 (referenced by Ch 20 but not provided for this answer).

Teratogenesis: Mechanism, Risk Factors and Prevention

Asked in: Paper I Nov 2021 — RGUHS MD General Medicine

Definition / Introduction — A **teratogen** is any agent (drug, chemical, physical factor, infectious organism or maternal metabolic state) that, acting during embryonic or fetal development, causes a permanent structural or functional abnormality in the conceptus. **Teratogenesis** is the process by which such abnormal development is initiated; the four classic manifestations are **death (abortion/stillbirth), structural malformation, intrauterine growth restriction (IUGR) and functional/behavioural deficit**. Only ~2–3% of major congenital anomalies are attributable to recognised drug/chemical teratogens, yet these are among the most *preventable* causes of birth defects, making preconception counselling a core internal-medicine responsibility for women of reproductive age.

Wilson's principles and the critical periods of development

The internist must grasp *when, to whom* and *how much* exposure produces harm — encapsulated in Wilson's six principles of teratology:

- ▶ **Genotype-dependence** — susceptibility depends on the genotype of the conceptus and how it interacts with the environment (e.g., slow vs fast hydroxylators, *MTHFR* polymorphisms).
- ▶ **Timing (developmental stage)** — susceptibility varies sharply with the stage of development at exposure (see critical periods below).
- ▶ **Mechanism-specific action** — each agent acts through a specific pathogenetic mechanism on developing cells/tissues.
- ▶ **Access depends on the agent** — manifestation requires the agent (or its metabolite) to reach the conceptus; this is governed by maternal absorption/metabolism and placental transfer (favoured by low molecular weight, lipid solubility, non-ionisation, low protein binding).
- ▶ **Four end-points** — the manifestations are *death, malformation, growth retardation and functional deficit*.
- ▶ **Dose-response** — severity and frequency rise with dose, from a *no-effect threshold* up to a wholly lethal level.

Critical periods (timing of exposure):

Stage	Timing (post-conception)	Dominant effect
Pre-implantation / blastogenesis	0–2 weeks	“All-or-none” — embryonic death and resorption, <i>or</i> complete recovery; structural defects uncommon
Embryonic period (organogenesis)	3–8 weeks	Maximum vulnerability to major structural malformations — organ-specific defects depending on what is forming
Fetal period	9 weeks–term	Functional deficits, growth restriction, minor anomalies (CNS, palate, teeth, external genitalia remain vulnerable)

This is why poor periconceptional glycaemic control in diabetes acts during the **critical first 5–8 weeks of embryonic growth**, increasing spontaneous abortion and congenital malformation, and why cytotoxic chemotherapy is *virtually never* given in the first trimester.

Mechanisms of teratogenesis

Teratogens converge on a limited number of cellular/molecular pathways:

- ▶ **Folate antagonism / impaired one-carbon metabolism** — antifolate and antiepileptic drugs (methotrexate, valproate, carbamazepine, phenytoin, trimethoprim) impair DNA synthesis and neural-tube closure → neural tube defects (NTDs) and orofacial clefts.
- ▶ **Disruption of the morphogen/retinoic-acid signalling pathway** — retinoids (isotretinoin) deregulate neural-crest migration → craniofacial, cardiac, thymic and CNS defects.

- ▶ **Neural-crest cell disruption** — impaired migration/apoptosis of crest cells underlies many craniofacial and conotruncal cardiac malformations (e.g., retinoids, alcohol).
- ▶ **Vascular disruption / hypoxia–ischaemia** — vasoconstriction or thrombosis interrupts blood supply to developing structures (limb-reduction and bowel-atresia patterns; cocaine, misoprostol).
- ▶ **Oxidative stress and free-radical injury** — reactive intermediates (e.g., of phenytoin, alcohol) damage embryonic macromolecules.
- ▶ **Receptor- or enzyme-mediated and endocrine disruption** — ACE-inhibitor/ARB blockade of the fetal renin–angiotensin system → renal tubular dysgenesis and oligohydramnios; androgens → virilisation; antithyroid drugs → fetal goitre/aplasia cutis.
- ▶ **Inhibition of cell proliferation / programmed cell death and impaired DNA synthesis** — cytotoxic chemotherapy, ionizing radiation.
- ▶ **Direct cytotoxic and tissue-tropic effects** — tetracycline chelates calcium in mineralising tissues (teeth, bone); aminoglycosides are cochleo-vestibulotoxic; intrauterine infection (e.g., rubella, CMV, Zika) directly destroys fetal tissue.

Major teratogenic agents and their characteristic effects

Agent	Characteristic effect on conceptus
ACE inhibitors / ARBs	Renal tubular dysgenesis, oligohydramnios, calvarial hypoplasia, IUGR, stillbirth and congenital anomalies — <i>contraindicated</i> in pregnancy
Warfarin	Fetal warfarin syndrome — <i>chondrodysplasia (chondromalacia) punctata</i> , nasal hypoplasia, stippled epiphyses; CNS injury and neonatal bleeding; avoid in 1st trimester (used only for mechanical valves; bridge to heparin at 36 weeks)
Valproate / other antiseizure drugs	NTDs (spina bifida), orofacial clefts, neurodevelopmental impairment — <i>discontinue before conception</i> ; prefer lamotrigine/levetiracetam
Phenytoin	<i>Fetal hydantoin syndrome</i> — digital/nail hypoplasia, facial dysmorphism, growth/cognitive deficit
Methimazole / carbimazole	<i>Aplasia cutis</i> , choanal/oesophageal atresia (crosses placenta more than PTU)
Isotretinoin / systemic retinoids	Retinoic-acid embryopathy — CNS, craniofacial (ear), cardiac and thymic defects; strict pregnancy-prevention programme
Methotrexate / aminopterin	Cranial dysostosis, limb defects, IUGR (aminopterin syndrome)
Lithium	Cardiac defects, classically <i>Ebstein's anomaly</i>

Agent	Characteristic effect on conceptus
Tetracyclines	Deciduous-tooth discoloration and bone-growth inhibition (2nd–3rd trimester)
Aminoglycosides (streptomycin)	Eighth-nerve (cochleo-vestibular) ototoxicity, may be irreversible
Thalidomide	Limb-reduction defects — <i>phocomelia/amelia</i> (historical prototype teratogen)
Diethylstilbestrol (prenatal)	Vaginal clear-cell adenocarcinoma and genital-tract anomalies in exposed daughters
Alcohol	Fetal alcohol spectrum disorder — IUGR, microcephaly, characteristic facies, intellectual disability
Cytotoxic chemotherapy / ionizing radiation	First-trimester exposure → abortion and malformation; both generally avoided
Infections (TORCH)	<i>Rubella</i> (cataract, cardiac, deafness), <i>CMV</i> (microcephaly, intracranial calcification, chorioretinitis), <i>Zika</i> (severe microcephaly, CNS malformation, fetal death), toxoplasma, syphilis, VZV, HSV

Risk factors for teratogenesis

- ▶ **Drug/medication exposure** — particularly the high-risk drugs above; polypharmacy and self-medication in early, often unrecognised, pregnancy.
- ▶ **Maternal disease/metabolic state** — *pregestational diabetes* with poor periconceptional control, *obesity*, untreated maternal PKU, and thyroid disease all raise the malformation rate.
- ▶ **Maternal infection** — primary first-trimester rubella, CMV, Zika, toxoplasmosis, syphilis.
- ▶ **Physical agents** — therapeutic/diagnostic *ionizing radiation* and sustained maternal *hyperthermia*.
- ▶ **Environmental/recreational toxins** — alcohol, tobacco, organic mercury (Minamata), lead, certain solvents.
- ▶ **Nutritional deficiency** — periconceptional *folate deficiency* (and antifolate drug use) — the lower the maternal folate, the greater the NTD risk.
- ▶ **Genetic susceptibility of the conceptus and timing/dose of exposure** (per Wilson's principles).
- ▶ **Advanced maternal age** — chiefly increases chromosomal (aneuploidy) risk rather than environmental teratogenesis.

Prevention and preconception counselling

Prevention is overwhelmingly *preconceptional and primary*:

- ▶ **Periconceptional folic acid** — 0.4 mg/day before and at conception (continued through the first 12 weeks) reduces NTDs (anencephaly, meningomyelocele, encephalocele, spina bifida) by ~80% and also lowers cleft-palate/lip risk; **high-risk women** (previous NTD-affected fetus, diabetes, sickle-cell disease, on antiepileptic drugs) need 4–5 mg/day. Population-level **food fortification** addresses poor supplement compliance.
- ▶ **Preconception optimisation of maternal disease** — tight glycaemic control before conception in diabetes; review and *switch teratogenic drugs* (stop ACE-I/ARB, valproate, warfarin, isotretinoin, statins; substitute pregnancy-compatible agents) ideally before conception.
- ▶ **Rational, lowest-effective-dose prescribing** in any woman of reproductive potential; treat the mother adequately (untreated maternal disease may itself harm the fetus).
- ▶ **Pregnancy-prevention programmes** for proven teratogens — e.g., the regulated isotretinoin programme: two negative pregnancy tests before initiation and a negative test before every refill, with mandated contraception.
- ▶ **Drug-safety classification** — the former FDA pregnancy categories A, B, C, D, X (X = contraindicated) have largely been replaced by the 2015 Pregnancy & Lactation Labeling Rule (PLLR) narrative format.
- ▶ **Immunisation** — ensure rubella and varicella immunity *before* pregnancy (MMR ≥3 months pre-conception); give influenza, COVID-19 and Tdap in pregnancy. Antenatal screening for rubella, syphilis, hepatitis B/C, HIV.
- ▶ **Avoid teratogenic exposures** — abstain from alcohol/tobacco; minimise diagnostic ionizing radiation; counsel on travel to Zika-endemic areas.
- ▶ **Antenatal surveillance** — maternal serum screening, detailed anomaly ultrasound (and fetal echocardiography in high-risk groups) for early detection.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **“Critical periods of human development” timeline** — a horizontal bar from fertilisation to term divided into: *Weeks 0–2 (pre-implantation = “all-or-none”), Weeks 3–8 (embryonic period = organogenesis = maximal structural-malformation risk, shown as solid red bars), Weeks 9–38 (fetal period = functional defects/growth restriction, shown as lighter bars)*. Add organ-specific sensitivity bars labelled *CNS, heart, limbs, eyes, ears, teeth, palate, external genitalia*.
- ▶ **Wilson’s-principles concept map** — central box “*TERATOGEN*” with arrows to the four outcome labels: *Death, Malformation, Growth retardation, Functional deficit*, and side labels *Genotype, Timing, Mechanism, Access/Placental transfer, Dose-response*.

Clinical / Diagnostic significance

- ▶ Establishing teratogenic causation requires consistent exposure during the relevant critical window, a recognisable pattern of anomalies, and a biologically plausible mechanism.
- ▶ A drug history must be taken in *every* woman of reproductive age; the highest-risk window (organogenesis) often precedes recognition of the pregnancy — hence preconception, not antenatal, intervention.
- ▶ Detection: maternal serum markers, **anomaly ultrasound**, fetal echocardiography, and amniocentesis/cordocentesis where indicated; congenital rubella confirmed by IgM on fetal blood, CMV/Zika by maternal serology/NAAT with serial ultrasound.
- ▶ Management pearls: substitute pregnancy-safe alternatives (labetalol/nifedipine for hypertension instead of ACE-I/ARB; LMWH instead of warfarin except mechanical valves; PTU in the first trimester for hyperthyroidism); supplement folic acid 4 mg/day with antiepileptic drugs; counsel on the option of therapeutic termination after high-risk first-trimester exposure.

High-yield exam pointers

- ▶ **Teratogen** = agent causing permanent structural/functional fetal abnormality; four end-points = *death, malformation, growth retardation, functional deficit*.
- ▶ **Organogenesis (weeks 3–8 post-conception) = period of maximum structural-malformation risk**; weeks 0–2 = “all-or-none”; fetal period = functional/growth effects.
- ▶ **Wilson’s six principles**: genotype, timing, mechanism, access, four end-points, dose–response.
- ▶ **ACE-I/ARB** → renal dysgenesis/oligohydramnios/stillbirth; **warfarin** → chondrodysplasia punctata + nasal hypoplasia; **valproate** → NTDs; **isotretinoin** → retinoic-acid embryopathy; **lithium** → Ebstein’s anomaly; **thalidomide** → phocomelia; **DES** → vaginal clear-cell adenocarcinoma; **tetracycline** → stained teeth; **aminoglycoside** → VIII-nerve deafness; **methimazole** → aplasia cutis.
- ▶ **Folic acid 0.4 mg/day** (high-risk **4–5 mg/day**) periconceptionally cuts NTDs ~80%.
- ▶ Prevention is *preconceptional*: optimise maternal disease, switch teratogenic drugs, ensure rubella/varicella immunity, avoid alcohol and unnecessary radiation.
- ▶ Old FDA categories **A–B–C–D–X** superseded by the **PLLR (2015)** narrative labelling.

SOURCE & COVERAGE

- ▶ **Harrison’s Principles of Internal Medicine, 22e** — “Medical Disorders During Pregnancy” (drug management in pregnancy: ACE-I/ARB, warfarin, antithyroid drugs, valproate/antiseizure drugs, chemotherapy/radiation, TORCH infections, diabetes and obesity in pregnancy); “Megaloblastic Anemias / Vitamin B12 and Folic Acid” (folic acid and NTD prevention); “Disorders of the Skin” (isotretinoin teratogenicity and pregnancy-prevention programme); “Treatment and Prophylaxis of Bacterial Infections / antimicrobials in pregnancy” (tetracyclines, aminoglycosides); “Approach to the Patient

with Cancer / cancer prevention” (diethylstilbestrol → vaginal clear-cell carcinoma; folic acid in prevention).

