Cardiology	17
Aortic Regurgitation	17
Atrial Fibrillation.....	22
Bradyarrhythmias.....	27
Bundle Branch Blocks.....	32
Cardiac Resynchronization Therapy	36
Cardiac Syncope	41
Cardiac tamponade	46
Cardiogenic pulmonary edema	52
Cardiomyopathies	57
Classify Cardiomyopathy. What are the risk factors, clinical presentations and prognosis of peripartum Cardiomyopathy?	62
Conducting system of the Heart and Electrocardiogram	67
Constrictive Pericarditis	72
Cor Pulmonale.....	77
Describe conduction system of the heart and add a note on complete heart block.....	82
Describe the structure of the Mitral Valve apparatus. Discuss the etiology, clinical features and management of Mitral Stenosis.....	87
Diastolic Heart Failure (Heart Failure with Preserved Ejection Fraction)	93
Differential Diagnosis of Mid-Diastolic Murmurs	98
Discuss the diagnosis and management of chronic heart failure with preserved ejection fraction .	103
Discuss the etiology, clinical manifestations and management of Acute ST elevation Myocardial infarction (STEMI).....	108
Early Invasive Strategy in Patients with Non-ST-Segment Elevation Acute Coronary Syndrome..	113
Emerging therapies and strategies in treatment of Heart failure.....	118
Endomyocardial fibrosis.....	123
Hypertrophic Cardiomyopathy.....	128
Left ventricular remodeling	133
Management of Supraventricular Tachycardia.....	138
Narrow QRS Tachycardia	143
Neurally mediated syncope.....	147
Pathogenesis and Management of Congestive Cardiac Failure	153
Pericarditis.....	158
QT Interval Prolongation and Torsades de Pointes	163
Stroke Prevention in Atrial Fibrillation.....	168

Syncope.....	174
Takotsubo cardiomyopathy.....	179
Treatment options for management of pulmonary embolism.....	184
What are the indications for coronary arteriography? What are the complications of the procedure?	188
Cardiac Resynchronization Therapy (CRT): Rationale, Indications and Contraindications.....	194
Atrial Fibrillation — Risk Factors and Management	198
Neurology	203
Acute Disseminated Encephalomyelitis.....	203
Aetiology, pathogenesis and management of Parkinson's disease	208
Alzheimer's Disease	213
Approach to Coma.....	218
Autosomal Recessive Ataxias.....	223
Benign Intracranial hypertension	228
Cerebral venous sinus thrombosis	233
Clinical features and management of Alzheimer's disease	237
Clinical features, pathophysiology and management of trigeminal neuralgia. Differentiate trigeminal neuralgia from trigeminal neuropathy.....	242
Describe the physiological anatomy of neuromuscular junction and explain how diseases involving the neuromuscular junction cause muscle weakness	247
Posterior (Vertebrobasilar) Circulation of the Brain: Anatomy and Clinical Relevance	252
Differential Diagnosis of Seizures	257
Paraneoplastic Neurological Syndromes: Presentation, Associated Tumours and Antibodies	262
Discuss the Causes and Management of Seizures.....	268
Acute Ischemic Stroke Involving the Right Internal Capsule	274
Discuss the indications and options for reperfusion therapy in acute stroke	279
Endovascular revascularization for acute ischemic stroke	283
Reversible Causes of Dementia and Differentiation of Alzheimer's Disease from Frontotemporal Dementia	287
Epilepsy syndromes.....	292
Etiology and management of orthostatic hypotension	298

Cardiology

Aortic Regurgitation

Asked in: Paper II Nov 2019 — RGUHS MD General Medicine

Definition / Introduction — Aortic regurgitation (AR) is the diastolic reflux of blood from the aorta into the left ventricle (LV) due to failure of competent coaptation of the aortic valve leaflets. It arises from **primary disease of the valve leaflets, dilation of the aortic root/ascending aorta, or a combination of both**. It imposes a *combined volume (preload) and pressure (afterload) overload* on the LV, and may present as a slowly tolerated **chronic** lesion or as a catastrophic **acute** lesion causing fulminant pulmonary oedema and cardiogenic shock.

Etiology and pathology

AR is conveniently classified by the structure primarily at fault (Harrison Table 273-1; Braunwald Table 69.1). In contemporary surgical series, **aortic root disease now accounts for >50% of patients** undergoing AVR for isolated AR.

Mechanism	Causes
Valvular (leaflet) disease	Congenital bicuspid aortic valve (BAV) — commonest in young; rheumatic heart disease (leaflet thickening, retraction, commissural fusion → mixed AS+AR); infective endocarditis (perforation/destruction, vegetation); myxomatous prolapse; calcific degeneration in the elderly; trauma; unicuspid/quadracuspid valves; bioprosthetic degeneration; paravalvular leak after TAVR; radiation; anorectic drugs
Aortic root / ascending aorta disease	Age-related (degenerative) dilation; systemic hypertension ; Marfan syndrome (cystic medial degeneration), annuloaortic ectasia, Ehlers-Danlos, osteogenesis imperfecta; aortic dissection ; syphilitic aortitis; ankylosing spondylitis ; Takayasu and giant-cell aortitis; Behçet, reactive/psoriatic arthritis
Combined valve + root	Bicuspid aortic valve with aortopathy; ankylosing spondylitis

- ▶ **Acute severe AR** is caused chiefly by **infective endocarditis, aortic dissection (type A), and trauma**.
- ▶ Root dilation sets up a *vicious cycle* — dilation separates the cusps → AR → further dilation → more AR.

Pathophysiology

- ▶ In contrast to mitral regurgitation (low-pressure run-off into the LA), in AR the **entire LV stroke volume is ejected into the high-pressure aorta**; the regurgitant volume may equal the effective forward stroke volume.
- ▶ **Chronic AR — combined preload + afterload overload**: increased end-diastolic volume (preload) is the major compensation. The LV undergoes **eccentric hypertrophy** (sarcomeres replicated *in series*, myocyte elongation) and chamber dilation, normalising wall stress (Laplace law: $\text{stress} \propto \text{pressure} \times \text{radius} \div \text{wall thickness}$). This permits a *normal effective forward stroke volume and normal EF* despite severe regurgitation. Hearts may reach the largest size in all of cardiology — **cor bovinum**, sometimes >1000 g.
- ▶ With time, wall thickening fails to keep pace → **afterload mismatch**, rising end-systolic volume, interstitial fibrosis, and a *fall in EF*. Crucially, **LV dysfunction often becomes irreversible before symptoms appear** — the central reason for serial surveillance.
- ▶ **Myocardial ischaemia** even with normal coronaries: O₂ demand is high (dilation, hypertrophy, raised systolic wall tension) while O₂ supply is reduced — coronary perfusion occurs mainly in diastole, when aortic pressure is low → reduced coronary driving pressure, subendocardial ischaemia, nocturnal angina.
- ▶ **Acute severe AR**: the normal-sized, non-compliant LV cannot accommodate the sudden regurgitant load → LV diastolic pressure rises steeply (>40 mmHg), forcing **premature mitral valve closure**, a sharp fall in forward stroke volume, compensatory tachycardia, and rapid pulmonary oedema/cardiogenic shock. The pulse pressure is **not** widened and peripheral signs are absent — masking severity.

Clinical features

Symptoms — Chronic AR has a long latent period; patients stay asymptomatic for 10–15 years. Early: uncomfortable awareness of the heartbeat, palpitations, head pounding (especially lying down). Later: **exertional dyspnoea** (first symptom of failing reserve) → orthopnoea, PND, diaphoresis; **angina** (often nocturnal, poorly responsive to nitrates) even without coronary disease; finally overt heart failure. Once symptomatic, the course is rapidly downhill — historically death ~4 years after angina and ~2 years after onset of heart failure.

Peripheral signs of a wide pulse pressure (chronic severe AR):

Eponym	Sign
Corrigan pulse	Water-hammer pulse — rapid rise, sudden collapse
de Musset sign	Head bob with each systole
Quincke sign	Visible capillary nail-bed pulsations
Müller sign	Systolic pulsation of the uvula

Eponym	Sign
Traube sign	“Pistol-shot” booming systolic + diastolic sounds over femorals
Duroziez sign	To-and-fro murmur on light femoral compression
Hill sign	Popliteal cuff systolic pressure >40 mmHg higher than brachial
Bisferiens pulse	Twin systolic peaks (esp. mixed AS+AR)

Precordium/auscultation: apex diffuse, hyperdynamic, displaced **down and to the left**; widened pulse pressure (high systolic, low diastolic, often <60 mmHg). The hallmark is a **high-pitched, blowing, decrescendo early-diastolic murmur** beginning immediately after A2, best heard in the **3rd–4th left intercostal space at the lower left sternal border**, with the patient *sitting, leaning forward, breath held in expiration*. A right-sternal-border murmur suggests **root/aortic dilation as the cause**. *Severity correlates with murmur duration (holodiastolic), not loudness*. Associated: soft/absent A2, S3 (LV dysfunction), a basal systolic ejection (flow) murmur, and the **Austin Flint murmur** — a low-pitched mid-to-late diastolic apical rumble from the regurgitant jet impinging on the anterior mitral leaflet (no organic mitral stenosis). Handgrip (↑afterload) intensifies the murmur. In **acute AR**, signs are deceptively subtle: soft S1, short soft diastolic murmur, near-normal pulse pressure, tachycardia, pulmonary oedema.

Investigations

- ▶ ECG — LV hypertrophy with “strain” (ST depression, T inversion in I, aVL, V5–V6); left axis deviation/QRS prolongation. In acute AR — sinus tachycardia; progressive heart block on serial tracings suggests an **aortic root abscess**.
- ▶ Chest X-ray — chronic: cardiomegaly with apex displaced down and left, dilated ascending aorta if root disease. Acute: near-normal heart size with florid pulmonary oedema.
- ▶ Transthoracic echocardiography (TTE) — cornerstone of diagnosis, aetiology, severity and serial follow-up. Defines leaflet/root anatomy; high-frequency **diastolic fluttering of the anterior mitral leaflet**; measures LV dimensions, volumes, EF and mass. Color/spectral Doppler grades severity.
- ▶ Doppler criteria of severe AR: central jet width >65% of LVOT; vena contracta >0.6 cm; regurgitant volume ≥60 mL/beat; regurgitant fraction ≥50%; effective regurgitant orifice ≥0.30 cm²; holodiastolic flow reversal in the proximal descending/abdominal aorta; pressure half-time <200 ms. Global longitudinal strain (GLS) detects subclinical dysfunction before EF falls.
- ▶ Cardiac MRI — most accurate for LV volumes, mass and regurgitant fraction; assesses aortic dimensions and **myocardial fibrosis (late gadolinium enhancement, T1 mapping/ECV)**; used when TTE is suboptimal/discordant.

- ▶ TEE / cardiac CT — detailed valve, root and ascending-aorta anatomy. **Cardiac catheterisation/aortography** when non-invasive data are discordant; **coronary angiography** before surgery in at-risk patients.

Staging (2020 ACC/AHA)

- ▶ **Stage A** — at risk (BAV, root disease, history of rheumatic fever); **Stage B** — progressive mild–moderate AR; **Stage C** — asymptomatic severe AR (C1 normal EF >55% with mild–moderate dilation; C2 EF ≤55% or LVESD >50 mm / indexed >25 mm/m²); **Stage D** — symptomatic severe AR.

Management

Acute severe AR — a *surgical emergency*; **AVR within 24–48 h** is life-saving. While stabilising: IV vasodilator (sodium nitroprusside) ± inotrope (dopamine/dobutamine). **Beta-blockers are avoided** (they blunt the compensatory tachycardia and prolong diastolic regurgitation) and **intra-aortic balloon counterpulsation is contraindicated** (augments diastolic regurgitation). With endocarditis, defer 5–7 days for antibiotics only if haemodynamically stable; operate at the first sign of instability or abscess; in dissection, repair the aorta concurrently.

Chronic AR — medical — No drug halts progression; vasodilators do *not* prolong the compensated phase in asymptomatic patients with normal BP. Treat **hypertension (SBP >140 mmHg)** with vasodilators (ACE-I/ARB, dihydropyridine CCB, hydralazine). **Beta-blockers/losartan** retard root growth in **Marfan syndrome** (atenolol and losartan equivalent in the paediatric trial). Symptomatic patients unfit for surgery receive guideline-directed heart-failure therapy. Avoid isometric/strenuous exercise with significant aortopathy.

Chronic AR — surgical indications (Class I/IIa):

- ▶ **Symptomatic severe AR (Stage D)** — AVR regardless of LV function.
- ▶ **Asymptomatic severe AR with EF ≤55% (Stage C2)** — AVR indicated.
- ▶ **Severe AR (Stage C/D) undergoing other cardiac surgery.**
- ▶ Asymptomatic severe AR, normal EF, but **LVESD >50 mm or indexed LVESD >25 mm/m²** — reasonable (newer data favour an even lower index threshold ≥20 mm/m²).
- ▶ **IIb: progressive EF decline (to 55–60%) on ≥3 serial studies or LVEDD >65 mm at low surgical risk.**
- ▶ *Delay beyond ~1 year of symptoms/dysfunction risks failure to recover normal LV size and function, hence 6–12 monthly surveillance.*

Surgical options — AVR with **mechanical or bioprosthetic valve** is standard (operative mortality ~1–2% for isolated pure AR). For root pathology: **valve-sparing aortic root reconstruction (David reimplantation procedure)**; **composite valve-graft conduit (Bentall)** when both valve and aneurysmal aorta need replacement; concomitant ascending-aorta replacement if diameter >45 mm. Ross

procedure (pulmonary autograft) in selected young adults at expert centres. **Aortic valve repair** is feasible in selected younger patients but, unlike mitral regurgitation, the majority of AR patients ultimately need replacement. **TAVI is NOT recommended for surgical candidates** with pure native AR (limited by annular dilation and lack of valvular calcium for anchoring).

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Pathophysiology flow diagram of AR:** boxes/arrows — *Aortic regurgitation* → ↑LV diastolic volume (↑preload) + ↑aortic systolic pressure (↑afterload) → *eccentric hypertrophy + chamber dilation (cor bovinum)* → *maintained EF/forward SV* → *afterload mismatch* → ↑LVESV, ↓EF, *interstitial fibrosis* → *LV failure*; side branch — ↓diastolic coronary perfusion + ↑O₂ demand → *subendocardial ischaemia*. Labels: LVEDP, effective stroke volume, regurgitant fraction, myocardial O₂ supply/demand.
- ▶ **Auscultation/peripheral-sign figure:** chest outline marking the **decrecendo early-diastolic murmur at 3rd–4th left ICS (lower left sternal border)**, **basal systolic flow murmur**, **apical Austin Flint rumble**, **displaced apex (down-and-left)**; annotate peripheral signs — Corrigan, de Musset, Quincke, Müller, Traube, Duroziez, Hill, bisferiens, wide pulse pressure.

Clinical / Diagnostic significance

- ▶ AR uniquely loads the LV with **both preload and afterload**; the danger is **silent, irreversible LV dysfunction preceding symptoms** — mandating serial echo (6–12 monthly in severe AR).
- ▶ The **decrecendo diastolic murmur intensity reflects severity poorly**; **duration (holodiastolic) and a wide pulse pressure are better markers**. Murmur loudest at the **right sternal border** points to root/aortic disease.
- ▶ A **deceptively normal pulse pressure in an acutely ill, tachycardic patient with pulmonary oedema** should raise suspicion of **acute severe AR (endocarditis/dissection)** — do not be reassured.
- ▶ **Austin Flint murmur** mimics mitral stenosis but lacks a loud S1/opening snap and occurs with a normal mitral valve.
- ▶ Newer prognostic markers — **indexed LVESV >45 mL/m², GLS, regurgitant fraction, and LGE-fibrosis on CMR** — increasingly refine the timing of intervention.

High-yield exam pointers

- ▶ Commonest cause of **chronic AR now = aortic root disease (>50%)**; commonest **valvular** cause in young = **bicuspid aortic valve**; commonest **acute** causes = **endocarditis, dissection, trauma**.
- ▶ **Eccentric hypertrophy** → **cor bovinum** (heart may exceed 1000 g) — largest LV in cardiology.
- ▶ Severe AR Doppler: **jet width >65% LVOT, vena contracta >0.6 cm, RVol ≥60 mL, RF ≥50%, ERO ≥0.30 cm², holodiastolic aortic flow reversal**.

- ▶ **Hill sign** = popliteal SBP >40 mmHg above brachial; **Duroziez** = to-and-fro femoral murmur; **Traube** = pistol-shot femorals.
- ▶ Operate for symptoms regardless of EF; or EF ≤55%; or LVESD >50 mm (>25 mm/m²); or LVEDD >65 mm.
- ▶ Acute AR = surgical emergency (AVR within 24–48 h); nitroprusside ± inotrope; AVOID beta-blockers and IABP.
- ▶ **David** = valve-sparing reimplantation; **Bentall** = composite valve-graft; replace ascending aorta if >45 mm.
- ▶ TAVI is not recommended for surgical candidates with isolated native AR.
- ▶ Beta-blockers/losartan slow root dilation in **Marfan syndrome**.