- ▶ **Coverage note:** Harrison 22e covers individual agent-specific teratogens and pregnancy drug-management well but does **not** contain a dedicated account of teratogenesis *mechanisms*, **Wilson’s principles of teratology**, the formal **critical-period framework**, or the named dysmorphic syndromes (fetal hydantoin/warfarin syndromes, FAS, Ebstein with lithium, aminopterin syndrome, thalidomide-phocomelia) and the FDA category/PLLR scheme — these are presented from **universally accepted standard internal-medicine/teratology** and are flagged here for transparency. No specialty teratology textbook was listed in the spec corpus.

Therapeutic Index

Asked in: Paper I Nov 2020 — RGUHS MD General Medicine

Definition / Introduction — The **therapeutic index (TI)** — also called the **therapeutic ratio** or, when expressed as a concentration range, the **therapeutic window** — is a quantitative measure of the *safety* of a drug. It expresses the separation between the dose (or plasma concentration) that produces the **desired therapeutic effect** and the dose (or concentration) that produces **toxicity**. A drug is “well-tolerated” when there is a **wide margin** between these two dose–response relations; conversely, when the curves lie close together the drug has a **narrow therapeutic index** and even small dosage increments may sharply increase the likelihood of harm. The concept therefore underpins rational dose selection, safety monitoring and the practice of therapeutic drug monitoring (TDM).

Quantitative basis — definitions and formulae

- ▶ Drug effects (both beneficial and adverse) follow a series of **quantal dose–response (cumulative frequency) curves**, where the proportion of a population showing a defined response is plotted against log dose/concentration (Fig. 71-1, Harrison).
- ▶ Three reference doses are read from these sigmoid curves:
 - **ED₅₀** (median *effective* dose) — dose producing the specified therapeutic effect in 50% of the population.
 - **TD₅₀** (median *toxic* dose) — dose producing a defined toxic effect in 50%.
 - **LD₅₀** (median *lethal* dose) — dose killing 50% (derived from animal/preclinical data).

Index	Formula	Meaning / use
Therapeutic Index (clinical)	$TI = TD_{50} / ED_{50}$	Higher ratio = safer drug

Index	Formula	Meaning / use
Therapeutic Index (preclinical)	$TI = LD_{50} / ED_{50}$	Animal data during drug development
Certain Safety Factor / Margin of Safety	$CSF = LD_1 / ED_{99}$ (or TD_1/ED_{99})	More reliable than TI; accounts for curve <i>slope</i> and overlap of extremes
Standard Safety Margin	$[(LD_1 - ED_{99})/ED_{99}] \times 100$	% dose increase from near-maximal efficacy to onset of lethality

- ▶ The TI is a **ratio with no units**; the larger the value, the greater the cushion between efficacy and toxicity.
- ▶ The plain TI (TD_{50}/ED_{50}) can be **misleading** when the two curves are not parallel, because it ignores the extremes of the population. The **certain safety factor** (LD_1/ED_{99}) corrects for this by comparing the dose that *just begins* to be toxic with the dose giving *near-maximal* benefit, and is the more clinically meaningful safety index.

Graphical representation (wide vs narrow ratio)

- ▶ **Wide therapeutic ratio:** the desired-effect and adverse-effect curves are **widely separated** — therapeutic doses carry a low probability of toxicity (e.g., penicillins, most modern antimicrobials).
- ▶ **Narrow therapeutic ratio:** the curves are **close / overlapping**, so the chance of toxicity at therapeutic doses is high; a **steep dose–response curve for adverse effects** is especially dangerous because a small dosage increment produces a large jump in toxicity risk.
- ▶ When a reproducible **concentration–effect** relationship exists, *plasma concentration* may be substituted for dose on the x-axis, which is the rationale for using measured drug levels (TDM) to steer therapy.

Narrow-therapeutic-index drugs and their target ranges

These agents require dose individualisation, level monitoring and caution with interactions/organ dysfunction.

Drug	Usual therapeutic range	Notes / monitoring caveat
Digoxin	HF 0.5–0.9 ng/mL; AF 0.5–2 ng/mL	Hypokalaemia potentiates toxicity; toxicity is a <i>clinical</i> diagnosis
Lithium	0.5–1.2 mmol/L	Thiazides/loop diuretics raise levels

Drug	Usual therapeutic range	Notes / monitoring caveat
Phenytoin	10–20 mg/L (5–10 in uraemia/hypoalbuminaemia); free target 0.5–2.0 mg/L	Capacity-limited (zero-order) kinetics; monitor <i>free</i> drug if low albumin/renal failure
Theophylline	5–15 mg/L (panic ≥ 30)	Clearance $\uparrow$ in smokers, $\downarrow$ in HF/cirrhosis
Valproic acid	50–100 mg/L (≤ 125 bipolar; panic > 150)	Concentration-dependent protein binding
Carbamazepine	4–12 mg/L	Auto-induces own metabolism
Gentamicin	Peak 4–8 mg/L, trough < 2 mg/L	Nephro-/oto-toxicity with high troughs
Vancomycin	Trough 10–20 mg/L	Trough-guided dosing; nephrotoxicity risk
Cyclosporine / Tacrolimus	CsA 100–300 ng/mL; Tac trough 8–12 ng/mL	Whole-blood (EDTA) trough; concentration-related nephrotoxicity
Warfarin	(INR-guided, not level)	Numerous CYP2C9/VKORC1 and drug interactions

Therapeutic window and therapeutic drug monitoring (TDM)

- ▶ The **therapeutic window** is the **concentration range** lying *above* the minimum effective concentration but *below* the toxic threshold; TDM aims to keep plasma levels within it.
- ▶ TDM is most valuable for drugs with: a **narrow therapeutic index**, a good **concentration–effect correlation**, **no easily measured clinical endpoint**, and **wide pharmacokinetic variability** — typically **anticonvulsants**, **antiarrhythmics**, **anti-rejection agents** and **certain antibiotics** (Harrison).
- ▶ **Timing matters**: for most maintenance dosing, sample at **trough** (just before the next dose at steady state) to confirm maintained efficacy — e.g., anticonvulsants and **vancomycin** (trough used because sustained high levels risk nephrotoxicity). When **peak**-related toxicity is the concern (e.g., QT prolongation with **sotalol/dofetilide**), the ECG/level is checked **~1–2 h post-dose** at steady state.
- ▶ **Steady state** is reached in **~4–5 elimination half-lives**; a level drawn before steady state under-reads the eventual value. A **loading dose** speeds attainment of effect but does *not* change the time to true steady state.
- ▶ **First- vs zero-order kinetics**: in first-order elimination, doubling the dose doubles the steady-state level (linear, predictable). For **zero-order (saturable)** drugs — **phenytoin**, **aspirin**,

fluoxetine, ethanol — a small dose increase causes a **disproportionate**, sometimes toxic, rise in concentration; this *functionally narrows* the therapeutic index and mandates small increments.

Factors that narrow or shift the therapeutic index

- ▶ **Altered clearance:** renal disease (digoxin, dofetilide, sotalolol → QT/arrhythmia), hepatic disease (↑ oral bioavailability of high first-pass drugs — morphine, midazolam, nifedipine), heart failure/shock (contracted volume of distribution → higher plasma/CNS levels).
- ▶ **Altered protein binding:** only free (unbound) drug is active; in renal/hepatic disease or hypoalbuminaemia a fall in binding from 99→98% **doubles** free drug — hence free-level monitoring for phenytoin/valproate.
- ▶ **Drug interactions:** CYP and P-glycoprotein **inhibitors** (amiodarone, azoles, macrolides, cimetidine) raise levels of narrow-index substrates (warfarin, digoxin, dabigatran), while **inducers** (rifampin, carbamazepine, phenytoin, St John's wort) lower them — both pushing the patient outside the window.
- ▶ **“High-risk pharmacokinetics”:** when an active narrow-index drug relies on a **single elimination pathway**, any genetic, disease or drug-interaction block of that pathway causes marked, sometimes toxic, accumulation.
- ▶ **Extremes of age & genetics:** the elderly (polypharmacy, reduced organ function) and pharmacogenomic variants (e.g., CYP2C9/VKORC1 for warfarin, TPMT for thiopurines) effectively shrink the safe margin.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Two stacked quantal dose–response graphs** (x-axis = *log dose/concentration*, y-axis = *cumulative % of population responding*). On EACH panel draw two sigmoid curves: a left “Desired/therapeutic effect” curve and a right “Adverse/toxic effect” curve.
 - **Top panel — Wide therapeutic ratio:** curves *widely separated*. Label ED_{50} and TD_{50} ; show the wide gap.
 - **Bottom panel — Narrow therapeutic ratio:** curves *close/overlapping* with a steep toxicity curve. Labels: ED_{50} , TD_{50} (or LD_{50}), **Therapeutic window/index** = TD_{50}/ED_{50} , **Margin of safety** = LD_1/ED_{99} , and arrows marking *minimum effective concentration* and *minimum toxic concentration*.

Clinical / Diagnostic significance

- ▶ **Drug selection & dosing:** prefer wide-TI drugs where possible; for narrow-TI agents, “start low, go slow,” use the smallest effective dose and titrate against levels or a clinical endpoint.
- ▶ **TDM** converts an abstract index into bedside practice — confirming adherence, diagnosing toxicity vs under-dosing, and guiding dose in renal/hepatic impairment.

- ▶ **Adverse drug reactions:** narrow-TI drugs are over-represented among the commonest culprits of ADR-related hospital admission (digoxin, warfarin, NSAIDs, opiates). **Type A** (dose-dependent, exaggerated pharmacology) reactions are the ones predicted by a low TI; **Type B** (idiosyncratic, dose-independent) reactions are *not* captured by the TI.
- ▶ **Drug development & regulation:** the preclinical LD_{50}/ED_{50} in animals is an early safety screen; a low TI demands tighter clinical-trial monitoring and may preclude approval.
- ▶ **Antidotes/rescue tied to the index:** digoxin-specific Fab (Digibind) for digoxin toxicity, leucovorin/glucarpidase rescue for methotrexate, and N-acetylcysteine for paracetamol all reflect the consequences of crossing a narrow window.

High-yield exam pointers

- ▶ $TI = TD_{50}/ED_{50}$ (clinical) or LD_{50}/ED_{50} (animal) — higher = safer; it is a **unitless ratio**.
- ▶ The **certain safety factor** (LD_1/ED_{99}) / standard safety margin is **more reliable** than TI because it accounts for curve slope and the extremes of the population.
- ▶ **Therapeutic window** = the *concentration range* above minimum effective and below toxic level; basis of TDM.
- ▶ Classic narrow-TI drugs: digoxin, lithium, warfarin, phenytoin, theophylline, aminoglycosides, vancomycin, cyclosporine/tacrolimus, antiarrhythmics, methotrexate.
- ▶ **Zero-order (saturable) kinetics** (phenytoin, aspirin, ethanol, fluoxetine) cause disproportionate level rises → behave as narrow-window drugs.
- ▶ Sample at **trough** for efficacy/most anticonvulsants and vancomycin; at **peak** (1–2 h) when peak toxicity (sotalol/dofetilide QT) is feared; interpret only at **steady state** (~4–5 half-lives).
- ▶ **Hypokalaemia worsens digoxin toxicity**; monitor **free phenytoin** in hypoalbuminaemia/renal failure; enzyme **inhibitors/inducers** and renal/hepatic disease shift the window.
- ▶ A **steep adverse-effect dose–response curve** is the single most dangerous feature — small dose rises cause large toxicity jumps.

SOURCE & COVERAGE

- ▶ **Harrison's Principles of Internal Medicine, 22e** — “Principles of Clinical Pharmacology” (Roden): therapeutic ratio/index/window concept and Fig. 71-1; dose–response relations; TDM, trough vs peak sampling (vancomycin, sotalol/dofetilide); first- vs zero-order kinetics; steady state and loading dose; high-risk pharmacokinetics; protein binding and free drug; Type A vs Type B ADRs; effects of renal/hepatic disease and drug interactions.
- ▶ **CMDT 2026** — Appendix: Therapeutic Drug Monitoring (Table e5–1): therapeutic concentration ranges, half-lives and monitoring caveats for digoxin, lithium, phenytoin, theophylline, valproate, carbamazepine, gentamicin, vancomycin, cyclosporine/tacrolimus and methotrexate.

- **Coverage note:** Harrison presents the therapeutic index *qualitatively* (therapeutic ratio/window with the dose–response figure). The *quantitative* formulae — $TI = TD_{50}/ED_{50}$ (or LD_{50}/ED_{50}), the certain safety factor = LD_1/ED_{99} and standard safety margin — are universally accepted standard pharmacology (Goodman & Gilman / KDT / Katzung) included here for completeness, as the corpus chapter does not state these ratios explicitly.

Transplant Organ Rejection: Types and Pathogenesis

Asked in: Paper I Nov 2021 — RGUHS MD General Medicine

Definition / Introduction — *Rejection* is the immune-mediated injury of a transplanted allograft caused by the recipient's recognition of donor **alloantigens** (chiefly mismatched **HLA** molecules) as foreign. It is classified by **tempo** (hyperacute, accelerated, acute, chronic) and by the **dominant effector arm** (T cell-mediated/cellular vs antibody-mediated/humoral). Understanding the pathogenesis underpins HLA matching, cross-matching, desensitization, and the entire framework of immunosuppression that has made transplantation the treatment of choice for end-stage organ failure.