Atrial Fibrillation

Asked in: Paper II May 2022 — RGUHS MD General Medicine

Definition / Introduction — Atrial fibrillation (AF) is a supraventricular arrhythmia characterised by seemingly disorganised, rapid and irregular atrial electrical activation with **loss of organised atrial mechanical contraction**. The chaotic atrial impulses bombard the AV node, which gates ventricular activation, producing an **irregularly irregular, usually rapid ventricular rate** (typically 110–160/min). It is the most common sustained arrhythmia and a major public health problem because of its strong association with stroke, heart failure, dementia and increased mortality.

Epidemiology and Risk Factors

- ▶ **Most common sustained arrhythmia**; prevalence rises steeply with age — >95% of AF patients are >60 years and prevalence in those >80 years is ~20%.
- ▶ Lifetime risk of developing AF for a 40-year-old man is ~25%. Slightly commoner in **men > women** and in **whites > blacks**.

- ▶ AF carries a **1.5–1.9-fold increase in mortality** even after controlling for underlying cardiac disease, and causes **~25% of all strokes**.
- ▶ AF is detected in up to **8.9%** of patients within 6 months of a *cryptogenic stroke* using insertable cardiac monitors.
- ▶ **Risk factors:** age, underlying cardiac disease, hypertension, diabetes mellitus, obesity, thyroid disease (hyperthyroidism), family history of AF, alcohol use and sleep-disordered breathing.
- ▶ **Identifiable precipitants:** hyperthyroidism, acute alcohol intoxication (“holiday heart”), myocardial infarction, pulmonary embolism, pericarditis, and cardiac surgery (AF occurs in up to **50%** of patients post-operatively).
- ▶ Consequences: increased risk of **dementia**, MRI-detected asymptomatic embolic infarcts, congestive heart failure and tachycardia-induced cardiomyopathy (when rate is uncontrolled for prolonged periods).

Pathophysiology

- ▶ Multifactorial; the diverse risk factors are proposed to converge on a **“final common pathway”** producing electrophysiologic remodelling of atrial tissue.
- ▶ Altered membrane channels and protein regulation cause **abnormal excitability**; **pulmonary vein musculature** exhibits enhanced automaticity, generating ectopic beats (PACs).
- ▶ Bouts of rapid atrial ectopy initiate atrial tachycardia or frank AF; sustained AF is maintained by a combination of automaticity-based **“drivers”** and areas of **functional reentry**.
- ▶ Progressive cellular and tissue remodelling → **shortening of atrial refractory periods**, abnormal conduction, **fibrosis** and **left atrial enlargement**, which perpetuate AF (“AF begets AF”).
- ▶ Non-pulmonary-vein triggers: posterior wall of left atrium, muscular sleeves of the **superior vena cava**, **coronary sinus**, and the **vein of Marshall** remnant.
- ▶ Loss of atrial systole and a noncompliant, fibrotic left atrium produce elevated filling pressures and volume overload — the **“stiff left atrial syndrome.”**

Classification (by Temporal Pattern)

Type	Definition	LA size / scar	AAD efficacy	Ablation
Paroxysmal	Self-terminates or cardioverted in ≤7 days	Normal–mildly enlarged	Low	PV isolation alone usually effective; first-line reasonable
Persistent	Continuous >7 days but <1 year	Mild–severely enlarged	Moderate	PV isolation + non-PV sources; usually after AAD failure

Type	Definition	LA size / scar	AAD efficacy	Ablation
Long-standing persistent	Persistent >1 year	Typically severely enlarged	High failure rate	PV isolation + substrate modification; often refractory

- ▶ **Nonvalvular AF** = AF *without* mitral stenosis (the term guides anticoagulant choice).
- ▶ **Subclinical AF** — short-lasting, asymptomatic episodes detected only by implantable loop recorders/pacemakers; associated with a **2.5-fold** increased stroke risk.

Clinical Presentation

- ▶ Manifestations arise from: (1) symptoms of the irregular, fast (or slow) ventricular rate; (2) haemodynamic consequences of lost atrial contraction; (3) cardioembolic events; and (4) long-term impact on cardiac function.
- ▶ **Palpitations**, awareness of heartbeat, fatigue, weakness, exercise intolerance, dyspnoea, presyncope — though many patients are **asymptomatic** / **unaware** of the irregularity.
- ▶ Loss of atrial “kick” reduces ventricular filling and stroke volume — especially decompensating in **HCM, coronary or valvular disease, HFrEF/HFpEF and amyloidosis**.
- ▶ With AV nodal disease or high vagal tone, bradycardia or **conversion pauses** (sinus node dysfunction / tachy-brady syndrome) may cause syncope.
- ▶ **Diagnosis** is by ECG (12-lead, ambulatory monitor, or implantable loop recorder): **absent P waves**, fibrillatory baseline best seen in **lead V1**, and an **irregularly irregular** ventricular response.

Treatment — Three Aims

The management of AF centres on three goals: (1) **symptom control by rate and/or rhythm control**; (2) **mitigation of thromboembolic (stroke) risk**; and (3) **addressing modifiable risk factors** for progression.

- ▶ **Emergency**: If significant haemodynamic compromise, pulmonary oedema or coronary ischaemia is present → **emergent (synchronised DC) cardioversion**.

Rate control

- ▶ Goal: prolong diastolic filling, improve cardiac output, prevent tachycardia-induced cardiomyopathy.
- ▶ Acute: **beta blockers** and/or **non-dihydropyridine calcium channel blockers (verapamil, diltiazem)** IV or oral.
- ▶ **Digoxin** — useful with labile BP or cardiomyopathy (no negative inotropy); acts synergistically as add-on. Chronic use associated with **increased mortality**, so its use has declined.

- ▶ Chronic targets: strict = resting HR <80/min (and <110 on moderate exertion); **lenient** = resting HR <110/min is as effective for CV death, HF hospitalisation, stroke and bleeding, and easier to achieve.
- ▶ “**Ablate and pace**”: AV junction ablation + permanent pacemaker for refractory rates; biventricular or **left bundle branch area pacing** minimises dyssynchrony and improves outcomes in permanent AF with narrow QRS.

Stroke prevention / anticoagulation

- ▶ Thrombus forms chiefly in the **left atrial appendage** (stagnant flow); risk assessed by **CHA₂DS₂-VASc**, bleeding risk by **HAS-BLED**.
- ▶ Anticoagulation recommended for CHA₂DS₂-VASc ≥1 (unless the sole point is female sex); annual stroke risk reaches nearly **20%** at high scores.
- ▶ **DOACs** (dabigatran, rivaroxaban, apixaban, edoxaban) were non-inferior to warfarin in nonvalvular AF, with **lower intracranial bleeding**; pooled data suggest small absolute superiority.
- ▶ **Warfarin is mandatory** for rheumatic mitral stenosis and mechanical valves (DOACs failed/inferior here). In nonvalvular AF warfarin cuts stroke by ~64% vs placebo, 37% vs antiplatelets.
- ▶ **Antiplatelets alone are inferior** and not safer; aspirin+clopidogrel < warfarin and bleeds more.
- ▶ Reversal: warfarin → vitamin K, FFP, PCC; dabigatran → **idarucizumab**; factor Xa inhibitors → **andexanet alfa**.
- ▶ **LAA closure device (Watchman)** for high stroke risk with contraindication to anticoagulation — comparable to warfarin, less major/haemorrhagic bleeding, non-inferior to DOACs.

Cardioversion and peri-cardioversion anticoagulation

- ▶ Pharmacologic cardioversion: IV **ibutilide** (class III) — avoid with baseline prolonged QT or severe LV dysfunction (risk of *torsades de pointes*).
- ▶ If AF >48 h or duration unknown: either anticoagulate **3 weeks before + ≥4 weeks after**, OR perform TEE (or delayed-acquisition cardiac CT) to exclude LAA thrombus before cardioversion, then anticoagulate ≥4 weeks (atrial mechanical recovery delayed — “**atrial stunning**”).

Rhythm control

- ▶ Preferred for symptomatic paroxysmal/persistent AF, difficult rate control, or AF-induced LV dysfunction; favoured in younger patients.
- ▶ **Early rhythm control** (within 1 year of presentation) reduces cardiovascular events; catheter ablation gives an **all-cause mortality benefit** in HFrEF.

- ▶ AADs without structural disease: class I (**flecainide, propafenone, disopyramide**). With structural/coronary disease: **sotalol, dofetilide** (~3% torsades risk; dofetilide initiated in hospital).
- ▶ **Amiodarone** is the most effective (maintains sinus rhythm in ~2/3) and safe in HF/CAD, but >40% develop toxicities (skin, liver, lung, thyroid). **Dronedarone** increases mortality in HF and long-standing persistent AF.
- ▶ **Catheter ablation (pulmonary vein isolation)** — first-line for paroxysmal AF; ~80% maintain sinus rhythm at 1 year after a single procedure. **Pulsed-field ablation** (electroporation) selectively targets myocardium and is non-inferior to thermal ablation.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Diagram 1 — ECG of AF:** A rhythm strip emphasising lead V1. Labels: *Absent P waves, Fibrillatory (f) waves / chaotic baseline, Irregularly irregular R-R intervals, Narrow QRS complexes.* (Optionally show a “blocked PAC” then “PAC initiates AF” as the trigger.)
- ▶ **Diagram 2 — Left atrium and pulmonary vein triggers:** Outline of the left atrium with four pulmonary veins. Labels: *Pulmonary vein musculature (ectopic triggers), Posterior LA wall, Left atrial appendage (thrombus site), Circumferential PV isolation ablation lesion set, Vein of Marshall.*

Clinical / Diagnostic significance

- ▶ AF is **not benign** — independent marker of mortality and the cause of ~25% of strokes; aggressive risk-factor modification (BP, obesity, alcohol, OSA, diabetes) is now a core treatment aim.
- ▶ **Always screen for thyrotoxicosis** and reversible precipitants in new-onset AF.
- ▶ **CHA₂DS₂-VASc** drives anticoagulation decisions; HAS-BLED quantifies but does not by itself withhold therapy.
- ▶ **TEE** before cardioversion when AF >48 h excludes LAA thrombus and shortens delay to cardioversion.
- ▶ Persistent uncontrolled rates → **tachycardia-induced cardiomyopathy**, which is largely reversible with rate control.
- ▶ Ablation complications to counsel: stroke (0.5–1%), tamponade (~1%), phrenic nerve palsy, PV stenosis, and the rare but lethal **atrio-oesophageal fistula** (<0.1%, presents 10 days–3 weeks later with fever/sepsis, stroke).

High-yield exam pointers

- ▶ AF = **irregularly irregular rhythm, absent P waves, fibrillatory baseline** best seen in V1.
- ▶ Three aims: **rate ± rhythm control, stroke prevention, risk-factor modification.**

- ▶ Stroke risk = **CHA₂DS₂-VASc**; bleeding risk = **HAS-BLED**; anticoagulate if score ≥ 1 (≥ 2 in men/ ≥ 3 women per practice; female-only point does not mandate).
- ▶ **DOACs preferred** in nonvalvular AF; **warfarin mandatory** in rheumatic MS / mechanical valves.
- ▶ Reversal agents: **idarucizumab** (dabigatran), **andexanet alfa** (Xa inhibitors).
- ▶ The **48-hour rule**: AF >48 h or unknown $\rightarrow$ 3 weeks pre + 4 weeks post anticoagulation, or TEE-guided cardioversion; beware **atrial stunning**.
- ▶ **Amiodarone** = most effective AAD but most toxic; **dronedarone contraindicated** in HF.
- ▶ **Pulmonary vein isolation** is first-line rhythm control for paroxysmal AF; thrombus forms in the **left atrial appendage**.
- ▶ Classify by duration: **paroxysmal** ≤ 7 days, **persistent** >7 days <1 year, **long-standing persistent** >1 year.

SOURCE & COVERAGE

Harrison's Principles of Internal Medicine, 22e — Ch 258 "Atrial Fibrillation" (Sauer, Romero, Zei). The chapter fully supports this answer; the conventional CHA₂DS₂-VASc threshold wording (anticoagulate men ≥ 2 / women ≥ 3) is standard textbook practice consistent with the chapter's "score ≥ 1 unless lone female point" statement.

Bradyarrhythmias

Asked in: Paper II Jul 2021 — RGUHS MD General Medicine

Definition / Introduction — A **bradyarrhythmia** is a sustained or intermittent heart rate <60 beats/min arising from disordered impulse *formation* in the sinoatrial (SA) node (**sinus node dysfunction, SND**) or disordered impulse *conduction* through the atrioventricular (AV) node and His–Purkinje system (**AV block / heart block**). It may be **physiologic** (high vagal tone, athletes, sleep) or **pathologic**, and clinically ranges from asymptomatic sinus bradycardia to syncope and asystolic sudden death. **Permanent pacing is the only reliable long-term therapy** for irreversible, symptomatic, or high-risk bradycardia.

Anatomy & physiology of the conduction axis

- ▶ **SA node**: crescent of fusiform pacemaker myocytes in the *sulcus terminalis* at the right atrial–SVC junction; supplied by the SA nodal artery (from **RCA in 55–60%**, left circumflex in 40–45%). Slow **phase-4 diastolic depolarization** driven by the **funny current (I_f)** plus **T- and L-type Ca²⁺ currents**; phase 0 upstroke is Ca²⁺-mediated (no fast Na⁺ channel). Normal automaticity **60–100/min**.

- ▶ **Intrinsic heart rate** (after autonomic blockade with atropine + propranolol) $\approx 100\text{--}110/\text{min}$, calculated as $118.1 - (0.57 \times \text{age})$; it declines $5\text{--}6/\text{min}$ per decade.
- ▶ **AV node**: $\sim 1 \times 3 \times 5 \text{ mm}$ at the apex of the **triangle of Koch** (boundaries: coronary sinus ostium, septal tricuspid annulus, tendon of Todaro); supplied by the AV nodal artery (RCA 80–90%, LCx 10%). Provides physiologic conduction delay and **decremental conduction**; subsidiary automaticity $20\text{--}60/\text{min}$.
- ▶ **His–Purkinje system**: fastest conduction ($1\text{--}3 \text{ m/s}$); His bundle and bundle branches are **insulated and NOT influenced by autonomic tone**; ventricular (idioventricular) escape is slow ($<40/\text{min}$) and unreliable.

Sinus node dysfunction (sick sinus syndrome) — subtypes

- ▶ **Sinus bradycardia / sinus arrest**: failure of impulse formation.
- ▶ **Sinoatrial exit block**: failure of the sinus impulse to propagate to the atrium — Type I (SA Wenckebach: progressive P-P shortening then a pause $<2\times$ the cycle) and Type II (sudden pause exactly twice the P-P interval).
- ▶ **Tachycardia–bradycardia (tachy-brady) syndrome**: alternating atrial tachyarrhythmia (usually AF/flutter) with symptomatic bradycardia or a long **offset pause** after tachycardia termination; rate-control drugs worsen the bradycardia — a common trigger for pacing.
- ▶ **Chronotropic incompetence**: failure to reach $\sim 85\%$ of age-predicted maximum $[(220 - \text{age}) \times 0.85]$ on exertion; a major cause of exercise intolerance.
- ▶ **Causes**: age-related **sinus node fibrosis** and pacemaker-cell loss (commonest), inferior/posterior MI (SA nodal ischaemia, *Bezold–Jarisch reflex*), carotid sinus hypersensitivity / neurally-mediated (cardioinhibitory vasovagal) syncope, post-cardiac surgery / transplant, AF-ablation injury.

AV (heart) block — ECG classification

Grade	ECG hallmark	Usual site	Escape / risk
First-degree	Fixed PR $>200 \text{ ms}$, every P conducts	AV node (AH delay)	Benign
2°, Mobitz I (Wenckebach)	Progressive PR lengthening $\rightarrow$ dropped QRS; grouped beating, RR shortens	AV node	Stable, often vagal/benign
2°, Mobitz II	Fixed PR then sudden dropped QRS; usually wide QRS	Infranodal (His–Purkinje)	Unreliable escape; risk of sudden CHB
2:1 block	Cannot classify I vs II from a single strip	PR $<160 \text{ ms}$ + wide QRS $\rightarrow$ infranodal	Localise by QRS/PR

Grade	ECG hallmark	Usual site	Escape / risk
Third-degree (complete)	AV dissociation, atrial rate > ventricular rate, regular slow QRS	Nodal or infranodal	Junctional (narrow, 40–60) vs ventricular (wide, <40) escape

- ▶ **Localising rule:** a **narrow QRS** escape implies block in the AV node/proximal His with a faster, more stable junctional escape; a **wide QRS** escape implies distal His/bundle-branch block with a slow, unreliable rhythm.
- ▶ **High-grade (advanced) block** = ≥ 2 consecutive non-conducted P waves with some conduction preserved.

Aetiology of AV conduction disease

- ▶ **Degenerative/idiopathic fibrosis (~50%):** *Lev's disease* (proximal bundle-branch fibrosis/calcification, elderly) and *Lenègre's disease* (distal sclerodegeneration, younger patients); accelerated by hypertension, diabetes, atherosclerosis; familial forms with SCN5A mutation.
- ▶ **Ischaemic:** transient block in 10–25% of acute MI. *Inferior MI* — block usually **proximal (intranodal)** in ~90%, narrow stable escape >40/min, often reversible (vagal/AV-nodal artery). *Anterior MI* — **infranodal**, wide unstable escape, extensive infarction, high mortality → temporary pacing.
- ▶ **Infective:** *Lyme carditis* (*Borrelia burgdorferi*; reversible with antibiotics), infective endocarditis with **peri-valvular abscess** (surgical emergency), viral myocarditis, **Chagas' disease**, toxoplasmosis.
- ▶ **Infiltrative/inflammatory:** **cardiac sarcoidosis** (suspect AV block age ≤ 60 → MRI/FDG-PET), amyloidosis, haemochromatosis, SLE, RA, scleroderma.
- ▶ **Iatrogenic/drug:** valve surgery, TAVR, alcohol septal ablation, catheter ablation; **β -blockers**, verapamil, diltiazem, digoxin; toxins.
- ▶ **Congenital:** maternal **anti-Ro/SLE** (neonatal lupus), structural CHD (TGA, ostium primum ASD, endocardial-cushion defects).
- ▶ **Neuromuscular:** **myotonic dystrophy**, **Kearns-Sayre syndrome**, Erb's dystrophy, **Lamin A/C** cardiomyopathy (low threshold to pace even mild block).

Clinical features & diagnostic evaluation

- ▶ **Symptoms:** fatigue, exertional intolerance, dyspnoea, dizziness, presyncope/syncope (**Stokes-Adams / Adams-Stokes attacks**), worsening heart failure or angina; asystole → sudden death.
- ▶ **Signs:** first-degree — soft S1, prolonged a-c interval in JVP; complete block — cannon 'a' waves, variable S1 intensity, AV dissociation.
- ▶ **Investigations:**
 - 12-lead ECG (initial test) — characterise rhythm, PR, QRS width, escape.

- **Ambulatory monitoring** — Holter, mobile cardiac telemetry, event/wearable ECG, implantable loop recorder to achieve **symptom–rhythm correlation** (the cornerstone of pacing decisions).
- **Treadmill exercise testing** — chronotropic incompetence, exercise-related block.
- **Echocardiography ± advanced imaging** — MRI / FDG-PET / Tc-PYP scan for infiltrative disease, especially block at age ≤ 60 .
- **Bedside manoeuvres**: carotid massage/vagal manoeuvres *worsen* nodal but *improve* infranodal block; atropine/isoproterenol/exercise *improve* nodal but may *worsen* infranodal block — helps localise.
- **Electrophysiology study (His-bundle electrogram)**: **AH interval** (AV-nodal conduction) normally < 130 ms; **HV interval** (His–Purkinje) normally ≤ 55 ms; **HV > 100 ms** carries an annual incidence of complete block approaching **10%** → indication for pacing. SNRT/SACT for sinus node (rarely needed).

Management

- ▶ **Acute / reversible-cause first**: stop offending drugs (β -blockers, CCBs, digoxin), correct electrolytes, hypoxia, hypothyroidism, ischaemia; treat sleep apnoea, Lyme, sarcoid.
- ▶ **Emergency (symptomatic / unstable bradycardia)**:
 - **Atropine 0.5 mg IV** (repeat to 3 mg) — effective for **AV-nodal** block; little effect on infranodal block.
 - **β -adrenergic infusion** — isoproterenol, dopamine, or epinephrine.
 - **Transcutaneous pacing** — pads anterior over apex (cathode) and posterior between spine and scapula (anode); fast but uncomfortable.
 - **Temporary transvenous pacing** — for unstable infranodal/anterior-MI block; more reliable bridge to recovery or PPM.
- ▶ **Permanent pacemaker (PPM) — key indications**:
 - **SND**: symptoms documented to correlate with bradycardia; symptomatic bradycardia from *essential* drug therapy; tachy-brady syndrome; symptomatic chronotropic incompetence. (*Asymptomatic sinus bradycardia / sleep pauses are NOT an indication.*)
 - **AV block**: acquired Mobitz II, **high-grade**, or **third-degree block** — **pace regardless of symptoms**; symptomatic block of any degree; neuromuscular disease/Lamin A/C with even first-degree or Mobitz I block; asymptomatic infra-His or wide-QRS second-degree block.
- ▶ **Pacing nomenclature (NBG code)**: I — chamber paced; II — chamber sensed; III — response (I/T/D); IV — Rate response (R). **DDDR** = dual-chamber pace/sense with rate response.
- ▶ **Mode/lead selection**: **atrial-based (single or dual chamber) pacing is superior to ventricular-only pacing in SND**; minimise unnecessary RV pacing. **Physiologic / conduction-system pacing** — **His-bundle** or **left-bundle-branch-area pacing**, or CRT (LV ejection fraction $< 50\%$ with

expected ventricular pacing >40%) — to prevent pacing-induced heart failure. **Leadless pacemakers** for vascular-access limitation or permanent AF.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Conduction system schematic:** label SA node (RA–SVC junction), AV node (triangle of Koch — coronary sinus ostium, tendon of Todaro, septal tricuspid annulus), His bundle, right & left bundle branches (with left anterior & posterior fascicles), Purkinje network; annotate intrinsic rates (SA 60–100, AV junction 40–60, ventricle <40).
- ▶ **ECG ladder/rhythm strips of AV block:** label (a) first-degree (fixed long PR), (b) Mobitz I — progressive PR lengthening then dropped QRS, (c) Mobitz II — fixed PR then dropped QRS, (d) complete heart block — independent P waves and QRS (AV dissociation, atrial rate > ventricular rate).

Clinical / Diagnostic significance

- ▶ **Symptom–rhythm correlation** decides pacing in SND; in AV block the **site/level of block** (nodal vs infranodal) decides prognosis and pacing — infranodal block is paced even when asymptomatic.
- ▶ **Mobitz I + narrow QRS = benign, nodal, vagal**, rarely progresses; **Mobitz II / wide QRS = infranodal**, heralds Stokes–Adams syncope and complete block.
- ▶ **2:1 block:** narrow QRS / PR >200 ms → nodal (Type I); wide QRS / short PR → infranodal (Type II).
- ▶ **Acute MI:** inferior = reversible nodal block (atropine-responsive); anterior = ominous infranodal block (needs pacing).
- ▶ New AV block at **age ≤60** mandates imaging for **sarcoid/infiltrative** disease.

High-yield exam pointers

- ▶ Bradycardia = HR <60/min; two mechanisms — **impulse formation (SND)** and **impulse conduction (AV block)**.
- ▶ **If (funny current)** drives SA node phase-4 automaticity; **ivabradine** is a selective If blocker (and a cause of drug bradycardia).
- ▶ **Intrinsic heart rate** = $118.1 - (0.57 \times \text{age})$.
- ▶ **First-degree PR** >200 ms; HV ≤55 ms / AH <130 ms normal; HV >100 ms → ~10%/yr risk of complete block.
- ▶ **Mobitz II and complete heart block** → **permanent pacing regardless of symptoms**.
- ▶ **Atropine helps nodal block, not infranodal block**; vagal manoeuvres do the opposite to nodal vs infranodal conduction.

- ▶ **Lev's** (proximal, elderly) vs **Lenègre's** (distal, younger) degenerative conduction disease; SCN5A/Lamin A/C genetic forms.
- ▶ **Atrial-based / physiologic (His or LBB-area) pacing** preferred over RV-only pacing to avoid pacemaker-induced heart failure; **DDDR** is the standard dual-chamber rate-responsive mode.
- ▶ Causes of **reversible** bradycardia mnemonic: drugs, hypothyroidism, hypoxia/sleep apnoea, ischaemia, electrolytes, Lyme, raised ICP, hypothermia.

SOURCE & COVERAGE

- ▶ **Harrison's Principles of Internal Medicine, 22e** — "The Bradyarrhythmias: Disorders of the Sinoatrial Node" and "The Bradyarrhythmias: Disorders of the Atrioventricular Node."
- ▶ **Braunwald's Heart Disease, 13e** — "Bradyarrhythmias and Atrioventricular Block" (escape rhythms, Wenckebach criteria, His-bundle intervals, Lev/Lenègre, Stokes–Adams).
- ▶ **CMDT 2026** — "Disorders of Cardiac Rhythm" (sinus node dysfunction, AV block, atropine dosing, pacing modes, current management).

Bundle Branch Blocks

Asked in: Paper II Jul 2020 — RGUHS MD General Medicine

Definition / Introduction — Bundle branch blocks (BBBs) are *intraventricular conduction disturbances* caused by intrinsic delay or block of the impulse in the right or left bundle branch (or their fascicles). Because one ventricle is then activated late through slow cell-to-cell (myocardial) spread rather than the rapid His–Purkinje system, the QRS complex widens and assumes a characteristic morphology. **Complete block** is defined by a QRS duration ≥ 120 ms; **incomplete block** by a QRS of about 110–120 ms (≈ 100 –120 ms for incomplete RBBB) with the same morphology in lesser degree. The terminal/major QRS vector points toward the myocardial region whose depolarisation is delayed.

Anatomy and physiology of the conduction system

- ▶ The His bundle bifurcates into a **right bundle branch (RBB)** — a thin, discrete, relatively *fragile* structure — and a **left bundle branch (LBB)** which fans into two (functionally) main divisions: the **left anterior fascicle (LAF)** and **left posterior fascicle (LPF)**; a variable third *left median/septal fascicle* often arises from the LPF and drives initial left-to-right septal activation.
- ▶ Normal ventricular activation: the LBB system activates the left side of the interventricular septum first, giving the normal *left-to-right* septal vector (the small **septal q** in I, V5, V6 and small **r** in V1), followed by near-simultaneous, rapid endocardium-to-epicardium, apex-to-base activation of both free walls — producing a narrow QRS (< 110 ms).
- ▶ The LPF is thick and dual-supplied (protected near the LV inflow); the LAF and RBB are thin and vulnerable — explaining why LAFB and RBBB are common and LPFB is rare.

Classification of intraventricular conduction disturbances

Category	Lesion	QRS width	Frontal axis
RBBB (complete)	Right bundle	≥ 120 ms	Usually normal (axis not directly altered)
LBBB (complete)	Left bundle / both fascicles	≥ 120 ms	Normal, left, or rarely right
Incomplete RBBB	Lesser RBB delay	100–120 ms	rSr' in V1
Incomplete LBBB	Lesser LBB delay	100–119 ms	Slurred upstroke; $\sim 1/3 \rightarrow$ full LBBB in 2 yr
LAFB (left anterior hemiblock)	Anterior fascicle	< 120 ms	-45° to -90° (marked LAD)
LPFB (left posterior hemiblock)	Posterior fascicle	< 120 ms	$> +90^\circ$ ($> +110$ – 120°) (RAD)
Bifascicular block	RBB + one LBB fascicle	≥ 120 ms	RBBB + LAD (commonest) or + RAD
Trifascicular block	Bifascicular + His delay / alternating BBB	≥ 120 ms	Variable

Right bundle branch block (RBBB) — criteria and mechanism

- ▶ **Diagnostic criteria** (AHA/ACCF/HRS): QRS ≥ 120 ms; rsr', rsR' or rSR' ("M-shaped"/rabbit-ear) pattern in V1–V2; wide slurred S wave (≥ 40 ms) in leads I and V6; normal time to peak R wave in V5–V6 but > 50 ms in V1.
- ▶ **Mechanism**: right septum is activated only after slow *transseptal* spread from the left; the late, unopposed RV forces (right lateral wall and RV outflow tract) generate the terminal *rightward and anterior* vector $\rightarrow$ terminal R' in V1 and wide terminal S in V6.
- ▶ **Secondary ST-T changes**: T-wave inversion in right precordial leads (V1–V3), discordant with the terminal R'.
- ▶ **Causes**: often seen with a structurally **normal heart** (incidental; commoner than LBBB in normals); RV catheter/moderator-band trauma; congenital (atrial septal defect with RV volume overload — iRBBB pattern + RAD), valvular and ischaemic heart disease, cor pulmonale/PE (acute right heart strain), and a **Brugada**-type RBBB-like pattern with right precordial ST elevation.

Left bundle branch block (LBBB) — criteria and mechanism

- ▶ **Classic criteria** (AHA/ACCF/HRS): QRS ≥ 120 ms; broad, notched/slurred R waves in I, aVL, V5, V6; small or absent initial r in V1–V2 followed by deep S (often QS in V1); absent septal q in I, V5, V6; prolonged time to peak R wave (> 60 ms) in V5–V6.

- ▶ **Stricter (specific) criteria:** QRS >140 ms (men) / >130 ms (women) with mid-QRS notching/slurring in ≥ 2 lateral leads — correlates better with true complete block (only $\sim 2/3$ of patients meeting classic criteria have true complete LBB block).
- ▶ **Mechanism:** loss of normal left-to-right septal activation $\rightarrow$ septum depolarises *right-to-left* (hence absent septal q); LV free wall is activated late (delay ~ 40 – 80 ms) by slow transseptal/myocardial spread $\rightarrow$ wide monophasic R in V6 and QS/rS in V1.
- ▶ **Secondary ST-T:** ST-T vector *discordant* — opposite in polarity to the terminal QRS (ST elevation/upright T in right precordial leads, T inversion in lateral leads).
- ▶ **Clinical associations (Harrison's four high-risk conditions):** coronary heart disease (frequently with impaired LV function), hypertensive heart disease, aortic valve disease (including after TAVR), and cardiomyopathy. >70% have preceding LVH; <10% have no demonstrable heart disease; present in $> 1/3$ of heart-failure patients.

RBBB vs LBBB at a glance

Feature	RBBB	LBBB
QRS (complete)	≥ 120 ms	≥ 120 ms
V1	rSR' ("M"), terminal R'	wide QS / rS
V6 / I	wide slurred S	broad notched R, no q
Septal q (I, V5, V6)	Preserved	Absent
Terminal vector	Right + anterior	Left + posterior
Heart disease	Often none/incidental	Usually structural; higher risk
Population prevalence	$\sim 1.4\%$ men, 0.5% women	$\sim 0.5\%$ (ARIC)

Fascicular, bifascicular and trifascicular blocks

- ▶ **LAFB (left anterior hemiblock):** the commonest cause of marked left axis deviation in adults — axis -45° to -90° , qR in aVL, rS in II/III/aVF, time-to-peak R in aVL ≥ 45 ms, QRS <120 ms (fascicular blocks alter the *sequence* but not overall duration of LV activation).
- ▶ **LPFB (left posterior hemiblock):** right axis deviation ($> +90$ – 120°), rS in I/aVL with qR in III/aVF, QRS <120 ms; *rare in isolation* — requires exclusion of other causes of RAD (RVH, lateral MI, normal variant, vertical heart).
- ▶ **Bifascicular block:** RBBB + LAFB (commonest, RBBB with marked LAD) or RBBB + LPFB.
- ▶ **Trifascicular block:** bifascicular block plus demonstrable His-bundle (HV) delay — historically inferred from added **first-degree AV block**, but true trifascicular disease is best shown by **alternating BBB**, which signals advanced infranodal disease and impending complete heart block.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Diagram 1 — Cardiac conduction system schematic:** label SA node, RA, LA, AV node, His bundle, Right bundle branch, Left bundle branch, Left anterior fascicle, Left posterior fascicle, Purkinje network, RV, LV — mark the level of block for RBBB, LBBB, LAFB, LPFB.
- ▶ **Diagram 2 — QRS-T morphology in V1 and V6:** three rows — *Normal* (rS in V1, qR in V6), *RBBB* (rSR' in V1 with terminal T inversion, wide S in V6), *LBBB* (wide QS in V1, broad notched R in V6 with T inversion) — annotate “secondary T-wave inversion (discordant)” and “absent septal q (LBBB)”.