Immunological basis — the alloimmune response

- **The target — HLA/MHC:** The major histocompatibility antigens are encoded on the short arm of **chromosome 6** (the HLA region). **Class I** (HLA-A, B, C) is expressed on all nucleated cells and presents to **CD8+** cells; **Class II** (HLA-DR, DQ, DP) is expressed on antigen-presenting cells (APCs) and presents to **CD4+** cells. HLA is highly **polymorphic**, so it becomes the principal immunologic target when mismatched. The number of mismatches at A, B and DR loci correlates with graft loss. ABO blood-group antigens and “minor” (non-HLA) antigens (e.g., endothelial antigens, the LIMS-1 locus) provide additional targets.
- **Allorecognition — two pathways (Fig. 325-1):**
 - **Direct pathway** — recipient T cells recognise *intact* donor MHC on **donor (passenger)** APCs: CD8 T cells recognise donor class I; CD4 T cells recognise donor class II. This drives **early, vigorous acute rejection**.
 - **Indirect pathway** — donor MHC is shed, processed and presented as **peptides** by **recipient (self)** APCs to CD4 T cells. This mirrors normal physiologic antigen recognition and sustains **chronic rejection** and **antibody production**.
- **Two-signal T-cell activation:** Signal 1 = TCR binding to alloantigen–MHC; **Signal 2** (costimulation) = CD28 on the T cell engaging CD80/CD86 on the APC. Both signals activate **calcineurin**, upregulating IL-2 and IFN- γ ; IL-2 acts via the **mTOR (target of rapamycin)**

pathway to drive clonal proliferation — the molecular targets of CNIs, belatacept and mTOR inhibitors respectively.

- **Two effector arms: T cell-mediated** (CD8 cytotoxic killing + CD4-driven cytokine inflammation) and **antibody-mediated** (follicular helper T cells [T_{fh}] → B-cell/plasma-cell differentiation → **donor-specific antibody [DSA]** → complement-dependent and -independent endothelial injury, marked by **C4d** deposition).

Classification of rejection by tempo and mechanism

Type	Onset	Dominant mechanism	Key pathology	Reversibility
Hyperacute	Minutes–hours	Preformed anti-donor antibody (ABO / anti-HLA class I) + complement	Vascular thrombosis, fibrinoid necrosis, cortical infarction	Irreversible — graft loss; prevent by cross-match
Accelerated	2–5 days	Anamnestic (memory) T-cell + antibody response in a sensitised recipient	Vascular + cellular injury	Often refractory to treatment
Acute — cellular (TCMR)	Days–weeks to months	Recipient CD4/CD8 T cells vs donor HLA	Interstitial mononuclear infiltrate, tubulitis, endothelialitis (Banff)	Usually reversible with steroids ± ATG
Acute — antibody-mediated (AMR)	Days–weeks	De novo / preformed DSA + complement	C4d+ peritubular capillaries, capillaritis, glomerulitis	Harder to treat; plasmapheresis, IVIG, rituximab
Chronic	Months–years	Combined indirect alloimmunity, chronic active AMR, non-immune injury	Interstitial fibrosis, tubular atrophy, vasculopathy (intimal proliferation), glomerulopathy	Largely irreversible ; slowly progressive

Pathogenesis of each type

- **Hyperacute rejection:** Caused by **preformed circulating antibodies** against donor antigens — natural anti-ABO isohaemagglutinins or **anti-HLA** antibodies from prior **transfusion**, **pregnancy**, **prior transplant**, or (rarely) vaccination/infection. Antibody binds graft endothelium, fixes complement, and triggers a fulminant **vasculitic thrombotic** event with immediate, irreversible graft loss. A **positive cytotoxic cross-match** (recipient serum + donor T

lymphocytes) predicts it and is **the only widely accepted absolute immunologic contraindication** to transplantation. Now largely *abolished* by routine ABO matching and cross-matching.

- ▶ **Accelerated rejection:** A rapid (2–5 day) anamnestic response in a **presensitised** recipient — secondary exposure to a previously primed antigen produces an immune response often **refractory to conventional treatment**. (A standard recognised category; Harrison emphasises the underlying mechanism of prior sensitisation rather than the eponymous label.)
- ▶ **Acute T cell-mediated (cellular) rejection (TCMR):** Recipient T cells respond to donor HLA. CD4+ cells recognise class II (HLA-DR) mismatch, proliferate and release proinflammatory cytokines; CD8+ cytotoxic cells recognise class I (HLA-A, -B) and lyse donor target cells via **perforin/granzyme B** and direct contact. Histology = immune-cell infiltration of the **interstitial, tubular and vascular** compartments (graded by the **Banff** classification). Clinically a **rise in serum creatinine** ± reduced urine output; treated with high-dose **methylprednisolone (0.5–1 g/day × 3 days)**, with ATG for steroid-resistant cases.
- ▶ **Acute antibody-mediated rejection (AMR):** Donor antigens drain to recipient lymph nodes, activating T_{fh} cells that drive B cells into **antibody-secreting plasma cells**. The resulting **DSA** (anti-HLA and non-HLA) deposit in the graft, injuring endothelium through complement-dependent and -independent routes. Diagnostic triad: (1) **C4d deposition** in peritubular capillaries/GBM, (2) **histologic microvascular injury** (capillaritis/glomerulitis), and (3) **circulating DSA**. Treatment is challenging — **plasmapheresis, IVIG, anti-CD20 (rituximab)** to deplete B cells, and **bortezomib** to target plasma cells.
- ▶ **Chronic rejection / chronic allograft dysfunction:** A slow, largely irreversible decline driven by **chronic active AMR**, indirect alloimmunity, and non-immune insults (CNI nephrotoxicity, hypertension, recurrent disease). Pathology = **interstitial fibrosis, tubular atrophy, transplant vasculopathy** (intimal proliferation, medial hypertrophy) and **glomerulopathy**. In the liver, the equivalent is **ductopenia** — the “**vanishing bile duct syndrome**” (progressive cholestasis, focal necrosis, vascular intimal fibrosis/foam cells), commoner after transplant for autoimmune liver disease and with limited reversibility.

Diagnosis and grading

- ▶ **Allograft biopsy is the gold standard** for distinguishing acute TCMR from AMR and from non-rejection causes (acute tubular injury, CNI toxicity, **BK polyomavirus** nephropathy, recurrent glomerular disease).
- ▶ **Banff classification** grades cellular rejection by the compartments infiltrated; **C4d immunostaining** of peritubular capillaries is the footprint of complement activation in AMR.
- ▶ **Immunologic work-up:** **Panel-reactive antibody (PRA)** quantifies sensitisation; **cytotoxic vs flow-cytometric cross-match** (more sensitive, detects anti-HLA IgG); **eplet matching** (especially class II DQ) refines risk.

- ▶ **Emerging non-invasive biomarkers:** donor-derived cell-free DNA, urinary chemokine CXCL9, urine exosome profiling — adjuncts to (not replacements for) biopsy.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Allorecognition pathways (redraw Fig. 325-1):** Label — *Donor APC* (MHC I + MHC II), *Recipient (self) APC*, *Direct pathway* (CD8 T cell → donor MHC I; CD4 T cell → donor MHC II), *Indirect pathway* (self-APC presenting processed allopeptide on MHC II to CD4 T cell), *Th1/Th2/Th17, Tfh* → *naïve B cell* → *plasma cell* → *antibody-mediated rejection*, *Cytotoxic CD8 T cell* → *perforin/granzyme B* → *cellular rejection and organ damage*.
- ▶ **Timeline bar of rejection types:** a horizontal time axis labelled — *Minutes–hours* = *Hyperacute (preformed Ab)*, *2–5 days* = *Accelerated (sensitised)*, *Days–weeks–months* = *Acute (TCMR / AMR)*, *Months–years* = *Chronic (fibrosis, vasculopathy)*; annotate dominant mechanism and reversibility above each band.

Clinical / Diagnostic significance

- ▶ **Prevention starts before surgery:** ABO compatibility, HLA typing (now molecular/genomic), and a negative cross-match. **Desensitization** (plasmapheresis + IVIG ± rituximab) and **kidney paired donation** allow safe transplantation of sensitised candidates.
- ▶ **Immunosuppression** is lifelong (except identical twins). **Induction** = depleting (ATG, alemtuzumab/anti-CD52) or non-depleting (**basiliximab**, anti-IL-2R α) agents; **Maintenance** = a **calcineurin inhibitor** (tacrolimus/cyclosporine) + **antimetabolite** (mycophenolate) ± steroids, with **mTOR inhibitors** (sirolimus/everolimus) or **belatacept** (CTLA-4-Ig blocking CD28 costimulation; BENEFIT trial) as alternatives.
- ▶ **Treatment of established rejection:** TCMR → pulse methylprednisolone, then ATG if refractory; AMR → plasmapheresis + IVIG + rituximab ± bortezomib.
- ▶ **Complications of the immunosuppressed state:** time-dependent **opportunistic infection** (CMV, BK virus, *Pneumocystis*, fungal), and **malignancy** (skin/lip cancers, EBV-driven PTL) — the balance against rejection must always be weighed.
- ▶ **Contrast — graft-versus-host disease (GVHD):** the *reverse* of rejection. In allogeneic haematopoietic-stem-cell/bone-marrow transplantation, **immunocompetent donor T cells** **attack recipient (host) tissues** (skin, gut, liver), producing acute and chronic GVHD — host-versus-graft is rejection, graft-versus-host is GVHD.

High-yield exam pointers

- ▶ **Three classic types** = Hyperacute, Acute, Chronic; add Accelerated (sensitised) for completeness. Acute subdivides into **cellular** (TCMR) and **antibody-mediated** (AMR).

- ▶ **Hyperacute** = preformed antibody + positive cytotoxic cross-match = only absolute immunologic contraindication; occurs in minutes–hours; now largely abolished by cross-matching.
- ▶ **TCMR**: CD4 → class II, CD8 → class I; Banff-graded interstitial/tubular infiltrate; steroid-responsive.
- ▶ **AMR diagnostic triad**: C4d+ peritubular capillaries, microvascular injury, circulating DSA.
- ▶ **Direct allorecognition** drives early acute rejection; **indirect** drives chronic rejection and antibody formation.
- ▶ **Two-signal model**: TCR–MHC (signal 1) + CD28–CD80/86 (signal 2) → calcineurin → IL-2 → mTOR — the drug-target map.
- ▶ **Chronic rejection** = interstitial fibrosis, tubular atrophy, **transplant vasculopathy**; liver equivalent = **vanishing bile duct syndrome (ductopenia)**; largely irreversible.
- ▶ **HLA on chromosome 6**: class I = A, B, C; class II = DR, DQ, DP; mismatch number predicts graft survival.
- ▶ **GVHD is the mirror image of rejection** (donor T cells vs host), seen in allogeneic HSCT.

SOURCE & COVERAGE

- ▶ **Harrison's Principles of Internal Medicine, 22e** — “Kidney Transplantation” (Immunology of Rejection: hyperacute, T cell-mediated and antibody-mediated rejection, direct/indirect allorecognition, HLA matching, cross-matching, Banff/C4d/DSA, immunosuppression, chronic allograft injury); “Liver Transplantation” (allograft rejection — acute endothelialitis/bile-duct injury and chronic ductopenic *vanishing bile duct syndrome*); “Introduction to the Immune System” (type II cytotoxic and type IV delayed-type hypersensitivity mechanisms; MHC class I/II antigen presentation; GVHD references).

Coverage note: The corpus has **no single dedicated “transplantation immunology / rejection” chapter**; the richest, fully grounded source is the **Kidney Transplantation** chapter, supplemented by the **Liver Transplantation** and **immune-system** chapters. Specific *timings* (e.g., hyperacute minutes–hours, accelerated 2–5 days) and the **accelerated rejection** category are universally accepted standard internal-medicine teaching included to satisfy the full scope of the question; the chapters explicitly emphasise hyperacute, acute (cellular + AMR) and chronic rejection and the mechanism of prior sensitisation.

Genetic Testing in Pregnancy — Indications, Methods and Ethical Issues

Asked in: Paper I 06 Apr 2026 — RGUHS MD General Medicine

Definition / Introduction — **Prenatal genetic testing** is the application of cytogenetic, molecular and biochemical techniques during pregnancy to detect chromosomal abnormalities, single-gene (Mendelian) disorders and structural malformations in the fetus. It encompasses **screening** (population-level risk estimation: maternal serum markers, ultrasound, cell-free DNA) and **diagnostic** testing on fetal cells obtained by amniocentesis, chorionic villus sampling (CVS) or cordocentesis, plus **preimplantation genetic testing (PGT)** on IVF embryos. Because the information generated is sensitive, heritable and may inform decisions about continuation of pregnancy, it is inseparable from **genetic counselling** and a distinct set of **ethical, legal and social implications (ELSI)**.

Indications for genetic testing in pregnancy

Testing is offered when the *a priori* risk of a fetal genetic disorder is increased:

- ▶ **Advanced maternal age** (≥ 35 years) — rising risk of trisomies (21, 18, 13) with maternal age.
- ▶ **Abnormality of the fetus on ultrasound** — structural malformations or soft markers prompting karyotype/microarray.
- ▶ **Increased risk on the maternal serum screen** — an abnormal “quad” test (α -fetoprotein, β -human chorionic gonadotropin, inhibin-A, unconjugated estriol) or first-trimester combined screen.
- ▶ **Family history of a chromosomal abnormality** or a known **balanced parental translocation** (a recognised recurrence-risk situation, e.g. translocation Down syndrome).
- ▶ **A Mendelian disorder amenable to genetic testing** — known familial pathogenic variant (e.g. cystic fibrosis, thalassaemia/haemoglobinopathy, fragile-X, Duchenne muscular dystrophy, Marfan/FBN1, homocystinuria).
- ▶ **Positive carrier screening** in one or both parents, **consanguinity**, or membership of an at-risk ethnic group (e.g. founder mutations).
- ▶ **Recurrent pregnancy loss / previous affected child / infertility undergoing IVF** (overlap with adult and preconceptional indications).

Note: The corpus also lists postnatal indications (multiple congenital anomalies, developmental delay, intellectual disability, autism, short stature, dysmorphism, disorders of sexual development) — useful to contrast prenatal vs paediatric indications in the answer.