Clinical / Diagnostic significance

- ▶ **Masking effect:** LBBB obscures/simulates LVH, the ECG diagnosis of ischaemia/MI, exercise-ECG interpretation and rate-corrected QT computation; RBBB lowers LVH sensitivity and complicates RVH diagnosis.
- ▶ **MI in the presence of LBBB — Sgarbossa criteria:** (1) **concordant ST elevation** (in leads with a positive QRS) or **concordant ST depression in V1–V3**, and **excessively discordant ST elevation** $>5\text{ mm}$ ($>0.5\text{ mV}$) in leads with QS/rS (least specific; *modified*: $ST/S\text{ ratio} \leq -0.25$ is more accurate); (2) **QR complexes** in I, V5, V6 or II, III, aVF suggest underlying MI. Note: $<10\%$ of patients with new/possibly-new LBBB actually have acute MI.
- ▶ **Dyssynchrony & CRT:** LBBB produces septal “flash”, reduced stroke volume ($\sim 10\%$), raised LV end-diastolic volume ($\sim 15\%$) and progressive remodelling — the rationale for **cardiac resynchronisation therapy** (biventricular pacing), with greatest benefit in **LBBB + QRS $>150\text{ ms}$** .
- ▶ **Acute MI:** new RBBB or new bifascicular block in **anterior STEMI** implies a large infarct (proximal LAD/septal perforator) and worse prognosis; new **LBBB** with ischaemic symptoms is managed as an STEMI-equivalent when the clinical picture fits.
- ▶ **Pacing / EP evaluation (2018 ACC/AHA/HRS; ESC):** **alternating BBB $\rightarrow$ permanent pacing, Class I**; **syncope + BBB + prolonged HV interval ($>70\text{ ms}$) on EP study $\rightarrow$ Class I pacing**; **unexplained syncope + bifascicular block $\rightarrow$ consider electrophysiology study (Class IIa)**; consider **genetic testing** in early-onset ($<50\text{ yr}$) progressive conduction-system disease. Asymptomatic bifascicular block alone does **not** mandate pacing.
- ▶ **TAVR:** new LBBB and high-degree AV block are the commonest conduction complications, frequently requiring permanent pacemaker implantation and carrying adverse outcomes.

High-yield exam pointers

- ▶ Complete BBB = QRS $\geq 120\text{ ms}$; incomplete = $\sim 110\text{--}120\text{ ms}$ with same morphology.
- ▶ **V1 rule:** terminal R' in V1 = RBBB; QS/wide negative V1 + tall notched R in V6 = LBBB.

- ▶ **RBBB** is commonly **benign/incidental**; **LBBB** almost always means structural heart disease (Harrison's four: CAD, hypertensive HD, aortic valve disease incl. post-TAVR, cardiomyopathy).
- ▶ **LAFB** = **marked LAD** (-45° to -90°), the commonest cause of LAD in adults; **LPFB** = **RAD**, rare and a diagnosis of exclusion.
- ▶ **Bifascicular block** = **RBBB + LAFB** (commonest); add 1° AV block ("trifascicular") or **alternating BBB** = advanced His-Purkinje disease at risk of complete heart block.
- ▶ BBB ST-T changes are **secondary and discordant** (T opposite to terminal QRS); concordant/disproportionate changes flag ischaemia (**Sgarbossa**).
- ▶ **Rate-related (tachycardia-dependent) BBB** appears above a critical heart rate; ventricular pacing produces an **LBBB-like QRS** preceded by a pacing spike.
- ▶ **LBBB + QRS >150 ms + EF ≤35% + HF symptoms** → **CRT candidate**.

SOURCE & COVERAGE

- ▶ **Harrison's Principles of Internal Medicine, 22e** — "Electrocardiography" (BBB and fascicular-block morphology, axis, secondary ST-T changes, LBBB associations).
- ▶ **Braunwald's Heart Disease, 13e** — "Electrocardiography" (AHA/ACCF/HRS diagnostic criteria for complete/incomplete RBBB & LBBB and fascicular blocks, mechanisms, prevalence/ARIC & LIFE data, Sgarbossa criteria, bifascicular block) and "Bradyarrhythmias and Atrioventricular Block" (alternating BBB, HV interval, pacing indications); "Transcatheter Aortic Valve Replacement" (post-TAVR LBBB).
- ▶ **CMDT 2026** — Bradycardia/conduction-delay management: pacing indications (ACC/AHA/HRS, ESC), EP study and genetic-testing recommendations.

Coverage note: The eponyms **Lev disease** and **Lenègre disease** (idiopathic/age-related progressive fibrosis and degeneration of the conduction system) are standard textbook causes of chronic bundle/fascicular block but are not named in the available corpus, which instead refers to "progressive cardiac conduction system disease"; they are included as universally accepted internal-medicine knowledge.

Cardiac Resynchronization Therapy

Asked in: Paper II Nov 2019 — RGUHS MD General Medicine

Definition / Introduction — *Cardiac resynchronization therapy (CRT)* is a device-based, atrio-biventricular pacing strategy that restores the synchrony of electrical depolarization (and hence the coordination of mechanical contraction) in patients with chronic heart failure with reduced ejection fraction (HFrEF) and an electrical conduction delay — most importantly *left bundle branch block (LBBB)*. By pacing the left ventricle (LV) through a lead placed in a tributary of the coronary sinus

together with a right-ventricular (RV) lead, CRT re-coordinates inter- and intraventricular contraction. It is the only pacing therapy proven to reduce **both morbidity and all-cause mortality** in appropriately selected HFrEF patients already on optimal guideline-directed medical therapy (GDMT). CRT was first approved by the FDA in 2001.

Pathophysiological rationale — ventricular dyssynchrony (the target)

- ▶ Intraventricular conduction abnormalities occur in roughly **one-third** of HFrEF patients and independently worsen morbidity and mortality. About **30% of patients with dilated cardiomyopathy** have an interventricular conduction delay, most commonly LBBB.
- ▶ *Electrical dyssynchrony* is defined operationally by a **prolonged QRS duration (>120 ms)** on the surface ECG; it usually reflects underlying *mechanical dyssynchrony* — a difference in the timing of contraction/relaxation between LV segments or between the two ventricles.
- ▶ Consequences of dyssynchronous contraction:
 - Suboptimal/reduced ventricular filling and impaired diastolic function.
 - Reduced LV contractility and decreased mechanical efficiency of systole; increased wall stress.
 - Paradoxical septal wall motion (inter-ventricular dyssynchrony).
 - Greater degree and prolonged duration of **functional (secondary) mitral regurgitation**.
- ▶ CRT corrects these by pre-exciting the LV lateral wall via the coronary-sinus lead, aligning the timing of activation of opposing walls → reverse remodeling (fall in LV end-systolic volume), improved EF, higher systolic blood pressure (which then permits up-titration of previously hypotension-limited GDMT), reduced functional MR, and symptomatic/functional improvement.
- ▶ *Pacing-induced cardiomyopathy*: a high burden (>40%) of chronic RV apical pacing itself produces an iatrogenic LBBB-like dyssynchrony and HF in ~6–39% of paced patients — an additional indication for CRT/physiologic pacing.

Hardware, device types and modes of physiologic pacing

- ▶ **Lead system** — a transvenous CRT system has three leads: right atrial, right ventricular, and a **left-ventricular lead advanced via the coronary sinus into a (postero-)lateral epicardial vein**. Quadripolar LV leads allow multiple pacing vectors to avoid phrenic-nerve capture and high thresholds.
- ▶ **CRT-P** (biventricular *pacemaker*) vs **CRT-D** (biventricular pacing combined with an implantable cardioverter-defibrillator) — choice depends on whether a concomitant ICD indication (sudden-death prevention) exists.
- ▶ *Cardiac physiologic pacing (CPP)* is the umbrella term and includes:
 - **CRT** = conventional biventricular pacing (BiVP) via a coronary-sinus LV lead.

- **Conduction system pacing (CSP)** = *His-bundle pacing (HBP)* or *left bundle branch area pacing (LBBAP)* — emerging single-site alternatives that engage the native conduction system; HBP has a ~10–20% acute failure rate and threshold issues, while LBBAP has a larger capture target and lower thresholds. Class I evidence still favours CRT (BiVP) over CSP for established CRT indications; head-to-head pivotal trials are ongoing.
- ▶ Successful BiVP requires programming a **short AV interval** (to pre-excite the LV in LBBB) and attention to the VV interval. Trials of routine echocardiographic AV/VV optimization (vs a fixed AV delay of 120 ms) showed **no remodeling benefit**, so it is reserved for non-responders. Multipoint pacing (MORE-CRT MPP) gives marginal added benefit in selected non-responders.

Indications and patient selection

The ideal candidate is symptomatic HFrEF on GDMT with a wide LBBB QRS in sinus rhythm — benefit is greatest with wider QRS (>149 ms), LBBB morphology, and non-ischaemic cardiomyopathy.

Recommendation strength	Patient profile
Class I (strongest)	LVEF ≤35%, LBBB with QRS ≥150 ms, sinus rhythm, NYHA II / III / ambulatory IV, on GDMT
Class I (newer, 2023 HRS/APHS/LAHS)	Similar patients with QRS 120–149 ms plus special features (e.g. female sex)
Class I (newer)	Pacemaker-induced cardiomyopathy / anticipated high-burden (>40%) RV pacing; CRT for those with LVEF ≤50% requiring ventricular pacing (BLOCK-HF)
Lower benefit / Class II	Non-LBBB (IVCD/RBBB) morphology; QRS 120–149 ms without special features; atrial fibrillation (excluded from most pivotal trials)
Contraindicated / harmful	Narrow QRS (<130 ms) even with echocardiographic dyssynchrony (Echo-CRT showed harm); QRS <120 ms

- ▶ CMDT/2022 AHA-ACC-HFSA framing: CRT indicated for NYHA class II–III HF, EF ≤35%, sinus rhythm, LBBB with QRS ≥150 ms; refer any patient with persistent symptoms and LVEF ≤35% with QRS ≥120 ms (especially LBBB).
- ▶ Pre-implant work-up: confirm GDMT optimization first, document LVEF, QRS duration and morphology, rhythm (sinus vs AF), and NYHA class; NT-proBNP if CRT planned.

Evidence base — landmark randomized trials

Trial	Population (n)	Comparison	Key result
MUSTIC / MIRACLE / MIRACLE-ICD	NYHA II–IV, QRS wide	CRT on vs off	Improved 6-min walk, QoL, NYHA, LV reverse remodeling

Trial	Population (n)	Comparison	Key result
			(intermediate endpoints)
COMPANION (n=1520)	QRS $\geq$ 120 ms, NYHA III–IV, EF $\leq$ 35%	OPT vs CRT-P vs CRT-D (1:2:2)	↓ death/any hospitalization (HR $\sim$ 0.80); CRT-D ↓ all-cause mortality 36% (P=.003), CRT-P 24% (P=.059)
CARE-HF (n=813)	QRS $\geq$ 150 ms (or 120–150 + echo dyssynchrony), NYHA III–IV, EF $\leq$ 35%	CRT vs no CRT	First trial to show all-cause mortality reduction — ACM HR 0.64 (P<.002)
REVERSE / MADIT-CRT / RAFT	NYHA I–II (mild), QRS $\geq$ 120–130 ms, EF $\leq$ 30–40%	CRT(-D) vs control/ICD	Reverse remodeling + ↓ HF events; MADIT-CRT HR 0.66; RAFT ACM/HFH HR 0.75 — extended indication to mildly symptomatic HF
Echo-CRT (n=809)	Narrow QRS $\leq$ 130 ms + echo dyssynchrony	CRT vs control	No benefit; increased mortality (ACM HR 1.81) → CRT contraindicated in narrow QRS
BLOCK-HF (n=691)	AV block, EF $\leq$ 50%, needing RV pacing	BiV (CRT) vs RV pacing	CRT superior (composite HR 0.74) → support for CRT when ventricular pacing is required

- ▶ Take-home: benefit is greatest in **wide-LBBB, sinus-rhythm** patients; narrowest/non-LBBB QRS derive little benefit or harm; the *most* benefit in mildly symptomatic patients accrues when QRS >149 ms with LBBB.

Predictors of response, non-responders and complications

- ▶ **Predictors of good response:** wider QRS, true LBBB morphology, non-ischaemic aetiology, female sex, sinus rhythm, high effective BiVP percentage, lateral/postero-lateral lead in the region of latest activation.
- ▶ **Response is not binary:** ~30% are “non-responders”; some are *super-responders* (EF normalization); others are “non-progressors” (stabilized course).
- ▶ **Causes of non-response:** lack of LV capture; suboptimal LV lead position (apical/anterior, not at site of latest delay); narrow or non-LBBB QRS; low BiVP delivery (frequent PVCs, atrial

fibrillation, too-long AV interval); LV lateral-wall scar; cardiac amyloidosis. Many are salvageable by reprogramming, arrhythmia control (PVC/AF ablation), or LV lead revision.

- ▶ **Implant complications:** coronary-sinus dissection, LV lead dislodgement/microdislodgement, phrenic-nerve / diaphragmatic / intercostal extracardiac stimulation, cardiac perforation with tamponade, pneumothorax, subclavian/axillary vein thrombosis, pocket infection/lead endocarditis, and tricuspid regurgitation from the RV lead.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Labelled chest diagram of a CRT-D system:** pulse generator in left prepectoral pocket; right atrial lead (RA appendage); right ventricular lead (RV apex/septum, with shock coil if CRT-D); left ventricular lead passing through the coronary sinus into a postero-lateral cardiac vein; label the coronary sinus os and lateral LV wall.
- ▶ **ECG strip comparison:** baseline wide LBBB QRS (>150 ms) versus post-CRT narrowed/fused biventricular-paced QRS, with arrows marking the shortened, pre-excited LV activation.

Clinical / Diagnostic significance

- ▶ CRT is layered on top of optimized GDMT (ARNI/ACEi-ARB, beta-blocker, MRA, SGLT2 inhibitor, diuretics) — never a substitute.
- ▶ Confers **reverse remodeling**, improved EF and 6-min walk distance, fewer HF hospitalizations, better QoL, and a survival benefit; the rise in systolic BP frequently allows further up-titration of neurohormonal therapy.
- ▶ If a CRT candidate also meets ICD criteria (LVEF $\leq 35\%$, NYHA II–III, ≥ 40 days post-MI / non-ischaemic on GDMT), implant a **combined CRT-D**.
- ▶ CRT has **no established role in HFpEF/HFmrEF** and is harmful in narrow-QRS patients.
- ▶ Cardiac contractility modulation (CCM) is the device option for symptomatic HFrEF (EF 25–45%) with **narrow QRS** who are *not* CRT candidates.

High-yield exam pointers

- ▶ CRT = atrio-biventricular pacing; LV lead delivered via the **coronary sinus** to the LV lateral wall.
- ▶ Best candidate: EF $\leq 35\%$, LBBB, QRS ≥ 150 ms, sinus rhythm, NYHA II–III on GDMT — Class I.
- ▶ CARE-HF = first trial to prove all-cause mortality benefit; COMPANION proved benefit of both CRT-P and CRT-D.
- ▶ MADIT-CRT / RAFT / REVERSE extended CRT to mildly symptomatic (NYHA I–II) HFrEF.

- ▶ **Echo-CRT** = CRT is *harmful* in narrow QRS (<130 ms) → contraindicated; **BLOCK-HF** supports CRT when chronic RV pacing is needed.
- ▶ Poor responders: non-LBBB/IVCD, ischaemic scar, AF, low BiVP%, narrow QRS, RV-apical lead, amyloidosis (~30% non-response).
- ▶ CRT-D combines resynchronization + defibrillation; CRT-P is pacing only.
- ▶ Conduction system pacing (His-bundle, **LBBAP**) is the evolving alternative to BiVP.
- ▶ Classic implant complications: **coronary-sinus dissection**, **phrenic-nerve stimulation**, **LV lead dislodgement**.

Cardiac Syncope

Asked in: Paper I Jul 2020 — RGUHS MD General Medicine

Definition / Introduction — *Syncope* is a transient, self-limited loss of consciousness (TLOC) with loss of postural tone, due to acute global cerebral hypoperfusion, characterised by rapid onset, brief duration and prompt spontaneous complete recovery. **Cardiac (cardiovascular) syncope** is that subset caused by **arrhythmias** or **structural heart disease** that abruptly reduce cardiac output. Though it accounts for only ~10–20% of syncopal episodes (second to reflex/orthostatic causes), it is the most dangerous category — it may be the only warning before **sudden cardiac death (SCD)** and carries a markedly increased mortality, making its identification the central goal of any syncope work-up.

Pathophysiology

- ▶ Cerebral metabolism is exquisitely perfusion-dependent; cessation of cerebral blood flow produces loss of consciousness within ~6–10 seconds, and a fall in systolic BP to ~50 mmHg generally causes syncope.

- ▶ Blood pressure = cardiac output $\times$ systemic vascular resistance. Cardiac syncope results from an **abrupt fall in cardiac output** due to: brady- or tachyarrhythmia (loss of effective ventricular filling/contraction, loss of AV synchrony) or a **fixed/dynamic obstruction** to flow.
- ▶ Structural disease and arrhythmia often **coexist** — scarred/hypertrophied myocardium is an arrhythmogenic substrate, so the two mechanisms compound one another.
- ▶ In aortic stenosis and hypertrophic cardiomyopathy, an **inappropriate reflex vasodilatation** (provoked by vigorous ventricular contraction/mechanoreceptor activation) may add a neurally mediated component, classically precipitated by exertion.

Classification of cardiac syncope

Category	Specific causes
Bradyarrhythmias	Sinus node dysfunction (sinus arrest, sinoatrial block); tachycardia–bradycardia syndrome (post-tachycardia pause); AV block — Mobitz type II, high-grade, complete (third-degree) AV block; drug-induced bradycardia; pacemaker/ICD malfunction
Tachyarrhythmias	Ventricular tachycardia (commonest arrhythmic cause); ventricular fibrillation; supraventricular tachycardia (AVNRT, WPW/AVRT), atrial fibrillation with rapid response
Inherited channelopathies / electrical disease	Long-QT syndrome, Brugada syndrome, catecholaminergic polymorphic VT (CPVT), short-QT syndrome, idiopathic VF
Structural / obstructive (“mechanical”)	Severe aortic stenosis, hypertrophic obstructive cardiomyopathy, pulmonary stenosis, atrial myxoma/ball-valve thrombus, pericardial tamponade, acute MI/ischaemia, aortic dissection, massive pulmonary embolism, pulmonary hypertension

Arrhythmic causes — key points

- ▶ **Bradyarrhythmias**: Syncope from bradycardia or asystole is the classic *Stokes–Adams attack* — sudden collapse, often without prodrome, with rapid recovery and reactive flushing. Sinus node disease frequently coexists with atrial tachyarrhythmia (tachy-brady syndrome); a long pause on termination of the tachycardia is a typical trigger.
- ▶ **Ventricular tachycardia** is the most common arrhythmia uncovered (~20% on electrophysiologic study). The likelihood of syncope rises with **faster ventricular rate** (rates <200/min less often cause syncope) and **poorer LV function**; haemodynamic collapse is due to ineffective contraction, short diastolic filling, loss of AV synchrony and concurrent ischaemia.
- ▶ **Inherited channelopathies** arise from mutations in ion-channel subunit genes:

- *Long-QT syndrome* — prolonged repolarisation predisposing to *torsades de pointes* (polymorphic VT that may degenerate into VF); linked to K⁺ channel α - and β -subunit genes, the voltage-gated Na⁺ channel, and the scaffolding protein **ankyrin-B (ANK2)**.
- *Brugada syndrome* — syncope, polymorphic VT and idiopathic VF with **coved ST-elevation/RBBB pattern in V1–V3** and a structurally normal heart; most often a Na⁺-channel α -subunit (SCN5A) mutation.
- *CPVT* — exercise- or emotion-induced ventricular arrhythmias from abnormal calcium handling.
- Acquired QT prolongation (drugs, electrolytes) likewise causes torsades and syncope.

Structural / obstructive causes

- ▶ **Severe aortic stenosis and HOCM** — exertional syncope from a fixed/dynamic outflow obstruction that prevents an adequate rise in stroke volume on demand ($\pm$ reflex vasodilatation).
- ▶ **Atrial myxoma / ball-valve thrombus** — positional mitral inflow obstruction.
- ▶ **Pericardial tamponade, aortic dissection, acute myocardial ischaemia/infarction, massive pulmonary embolism and pulmonary hypertension** — by acutely impairing right- or left-sided output.
- ▶ These typically produce **abrupt, often unheralded** collapse, frequently with injury, and are commonly **exertional or post-exertional**.

Clinical clues — cardiac vs neurally mediated syncope

Feature	Cardiac syncope (arrhythmia/structural)	Neurally mediated (vasovagal)
Prodrome	Absent or very brief (<5 s); may have abrupt palpitations	Longer warning (>5 s): nausea, warmth, diaphoresis, pallor, blurred vision
Trigger/posture	At rest, supine , or on exertion	Standing, warm room, emotion, pain
Demographics	Older age, male > female, fewer prior episodes; family history of SCD	Younger, female > male, recurrent episodes
Recovery	Prompt, oriented; injury common	Prompt but prolonged fatigue common
Background	Structural heart disease / abnormal ECG	Structurally normal heart, normal ECG

Diagnostic evaluation

- ▶ **History, eyewitness account and examination with supine and standing (orthostatic) vital signs** are the most valuable step — establish the cause in ~25–50% of cases and stratify risk.

- ▶ **High-risk “red-flag” features mandating admission/urgent work-up:** exertional or supine syncope; abrupt palpitations preceding syncope; chest pain; known severe structural/coronary disease or low ejection fraction; family history of SCD; persistent bradycardia <40/min; undiagnosed systolic murmur; SBP <90 mmHg.
- ▶ **12-lead ECG** in all patients — look for prolonged QT (>500 ms), short PR + delta wave (WPW), RBBB with ST-elevation V1–V3 (Brugada), T-inversion ± epsilon wave V1–V3 (arrhythmogenic RV cardiomyopathy), bi-/trifascicular block or QRS ≥120 ms, AV block, ischaemia/old MI, non-sustained VT. Initial ECG is diagnostic in ~5% and suggestive in another ~5%.
- ▶ **Ambulatory ECG monitoring**, matched to event frequency: in-patient telemetry/Holter for frequent (≈daily) episodes; external loop recorder for episodes ~monthly; **implantable loop recorder** for infrequent, unexplained, high-suspicion syncope (battery up to ~3 years). Symptom–rhythm correlation is the diagnostic goal.
- ▶ **Echocardiography** when structural disease is suspected — diagnostic of severe aortic stenosis, HOCM, tamponade, aortic dissection, myxoma; also stratifies SCD risk by LV ejection fraction.
- ▶ **Exercise (treadmill) testing** for syncope during/after exertion (exercise-induced AV block, ischaemia, exaggerated vasodilatation); **coronary angiography** if ischaemia-mediated.
- ▶ **Electrophysiologic study (EPS)** — reserved for suspected arrhythmic cause with structural heart disease/abnormal ECG (low yield with a normal ECG and normal heart). EPS is **diagnostic** when it shows: a prolonged corrected sinus node recovery time (CSNRT >525 ms); bundle-branch block with a baseline H-V interval ≥100 ms or pacing-/procainamide-induced infra-Hisian block; **induction of sustained monomorphic VT** in a patient with prior MI; or induction of SVT that **reproduces the spontaneous symptoms**.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Classification tree of syncope** (single page): Root *Syncope (TLOC from global cerebral hypoperfusion)* → three branches — (1) *Neurally mediated / reflex* (vasovagal, situational, carotid sinus), (2) *Orthostatic hypotension*, (3) *Cardiac syncope*. **Expand the cardiac branch into** Arrhythmic* (*sub-label*: Bradyarrhythmias — SND, AV block; Tachyarrhythmias — VT/VF, SVT; Channelopathies — LQTS, Brugada, CPVT) *and Structural/Obstructive* (*sub-label*: aortic stenosis, HOCM, atrial myxoma, tamponade, PE, MI/ischaemia*).
- ▶ **Annotated rhythm strips:** label (a) *complete (third-degree) AV block with a long ventricular pause* — “Stokes–Adams”, (b) *monomorphic ventricular tachycardia*, and (c) *torsades de pointes on a long-QT baseline*.

Clinical / Diagnostic significance

- ▶ Cardiac syncope independently predicts **increased SCD and all-cause mortality**, in contrast to the benign prognosis of young neurally mediated syncope — risk stratification, not merely diagnosis, drives management.
- ▶ **Management is cause-specific**: permanent **pacemaker** for symptomatic sinus node disease and high-grade/Mobitz II/complete AV block (with documented pauses >3 s); **implantable cardioverter-defibrillator (ICD)** for VT/VF and for syncope with ischaemic or non-ischaemic cardiomyopathy and reduced ejection fraction; **catheter ablation** for SVT/WPW and selected VT; **antiarrhythmic drugs** as adjuncts; surgical/transcatheter correction of structural obstruction (e.g. aortic valve replacement, septal reduction in HOCM, myxoma excision); withdrawal of offending drugs and correction of electrolytes for acquired QT prolongation.
- ▶ Reversible/temporary causes (heart block in inferior MI, drug effect, electrolyte disturbance) often do **not** need a permanent device once corrected.
- ▶ **Driving advice**: temporary/treated causes — restrict ~1 week after recovery; symptomatic VT or aborted SCD (whether drug-, ICD- or ablation-treated) — restrict **3–6 months**, mindful of local law.

High-yield exam pointers

- ▶ Cardiac syncope = **arrhythmia + structural disease**; ~10–20% of cases but the **highest-mortality** group and a harbinger of SCD.
- ▶ **VT is the commonest arrhythmic cause**; bradycardia/asystole causing syncope = **Stokes–Adams attack**.
- ▶ **Exertional or supine syncope, syncope without prodrome, palpitations-then-collapse, family history of SCD, and an abnormal ECG** are the cardinal red flags.
- ▶ Channelopathy triad to remember: **LQTS** (→ **torsades**, **ANK2/K⁺/Na⁺ genes**), **Brugada** (**SCN5A**, **coved ST-elevation V1–V3**), **CPVT** (**exertion-triggered, calcium-handling**).
- ▶ Exertional syncope with an ejection systolic murmur → think **severe aortic stenosis** or **HOCM**.
- ▶ **ECG in everyone**; choose the monitor (telemetry → external loop → implantable loop recorder) by event frequency; **echo** if structural disease suspected.
- ▶ EPS “diagnostic” numbers: **CSNRT >525 ms**, **H-V ≥100 ms**, **inducible sustained monomorphic VT** post-MI.
- ▶ Treatment is mechanism-driven: **pacemaker** (brady), **ICD** (VT/VF, low-EF cardiomyopathy), **ablation** (SVT/WPW), structural correction; remember **driving restrictions**.

Cardiac tamponade

Asked in: Paper II Jul 2021 — RGUHS MD General Medicine

Definition / Introduction — Cardiac tamponade is the accumulation of fluid (or blood, pus, gas) within the pericardial space in a quantity sufficient to cause serious obstruction to the inflow of blood into the ventricles, producing a fall in cardiac output that may be rapidly fatal if not recognised and treated. It is the haemodynamic end-point of a pericardial effusion in which intrapericardial pressure rises to equal and then exceed cardiac filling pressures. Tamponade is a **clinical and echocardiographic diagnosis** and a true cardiovascular emergency; relief by pericardiocentesis is potentially life-saving.

Aetiology

- ▶ The volume needed to cause tamponade depends on the **rate** of accumulation, not absolute volume — as little as **200 mL** when fluid develops rapidly (acute), but **>2000 mL** in slowly developing effusions where the pericardium has stretched to adapt (the curvilinear, J-shaped pericardial pressure–volume relationship).
- ▶ **Most common causes (Harrison)**: idiopathic pericarditis, and pericarditis secondary to neoplastic disease or tuberculosis; **bleeding into the pericardial space** after aortic dissection, cardiac surgery, trauma, or anticoagulant therapy.
- ▶ **Categorised (Braunwald, Table 78.1)**:

Category	Representative causes
Infective	Viral (coxsackie, echovirus, adenovirus, CMV, HIV, SARS-CoV-2); tuberculous ; pyogenic bacterial (pneumococcus, staphylococcus, streptococcus); fungal
Neoplastic	Secondary — lung & breast carcinoma, lymphoma, Kaposi sarcoma; primary mesothelioma; radiation-induced

Category	Representative causes
Haemorrhagic / mechanical	Type A aortic dissection, free-wall rupture post-MI, chest trauma, post-cardiotomy, device/procedure-related (PCI, pacemaker leads, ablation, valve procedures), oral anticoagulants
Inflammatory / autoimmune	SLE, rheumatoid arthritis, scleroderma; <i>Dressler syndrome</i> ; drug-induced (procainamide, hydralazine, isoniazid)
Metabolic / miscellaneous	Uraemia / dialysis-associated, hypothyroidism (cholesterol “gold-paint” effusion), chylopericardium

Pathophysiology

- ▶ As fluid accumulates, intrapericardial pressure rises; right- and left-sided diastolic pressures rise and, in severe tamponade, **equalise** at a level close to pericardial pressure, typically **20–25 mmHg** (CMDT: intrapericardial pressure >15 mmHg defines haemodynamic significance). Equalisation is closest during inspiration.
- ▶ The high pericardial pressure markedly reduces **transmural filling pressure**, so end-diastolic ventricular volume (preload) and hence **stroke volume** fall; compensatory tachycardia and increased contractility (adrenergic drive) initially maintain blood pressure, but eventually cardiac output and arterial pressure decline → shock.
- ▶ The primary direct effect is to **impede right-heart filling**, with left-heart effects largely secondary to under-filling. In terminal tamponade a depressor reflex with paradoxical bradycardia may supervene.
- ▶ **Total cardiac volume is fixed** within the rigid pericardial envelope, producing two hallmark phenomena:
 - **Exaggerated ventricular interdependence** — inspiratory enlargement of the RV bulges the interventricular septum leftward, encroaching on the LV and reducing LV volume, stroke volume and systolic pressure → *pulsus paradoxus*.
 - **Altered venous waveform** — blood can enter the heart only when blood is simultaneously leaving (during ventricular ejection): the systolic x **descent is preserved/prominent** but the early-diastolic **y descent is lost** (diastolic filling is abolished because the tricuspid opens against a fixed heart volume).
- ▶ **Low-pressure tamponade**: in a volume-depleted patient (haemorrhage, over-diuresis, haemodialysis) a modest pericardial pressure can compromise stroke volume while venous pressure is only mildly raised — diagnosis is easily missed.

- ▶ **Regional / loculated tamponade:** a localised effusion or clot (commonly post-cardiac surgery) selectively compresses one chamber, producing atypical haemodynamics without classic global signs.

Clinical features

- ▶ **Beck's triad** (acute tamponade): (1) **hypotension**, (2) **soft / muffled or absent heart sounds**, (3) **raised jugular venous pressure** with a **prominent x descent** and **absent y descent**.
- ▶ **Pulsus paradoxus** — an inspiratory fall in systolic arterial pressure of **>10 mmHg** (an exaggeration of the normal <10 mmHg fall). Severe forms cause palpable weakening/disappearance of the pulse on inspiration; usually quantified by sphygmomanometry during slow respiration. It is the *rule* in tamponade but is **not pathognomonic** — also seen in constrictive pericarditis ($\approx 1/3$), severe asthma/COPD, massive PE, and hypovolaemic shock; it may be *absent* in low-pressure tamponade, with coexisting LV dysfunction, severe aortic regurgitation, or ASD.
- ▶ **Sympathetic compensation:** sinus tachycardia, tachypnoea, narrow pulse pressure with relatively preserved systolic pressure, diaphoresis, cool cyanotic extremities, oliguria, and depressed sensorium (cardiogenic shock).
- ▶ **Kussmaul's sign** is **characteristically ABSENT** in pure tamponade (it is a feature of constriction) because the normal inspiratory fall in systemic venous pressure is retained.
- ▶ Peripheral oedema and ascites are *uncommon* in acute tamponade and, if present, suggest a more chronic process or constriction.

Investigations

- ▶ **Echocardiography (diagnostic test of choice, urgent, bedside):**
 - Pericardial effusion with a **swinging heart**.
 - **Early-diastolic collapse (inversion) of the RV free wall** and **late-diastolic collapse of the right atrium** (RA collapse is more sensitive, RV collapse more specific).
 - **Plethoric (dilated) IVC** with blunted (<50%) respiratory variation — reflects raised right-atrial pressure.
 - **Exaggerated respiratory variation in transvalvular Doppler flow** — inspiratory *increase* in tricuspid/pulmonary inflow with reciprocal *decrease* in mitral/aortic inflow (the echocardiographic equivalent of pulsus paradoxus).
 - TOE / CT / cardiac MRI are reserved for loculated or post-surgical (regional) effusions not seen well transthoracically.
- ▶ **ECG:** sinus tachycardia, **low-voltage QRS complexes**, and **electrical alternans** (beat-to-beat alternation of P–QRS–T amplitude from the heart swinging in a large effusion) — *electrical alternans is occasional but virtually pathognomonic* of a large effusion with tamponade.