Methods I — Sampling techniques (when and how fetal material is obtained)

Method	Timing (gestation)	Technique	Material / typical analysis
Cell-free DNA (cfDNA) screen (NIPT)	from ~10 weeks	Maternal venous blood — non-invasive	Fetal + maternal cfDNA; screens common chromosomal

Method	Timing (gestation)	Technique	Material / typical analysis
			aneuploidies and fetal sex; a <i>screen</i> , not diagnostic
Maternal serum screen / ultrasound	1st–2nd trimester	Non-invasive	Quad markers, nuchal translucency, anomaly scan — risk estimation
Chorionic villus sampling (CVS)	weeks 9–12	Trans-cervical or trans-abdominal biopsy of chorion	Cytogenetic + mutational analysis; <i>earliest</i> diagnostic test — relevant when termination is a consideration
Amniocentesis	~16 weeks	Aspiration of amniotic fluid	Cultured amniocytes for karyotype , FISH , mutational analysis
Percutaneous umbilical blood sampling (PUBS / cordocentesis)	from ~18 weeks	Aspiration of fetal blood	Late-gestation diagnosis (rapid karyotype, fetal anaemia/infection work-up)
Preimplantation genetic testing (PGT)	pre-implantation	Single cell from 4- to 8-cell embryo, or first polar body of the oocyte (with IVF)	Avoids therapeutic abortion; costly and labour-intensive

- ▶ **Non-invasive (screening)** = cfDNA, serum markers, ultrasound — no procedure-related fetal loss; abnormal results require **confirmation** by an invasive diagnostic test.
- ▶ **Invasive (diagnostic)** = CVS, amniocentesis, PUBS — definitive but carry a procedure-related risk.

Methods II — Laboratory analytic techniques

Once fetal cells/DNA are obtained, the genome is interrogated at three levels:

- ▶ **Cytogenetics** — **chromosome level**: *karyotype* analysis (numerical and large structural abnormalities), **fluorescence in situ hybridisation (FISH)** for targeted aneuploidy/microdeletions.
- ▶ **Cytogenomics** — **sub-microscopic level**: **chromosomal microarray / array-based testing** for copy-number variants (deletions/duplications), and **multiplex ligation-dependent probe amplification (MLPA)** for single-exon deletions/duplications.
- ▶ **Molecular** — **sequence level**: PCR amplification from minute DNA samples, **direct (Sanger) DNA sequencing** for known single-gene disorders and prenatal diagnosis, and **next-generation /**

massively parallel sequencing — targeted gene panels, whole-exome sequencing (WES) and whole-genome sequencing (WGS) for undiagnosed syndromes.

- ▶ **Analysis of cfDNA (“liquid biopsy”)** from a maternal sample provides minimally invasive screening for fetal chromosomal abnormalities and sex.
- ▶ The optimal family strategy is to **test an affected family member first** to identify the pathogenic variant, then offer **targeted variant testing** to the fetus/at-risk relatives.

Ethical issues involved

Prenatal genetic testing raises ethical, legal and social concerns that the candidate must be able to enumerate:

- ▶ **Genetic privacy & non-discrimination:** Genetic data is sensitive and should not be accessed without **explicit consent**; disclosure risks **discrimination by insurers or employers**. The U.S. **Genetic Information Nondiscrimination Act (GINA, 2008)** protects *asymptomatic* individuals in health insurance and employment but **does not protect the symptomatic individual** and **does not cover disability, long-term-care or life insurance**; the Affordable Care Act (2014) partly fills this gap.
- ▶ **Informed consent & non-directive counselling:** Couples must understand what the test can and cannot determine, its limitations, the possibility of inconclusive results, and the implications for the fetus and other relatives. Counselling is **non-directive** and supports **reproductive autonomy** — the decision (including continuation vs termination of pregnancy) rests with the parents.
- ▶ **Termination of pregnancy:** Earlier diagnosis (CVS) is valued *because* it allows earlier decision-making; this links prenatal testing to the morally contested issue of **selective termination** and concerns about devaluing disability.
- ▶ **Incidental / secondary findings:** Comprehensive sequencing (WES/WGS) may reveal **medically actionable** conditions but also **untreatable** disorders and **variants of uncertain significance (VUS)** unrelated to the test indication — a recognised ethical dilemma causing anxiety.
- ▶ **Uncertainty & psychosocial harm:** “Excluding a specific disorder is never equivalent to the assurance of a normal child”; results generate **anxiety, despair and survivor guilt**, and most adult-onset results are only *predictive* of risk, not deterministic.
- ▶ **Testing of children for adult-onset disease:** Professional bodies caution against testing for adult-onset disorders in childhood where no childhood intervention exists, to preserve the **future child’s right to decide** (exceptions: MEN-2 → prophylactic thyroidectomy; FAP → colonoscopy from 10–15 yr).
- ▶ **Direct-to-consumer (DTC) testing:** Variable validity, inadequate counselling, confidentiality and **regulatory** concerns (CLIA/CAP accreditation; ACMG position statement).
- ▶ **Equity — the “genomics divide”:** High cost may widen global inequities; WHO initiatives aim to attenuate these.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Diagram 1 — Prenatal testing timeline** (gestation in weeks on a horizontal axis). Labels: *cfDNA / NIPT (~10 wk)*, *CVS — chorionic villus sampling (9–12 wk, trans-cervical/trans-abdominal)*, *First-trimester combined screen (nuchal translucency)*, *Maternal serum “quad” screen (2nd trimester)*, *Amniocentesis (~16 wk, amniotic fluid)*, *Anomaly ultrasound (~18–20 wk)*, *PUBS / cordocentesis (≥ 18 wk, fetal blood)*; annotate **Non-invasive (screening)** vs **Invasive (diagnostic)**.
- ▶ **Diagram 2 — Three-tier methods pyramid**. Labels: base *Chromosome level: karyotype, FISH*; middle *Cytogenomic: chromosomal microarray (CNV), MLPA*; apex *Molecular: PCR, Sanger sequencing, NGS panels / WES / WGS, cfDNA*.

Clinical / Diagnostic significance

- ▶ Distinguishes a **screening** result (cfDNA, serum, ultrasound — gives a risk) from a **diagnostic** result (CVS/amniocentesis/PUBS — confirms or excludes) — abnormal screens **must** be confirmed invasively before irreversible decisions.
- ▶ **CVS earlier than amniocentesis** is decisive when termination is being considered; **PUBS** is reserved for late gestation and fetal blood disorders/infection.
- ▶ In **Down syndrome**, cytogenomic analysis is performed even with simple trisomy 21 to detect an **unbalanced translocation**, because a parent with a **balanced translocation** carries a substantial recurrence risk.
- ▶ **PGT with IVF** allows selection of unaffected embryos, avoiding therapeutic abortion, for couples with a known familial pathogenic variant.
- ▶ Every prenatal test must be wrapped in **pre-test counselling, informed consent and post-test counselling**, with the option of **DNA banking** and onward testing of relatives.

High-yield exam pointers

- ▶ **Amniocentesis ~16 wk; CVS weeks 9–12; PUBS/cordocentesis ≥ 18 wk; cfDNA from maternal blood (non-invasive).**
- ▶ **Quad test = AFP + β -hCG + inhibin-A + unconjugated estriol.**
- ▶ **Amniotic fluid cells $\rightarrow$ karyotype, FISH, mutational analysis.**
- ▶ **Three method tiers: karyotype/FISH $\rightarrow$ microarray/MLPA $\rightarrow$ PCR/Sanger/NGS (panel, WES, WGS).**
- ▶ **GINA (2008) protects asymptomatic people in health insurance/employment; not symptomatic, not life/disability/long-term-care insurance.**
- ▶ **Counselling is non-directive; respect reproductive autonomy; consent must cover incidental findings & VUS.**

- ▶ “Excluding a disorder ≠ guarantee of a normal child.”
- ▶ Test the **affected family member first** to find the variant, then do targeted fetal testing.
- ▶ PGT analyses a single cell from a 4–8-cell embryo or the first polar body.

SOURCE & COVERAGE

- ▶ **Harrison’s Principles of Internal Medicine, 22e** — “Principles of Human Genetics” (indications for testing, amniocentesis/CVS/PUBS/cfDNA timing and technique, quad test, preimplantation/preconceptual diagnosis, mutational-analysis methods, GINA and ethical issues).
- ▶ **Harrison’s Principles of Internal Medicine, 22e** — “The Integration of Inherited Genetics into Clinical Practice” (methodologic approaches: karyotype/FISH/MLPA/microarray/PCR/NGS; pre- and post-test counselling, informed consent, DNA banking, testing children for adult-onset disease, DTC testing/ACMG, VUS, GINA limitations).
- ▶ **CMDT 2026** — “Genetic & Genomic Disorders” (Down syndrome: cytogenomic analysis to detect unbalanced translocation and recurrence risk; cfDNA for fetal sex-chromosome aneuploidy; prenatal diagnosis in single-gene disorders).

Coverage note: This is an internal-medicine corpus; it covers prenatal **methods and ethics** well but does not provide obstetric-grade detail (e.g. exact cfDNA/NIPT detection rates and false-positive rates, nuchal-translucency cut-offs, procedure-related miscarriage rates, or ACOG/ISPD screening protocols). Such figures should be drawn from a dedicated obstetrics/medical-genetics text. The principle that genetic counselling is **non-directive** is stated as universally accepted standard practice rather than verbatim from these chapters.

What are the indications for genetic counselling? List genetic conditions that can be tested and the interventions that can be instituted

Asked in: Paper I May 2025 — RGUHS MD General Medicine

Definition / Introduction — **Genetic counselling** is the communication process by which trained professionals (clinical geneticists and genetic counsellors, working with the primary physician) help individuals and families understand the medical, psychological and familial implications of a genetic contribution to disease, the available testing options, and the risk of recurrence or transmission. It is **non-directive and consent-based**, and—because genetic information affects *entire families*—must precede any predictive genetic testing. Its goals are accurate risk assessment, informed reproductive and medical decision-making, and linkage to **risk-reducing interventions, surveillance and supportive services**.

Indications for genetic counselling and testing

The triggers span the entire life cycle (Harrison Table 479-4) and are best grouped as personal/family-history “red flags” plus stage-specific indications.

Family-history and clinical red flags (refer for counselling when present):

- ▶ **Two or more first-degree relatives** with the same or related condition (asthma, premature cardiovascular disease, type 2 diabetes, breast, colon or melanoma) — relative risk rises 2- to 5-fold.
- ▶ **Young age of disease onset** (e.g., a 30-year-old non-smoking woman with myocardial infarction; breast cancer < 50 years).
- ▶ **Unusual or “sentinel” diagnoses** — male breast cancer, medullary thyroid cancer, bilateral/multifocal tumours.
- ▶ **Multiple related primary cancers in one individual** (e.g., colon *and* endometrial cancer → Lynch syndrome).
- ▶ **Absence of expected non-hereditary risk factors** for a disease (e.g., unprovoked deep-vein thrombosis suggests inherited thrombophilia).
- ▶ **Physical clues** — xanthomas in youth (familial hypercholesterolaemia); trichilemmomas with breast cancer (Cowden/*PTEN*).
- ▶ **High-risk ethnicity** — ~2.5% of Ashkenazi Jews carry one of three founder *BRCA1/BRCA2* pathogenic variants.
- ▶ **A known pathogenic variant already identified in the family** (cascade testing of at-risk relatives).

Indications by life stage (Table 479-4):

Timing	Indications for testing/counselling
Prenatal	Advanced maternal age (> 35 yr); fetal abnormality on ultrasound; abnormal maternal serum/“quad” screen (α -fetoprotein, β -hCG, inhibin-A, unconjugated estriol); family history of chromosomal abnormality; Mendelian disorder amenable to testing
Neonatal & childhood	Multiple congenital anomalies; intellectual disability/developmental delay; autism spectrum disorder; dysmorphic features; failure to thrive; short stature; disorders of sexual development; known familial chromosomal alteration; childhood cancer
Adult	Infertility; recurrent miscarriage; familial cancer; suspected adult-onset Mendelian/cardiac/neurologic disorder; reproductive decision-making

- ▶ **Preconception/reproductive** counselling: carrier screening of couples, consanguinity, prior affected child, and consideration of **preimplantation genetic testing (PGT)** with IVF.
- ▶ **Pharmacogenetic** indications: before drugs with heritable toxicity (e.g., *TPMT*/thiopurines, *DPYD*/fluoropyrimidines).

Components and process of genetic counselling

- ▶ **Confirm the diagnosis first** — clinical, pathological or biochemical, since a precise phenotype directs gene selection.
- ▶ **Construct a three-generation pedigree** documenting first- and second-degree relatives, ages/age of onset, ethnicity, consanguinity and confirmed diagnoses (records, pathology reports, death certificates).
- ▶ **Pretest education and informed consent** — explain purpose, what the test can and cannot reveal, possible results (positive / true-negative / **uninformative negative** / **variant of uncertain significance**, VUS / secondary findings), limitations, and psychosocial, insurance and familial implications.
- ▶ **Optimal testing strategy** — test an **affected family member first**; if a pathogenic variant is found, offer **cascade testing** to relatives. A relative testing negative for a known familial variant reverts to **general-population risk**.
- ▶ **Post-test counselling** — disclose result in the context of personal/family history, formulate a management plan, and arrange follow-up.
- ▶ **Special situation** — **children**: testing for *adult-onset* disorders with no childhood intervention (e.g., Huntington's) is generally **deferred** to preserve future autonomy; but testing is offered when childhood intervention exists (MEN2 → prophylactic thyroidectomy; FAP → colonoscopy from age 10–15 yr).
- ▶ **Ethical/legal**: genetic privacy, the **Genetic Information Nondiscrimination Act (GINA, 2008)** protecting against health-insurance and employment discrimination (not life/disability/long-term-care insurance), and the option of **DNA banking**.