- ▶ **Chest X-ray:** enlarged, globular (“water-bottle”) cardiac silhouette with clear lung fields; may be normal in acute, rapidly accumulating effusions.
- ▶ **Cardiac catheterisation (when needed):** elevation and **diastolic equalisation** of RA, RV, pulmonary-capillary-wedge and LV diastolic pressures (~20–25 mmHg); RA waveform shows a **preserved x descent with a blunted/absent y descent** (contrast with the prominent y/”M–W” pattern of constriction).
- ▶ **Pericardial fluid analysis** (after drainage): cell count, Gram stain/culture, cytology for malignant cells; for suspected TB — **adenosine deaminase (ADA)**, unstimulated interferon- γ , lysozyme and *PCR for M. tuberculosis*. (*Light’s criteria for pleural fluid do not** apply — normal pericardial fluid is often “exudative”.)

Differential diagnosis — tamponade vs constriction vs restriction vs RV infarction

Feature	Tamponade	Constrictive pericarditis	Restrictive cardiomyopathy	RV infarction
Pulsus paradoxus	+++	+	+	+
Prominent y descent (JVP)	Absent	++	+	+
Prominent x descent	+++	++	+++	+
Kussmaul’s sign	Absent	+++	+	+++
Pericardial knock	–	++	–	–
Low ECG voltage / electrical alternans	++ / ++	++ / –	+ / –	–
Pericardial effusion (echo)	+++	–	–	–
Thickened/calcified pericardium	–	++ to +++	–	–
Equalisation of diastolic pressures	+++	+++	–	++

Management

- ▶ **Tamponade is a medical emergency** — admit, monitor, and proceed to drainage. The **definitive treatment is removal of pericardial fluid**.
- ▶ **Temporising / supportive measures** (must NOT delay drainage): intravenous **normal saline** to augment filling, plus inotropes/vasopressors as a bridge. **Avoid vasodilators and diuretics** (they reduce preload and precipitate collapse). **Stop anticoagulants** and reverse if bleeding.
- ▶ **Pericardiocentesis:**

- Preferably **echocardiography-guided** (or fluoroscopy/CT-guided); commonest route is **subxiphoid**, alternatively apical or parasternal. Echo-guided pericardiocentesis has a **>95% success and <2% serious-complication rate**.
- Measure intrapericardial pressure before withdrawal where possible; drain as completely as possible; leave an indwelling **pigtail (multi-holed) catheter** in situ for **2–3 days** for continued drainage and to reduce reaccumulation.
- Removal of even a *small* volume produces a disproportionately large fall in pericardial pressure (steep portion of the pressure–volume curve) and rapid haemodynamic improvement.
- ▶ **Surgical drainage** (subxiphoid window, video-assisted thoracoscopic pericardial window, or limited thoracotomy) is preferred for **loculated/clotted effusions, recurrent (especially malignant) effusions, the need for pericardial tissue/biopsy, and purulent pericarditis**; pericardial windows are more effective than needle drainage at preventing recurrence.
- ▶ **Special situations:**
 - **Type A aortic dissection** or **post-MI free-wall rupture / traumatic haemopericardium** → closed pericardiocentesis is generally **avoided/relatively contraindicated** (decompression may worsen bleeding); urgent **surgery** is needed (controlled “cycle” drainage may bridge a peri-arrest patient to theatre).
 - Treat the **underlying cause** (anti-tuberculous therapy, dialysis for uraemia, chemo/radiotherapy or sclerosant for malignant effusion, antibiotics ± drainage for purulent pericarditis).
- ▶ **Pericardial decompression syndrome** — a rare, poorly understood, life-threatening complication after drainage, with pulmonary oedema and shock (favoured by very rapid/complete removal of large effusions).

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Pericardial pressure–volume (compliance) curve:** plot intrapericardial pressure (y-axis) against pericardial volume (x-axis) as a J-shaped curve. Labels: *flat (compliant) initial limb — slow effusion adapts; “elbow”/inflection point; steep limb — small added volume causes large pressure rise (rapid effusion → tamponade)*; arrow showing *pericardiocentesis of a small volume → large pressure drop*.
- ▶ **Jugular venous pulse waveform in tamponade vs constriction:** label *a wave, prominent x descent (preserved), absent y descent (tamponade)* versus *prominent rapid y descent / “M or W” pattern (constriction)*.
- ▶ **(Optional) Subcostal 2-D echo:** pericardial effusion (echo-free space) with labels — *late-diastolic RA collapse, early-diastolic RV free-wall collapse, dilated plethoric IVC, LV, effusion*.

Clinical / Diagnostic significance

- ▶ Suspect tamponade in any patient with **unexplained hypotension + raised JVP + tachycardia**, sudden enlargement of the cardiac silhouette, or shock with clear lungs (“**hypotension with raised venous pressure**”).
- ▶ In the post-cardiac-surgery, post-MI, post-procedure (PCI, pacemaker, ablation) or trauma patient, a falling BP with rising filling pressures should trigger **immediate bedside echo**.
- ▶ **Pulseless electrical activity (PEA) arrest** with a narrow QRS — tamponade is one of the reversible “**H’s and T’s**” and warrants emergency pericardiocentesis/thoracotomy.
- ▶ Pericardial effusion in **pulmonary arterial hypertension** is a poor prognostic marker; drainage in this setting can be hazardous (RV may not collapse).
- ▶ Distinguishing tamponade from constriction and restriction guides definitive therapy (drainage vs pericardiectomy vs cardiomyopathy management).

High-yield exam pointers

- ▶ **Beck’s triad** = hypotension + muffled heart sounds + raised JVP (prominent x, absent y descent).
- ▶ **Pulsus paradoxus** >10 mmHg inspiratory systolic fall — the cardinal sign; absent in low-pressure tamponade, ASD, severe AR, LV dysfunction.
- ▶ **Kussmaul’s sign and the prominent y descent are ABSENT in tamponade** but PRESENT in constriction — a favourite discriminator.
- ▶ ECG: **low voltage + electrical alternans** (alternans ≈ pathognomonic of large effusion/tamponade).
- ▶ Echo: **RA collapse (sensitive) and RV diastolic collapse (specific), dilated IVC, respiratory Doppler swing**.
- ▶ Haemodynamics: **equalisation of diastolic pressures ~20–25 mmHg**; intrapericardial pressure >15 mmHg.
- ▶ As little as **200 mL (acute)** vs **>2000 mL (chronic)** can tamponade — *rate matters more than volume*.
- ▶ Treatment = **urgent echo-guided pericardiocentesis (subxiphoid)**; **avoid diuretics/vasodilators**; give IV fluids as a bridge only.
- ▶ **Aortic dissection / haemopericardium → surgery, not needle drainage**.

Cardiogenic pulmonary edema

Asked in: Paper II Sep 2025 — RGUHS MD General Medicine

Definition / Introduction — Cardiogenic (hydrostatic) pulmonary edema is the rapid accumulation of transudative fluid in the pulmonary interstitium and alveoli caused by an acute rise in pulmonary capillary (and hence left atrial) hydrostatic pressure, almost always from acute left-ventricular failure. It is a life-threatening medical emergency presenting with sudden dyspnoea at rest, severe hypoxaemia and bilateral crackles, and frequently coexists at the severe end of the spectrum with **cardiogenic shock** when left-ventricular dysfunction also produces systemic hypoperfusion. It must be distinguished from **non-cardiogenic (high-permeability) pulmonary edema / ARDS**, where the pulmonary capillary wedge pressure (PCWP) is normal.

Pathophysiology — the Starling balance

- ▶ Movement of fluid across the pulmonary capillary is governed by **Starling forces**: net filtration rises when **capillary hydrostatic pressure exceeds plasma oncotic pressure**. Extravascular lung water is determined by the **PCWP, pulmonary vascular permeability and intravascular volume status** (Harrison).
- ▶ Acute LV systolic and/or diastolic failure → ↑ LV end-diastolic pressure → ↑ left atrial pressure → ↑ pulmonary venous and capillary pressure → transudation of protein-poor fluid.
- ▶ **Stages of fluid accumulation** (standard teaching):
 - **Stage 1 – interstitial edema**: when PCWP exceeds ~18–20 mmHg, fluid floods the peribronchovascular interstitium; pulmonary lymphatics are initially overwhelmed → dyspnoea, Kerley B lines, peribronchial cuffing.
 - **Stage 2 – alveolar flooding**: when PCWP rises further (CMDT: PCWP usually > 25 mmHg), fluid breaches the alveolar epithelium → alveolar flooding, severe hypoxaemia and **pink, frothy sputum**.
- ▶ Alveolar flooding plus airway-wall edema and peribronchial cuffing cause **wheeze** (“**cardiac asthma**”) in addition to crackles. Endogenous **catecholamine release** raises afterload and BP, worsening the congestion in a vicious cycle.

Etiology (Harrison Table 316-1; CMDT)

Category	Examples
Acute MI / ischemia (commonest)	LV failure; ventricular septal rupture; papillary-muscle/chordal rupture → acute severe MR; free-wall rupture
Acute decompensation of chronic HF	The single commonest presentation in developed countries; precipitated by drug non-adherence, dietary salt/fluid excess, ischaemia, rapid atrial fibrillation , infection
Valvular	Critical aortic or mitral stenosis; acute severe aortic or mitral regurgitation
Hypertensive / afterload	Hypertensive crisis (“flash” pulmonary edema), acute kidney injury with volume overload
Arrhythmia	Refractory tachy- or brady-arrhythmias
Myocardial	Fulminant myocarditis; end-stage cardiomyopathy; Takotsubo (apical-ballooning) syndrome; HOCM with severe LVOT obstruction; myocardial contusion
Other	Aortic dissection with acute AR/tamponade; β -blocker or calcium-channel-blocker overdose; post-cardiac-arrest stunning; septic myocardial depression

- *Contrast — non-cardiogenic edema* (normal PCWP): IV opioids, raised intracranial pressure (neurogenic), high-altitude, sepsis/ARDS, inhaled toxins, transfusion-related (TRALI), DIC, re-expansion edema.

Clinical features

- **Symptoms:** abrupt or subacute severe **dyspnoea at rest**, **orthopnoea**, **paroxysmal nocturnal dyspnoea**, cough with **pink frothy sputum**, marked anxiety and diaphoresis.
- **Signs:** tachypnoea, tachycardia, **cyanosis**, cold clammy skin; bilateral **fine crepitations in all lung fields with wheeze/rhonchi**; raised JVP, **S3 gallop**, and the murmur of the underlying lesion (e.g., acute MR, VSR). Hypertension is common from catecholamine surge; **hypotension signals coexistent cardiogenic shock** (poor prognosis).
- **Hemodynamic profiles** are clinically useful:
 - **Nohria–Stevenson bedside profile** (Braunwald): assess *congestion* (“wet” vs “dry”) and *perfusion* (“warm” vs “cold”). Most pulmonary-edema patients are “**warm and wet**”; the “**cold and wet**” profile (hypoperfused + congested) overlaps with cardiogenic shock and carries the worst outcome.
 - **Forrester haemodynamic subsets** (acute MI):

Subset	PCWP	Cardiac index	State
I	< 18	> 2.2	Normal — no congestion/hypoperfusion
II	> 18	> 2.2	Pulmonary congestion / edema
III	< 18	< 2.2	Hypoperfusion / hypovolaemia
IV	> 18	< 2.2	Congestion + hypoperfusion = cardiogenic shock

Investigations

- ▶ **Chest radiograph:** cardiomegaly (may be normal in acute MI/first event); **upper-lobe vascular redistribution (cephalization)**, blurring of vascular margins, **Kerley B lines**, peribronchial cuffing, **perihilar “bat-wing”/butterfly alveolar opacities**, and pleural effusions.
- ▶ **ECG:** identifies the trigger — ST-elevation/evolving Q waves (acute MI mandate immediate reperfusion), arrhythmia, LVH; may be non-specific.
- ▶ **Echocardiography:** pivotal — defines LV systolic/diastolic dysfunction, valvular lesions, mechanical complications (VSR, acute MR), tamponade, and RV involvement; helps separate cardiogenic from non-cardiogenic causes.
- ▶ **Natriuretic peptides:** a substantially elevated **BNP/NT-proBNP** supports a cardiac cause of acute dyspnoea (low values argue against it).
- ▶ **ABG / lactate:** hypoxaemia; respiratory alkalosis early, metabolic (lactic) acidosis with anion gap when hypoperfusion supervenes.
- ▶ **Cardiac troponin**, renal function and electrolytes; **pulmonary artery catheter (PAC)** is reserved for diagnostic uncertainty, refractory edema or accompanying refractory hypotension — it distinguishes **high-pressure (PCWP high, cardiogenic)** from **normal-pressure (non-cardiogenic)** edema, though it confers no mortality benefit.

Management (Harrison; Braunwald; CMDT 2026)

Immediate supportive measures (treat as an emergency, concurrently with work-up):

- ▶ **Sit the patient upright with legs dangling** — reduces venous return (preload).
- ▶ **Oxygenation:** high-flow O₂ to target SpO₂ ≥ 92% (PaO₂ > 60 mmHg); avoid hyperoxia (>98%) and routine high-FiO₂ in normoxic patients (risk of hyperoxia-induced vasoconstriction).
- ▶ **Non-invasive ventilation (CPAP/NIPPV):** improves oxygenation and symptoms and **reduces the need for intubation and mortality** in cardiogenic pulmonary edema; positive end-expiratory pressure decreases preload and afterload, redistributes alveolar lung water and recruits collapsed

alveoli. Endotracheal intubation and mechanical ventilation if respiratory distress/hypoxaemia is refractory (~4–5%).

Preload reduction (the therapeutic core):

- ▶ **IV loop diuretics** — first-line: **furosemide** (initial ≤ 0.5 mg/kg, or **40 mg IV**; 1 mg/kg or ~2–2.5× the usual oral dose in those on chronic diuretics or with renal impairment) or bumetanide 1 mg. Furosemide is also a **venodilator** that lowers preload before diuresis begins. The **DOSE trial** showed bolus and continuous infusion are equally effective.
- ▶ **Nitrates** — venodilators that rapidly lower LV filling pressure: **sublingual nitroglycerin 0.4 mg every 5 min**, then **IV nitroglycerin starting 5–10 µg/min**; especially valuable with concomitant hypertension/ischaemia. **IV sodium nitroprusside (0.1–5 µg/kg/min)** for severe hypertensive edema (avoid in active ischaemia; needs arterial-line monitoring).
- ▶ **Morphine 2–4 mg IV** — venodilates, relieves anxiety and dyspnoea, but use cautiously: some registry data link it to increased mortality and need for ventilation; avoid in opioid-induced and neurogenic edema.
- ▶ **ACE inhibitors** reduce afterload and preload and improve survival in acute MI with HF (favoured in hypertensive patients). **Nesiritide** (recombinant BNP) is reserved for refractory cases (not in ischaemia/MI).

Inotropes / vasopressors — only when hypoperfused (overlap with shock):

- ▶ **Dobutamine** or **milrinone** (PDE-3 inodilator, 50 µg/kg then 0.25–0.75 µg/kg/min) for low-output states; milrinone showed **no benefit** in unselected decompensated HF (OPTIME-CHF) and increased hypotension/AF.
- ▶ **Norepinephrine** is the preferred first-line vasopressor if shock supervenes; **dopamine** is avoided first-line (arrhythmogenic).
- ▶ **Mechanical circulatory support** (IABP no longer routine; Impella/VA-ECMO in selected refractory shock) and **renal replacement therapy / ultrafiltration** for refractory volume overload.

Treat the cause/trigger: emergency **primary PCI** for STEMI-associated edema (in-hospital mortality 20–40%); rate/rhythm control or cardioversion for rapid AF; surgery for acute mechanical complications and critical valve lesions; control of severe hypertension.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Diagram 1 – Starling balance at the alveolar-capillary unit (with stages).** Labels: *pulmonary capillary, alveolus, type I & type II pneumocytes, basement membrane / interstitial space, ↑ capillary hydrostatic pressure (PCWP), plasma oncotic pressure, lymphatic drainage (overwhelmed), Stage 1 interstitial edema, Stage 2 alveolar flooding (transudate / pink frothy fluid).*

- ▶ **Diagram 2 – Chest radiograph of cardiogenic pulmonary edema.** Labels: *cardiomegaly, upper-lobe vascular redistribution (cephalization), Kerley B lines, peribronchial cuffing, perihilar bat-wing / butterfly alveolar opacities, blunted costophrenic angle (pleural effusion).*

Clinical / Diagnostic significance

- ▶ Echocardiography + BNP + ECG rapidly separate cardiogenic from non-cardiogenic edema and identify a treatable mechanical or ischaemic cause — directing emergency reperfusion or surgery.
- ▶ PCWP is the pivotal discriminator: **high (> 18–25 mmHg) = cardiogenic**; normal/low = ARDS/high-permeability edema, which does not respond to diuresis.
- ▶ **Blood pressure dictates therapy:** hypertensive “flash” edema responds dramatically to vasodilators + NIV + diuretics; hypotensive edema (cardiogenic shock) needs inotropes/pressors and revascularisation, and **over-aggressive vasodilatation/diuresis can precipitate iatrogenic shock.**
- ▶ A first inferior MI presenting with shock/edema should prompt a search for RV infarction or a mechanical complication.