Genetic conditions that can be tested — gene, inheritance and intervention

Predictive testing is **presymptomatic** when a variant confers near-100% disease likelihood (e.g., Huntington's) and **predisposition** testing when risk is < 100% (e.g., hereditary colon cancer). Representative tractable disorders (Harrison Table 480-2):

System / disorder	Inheritance	Gene(s)	Key intervention(s)
Lynch syndrome (HNPCC)	AD	<i>MLH1</i> , <i>MSH2</i> , <i>MSH6</i> , <i>PMS2</i> (<i>EPCAM</i>)	Early/frequent colonoscopy; risk-reducing surgery; aspirin

System / disorder	Inheritance	Gene(s)	Key intervention(s)
Familial adenomatous polyposis	AD	<i>APC</i>	Colonoscopy from 10–15 yr; prophylactic colectomy; chemoprevention
Hereditary breast & ovarian cancer	AD	<i>BRCA1</i> , <i>BRCA2</i> (also <i>PALB2</i> , <i>CHEK2</i> , <i>ATM</i>)	Risk-reducing salpingo-oophorectomy; breast MRI surveillance; risk-reducing mastectomy; PARP inhibitors
Hereditary diffuse gastric cancer	AD	<i>CDH1</i>	Prophylactic gastrectomy; enhanced breast surveillance
Factor V Leiden	AD	<i>F5</i>	Avoid thrombogenic risk factors
Haemophilia A / B	X-linked	<i>F8</i> / <i>F9</i>	Factor VIII / IX replacement
G6PD deficiency	X-linked	<i>G6PD</i>	Avoid oxidant drugs and certain foods
Sickle cell disease	AR	<i>HBB</i>	Hydroxyurea; haematopoietic stem-cell transplant; gene therapy
Hypertrophic cardiomyopathy	AD	<i>MYBPC3</i> , <i>MYH7</i> , <i>TNNT2</i> , <i>TPM1</i>	Echo screening; beta blockers; myectomy; avoid strenuous exertion
Long QT syndrome	AD/AR	<i>KCNQ1</i> , <i>SCN5A</i> , <i>KCNE1</i> , <i>KCNE2</i>	ECG screening; antiarrhythmics; ICD
Marfan syndrome	AD	<i>FBN1</i>	Beta blockers/ARBs; aortic monitoring; valve/root replacement
Familial Mediterranean fever	AR	<i>MEFV</i>	Colchicine
Hereditary haemochromatosis	AR	<i>HFE</i>	Therapeutic phlebotomy
α 1-antitrypsin deficiency	AR	<i>SERPINA1</i>	Avoid smoking/occupational toxins
Cystic fibrosis	AR	<i>CFTR</i>	Airway clearance; CFTR modulators ; lung transplant
MEN type 2	AD	<i>RET</i>	Prophylactic thyroidectomy; screen for pheochromocytoma/hyperparathyroidism
Familial hypocalciuric hypercalcaemia	AD	<i>CASR</i>	Avoid parathyroidectomy; calcimimetics

System / disorder	Inheritance	Gene(s)	Key intervention(s)
Polycystic kidney disease	AD/AR	<i>PKD1, PKD2, PKHD1</i>	BP control; treat UTIs; renal transplant
Nephrogenic diabetes insipidus	X-linked/AR	<i>AVPR2, AQP2</i>	Fluids; thiazides ± amiloride
Malignant hyperthermia	AD	<i>RYR1, CACNA1S</i>	Avoid precipitating anaesthetics
Duchenne muscular dystrophy	X-linked	<i>DMD</i>	Glucocorticoids; exon-skipping antisense oligonucleotides ; stop-codon readthrough
Wilson disease	AR	<i>ATP7B</i>	Zinc; trientine (chelation)
Huntington disease	AD	<i>HTT</i>	Supportive care; PT/OT; presymptomatic testing

Interventions that can be instituted after genetic risk identification

Harrison classifies post-test interventions into four categories, scaling with how “actionable” the disorder is:

- ▶ (1) **Surveillance / heightened awareness** — intensified, earlier or more frequent screening (e.g., breast MRI in *BRCA* carriers; colonoscopy in Lynch/FAP; echocardiography in HCM/Marfan; ECG in long QT).
- ▶ (2) **Specific medical/surgical intervention** —
 - *Chemoprevention*: aspirin (Lynch); tamoxifen/raloxifene/exemestane (*BRCA*).
 - *Risk-reducing surgery*: salpingo-oophorectomy ± mastectomy (*BRCA*); colectomy (FAP); gastrectomy (*CDH1*); prophylactic thyroidectomy (MEN2).
 - *Disease-modifying drugs*: phlebotomy (haemochromatosis); colchicine (FMF); zinc/trientine (Wilson); beta blockers/ARBs (Marfan); CFTR modulators (CF).
 - *Molecularly targeted/novel therapy*: **PARP inhibitors** for *BRCA1/2*- and *PALB2*-associated cancers; **transthyretin stabilisers** for TTR cardiac amyloid; **exon-skipping/readthrough agents** for DMD; **gene therapy/replacement** for spinal muscular atrophy and sickle cell disease (including CRISPR-Cas9-based therapy, FDA-approved 2023).
- ▶ (3) **Risk avoidance** — avoid oxidant drugs (G6PD); avoid triggering anaesthetics (malignant hyperthermia); avoid smoking (α 1-antitrypsin); avoid strenuous exercise/dehydration (HCM); diet modification (hyperkalaemic periodic paralysis).
- ▶ (4) **Referral to support services** — for disorders with limited treatment (e.g., Huntington’s): PT/OT, social work, support groups, and consideration of PGT/**prenatal diagnosis** for reproductive choices.

- ▶ **Pharmacogenetic interventions** individualise drug therapy and avoid toxicity — *TPMT* (thiopurines), *DPYD* (5-FU/capecitabine), *G6PD*, malignant hyperthermia, and *CYP2C9/VKORC1* (warfarin, though clinical-algorithm superiority is unproven).

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Three-generation pedigree (Harrison Fig. 480-1 style)**: draw squares (males)/circles (females), a diagonal line for deceased, an *arrow* marking the **proband**, with affected individuals shaded and annotated with diagnosis + age (e.g., “Breast ca 44”, “Ovarian ca 54”); show paternal-side breast/ovarian clustering suggesting *BRCA1/2*. Labels: I–IV generations, proband arrow, key (breast cancer, ovarian cancer).
- ▶ **Algorithm “Approach to genetic testing” (Fig. 480-2)**: boxes — *Patient identified by clinical/family history* → *Pretest counselling + informed consent (multigene panel/WES)* → *Mutational analysis* → *Interpretation in context of personal/family history* → *Post-test counselling & treatment implications for patient and family* → *Return to primary-care follow-up*.

Clinical / Diagnostic significance

- ▶ **Methods of testing**: PCR-based DNA sequencing; cytogenetics/karyotype; FISH; MLPA for copy-number changes; **massively parallel (next-generation) sequencing** — multigene panels, **whole-exome (WES)** and whole-genome sequencing; immunohistochemistry for mismatch-repair proteins (universal Lynch screening).
- ▶ **Prenatal techniques**: **amniocentesis** (~16 weeks), **chorionic villus sampling** (9–12 weeks, earlier if termination considered), **percutaneous umbilical blood sampling/cordocentesis** (~18 weeks), and non-invasive **cell-free fetal DNA** from maternal blood.
- ▶ **Interpretation caveats**: an *uninformative negative* does not exclude disease; manage by personal/family history. A **VUS** should not drive management until reclassified. Beware **incidental/secondary findings** (ACMG SF actionable-gene list) and direct-to-consumer testing (variable quality; results “not for medical management”).
- ▶ **Population screening** (e.g., *BRCA*, Lynch, *LDLR*, *TTR*) is emerging but limited by penetrance, VUS handling and equity concerns.

High-yield exam pointers

- ▶ **Test the affected relative first**; then offer **cascade testing** — most informative and cost-effective strategy.
- ▶ **Genetic testing must never precede counselling and informed consent**.
- ▶ **Presymptomatic** (Huntington’s, ~100% risk) vs **predisposition** (hereditary colon cancer, < 100%) testing — know the distinction.

- ▶ **Quad test** = AFP + β -hCG + inhibin-A + unconjugated estriol; abnormal result is a prenatal indication.
- ▶ **Advanced maternal age** > 35 years is a classic amniocentesis indication.
- ▶ **MEN2** → **prophylactic thyroidectomy**; **FAP** → **colonoscopy from 10–15 yr** — the two paediatric exceptions to deferring adult-onset testing.
- ▶ **GINA (2008)** protects against health-insurance/employment (not life/disability) discrimination.
- ▶ **BRCA1/2**: risk-reducing salpingo-oophorectomy proven to reduce mortality; **PARP inhibitors** are the targeted therapy.
- ▶ Four intervention categories: **surveillance**, **specific medical/surgical therapy**, **risk avoidance**, **supportive referral**.

SOURCE & COVERAGE

- ▶ **Harrison's Principles of Internal Medicine, 22e** — “The Integration of Inherited Genetics into Clinical Practice” (family history/pedigree, testing strategies, informed consent, follow-up care, Table 480-2 conditions–genes–interventions, GINA, presymptomatic vs predisposition testing, therapeutic interventions, pharmacogenetics) and “Principles of Human Genetics” (prenatal diagnosis—amniocentesis/CVS/PUBS/cfDNA, Table 479-4 indications across the life span, postnatal cytogenetic indications, ethical issues).

Coverage note: This topic is covered well by Harrison; the spec lists no dedicated subspecialty textbook and CMDT was not required, so the answer is grounded in Harrison 22e chapters 479–480. All genes, inheritance patterns, doses/timings (amniocentesis 16 wk, CVS 9–12 wk, PUBS ~18 wk) and interventions are verbatim from these chapters.

What are the pathways of complement system and the effector actions of each? Discuss how it impacts immunity

Asked in: Paper I May 2025 — RGUHS MD General Medicine

Definition / Introduction — The **complement system** is a major soluble effector arm of *innate immunity*: a cascade of ~30 plasma and membrane proteins (predominantly **serine proteases**, regulators and receptors) that are activated sequentially, each cleaving and activating the next. Activation proceeds via **four pathways** — three initiating routes (**classical**, **lectin/MBL**, **alternative**) that converge on cleavage of C3, and a shared **terminal pathway** that assembles the lytic **membrane attack complex (MAC)**. Its three cardinal effector functions are **opsonisation**, generation of **inflammatory anaphylatoxins**, and **cytolysis**, and it forms the principal molecular bridge linking innate to adaptive immunity.

The three initiating pathways and the common terminal pathway

Feature	Classical pathway	Lectin (MBL) pathway	Alternative pathway
Trigger	Antigen–antibody immune complexes (IgM, IgG1, IgG2, IgG3) bound to C1q	Microbial surfaces bearing terminal mannose groups	Spontaneous C3 “tick-over”; C3b deposited directly on microbes / “altered self” (tumour cells) — <i>antibody-independent</i>
Recognition / initiating proteins	C1 complex = C1q–C1r–C1s	MBL (a collectin) + MASP-1 and MASP-2 (substitute for C1q, C1r, C1s)	Factor D, factor B, C3; stabilised by properdin (factor P)
Early activation	C1s cleaves C4 → C4a + C4b and C2 → C2a + C2b	MASPs cleave C4 and C2 (identical to classical from here on)	Factor D cleaves factor B (bound to C3b) → Bb
C3 convertase	C4b2a	C4b2a	C3bBb (properdin-stabilised)
C5 convertase	C4b2a3b	C4b2a3b	C3bBb3b
Immunological role	Links adaptive → innate immunity via specific antibody	Pattern-recognition of carbohydrate (true innate)	Powerful amplification loop for any C3b deposited by any pathway

- ▶ All three routes converge at **C3 cleavage** ($C3 \rightarrow C3a + C3b$) and then on the **terminal pathway**: the C5 convertase cleaves $C5 \rightarrow C5a + C5b$; C5b sequentially recruits C6, C7, C8 and multiple C9 (poly-C9) to form the MAC (C5b-9), which inserts into the lipid bilayer of bacteria or target cells and causes osmotic lysis.
- ▶ The cascade is *enzymatic and amplifying* — a single convertase cleaves many C3 molecules, so a small trigger produces a large effector response. The components are mostly serine proteases acting in a defined order.

Effector actions of complement

Effector molecule(s)	Action	Immunological consequence
C3b (and C4b, C1q, iC3b)	Opsonisation — coats microbe/target	Binds phagocyte complement receptors (CR1/CD35, CR3) → enhanced phagocytosis and clearance
C3a, C5a (also weak C4a)	Anaphylatoxins	Mast-cell/basophil degranulation, ↑ vascular permeability, smooth-muscle contraction; C5a is a potent neutrophil

Effector molecule(s)	Action	Immunological consequence
		chemoattractant and activator → acute inflammation
C5b-9 (MAC)	Cytolysis / membrane perturbation	Direct lysis of bacteria (esp. <i>Neisseria</i>) and of antibody-coated cells
C3b/C4b on immune complexes	Immune-complex solubilisation & clearance	ICs bound by erythrocyte CR1 (CD35) are ferried to liver/spleen reticulo-endothelial system for safe disposal
C3d-antigen on B cells	Immune adjuvant	C3d engages CR2 (CD21) on B cells, lowering the threshold for B-cell activation — couples innate sensing to antibody production

- In summary (Harrison): complement cleavage products **facilitate microbe/damaged-cell clearance** (C1q, C4, C3), **promote inflammation** (anaphylatoxins C3a, C5a), and **promote lysis** (MAC).

Regulation of complement (why self is spared)

Tight regulation prevents bystander injury to host tissue; loss of a regulator causes characteristic disease.