High-yield exam pointers

- ▶ Cardiogenic pulmonary edema = **hydrostatic edema from ↑ PCWP**; commonest cause is **acute LV failure due to MI / decompensated chronic HF.**
- ▶ **Pink frothy sputum + bilateral crackles + S3 + orthopnoea/PND** is the classic bedside picture; wheeze = “cardiac asthma”.
- ▶ CXR: **cephalization, Kerley B lines, peribronchial cuffing, bat-wing alveolar shadowing, pleural effusion.**
- ▶ PCWP > 18 mmHg → **interstitial**; > 25 mmHg → **alveolar flooding**; normal PCWP = non-cardiogenic.
- ▶ First-line emergency bundle (mnemonic **LMNOP**): Lasix (loop diuretic), Morphine, Nitrates, Oxygen/NIV, Position (upright, legs dependent).
- ▶ NIV/CPAP **reduces intubation and mortality**; sit up, target SpO₂ ≥ 92%, avoid routine hyperoxia.
- ▶ Nohria “**warm-and-wet**” is the typical profile; “**cold-and-wet**” overlaps with shock and has the worst prognosis.
- ▶ Forrester subset II = **pulmonary edema**; subset IV = **cardiogenic shock**; STEMI with edema → **emergency primary PCI** (mortality 20–40%).

SOURCE & COVERAGE

- ▶ **Braunwald's Heart Disease, 13e** — “Diagnosis and Management of Decompensated Heart Failure” (NIV/CPAP evidence, loop-diuretic dosing, Nohria warm/cold-wet/dry profiles) and “Chest Radiography in Cardiovascular Disease” (cephalization, Kerley B lines).
- ▶ **CMDT 2026** — “Heart Failure & Cardiomyopathy: Acute Heart Failure & Pulmonary Edema” (precipitants, clinical picture, CXR butterfly pattern, PCWP > 25 mmHg, morphine/diuretic/nitrate/nesiritide regimens, DOSE trial).
- ▶ *Coverage note:* The PCWP staging thresholds (interstitial ~18–20 mmHg) and the LMNOP mnemonic are universally accepted standard internal medicine used to organise corpus-sourced facts; CMDT explicitly supports the > 25 mmHg alveolar-edema threshold.

Cardiomyopathies

Asked in: Paper II Sep 2025 — RGUHS MD General Medicine

Definition / Introduction — *Cardiomyopathy* denotes primary disease of the heart muscle itself, traditionally excluding myocardial dysfunction arising from coronary, valvular, hypertensive or congenital heart disease (though common usage admits ischaemic, valvular and hypertensive “cardiomyopathy”). It is best understood as a heterogeneous group of myocardial diseases with mechanical and/or electrical dysfunction, frequently genetic, that may be confined to the heart or part of a systemic disorder. Classification rests on a **phenotype-first** morphologic approach — **hypertrophic** (HCM), **dilated** (DCM) and **restrictive** (RCM) — now complemented by **arrhythmogenic cardiomyopathy** (ACM/ARVC) and increasingly informed by genotype.

Classification

Three classic morphologic phenotypes plus the arrhythmogenic phenotype, defined by left-ventricular (LV) wall thickness, ejection fraction (LVEF) and diastolic physiology:

Phenotype	Defining criteria	Key features	Common challenges
HCM	Septal/wall thickness ≥15 mm (men), ≥13 mm (women); LVEF ≥ normal, usually >0.60; LV cavity ≤ normal	Asymmetric septal, concentric, mid-ventricular or apical patterns; sarcomere	Distinguish from athlete's heart, hypertensive heart, amyloid, storage disease

Phenotype	Defining criteria	Key features	Common challenges
		disease; outflow obstruction in ~30%	(Fabry, Danon, PRKAG2)
DCM	LVEF ≤ 0.50 (most ≤ 0.40) and/or LV dilation (LVEDD $> 95\%$ predicted / LVEDV $> 112\%$)	Global hypokinesis, mitral regurgitation; ~30% spontaneously recover (“reverse remodelling”)	Exclude coronary, valvular and primary structural disease
RCM	Moderate–severe diastolic dysfunction / raised filling pressures; LVEF usually mildly reduced (~30–50%)	Marked biatrial enlargement , right-sided congestion dominates; wall thickness normal or increased	Differentiate from constrictive pericarditis ; identify amyloid/storage
ARVC / ACM	Ventricular arrhythmias dominate before/without reduced LVEF; <i>2010 modified Task Force Criteria</i>	Fibrofatty replacement; desmosomal genes; RV-dominant (ARVC), LV-dominant (ACM-LV) or biventricular	Distinguish PVC-related CM from genetic ACM

- ▶ The AHA (Maron) scheme divides cardiomyopathies into *primary* (genetic, mixed, acquired) and *secondary* (systemic infiltrative/storage/inflammatory), and uniquely includes electrical disorders (channelopathies).
- ▶ The ESC 2023 scheme keeps the phenotypic approach but adds a *non-dilated left ventricular cardiomyopathy* category (LV systolic dysfunction without dilation). *Left-ventricular non-compaction (LVNC)* is regarded as a trait rather than a distinct disease.
- ▶ Phenotypes **overlap and evolve**: DCM may reverse-remodel to higher LVEF, and ~5% of HCM progresses to “burned-out” HCM with reduced EF (HCM-rEF).

Hypertrophic Cardiomyopathy (HCM)

- ▶ **Genetics/pathology**: Commonest inherited cardiac disease, prevalence ~1:500; autosomal dominant with age-dependent, incomplete penetrance. A sarcomere variant is found in ~40–50%; ~80% involve MYH7 (β -myosin heavy chain) or MYBPC3 (myosin-binding protein C). Histology shows **myocyte disarray**, interstitial and replacement fibrosis (late gadolinium enhancement on MRI), and small-vessel disease causing microvascular ischaemia.
- ▶ **Pathophysiology of obstruction**: Dynamic LV outflow tract (LVOT) obstruction in ~30% at rest and a further ~30% on provocation, initiated by drag forces drawing an enlarged anterior mitral leaflet onto the hypertrophied septum — **systolic anterior motion (SAM)** with posteriorly-directed mitral regurgitation. The murmur is harsh, late-peaking, and *augmented* by Valsalva or standing (reduced preload).

- ▶ **Treatment:** β -blockers and non-dihydropyridine calcium-channel blockers (**verapamil**) are first line; **disopyramide** (negative inotrope) for refractory obstruction. **Cardiac myosin inhibitors** — **mavacamten** (FDA-approved), **aficamten** (investigational) — relieve symptomatic obstruction (monitor LVEF). Refractory severe symptoms (~5%): **septal myectomy** or **alcohol septal ablation** (chief complication: complete heart block needing pacing). Avoid digoxin/vasodilators/excess diuresis.
- ▶ **Sudden cardiac death (SCD):** Baseline risk ~0.5%/year. **Major risk factors:** prior cardiac arrest/sustained VT, unexplained syncope, family history of SCD, LV wall ≥ 30 mm, LV apical aneurysm, LVEF $< 50\%$, plus modifiers (extensive LGE, non-sustained VT). The **ESC HCM Risk-SCD calculator** guides ICD: $\geq 6\%$ 5-yr risk $\rightarrow$ ICD advised, 4–6% $\rightarrow$ consider, $< 4\%$ $\rightarrow$ not advised.

Dilated Cardiomyopathy (DCM) and acquired causes

- ▶ Familial in 30–40%, monogenic cause identifiable in ~25%; the commonest gene is **truncating variant of titin (TTN, ~25% of familial DCM)**; **LMNA (lamin A/C)** and **FLNC (filamin C)** carry high arrhythmic risk and warrant early ICD (before LVEF falls to 0.35).
- ▶ **Major acquired causes:** prior myocarditis (viral — coxsackie, adenovirus, COVID-19, HIV; *Trypanosoma cruzi* — Chagas); **toxic** — alcohol (≥ 60 –80 g ethanol/day for ≥ 5 yr; “holiday heart” AF; reversible with abstinence), **anthracyclines** (doxorubicin — dose-related, dexrazoxane chelation), **trastuzumab** (anti-HER2, often reversible), checkpoint inhibitors; **endocrine/metabolic** — thyroid disease, pheochromocytoma, haemochromatosis, thiamine deficiency (beri-beri), selenium deficiency (Keshan); **tachycardia-mediated CM**.
- ▶ **Peripartum cardiomyopathy (PPCM):** LVEF ≤ 0.45 in the last trimester to 5–6 months postpartum (commonly first 2 weeks) without other cause; ~1:1000–1:4000 deliveries; associated with antiangiogenic signalling (sFLT1), an abnormal prolactin fragment, and TTN variants (~15%). Higher risk and poorer recovery in Black women. Avoid ACE-inhibitors/ARBs antenatally (use hydralazine-nitrate); anticoagulate if LVEF < 0.35 ; LVEF recovers to ≥ 0.50 in 50–80%.
- ▶ **Takotsubo (stress / “broken-heart”) syndrome:** apical ballooning with basal sparing in older women after intense stress; catecholamine-mediated; mimics infarction but coronaries patent; usually recovers in days–weeks (recurrence ~2%/yr).
- ▶ **Therapy:** guideline-directed medical therapy as for HFrEF — the **four pillars:** ARNI/ACE-inhibitor/ARB, β -blocker, mineralocorticoid-receptor antagonist, **SGLT2 inhibitor**, plus diuretics, device therapy (CRT for LBBB, primary-prevention ICD for persistent LVEF ≤ 0.30 –0.35) and anticoagulation for AF/LV thrombus.

Restrictive Cardiomyopathy and Cardiac Amyloidosis

- ▶ **RCM physiology:** stiff, non-compliant ventricles with preserved cavity size; biatrial enlargement; raised biventricular filling pressures; right-sided congestion (oedema, ascites), **prominent Y**

descent, positive Kussmaul sign, $S_4 > S_3$; haemodynamics show a “square-root” (dip-and-plateau) sign.

- **Causes:** *infiltrative* (amyloid — commonest), *storage* (haemochromatosis, Fabry, glycogen storage), *fibrotic* (radiation, scleroderma, **endomyocardial fibrosis**, **Löffler endocarditis** from hypereosinophilia), carcinoid, and genetic (DES desminopathy, sarcomeric overlap with HCM).
- **Cardiac amyloidosis:** extracellular fibrillar deposition staining with **Congo red** → **apple-green birefringence**; nonbranching fibrils ~10 nm. Two dominant precursors:

Feature	AL (light-chain)	ATTR (transthyretin)
Source	Clonal plasma cells ($\lambda > \kappa$ free light chains)	Liver TTR — wild-type (ATTRwt) or variant (ATTRv)
Demographics	Younger; plasma-cell dyscrasia/myeloma	Elderly men (ATTRwt, M:F ~20:1); ATTRv Val122Ile in ~3.5% African-Americans
Extra-cardiac clues	Periorbital purpura, macroglossia, nephrotic proteinuria, autonomic neuropathy	Bilateral carpal tunnel syndrome, spinal stenosis, ruptured biceps tendon
Diagnosis	Tissue biopsy mandatory (fat-pad/cardiac); mass spectrometry typing	Tc-PYP/DPD bone scintigraphy positive (grade ≥ 2) <i>after excluding plasma-cell dyscrasia</i>
Untreated survival from HF onset	~6 months (worst prognosis)	ATTRwt ~4–5 yr; Val122Ile ~2–3 yr
Specific therapy	Dara-CyBorD (daratumumab, bortezomib, cyclophosphamide, dexamethasone); $\pm$ autologous SCT	Stabilisers tafamidis, acoramidis; TTR silencers patisiran/eplontersen/vutrisiran

- **Imaging clues:** thick walls with **low ECG voltage**, biatrial enlargement, and **apical-sparing “bull’s-eye” longitudinal-strain** pattern; CMR shows expanded extracellular volume, diffuse subendocardial LGE and abnormal myocardial nulling. NT-proBNP and troponin are disproportionately elevated. Avoid ACE-inhibitors/ β -blockers (poorly tolerated); anticoagulate AF; ICD rarely useful.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- **Morphologic phenotypes (4-panel cross-section):** *Normal* heart; *DCM* — globally dilated thin-walled LV with enlarged LA; *HCM* — asymmetric septal hypertrophy, small LV cavity, anterior mitral leaflet showing **SAM** and **LVOT gradient**; *RCM* — normal-size cavity, mildly thickened walls with **massive biatrial enlargement**. Labels: *LV cavity*,

interventricular septum, LV free wall, RV, left atrium (LA), mitral valve, SAM, LVOT obstruction.

- ▶ **Cardiac-amyloid strain “bull’s-eye”:** concentric polar map with **preserved apical strain (red)** and **impaired basal strain (blue)** — label *apical sparing, impaired base*.

Clinical / Diagnostic significance

- ▶ **Presentation:** exertional dyspnoea/fatigue, congestion, arrhythmias (AF), embolic events (LV/apical thrombus) or SCD; “*congestive heart failure*” is a *syndrome, not an aetiology* — always seek the cause.
- ▶ **Work-up (Harrison Table 266-2):** detailed family history (SCD, pacemaker/AF by middle age, muscular dystrophy), ECG, chest radiograph, 2-D/Doppler **echocardiography** (initial modality), **cardiac MRI** (tissue characterisation, LGE, T1/T2 mapping), bloods (TSH, iron studies/transferrin saturation >45–60%, troponin, eosinophils, serum/urine immunofixation + free light chains), genetic counselling/multigene panel, and **endomyocardial biopsy** when a specific therapy-altering diagnosis (giant-cell, eosinophilic, sarcoid, amyloid, Fabry) is suspected.
- ▶ **RCM vs constrictive pericarditis** is the pivotal differential — both cause right-sided congestion and Kussmaul sign; pericardial thickening/calcification, respiratory septal shift and discordant ventricular pressures favour constriction (surgically curable), whereas biatrial enlargement, low voltage and positive bone scan/LGE favour restrictive amyloid.
- ▶ **Therapeutic leverage:** many cardiomyopathies are *treatable* — abstinence in alcoholic CM, phlebotomy/chelation in haemochromatosis, enzyme replacement/migalastat in Fabry, tafamidis in ATTR, Dara-CyBorD in AL, and reverse remodelling on GDMT.

High-yield exam pointers

- ▶ Three classic phenotypes = HCM, DCM, RCM; fourth = **arrhythmogenic (ARVC/ACM)**; LVNC is a trait.
- ▶ HCM commonest gene pair **MYH7 + MYBPC3** (~80%); hallmark = SAM + dynamic LVOT obstruction; murmur ↑ with Valsalva/standing.
- ▶ HCM is the **leading cause of SCD in the young athlete**; ICD by ESC Risk-SCD score (≥6% → implant). Newest drug class = **myosin inhibitors (mavacamten)**.
- ▶ DCM commonest genetic cause = **titin (TTN) truncation**; LMNA/FLNC = arrhythmic, early ICD.
- ▶ Cardiac amyloid: **Congo red apple-green birefringence**; **apical-sparing bull’s-eye strain**; ATTR diagnosed *non-invasively* by Tc-PYP scan after excluding light chains.
- ▶ **AL clues** = periorbital purpura, macroglossia; **ATTR clues** = bilateral carpal tunnel, ruptured biceps tendon; AL prognosis worst (~6 months untreated).

- ▶ **ARVC** = desmosomal disease (PKP2, DSP, DSG2, DSC2, JUP); **epsilon wave**, T-inversion V1–V3, fibrofatty RV replacement; *Naxos* (with woolly hair/palmoplantar keratoderma) and *Carvajal* syndromes.
- ▶ **Peripartum CM** = LVEF ≤ 0.45 , last trimester–6 months postpartum; avoid ACE-i antenatally; anticoagulate if LVEF < 0.35 .
- ▶ **Takotsubo** = apical ballooning, post-stress, women, coronaries normal, usually reversible.

Classify Cardiomyopathy. What are the risk factors, clinical presentations and prognosis of peripartum Cardiomyopathy?

Asked in: Paper II 08 Apr 2026 — RGUHS MD General Medicine

Definition / Introduction — *Cardiomyopathy* denotes primary disease of the heart muscle itself, traditionally excluding myocardial dysfunction arising from coronary, valvular, hypertensive or congenital disease (though common usage now admits ischaemic, valvular and hypertensive “cardiomyopathy”). It is classified by **morphology and function** into three classic phenotypes — hypertrophic (HCM), dilated (DCM) and restrictive (RCM) — with arrhythmogenic cardiomyopathy (ACM/ARVC) and left ventricular non-compaction (LVNC) as evolving fourth/fifth categories, and increasingly by **aetiology** (genetic vs acquired). *Peripartum cardiomyopathy (PPCM)* is a distinct acquired DCM developing toward the end of pregnancy or in the months after delivery.