Regulator	Type	Function	Loss / dysfunction causes
C1 inhibitor (C1-INH)	Plasma serpin	Inactivates C1r/C1s, MASPs and kallikrein; limits bradykinin generation	Hereditary angioedema (↓C4, ↓C2)
Factor H	Plasma	Cofactor for factor I; decay of alternative C3 convertase	aHUS, C3 glomerulopathy; deficiency → haemolytic-uraemic syndrome
Factor I	Plasma protease	Cleaves/inactivates C3b and C4b	Pyogenic infections
DAF / CD55	GPI-anchored membrane	Accelerates decay of C3/C5 convertases; blocks C3-fragment binding	Lost in PNH

Regulator	Type	Function	Loss / dysfunction causes
CD59 (protectin)	GPI-anchored membrane	Blocks MAC (C9) insertion	Lost in PNH → intravascular haemolysis
MCP / CD46	Membrane	Cofactor for factor I	aHUS

Impact on immunity — how complement shapes host defence

- ▶ **Frontline innate defence:** lyses and opsonises pathogens within minutes of exposure, before antibody is available; the lectin and alternative pathways need no prior immunity (true pattern-recognition / innate arms).
- ▶ **Bridge to adaptive immunity:** classical-pathway activation via **immune-complex binding to C1q links innate and adaptive systems** through specific antibody; C3d-coated antigen amplifies B-cell responses (CR2/CD21), so complement is also an *adjuvant* for antibody production.
- ▶ **Inflammation & leukocyte recruitment:** C5a and C3a recruit and activate neutrophils, mast cells and basophils (which bear C3a/C5a receptors), orchestrating acute inflammation.
- ▶ **Immune-complex homeostasis:** efficient IC clearance prevents tissue deposition; *early* complement deficiency → defective clearance → **immune-complex disease** (SLE-like syndromes, glomerulonephritis, vasculitis).
- ▶ **A double-edged sword:** the same effectors that protect can injure host tissue when dysregulated — e.g. complement-fixing (C1-binding) IgM/IgG mediates **type II cytotoxic** reactions (transfusion haemolysis, Goodpasture's, pemphigus vulgaris) and contributes to **type III immune-complex injury**.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Diagram 1 — The four pathways converging on C3 and the MAC.** Three parallel columns feeding a common stem. Labels: *Classical* (Ag-Ab complex → C1q-C1r-C1s → C4, C2 → C4b2a); *Lectin* (mannose → MBL + MASP-1/2 → C4, C2 → C4b2a); *Alternative* (microbial surface, C3 tick-over → factor B, factor D, properdin → C3bBb); arrows from all three to C3 → C3a + C3b; then C5 convertase → C5 → C5a + C5b → C6, C7, C8, C9 (poly-C9) = MAC (C5b-9) → cell lysis. Side annotations: C3a/C5a = **anaphylatoxins (inflammation)**, C3b = **opsonin (phagocytosis)**, MAC = **lysis**.
- ▶ **Diagram 2 — Membrane regulators in PNH.** RBC membrane with GPI-anchored CD55 (blocks C3 convertase) and CD59 (blocks MAC); show their loss after PIGA mutation → C3b deposition → MAC-mediated **intravascular haemolysis**; mark site of **eculizumab** (anti-C5) block.

Clinical / Diagnostic significance

- ▶ **Pattern of deficiency predicts the disease (Table 360-12):**
 - Early classical components (C1q, C1r, C1s, C4, C2) → immune-complex syndromes (SLE, SLE-like, GN, vasculitis) and pyogenic infection with encapsulated organisms (*S. pneumoniae*).
 - C3 / alternative pathway (C3, factor D) → severe pyogenic infections + immune-complex disease.
 - Properdin → invasive *Neisseria* infection; factor H/I → HUS / pyogenic infection.
 - Terminal/MAC components (C5–C8; rarely C9) → recurrent *Neisseria* (meningococcal) infections.
- ▶ **Acquired complement disorders:**
 - **Paroxysmal nocturnal haemoglobinuria (PNH):** acquired PIGA mutation blocks GPI-anchor synthesis → loss of CD55 + CD59 → MAC-mediated **intravascular haemolysis**, haemoglobinuria, thrombosis; Coombs-negative. Treated with **eculizumab/ravulizumab** (anti-C5); **pegcetacoplan** (anti-C3) also curbs C3d-mediated extravascular haemolysis.
 - **Hereditary angioedema:** C1-INH deficiency → unopposed kallikrein/bradykinin → recurrent **non-pruritic, non-urticarial angioedema** with GI involvement; complement screen shows low C4 (and C2).
- ▶ **Therapeutics targeting complement:** eculizumab/pezelimab (anti-C5) for PNH/aHUS/CHAPLE; C3-directed agents; recombinant C1-INH for HAE — illustrating complement as a druggable pathway.
- ▶ **Useful tests:** CH50 (screens the entire classical→terminal pathway; zero/very low suggests a complete component deficiency), AH50 (alternative pathway), and individual **C3/C4 levels** (low C4 with normal C3 favours classical-pathway/C1-INH problems; low C3 favours alternative-pathway activation).

High-yield exam pointers

- ▶ **Four pathways = classical + lectin + alternative (initiating) + terminal (common).** All converge on C3, then MAC (C5b-9).
- ▶ **C3 convertases:** classical/lectin = C4b2a; alternative = C3bBb (properdin-stabilised). C5 convertases: C4b2a3b and C3bBb3b.
- ▶ **Lectin pathway** uses MBL + MASP-1/MASP-2 in place of C1q/C1r/C1s; triggered by **mannose**.
- ▶ **Three effectors:** opsonisation (C3b), anaphylatoxins (C3a, C5a; C5a = chemotactic), lysis (MAC); plus **immune-complex clearance** (RBC CR1/CD35) and **B-cell adjuvant** (C3d–CR2/CD21).
- ▶ **Antibody isotypes fixing classical complement:** IgM (most potent) and IgG1, IgG2, IgG3 (via C1q); IgG4 and IgA do not fix classical complement.

- ▶ Early-component deficiency → SLE / immune-complex disease; terminal (MAC) deficiency → recurrent *Neisseria*.
- ▶ PNH = loss of GPI-anchored CD55 + CD59 (PIGA); treat with anti-C5 eculizumab.
- ▶ Hereditary angioedema = C1-INH deficiency, bradykinin-mediated, low C4, no urticaria.
- ▶ Complement is the key molecular bridge between innate and adaptive immunity.

SOURCE & COVERAGE

- ▶ **Harrison's Principles of Internal Medicine, 22e** — “Introduction to the Immune System” (four pathways, MASP/MBL, C3/C5 convertase convergence, MAC, anaphylatoxins, opsonisation, immune-complex clearance, Table 360-12 Complement Deficiencies and Associated Diseases, antibody complement-fixation); “Mechanisms of Regulation and Dysregulation of the Immune System” (complement-targeting biologics — eculizumab/pezelimab); “Hemolytic Anemias” (PNH — CD55/CD59, PIGA, eculizumab/pegcetacoplan); “Urticaria, Angioedema, and Allergic Rhinitis” (C1-INH deficiency / bradykinin-mediated hereditary angioedema, low C4/C2).
- ▶ **Coverage note:** The precise **convertase subunit formulae** (C4b2a, C3bBb, C4b2a3b, C3bBb3b), the **CR2/CD21–C3d** B-cell adjuvant link, properdin's *stabilising* role, and the laboratory screens **CH50/AH50** are universally accepted standard immunology (Janeway/Abbas) used to complete the answer; Harrison states the pathway proteins (C1/C4/C2; factor D/B/C3; MBL/MASP) and effector outcomes but does not spell out every convertase formula verbatim.

What is polymerase chain reaction? How is DNA sequencing done? Give examples of its use in diagnosis of disease conditions

Asked in: Paper I May 2025 — RGUHS MD General Medicine

Definition / Introduction — The **polymerase chain reaction (PCR)** is a *nucleic acid amplification test (NAAT)* that amplifies a specific region of DNA in vitro into millions of copies using sequence-specific oligonucleotide primers and a thermostable DNA polymerase. **DNA sequencing** is the determination of the precise order of nucleotide bases (A, T, G, C) in a DNA segment, performed historically by the *Sanger (dideoxy chain-termination)* method and now predominantly by *next-generation (massively parallel) sequencing*. Together these molecular tools underpin modern diagnosis of inherited, infectious and neoplastic disease, allowing genetic testing and mutational analysis from minute amounts of DNA extracted from leukocytes, buccal cells, or even single cells.

Principle, requirements and components of PCR

- ▶ **Principle** — *exponential, primer-directed enzymatic amplification* of a target sequence; each cycle theoretically doubles the template, so n cycles yield $\approx 2^n$ copies (25–40 cycles produce millions to billions of copies).
- ▶ **Template** — the double-stranded DNA containing the region of interest (genomic, plasmid, or, after reverse transcription, cDNA).
- ▶ **Primers** — a pair of short single-stranded oligonucleotides (~18–25 bp) complementary to sequences flanking the target; they define specificity. *Even a single base-pair mismatch, particularly near the 3' end of the primer, may abolish amplification* (Harrison).
- ▶ **Thermostable DNA polymerase** — *Taq polymerase* (from the thermophilic bacterium *Thermus aquaticus*), which survives repeated high-temperature denaturation.
- ▶ **dNTPs** (the four deoxynucleotide building blocks), **Mg²⁺-containing buffer**, and a programmable **thermal cycler**.
- ▶ A key strength is sensitivity: PCR enables genetic and mutational analysis with very small quantities of DNA, and **DNA sequencing can be performed directly on PCR products**.

The three steps of a PCR cycle

Step	Temperature (typical)	Event
1. Denaturation	~94–95 °C	Double-stranded template separates into two single strands
2. Annealing	~50–65 °C	Primers hybridise to their complementary flanking sequences
3. Extension (elongation)	~72 °C	<i>Taq</i> polymerase synthesises the new strand 5'→3' from each primer

- ▶ The cycle is repeated 25–40 times; an initial denaturation and a final extension flank the cycling. Product is detected by *agarose gel electrophoresis*, fluorescence (real-time PCR), or downstream sequencing.

Modifications / types of PCR

Variant	Key feature & use
Reverse-transcriptase PCR (RT-PCR)	RNA first converted to cDNA by reverse transcriptase, then amplified — used for RNA viruses (HIV, HCV, SARS-CoV-2, influenza) and fusion transcripts
Real-time / quantitative PCR (qPCR)	Fluorescent signal measured per cycle → <i>quantifies</i> template (e.g. HIV/HBV/HCV viral load); RT-qPCR combines both

Variant	Key feature & use
Multiplex PCR	Several primer sets in one reaction → <i>syndromic panels</i> (respiratory, gastroenteritis, meningoencephalitis) detecting many pathogens at once
Nested PCR	Two sequential amplifications with internal primers → increased sensitivity/specificity (standard molecular biology)
Isothermal amplification (e.g. LAMP)	Amplifies at a single temperature without thermal cycling → point-of-care/field and resource-limited settings

DNA sequencing — Sanger (first-generation) method

- ▶ **Principle: dideoxy chain termination.** The denatured template, a primer, DNA polymerase, normal dNTPs and a small proportion of fluorescently-labelled **dideoxynucleotides (ddNTPs)** are combined.
- ▶ Because ddNTPs lack the **3'-hydroxyl group**, their incorporation halts further chain elongation, generating a nested set of fragments terminating at every base position.
- ▶ Fragments are resolved by size on **capillary electrophoresis**; the fluorescent terminators are read off as a **chromatogram** (Harrison shows “*chromatograms of sequence analyses after amplification of genomic DNA by PCR*” — Fig. 479-10B).
- ▶ Sanger sequencing of PCR products remains the reference standard for *single-gene/targeted* mutation confirmation.

Next-generation (NGS) and third-generation sequencing

- ▶ **Next-generation / massively parallel sequencing** produces *millions of sequences concurrently*, far beyond the capacity of prior dye-terminator methods, with cost per genome falling steeply.
- ▶ Clinical formats:
 - **Targeted gene panels** — multiple candidate genes captured by hybridisation then deep-sequenced (locus-heterogeneous disorders, somatic tumour panels).
 - **Whole-exome sequencing (WES)** — all coding exons; used for undiagnosed/rare syndromes.
 - **Whole-genome sequencing (WGS)** — entire genome, including non-coding regions.
 - **RNA sequencing (RNA-Seq)** — gene fusions, aberrant expression.
- ▶ **16S ribosomal RNA gene sequencing** identifies fastidious/unculturable bacteria; **metagenomic** (“shotgun”) and **cell-free DNA sequencing** allow *unbiased* pathogen discovery (e.g. *Leptospira* DNA found in CSF → neuroleptospirosis confirmed by retrospective PCR). **Long-read (third-generation)** platforms resolve repeats, plasmids and structural variants.

- *Caveats*: NGS detects numerous **variants of uncertain significance (VUS)** and incidental (secondary) findings, demands heavy bioinformatics, and may miss copy-number variants if not specifically analysed.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- **Diagram 1 — One PCR cycle**: draw double-stranded template; arrow to *Denaturation* (~94 °C) showing two separated single strands; *Annealing* (~55 °C) showing forward and reverse primers bound; *Extension* (~72 °C) with Taq polymerase synthesising new strands; loop arrow back labelled “repeat ×25–40 → exponential 2ⁿ amplification.” Label: **template, primers, Taq polymerase, dNTPs, 5'/3' ends.**
- **Diagram 2 — Sanger sequencing**: template + primer + DNA polymerase + dNTPs + labelled ddNTPs; show a ladder of chain-terminated fragments of increasing length; arrow to **capillary electrophoresis** and a four-colour **chromatogram** read 5'→3'. Label: **ddNTP (no 3'-OH), chain termination, fluorescent peaks A/T/G/C.**

Clinical / Diagnostic significance

- **Infectious disease (NAAT-based)**:
 - *Tuberculosis* — PCR amplification of the **rpoB gene** identifies *M. tuberculosis* directly in sputum and simultaneously detects **rifampicin resistance** (Xpert-type NAAT-R); CMDT: NAAT sensitivity/specificity 85–97% in smear-positive specimens, resistance-marker specificity > 98%.
 - *HIV* — **RT-qPCR viral load** for diagnosis/monitoring; **genotypic resistance testing** is standard before therapy (e.g. the **K103N** reverse-transcriptase mutation predicts efavirenz resistance).
 - *Hepatitis B/C, SARS-CoV-2, influenza* — PCR/RT-PCR for detection and treatment response; multiplex **respiratory viral panels**.
 - *Antibiotic resistance* — **mecA** (PBP2A) PCR for **MRSA**; **van** genes for **VRE**; multiplex carbapenemase PCR (**KPC, NDM, OXA-48, IMP1, VIM**).
- **Inherited single-gene disorders**: PCR-based mutation panels detect **CFTR ΔF508** (cystic fibrosis), **β-globin Glu6Val/E6V** (sickle cell), and **trinucleotide-repeat expansions** (fragile X, Huntington's CAG repeat), including premutation sizing. Used for carrier testing, **prenatal diagnosis** (amniocentesis/CVS with FISH + mutational analysis), and non-invasive prenatal **cfDNA** screening for aneuploidy/fetal sex.
- **Oncology / haematology**: RT-PCR for **BCR-ABL1 [t(9;22)]** diagnoses and monitors CML/Ph⁺ ALL minimal residual disease; tumour **mutational profiling/NGS** identifies *actionable driver mutations* guiding targeted therapy; **liquid-biopsy cfDNA** for minimally invasive diagnosis and surveillance; **BRCA1/BRCA2** testing for hereditary cancer risk.

- ▶ **Pharmacogenomics:** genotyping guides drug choice and dosing.
- ▶ **Pitfalls:** interpret NAAT against **pre-test probability** (a negative result in high-probability TB does not exclude disease); risk of **contamination/false positives**; detection of a microbial sequence alone does not prove causation (Koch's postulates); allelic heterogeneity means a negative targeted panel does not exclude a mutation elsewhere.

High-yield exam pointers

- ▶ PCR = in-vitro amplification needing **template, two primers, Taq polymerase (from Thermus aquaticus), dNTPs, Mg²⁺, thermal cycler**.
- ▶ Three steps: **Denaturation** (~94 °C) → **Annealing** (~55 °C) → **Extension** (~72 °C); ≈2ⁿ amplification over 25–40 cycles.
- ▶ RT-PCR for RNA (HIV, HCV, SARS-CoV-2); **qPCR** quantifies (viral load); **multiplex** = syndromic panels.
- ▶ **Sanger sequencing** uses **dideoxynucleotides (no 3'-OH)** → **chain termination**, read as a chromatogram; **NGS** = massively parallel (WES, WGS, panels).
- ▶ TB: **rpoB** PCR detects organism and **rifampicin resistance**; MRSA = **mecA**; VRE = **van** genes.
- ▶ Heme-onc: **BCR-ABL1** RT-PCR for CML/MRD; tumour NGS for **actionable mutations**; **cfDNA liquid biopsy**.
- ▶ Genetic: CFTR ΔF508, sickle E6V, fragile X / **Huntington repeat expansions**; prenatal cfDNA (NIPT).
- ▶ **16S rRNA / metagenomic / cfDNA sequencing** identifies culture-negative and novel pathogens.

SOURCE & COVERAGE

- ▶ **Harrison's Principles of Internal Medicine, 22e** — “Principles of Human Genetics” (mutational analysis, Sanger chromatograms after PCR amplification, NGS/WES/WGS, targeted panels, repeat-expansion and single-gene examples, prenatal diagnosis) and “Microbial Genomics and Infectious Disease” (NAAT/PCR definitions, RT-PCR, multiplex syndromic panels, 16S rRNA and metagenomic/cfDNA sequencing, rpoB/TB, HIV genotyping K103N, mecA/MRSA, van/VRE, carbapenemase panels, MALDI-TOF context).
- ▶ **CMDT 2026** — “Pulmonary Disorders” (NAAT-TB and resistance-marker performance characteristics for tuberculosis).
- ▶ *Coverage note:* The corpus covers PCR and DNA sequencing as laboratory techniques only thinly (spec gap = true). The **step-level mechanism of PCR** (denaturation/annealing/extension temperatures, *Taq*/Thermus aquaticus) and the **dideoxy chain-termination basis of Sanger sequencing** are not described in mechanistic detail in Harrison/CMDT; these are included as universally accepted standard molecular

biology. All disease examples, the rpoB/mecA/van/carbapenemase/HIV-genotype details, the NGS/16S/metagenomic content and the single-gene/repeat-expansion examples are directly grounded in the cited chapters.

When, Where and How Do You Monitor Drug Therapy? Illustrate with Examples

Asked in: Paper I 06 Apr 2026 — RGUHS MD General Medicine

Definition / Introduction — *Monitoring of drug therapy* is the systematic process of assessing whether a prescribed drug is producing the intended benefit while staying within a safe exposure range, so that the dose can be individualised. It is achieved by tracking **clinical endpoints**, **physiological/biochemical surrogate markers**, **direct plasma (serum/whole-blood) drug-concentration measurement** — *therapeutic drug monitoring (TDM)* — and increasingly by **pharmacogenomic testing**. The unifying rationale is the **therapeutic window** (therapeutic index/ratio): the separation between the concentration needed for efficacy and that producing toxicity. Where this window is narrow and a definable concentration–effect relationship exists, monitoring lets the clinician keep the drug above the minimum effective and below the toxic concentration.

Goals and the four modalities of monitoring (HOW)

- ▶ The desired goal of any drug therapy is to **maximise the likelihood of benefit while minimising the risk of adverse drug reactions (ADRs)**. Monitoring operationalises this for the individual patient, because outcome varies widely owing to pharmacokinetic and pharmacodynamic differences (genetics, organ dysfunction, drug interactions, adherence, age).
- ▶ **1. Clinical/symptomatic endpoints** — the simplest method: relief of pain or palpitations, seizure frequency, mood; the patient reports efficacy. Useful when effect is directly observable.
- ▶ **2. Physiological / biochemical surrogate markers** — objective, repeatable tests that track effect: blood pressure (antihypertensives), INR (warfarin), aPTT/anti-Xa (heparin), blood glucose and HbA1c (insulin/oral hypoglycaemics), TSH (levothyroxine), LDL cholesterol (statins), QT interval on ECG (sotalol, dofetilide).
- ▶ **3. Plasma drug-concentration measurement (TDM)** — quantifying the drug itself; reserved for agents where concentration predicts effect/toxicity but no easy clinical surrogate exists (anticonvulsants, antirejection agents, antiarrhythmics, antibiotics).
- ▶ **4. Toxicity surveillance and pharmacogenomic testing** — periodic organ-function/haematology checks to catch dose-dependent toxicity, plus pre-emptive genotyping to predict variant responders.

WHEN do you monitor — indications and timing

- ▶ **Patient-side (clinical) indications to measure a drug level:** narrow therapeutic index drug; suspected **toxicity** that mimics the underlying disease (e.g. digoxin, lithium, phenytoin); **failure of efficacy** (to detect non-adherence, an interaction, or use of expired/degraded drug); suspected **non-adherence**, especially in chronic disease (hypertension, HIV) and multi-dose regimens; after a **dose change**, or after starting/stopping an interacting drug; in **organ dysfunction** (renal/hepatic) and at extremes of age; and for drugs with **saturable (zero-order) kinetics** such as phenytoin, where small dose increments cause disproportionate rises.
- ▶ **Pharmacokinetic timing — sample at steady state:** steady state is reached after ~4–5 **elimination half-lives** following initiation or any dose change; levels drawn earlier underestimate the eventual concentration.
- ▶ **Trough vs peak:** for *efficacy and most chronic dosing*, draw a **trough** — the lowest concentration, **just before the next dose** at steady state (anticonvulsants, vancomycin, ciclosporin, tacrolimus). For drugs where **toxicity tracks the peak**, sample at the anticipated peak — e.g. evaluate the ECG/QT 1–2 h post-dose at steady state with sotalol/dofetilide; draw an **aminoglycoside peak** 30 min after the end of a 30–60 min infusion.
- ▶ **Drug-specific timing pitfalls:** digoxin must **not** be drawn within **6 h of an oral** (or 4 h of an IV) dose because distribution is incomplete; **lithium** is sampled at a standard **12 h post-dose**; **methotrexate** is checked at **48 h** to guide leucovorin rescue.

WHERE do you monitor — specimen, site and setting

- ▶ **Specimen/matrix:** most TDM uses **serum from a plain (red-top) tube**, drawn at trough. Two important exceptions are **ciclosporin and tacrolimus**, which partition into red cells and require **whole blood in an EDTA (lavender-top) tube**.
- ▶ **Free vs total drug:** only **unbound drug** is pharmacologically active. For highly protein-bound drugs in hypoalbuminaemia/uraemia (classically **phenytoin**, and **valproate**), measure the **free (unbound) concentration** — target free phenytoin 0.5–2 mg/L — because total levels mislead.
- ▶ **Sampling site of effect:** plasma concentration is only a surrogate for concentration at the target. Where tissue and plasma levels diverge (e.g. **P-glycoprotein** excluding drug from brain at the blood–brain barrier; drug acting outside plasma), plasma TDM is **not** a reliable guide and clinical/physiological monitoring is preferred.
- ▶ **Clinical setting:** ranges from the **ward/ICU** (vancomycin and aminoglycoside levels, lithium, antiepileptics, immunosuppressants, anticoagulation) to the **outpatient/anticoagulation clinic** (INR, HbA1c, TSH, BP) and **pharmacovigilance systems** (spontaneous ADR reporting, e.g. MedWatch) for population-level safety signals.

Which drugs need plasma-concentration monitoring (TDM) — criteria + ranges

A drug warrants plasma TDM when **most** of the following apply: narrow therapeutic index; good concentration–effect/toxicity correlation; wide inter-individual pharmacokinetic variability; **no easily measured clinical endpoint**; toxicity that resembles the disease being treated; or saturable kinetics. By contrast, drugs with a direct surrogate (warfarin→INR, heparin→aPTT, insulin→glucose) do **not** need level monitoring.

Drug	Effective (target) concentration	Sampling note
Digoxin	0.5–0.9 ng/mL (heart failure); 0.5–2 ng/mL (AF)	Trough; not within 6 h of oral dose; hypokalaemia potentiates toxicity
Lithium	0.5–1.2 mmol/L	12 h post-dose; thiazide/loop diuretics raise levels
Phenytoin	10–20 mg/L (5–10 in uraemia/hypoalbuminaemia); free 0.5–2 mg/L	Trough; zero-order (capacity-limited) kinetics
Valproate (total)	50–100 mg/L (50–125 for bipolar)	Total + free preferred in renal/liver disease
Carbamazepine	4–12 mg/L	Auto-induces own metabolism
Phenobarbital	10–40 mg/L	—
Theophylline	5–15 mg/L (panic ≥30)	Clearance ↑1.5–2× in smokers
Vancomycin	Trough 10–20 mg/L	Trough used for efficacy and to limit nephrotoxicity
Gentamicin / Tobramycin	Conventional peak 4–8 / 5–10 mg/L; trough <2 mg/L	Peak 30 min post-infusion; trough pre-dose
Amikacin	Peak 20–30 mg/L; trough <8 mg/L	Once-daily high-dose: peak ~60, trough <5
Ciclosporin	100–300 ng/mL (12-h trough)	Whole blood (EDTA)
Tacrolimus	Trough 8–12 ng/mL	Whole blood; CYP3A5-dependent dosing
Methotrexate	<0.1 µmol/L at 48 h	Higher → escalate leucovorin ; glucarpidase if renal failure

Surrogate monitoring, toxicity surveillance and pharmacogenomic (“pre-emptive”) monitoring

- Surrogate endpoints (no drug level needed): *warfarin* → INR (target ~2–3); *unfractionated heparin* → aPTT (~1.5–2.5×) or anti-Xa; *insulin* / *sulfonylureas* → capillary glucose and HbA1c; *antihypertensives* → BP; *levothyroxine* → TSH; *statins* → LDL-C for efficacy.

- ▶ **Toxicity surveillance (organ-function/haematology):** serum creatinine/eGFR with aminoglycosides, vancomycin and digoxin (and dose-reduce renally cleared dofetilide/sotalol to avoid QT prolongation); LFTs with valproate, methotrexate and anti-tubercular drugs; CBC with carbamazepine, methotrexate and clozapine; serum K^+ with digoxin (hypokalaemia potentiates toxicity).
- ▶ **Pharmacogenomic testing** identifies variant responders *before or during* therapy:

Gene	Drug	Why test / action
TPMT / NUDT15	Azathioprine, 6-mercaptopurine	Loss-of-function → life-threatening myelosuppression; reduce dose/avoid
*HLA-B1502**	Carbamazepine (Asian/Indian ancestry)	Avoid — risk of SJS/TEN
*HLA-B5701**	Abacavir	Avoid — hypersensitivity reaction
*HLA-B5801**	Allopurinol (Han Chinese/Korean/Thai)	Avoid — SJS/TEN
G6PD	Rasburicase, tafenoquine, primaquine	Deficiency → haemolysis/methaemoglobinaemia; use alternative
CYP2C19	Clopidogrel	Loss-of-function → poor bioactivation, more CV events
CYP2C9 / VKORC1	Warfarin	Predict lower maintenance dose (–1639G>A)
DPYD	5-FU, capecitabine	Deficiency → severe/fatal toxicity; reduce/avoid
*UGT1A128**	Irinotecan	Reduced glucuronidation → neutropenia, diarrhoea
SLCO1B1 (c.521T>C)	Simvastatin	↑ levels → statin myopathy

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Therapeutic window curve** (after Harrison Fig. 71-1): two overlapping sigmoid dose/concentration–response curves on the same axes — label “*Desired (therapeutic) effect*” (left curve) and “*Adverse effect / toxicity*” (right curve); shade the gap between them as the “**Therapeutic window / index**”; mark the *Minimum effective concentration* and *Minimum toxic concentration*; draw a *narrow window* inset where the curves nearly overlap (e.g. digoxin, lithium).
- ▶ **Steady-state accumulation curve** (after Fig. 71-4): concentration (y-axis) vs time in half-lives (x-axis) showing step-wise rise to a plateau; label “*Steady state at ~4–5 half-lives*”,

Gene	Drug	Why test / action
		“Trough — sample here (pre-dose)”, “Peak”, and show a loading dose reaching the plateau sooner without changing the final steady state.

Clinical / Diagnostic significance

- ▶ Converts empirical prescribing into **individualised, dose-optimised therapy**, reducing both treatment failure and dose-dependent toxicity.
- ▶ For **first-order drugs**, the steady-state level is linearly proportional to dose — if you want to double the level, double the dose; this does **not** hold for **zero-order** drugs (phenytoin, aspirin, fluoxetine), where a small increment can produce a disproportionate, toxic rise.
- ▶ A measured level distinguishes the differential of a deteriorating patient: e.g. worsening features on **digoxin/lithium/phenytoin** may be toxicity rather than disease progression.
- ▶ **Failure of efficacy** with a sub-therapeutic level points to **non-adherence, a drug interaction, or degraded/expired drug** — a frequent, correctable problem in chronic disease.
- ▶ In **renal disease**, reduce dose of renally cleared drugs (digoxin, dofetilide, sotalol) and consider free phenytoin; in **hepatic disease/cirrhosis**, oral bioavailability of high first-pass drugs (morphine, midazolam, nifedipine) roughly doubles — start low.

High-yield exam pointers

- ▶ **TDM indications mnemonic:** narrow therapeutic index + good concentration–effect correlation + no clinical surrogate + wide PK variability + toxicity mimicking disease + saturable kinetics.
- ▶ **Sample at steady state** = ~4–5 half-lives; trough = just before the next dose; aminoglycoside **peak** 30 min post-infusion.
- ▶ **Specimen:** serum (plain red-top) for most; **whole blood EDTA** for ciclosporin and tacrolimus.
- ▶ **Free-drug monitoring** for highly protein-bound **phenytoin/valproate** in uraemia/hypoalbuminaemia.
- ▶ **Phenytoin** = classic zero-order drug → small dose change, large level change.
- ▶ **Digoxin:** target 0.5–0.9 ng/mL in HF; don’t sample <6 h after oral dose; **hypokalaemia** potentiates toxicity.
- ▶ Drugs monitored by **surrogate, not level:** warfarin (INR), heparin (aPTT), insulin (glucose/HbA1c), antihypertensives (BP), levothyroxine (TSH).
- ▶ **QT interval** at 1–2 h post-dose for sotalol/dofetilide; **vancomycin trough** for efficacy/nephrotoxicity.
- ▶ **Pre-emptive pharmacogenomics:** TPMT/NUDT15 (thiopurines), HLA-B1502 (*carbamazepine*), HLA-B5701 (abacavir), HLA-B*5801 (allopurinol), G6PD (rasburicase/primaquine), DPYD (5-FU).

SOURCE & COVERAGE

- ▶ CMDT 2026 — Appendix e5: "Therapeutic Drug Monitoring" (Table e5-1 target concentrations, half-lives, sampling specimens/timing) and "Selected Pharmacogenetic Tests: Clinical Relevance" (Table e5-2 — TPMT/NUDT15, HLA-B*57:01/*58:01, G6PD, CYP2C19, CYP2C9/VKORC1, DPYD, UGT1A1, SLCO1B1).
- ▶ *Coverage note*: INR target ~2–3 and heparin aPTT ~1.5–2.5× are stated as universally accepted standard internal medicine; the corpus confirms these drugs are monitored by INR/aPTT but does not quote the numeric targets in the chapters used.

X-linked Disorders

Asked in: Paper I Nov 2022 — RGUHS MD General Medicine

Definition / Introduction — X-linked disorders are monogenic diseases caused by mutations in genes residing on the **X chromosome**, so their transmission and expression are governed by sex. Because males carry only a single X (they are **hemizygous**), a mutant allele is fully expressed in them regardless of whether it is dominant or recessive, whereas heterozygous females show variable expression that depends on the degree of **X-inactivation** and the function of the gene. X-linked conditions account for roughly 5% of **human monogenic disorders** (about 65% are autosomal dominant and 25% autosomal recessive). The two hallmark pedigree features are **absence of father-to-son (male-to-male) transmission** and the fact that **all daughters of an affected male are obligate carriers**.

Genetic basis and terminology

- ▶ **Sex-chromosome transmission**: A daughter *always* inherits her father's single X plus one of her mother's two X chromosomes; a son inherits the Y from his father and one **maternal X**. Hence an affected father can never pass an X-linked allele to a son.
- ▶ **Hemizygosity**: Males have one X, so a single mutant allele produces the phenotype. Females may be **heterozygous** or **homozygous**; the qualifiers *X-linked dominant* and *X-linked recessive* therefore strictly describe expression of the mutant phenotype **in women**.
- ▶ **X-inactivation (functional mosaicism, "Lyonization")**: In every somatic cell of a female, most genes on one of the two X chromosomes are silenced. Random inactivation gives a ~50:50 mix of cells expressing each X; **skewed (non-random) inactivation** can unmask disease in a carrier ("manifesting carrier").

- ▶ **Carrier expression is gene-dependent:** Most heterozygous carriers of factor VIII deficiency (haemophilia A) are asymptomatic because enough factor VIII is made; in contrast, females heterozygous for α -galactosidase A deficiency (Fabry's disease) may develop mild painful neuropathy and other features.

X-linked recessive vs X-linked dominant — characteristic features

Feature	X-linked recessive (XLR)	X-linked dominant (XLD)
Males (hemizygous)	Affected by a single mutant allele	Affected; often severe, may be lethal in utero
Heterozygous females	Usually unaffected carriers (may manifest if X-inactivation skewed)	Affected (variable, generally milder than males)
Father → son transmission	Absent	Absent
Affected father's daughters	All obligate carriers	All affected
Pedigree pattern	“Criss-cross”; chiefly males affected, skipped generations	Affected in successive generations; ~2:1 female:male excess
Examples	Haemophilia A/B, G6PD deficiency, Duchenne/Becker MD, Fabry, Fragile X	Rett syndrome (MECP2)

Pedigree and segregation patterns

- ▶ **Affected male × normal female:** all daughters are obligate carriers, all sons unaffected (no male-to-male spread).
- ▶ **Carrier female × normal male (XLR):** each son has a **50% chance of being affected**; each daughter has a **50% chance of being a carrier** (standard Mendelian extension).
- ▶ **Skipped generations** with predominantly affected males are typical of XLR — the disease appears to “jump” through unaffected carrier females (criss-cross inheritance).
- ▶ XLD pedigrees resemble autosomal dominant transmission but show **no father-to-son transmission** and an excess of affected females.

Important X-linked disorders (grounded in Harrison 22e)

Disorder	Gene / product	Pattern	Key point / management
Haemophilia A	F8 / factor VIII	XLR	Factor VIII replacement; carrier females usually asymptomatic
Haemophilia B	F9 / factor IX	XLR	Factor IX replacement

Disorder	Gene / product	Pattern	Key point / management
G6PD deficiency	G6PD	XLR	Avoidance of oxidant drugs and certain foods
Fabry's disease	α -galactosidase A (GLA)	XLR	Lipid-storage defect; heterozygous females may have mild neuropathy
Duchenne / Becker MD	DMD / dystrophin	XLR	Commonest muscular dystrophy; corticosteroids, physiotherapy, antisense-oligonucleotide exon skipping, stop-codon read-through
Nephrogenic diabetes insipidus	AVPR2 (AQP2 is AR)	XL	Vasopressin-resistant; thiazide/low-solute measures
Fragile X (FRAXA / FRAXE)	FMR1 / FMR2 protein	XLR	CGG / GCC repeat expansion; intellectual disability
Spinobulbar muscular atrophy (Kennedy)	Androgen receptor (CAG)	XLR	Trinucleotide-repeat disease, Xq12
Androgen insensitivity	Androgen receptor	XL recessive (missense)	Complete/partial; 46,XY with female phenotype
Rett syndrome	MECP2 (methyl-binding protein)	XLD	Developmental regression + stereotypic hand movements in girls

- ▶ **Duchenne muscular dystrophy** is the **commonest cause of muscular dystrophy**, reflecting the very large DMD gene (2.3 Mb, 79 exons); the phenotype is expressed in hemizygous males who have only one X. Dystrophin is part of a large complex linking the cytoskeleton to the muscle membrane. DMD mutations cause severe **Duchenne** or milder **Becker** disease depending on the severity of the protein defect (allelic heterogeneity).

X-linked dominant and X-linked trinucleotide-repeat disorders

- ▶ **X-linked dominant**: mutant allele expressed in heterozygous females and hemizygous males; many are **lethal or very severe in males** (e.g., **Rett syndrome (MECP2)**, which predominantly affects girls). *Standard additional examples*: X-linked (vitamin D-resistant) hypophosphataemic rickets and incontinentia pigmenti.

- ▶ **X-linked trinucleotide-repeat (dynamic-mutation) disorders** (Harrison Table 479-5):
 - **Fragile X (FRAXA)**: CGG repeat, Xq27.3; normal 6–50 → disease 200–300 (full mutation), FMR-1 protein.
 - **Fragile X (FRAXE)**: GCC repeat, Xq28; FMR-2 protein.
 - **Spinobulbar muscular atrophy (Kennedy)**: CAG repeat, Xq12; normal 11–34 → disease 40–62; androgen receptor.
- ▶ **Anticipation**: when repeat length increases across generations, disease becomes more severe or presents earlier — a key feature of these dynamic-mutation X-linked diseases.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **X-linked recessive pedigree (3 generations)**: labels — *Affected male* (filled square), *Carrier female* (circle with central dot), *Unaffected male/female* (open symbols), “No male-to-male transmission”, “All daughters of affected male = obligate carriers”, “Skipped generation / criss-cross inheritance”.
- ▶ **Punnett square — carrier mother ($X^A X$) × normal father ($X Y$)**: label gametes X^A , X (mother) and X , Y (father); offspring boxes — *Unaffected daughter* (XX), *Carrier daughter* ($X^A X$), *Unaffected son* (XY), *Affected son* ($X^A Y$); annotate “50% sons affected, 50% daughters carriers.”

Clinical / Diagnostic significance

- ▶ **Carrier detection and counselling**: identifying obligate/possible carrier females (daughters of affected men, mothers of an affected son) allows **genetic counselling, prenatal diagnosis and recurrence-risk estimation**; molecular testing is now routine for monogenic disorders.
- ▶ **Manifesting carriers**: skewed X-inactivation explains why some carrier women (e.g., Fabry, occasionally DMD) show clinical features — do not assume all female carriers are asymptomatic.
- ▶ **Genotype–phenotype and management**: DMD mutation type predicts Duchenne vs Becker severity; targeted therapies include **exon-skipping antisense oligonucleotides** and **stop-codon read-through**. G6PD carriers/patients must **avoid oxidant drugs and fava beans**; haemophilia is managed with the **specific deficient factor**.
- ▶ **Sex-reversal correlate (Y-linked)**: SRY/testis-determining factor and AZF deletions are male-specific — useful contrast in disorders-of-sex-development work-up.

High-yield exam pointers

- ▶ **No male-to-male transmission** is the single most discriminating feature of X-linked inheritance.
- ▶ **All daughters of an affected male are obligate carriers**; affected sons inherit the mutant X from a carrier mother.
- ▶ Males are **hemizygous** → express both X-linked recessive and dominant alleles fully.

- ▶ *X-linked dominant / recessive* terminology applies to **expression in females**, modulated by **X-inactivation**.
- ▶ Haemophilia A (factor VIII), haemophilia B (factor IX), G6PD deficiency, Fabry, DMD/Becker, Fragile X, Kennedy disease = classic XLR; Rett syndrome (MECP2) = classic XLD.
- ▶ DMD (dystrophin, 2.3 Mb, 79 exons) is the commonest muscular dystrophy; allelic severity → Duchenne vs Becker.
- ▶ Fragile X, Kennedy disease are X-linked trinucleotide-repeat disorders showing anticipation.
- ▶ Carrier females may be symptomatic (“manifesting carriers”) through skewed X-inactivation.

SOURCE & COVERAGE

Harrison’s Principles of Internal Medicine, 22e — Ch 479 “Principles of Human Genetics” (X-linked & Y-linked inheritance, X-inactivation, genotype–phenotype correlation, Tables 479-2/479-5) and Ch 480 “The Integration of Inherited Genetics into Clinical Practice” (monogenic disorders with genetics-based interventions — haemophilia A/B, G6PD deficiency, nephrogenic DI, DMD; genetic counselling/carrier testing). **Coverage note:** The eponym “*Lyonization/Lyon hypothesis*” for X-inactivation, the gene symbol *GLA* for Fabry’s α-galactosidase A, the carrier-cross segregation ratios (50% affected sons / 50% carrier daughters), the female:male excess in XLD, and the additional XLD examples (X-linked hypophosphataemic rickets, incontinentia pigmenti) are universally accepted standard genetics added for completeness and are not stated verbatim in Ch 479/480; the X-inactivation mechanism, hemizyosity, transmission rules and all listed disorders/genes are grounded in the provided text.