A. Classification of cardiomyopathy

1. Morphological / functional classification (the traditional working scheme; WHO 1995):

Phenotype	Defining criteria	Key features / mimics
Hypertrophic (HCM)	Septal/wall thickness ≥ 15 mm (men), ≥ 13 mm (women); LVEF normal/high, usually > 0.60 ; LV cavity $\leq$ normal	Asymmetric septal, sigmoid, concentric or apical patterns; distinguish from athlete's heart, hypertension, aortic stenosis;

Phenotype	Defining criteria	Key features / mimics
		mimicked by storage diseases — <i>Anderson-Fabry</i> (GLA), <i>PRKAG2</i> , <i>Danon</i> (LAMP2) and amyloid
Dilated (DCM)	LVEF ≤ 0.50 (most present ≤ 0.40) $\pm$ LV dilation (LVEDD/LVEDV increased)	Convergent end-phenotype of many injuries; functional MR; $\sim 1/3$ of recent-onset cases recover (“HFimpEF”)
Restrictive (RCM)	Functional diagnosis: moderate-severe diastolic dysfunction / raised filling pressures; LVEF mildly reduced	Least common; marked biatrial enlargement , right-heart failure dominates; marked wall thickening suggests amyloidosis , storage/metabolic disease
Arrhythmogenic (ACM-LV / ACM-RV = ARVC)	DCM-type morphology with ventricular arrhythmias <i>out of proportion</i> to dysfunction; ARVC by 2010 modified Task Force criteria	LGE patterns on CMR; ICD considered even at LVEF > 0.35 ; sarcoid/Chagas can mimic
LV non-compaction (LVNC) — trait	Non-compacted : compacted myocardium ratio > 2.3	May overlay HCM/DCM/dystrophies; trabeculation can be physiological in pregnancy/athletes

2. Aetiological classification of DCM (Harrison Table 269-1) — a high-yield framework:

- **Inflammatory / infective** — viral (coxsackie, adenovirus, COVID-19, HIV), parasitic (*Trypanosoma cruzi* — Chagas), bacterial (diphtheria), spirochaetal (Lyme), rickettsial (Q fever).
- **Non-infective inflammatory** — sarcoidosis, giant-cell & eosinophilic myocarditis, collagen-vascular disease, checkpoint-inhibitor myocarditis, transplant rejection.
- **Toxic** — alcohol (commonest toxin), catecholaminergic stimulants (cocaine, amphetamines), chemotherapy (anthracyclines, trastuzumab), hydroxychloroquine/chloroquine, anabolic steroids, heavy metals (lead, mercury, cobalt).
- **Metabolic** — thiamine/selenium (Keshan)/carnitine deficiency, $\text{Ca}^{2+}/\text{PO}_4^{3-}/\text{Mg}^{2+}$ depletion, thyroid disease, pheochromocytoma, diabetes, obesity, haemochromatosis.
- **Genetic / familial** — $\sim 30\%$ of DCM; autosomal-dominant predominantly; *TTN* truncations, *LMNA*, *MYH7*, *TNNT2*, dystrophinopathies (Duchenne/Becker), mitochondrial (Kearns-Sayre).
- **Miscellaneous (overlap)** — **peripartum**, tachycardia-induced (uncontrolled SVT, high PVC burden), LVNC, arrhythmogenic.

> A **two-hit model** is increasingly recognised — a genetic predisposition is unmasked by an acquired trigger (infection, toxin, **pregnancy**, tachycardia). The pragmatic clinical split remains **primary** (genetic, mixed, acquired) vs **secondary** (systemic-disease) cardiomyopathy.

B. Peripartum cardiomyopathy — definition & risk factors

- ▶ **Definition:** PPCM is a **diagnosis of exclusion** — *de novo* LV systolic dysfunction ($LVEF \leq 0.45$) presenting in the **last month of pregnancy or within ~5–6 months postpartum**, with no other identifiable cause of heart failure; **most cases present within the first 2 weeks after delivery**.
- ▶ **Incidence:** 1:1000 to 1:4000 deliveries in the USA; striking geographic/ethnic variation — close to 1% of deliveries in parts of Nigeria (highest in Hausa & Fulani) vs ~1 in 15,000 in Japan.
- ▶ **Risk factors:**
 - Older maternal age; increased parity / multiparity.
 - Multiple (twin) gestation.
 - Hypertensive disorders of pregnancy / pre-eclampsia — present in *up to half* of cases.
 - Black / African ancestry — risk ~four-fold higher in Black women, with slower and less complete recovery.
 - Malnutrition and tocolytic therapy for premature labour.
 - Genetic susceptibility — TTN truncating variants in ~15% (overall pathogenic/likely-pathogenic truncations ~15% — similar to non-PPCM DCM), predicting poorer recovery.
- ▶ **Pathogenesis (“vasculo-hormonal” model):** late-gestation **oxidative stress** drives **antiangiogenic signalling** — high soluble FLT1 (sFLT1), an inhibitor of VEGF (also elevated in pre-eclampsia) — together with **cathepsin-D-mediated cleavage of prolactin** into a toxic **16-kDa prolactin fragment** that promotes **endothelial and cardiomyocyte apoptosis**. This is the rationale for **bromocriptine** (prolactin suppression).

C. Clinical presentation, diagnosis & management

- ▶ **Presentation:** typically the **syndrome of congestion** — exertional dyspnoea, orthopnoea, fatigue, pedal/abdominal oedema — easily mis-attributed to normal late pregnancy. **Atrial and ventricular arrhythmias** occur; **LV thrombus / systemic or pulmonary embolism** (especially $LVEF < 0.35$); rarely cardiogenic shock.
- ▶ **Diagnostic clues & work-up:** raised BNP/NT-proBNP and troponin, elevated central venous pressure, and echocardiography ($LVEF \leq 0.45$) is usually sufficient. CMR may help in complex cases — **gadolinium should be avoided antepartum**. Always **exclude** pulmonary embolism, spontaneous coronary artery dissection and other de-novo cardiomyopathies (familial DCM, HCM, LVNC, ARVC). **Genetic testing** is reasonable (informs prognosis and family screening).
- ▶ **Management:**
 - **Diuresis** with loop diuretics to restore euvolaemia (use cautiously).

- **Antepartum:** RAS inhibitors (ACEi/ARB/ARNI), aldosterone antagonists and SGLT2i are contraindicated (fetotoxic). Afterload reduction with hydralazine + nitrate; digoxin and β -blockers (metoprolol preferred over carvedilol) for rate/arrhythmia control; close maternal-fetal medicine collaboration with a plan for emergency delivery.
- **Postpartum:** full guideline-directed therapy for HFrEF — **metoprolol**, **enalapril/captopril/lisinopril** and **spironolactone** are compatible with breastfeeding (avoid eplerenone, ARNI, SGLT2i, DOACs while breastfeeding).
- **Anticoagulation** for ~6 weeks if LVEF <0.35 or marked dilation (once obstetric bleeding settles).
- **Bromocriptine** — *class IIb* in ESC HF guidelines (with anticoagulation); **not routinely recommended** by the 2022 AHA/ACC/HFSA guideline; large RCT ongoing.
- **Wearable cardioverter-defibrillator** is reasonable when LVEF <0.35, given early arrhythmic risk; **breastfeeding is now generally encouraged** where fluid balance permits.

D. Prognosis of peripartum cardiomyopathy

- ▶ **Recovery is comparatively favourable:** LVEF improves to ≥ 0.50 in 50–80%, usually within 6 months. In the North American IPAC study ~70% had LVEF >0.50 at 1 year; the ESC EORP registry showed recovery in ~66%.
- ▶ **One-year mortality:** ~4–11% in the USA (higher in Black women), ~8% in the ESC EORP registry, and reported up to two-fold higher in Africa.
- ▶ **Predictors of poor recovery / adverse outcome:**
 - LVEF <0.30 at presentation; LV end-diastolic dimension ≥ 6.0 cm.
 - Black race; presentation >6 weeks after delivery.
 - Elevated natriuretic peptides, troponin and sFLT1; positive genetic testing (e.g., TTN).
- ▶ **Subsequent pregnancies** carry substantial risk of relapse and death — **contraindicated where there is any residual LV dysfunction** (mWHO class IV); recurrence risk correlates with the degree of recovery. PPCM is the **4th commonest indication for cardiac transplantation in women** in the USA (~5%), with post-transplant outcomes similar to other indications.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Morphological classification montage** — four LV cross-sections side by side, labelled: HCM (thick asymmetric septum, small slit-like cavity), DCM (globular dilated thin-walled LV), RCM (normal-sized cavity with grossly dilated biatrial chambers), ARVC/ACM (dilated, fibro-fatty right ventricle). Annotate LVEF and wall-thickness criteria.
- ▶ **PPCM “vasculo-hormonal” pathogenesis flowchart** — labels: *Late pregnancy/puerperium* → *Oxidative stress* → two arrows to *sFLT1 (anti-VEGF)* and *Cathepsin-D cleaves prolactin* → *16-kDa prolactin fragment* → *Endothelial + cardiomyocyte apoptosis / microvascular*

dysfunction → LV systolic dysfunction (LVEF $\leq 45\%$); side-box Genetic susceptibility — TTN truncating variant (~15%); timeline bar last trimester → 5–6 months postpartum (peak: first 2 weeks).

Clinical / Diagnostic significance

- ▶ Distinguishing the **phenotype** guides initial work-up, while **aetiology** (especially genetic vs acquired) drives family screening, ICD decisions and prognosis.
- ▶ In a peripartum woman with new heart failure, **PPCM is the commonest cause** but remains a **diagnosis of exclusion** — rule out PE, coronary dissection and unmasked familial/structural disease.
- ▶ **sFLT1, BNP/troponin and TTN status** are emerging prognostic biomarkers; **avoid gadolinium and RAS blockade/SGLT2i antepartum**.
- ▶ Counsel against further pregnancy if LV function does not fully normalise; document contraception.

High-yield exam pointers

- ▶ Three classic phenotypes = **HCM, DCM, RCM**; add **ARVC/ACM** and **LVNC**; HCM wall ≥ 15 mm (M)/ ≥ 13 mm (W), DCM LVEF ≤ 0.40 for therapy & ≤ 0.30 – 0.35 for primary-prevention ICD.
- ▶ **Amyloidosis** = commonest RCM; **alcohol** = commonest toxic DCM; **TTN** = commonest DCM gene.
- ▶ **PPCM** = LVEF ≤ 0.45 , last month of pregnancy to ~5 months postpartum, **peak in first 2 weeks after delivery**; incidence **1:1000–1:4000 (USA)**.
- ▶ Risk factors: **older age, multiparity, twins, pre-eclampsia/HTN, Black race (4×), malnutrition, tocolytics, TTN variant**.
- ▶ Pathogenesis: **16-kDa prolactin fragment + sFLT1** → “vasculo-hormonal” injury → rationale for **bromocriptine**.
- ▶ **No ACEi/ARB/ARNI/MRA/SGLT2i before delivery**; use **hydralazine-nitrate, β -blocker, digoxin, diuretic**; anticoagulate if LVEF < 0.35 .
- ▶ Recovery (LVEF ≥ 0.50) in **50–80%**; 1-year mortality **4–11%**; poor prognosis if LVEF < 0.30 , **LVEDD ≥ 6 cm, Black race, late presentation, high sFLT1/troponin**.
- ▶ Subsequent pregnancy **contraindicated with residual LV dysfunction**; 4th commonest transplant indication in women.

SOURCE & COVERAGE

- ▶ **Harrison's Principles of Internal Medicine, 22e** — “Classification of Cardiomyopathy” (morphological classification, Table 266-1; initial evaluation) and “Dilated Cardiomyopathies” (aetiological Table 269-1; Peripartum Cardiomyopathy section — incidence, risk factors, sFLT1/16-kDa prolactin, TTN, management, prognosis); “Genetic Cardiomyopathies”.
- ▶ **Braunwald's Heart Disease, 13e** — “The Dilated, Restrictive, and Infiltrative Cardiomyopathies” (PPCM genetics, bromocriptine class IIb/AHA stance, recovery ~50%, transplant data) and “Pregnancy and Heart Disease” (risk factors, IPAC ~70% recovery & predictors, ESC EORP 8% 1-yr mortality, mWHO contraindication, drug safety in lactation).
- ▶ **CMDT 2026** — “Heart Failure & Cardiomyopathy” (dilated cardiomyopathy epidemiology/work-up, LV-thrombus anticoagulation, referral thresholds).

Coverage note: The corpus grounds the morphological and aetiological classifications fully; the formal AHA 2006 (primary genetic/mixed/acquired vs secondary) and ESC MOGE(S) nomenclature are universally accepted but are referenced only implicitly in this corpus, so they are mentioned briefly rather than tabulated.

Conducting system of the Heart and Electrocardiogram

Asked in: Paper I Dec 2023 — RGUHS MD General Medicine

Definition / Introduction — The **cardiac conduction system** is the network of specialized, automatic and rapidly-conducting myocardial fibres that initiates each heartbeat and delivers the impulse in an orderly sequence from atria to ventricles, ensuring coordinated, synchronous mechanical contraction. The **electrocardiogram** (ECG/EKG) is the noninvasive graphical recording of the depolarization (stimulation) and repolarization (recovery) electrical activity of the working atrial and ventricular myocardium, detected by metallic electrodes on the limbs and chest wall. Because the cardiac depolarization and repolarization wavefronts have direction and magnitude, they can be represented as **vectors**, and the surface ECG is the summed projection of these vectors onto standardized leads.

Anatomy and sequence of the conduction system

The electrical currents that spread through the heart are produced by three components: **cardiac pacemaker cells**, **specialized conduction tissue**, and **the heart muscle itself**. The orderly route of a normal impulse is:

- ▶ **Sinoatrial (SA) node** — the dominant pacemaker, situated at the lateral junction of the **superior vena cava and right atrium**; possesses spontaneous **automaticity** and is richly innervated by autonomic fibres for dynamic heart-rate control.

- ▶ **Atrial myocardium** — depolarization spreads across the right then the left atrium via **preferential conduction pathways**, inducing atrial systole; inscribes the **P wave**.
- ▶ **Atrioventricular (AV) node** — the AV nodal and His-bundle areas together form the **AV junction**; conduction here is deliberately **slow**, providing physiologic AV synchrony (the PR interval). In normal hearts the AV node is the **only electrical connection** between atria and ventricles.
- ▶ **Bundle of His → right and left bundle branches** — the His bundle bifurcates; the main left bundle fans out into **left anterior and left posterior fascicles**.
- ▶ **Purkinje fibres** — an endocardial network that rapidly and synchronously activates both ventricles. Depolarization then spreads through the ventricular wall from **endocardium to epicardium**, triggering coordinated ventricular contraction.

Structure	Property / role	Conduction velocity
SA node	Primary pacemaker; <i>If</i> (funny) current automaticity; autonomic control	Nodal (slow)
Atrial myocardium	Inscribes P wave; atrial systole	0.3–0.4 m/s
AV node	Slow conduction → AV delay (PR interval); sole AV connection	Slow
His–bundle branches–fascicles	Rapid transmission to ventricles	High
Purkinje fibres	Endocardial, synchronizes ventricular activation	2–3 m/s

Conduction is faster in Purkinje fibres (2–3 m/s) than in myocardial cells (0.3–0.4 m/s), partly due to different connexins in their gap junctions.

Cellular electrophysiology, automaticity and autonomic control

The cardiac **action potential (AP)** drives all electrophysiologic behaviour and has five phases (0–4): **rapid upstroke, early repolarization, plateau, late repolarization, and diastole**. Ionic currents flux through voltage-gated channels and gap-junction (connexin) complexes:

Current	Gene	Protein	Principal AP role
I _{Na}	SCN5A	Nav1.5	Phase 0 upstroke (atrial/ventricular)
I _{Ca-L}	CACNA1C	Cav1.2	Plateau (phase 2); phase 0 of nodal tissue
I _{to}	KCND3 / KCNIP2	Kv4.3 / KChIP2	Phase 1 early repolarization
I _{Kr}	KCNH2 / KCNE2	HERG / MiRP-1	Phase 3 repolarization

Current	Gene	Protein	Principal AP role
I _{Ks}	KCNQ1 / KCNE1	KVLQT1 / minK	Phase 3 repolarization
I _{K1}	KCNJ2	Kir2.1	Phase 4 — sets resting membrane potential
I _{Kur}	KCNA5	Kv1.5	Atrial repolarization
I _f (funny)	—	Semiselective Na/Ca channel	SA-node phase 4 automaticity ; target of ivabradine

- **Automaticity** = spontaneous phase-4 depolarization; a normal property of the SA node, AV node and His-Purkinje system. In the SA node the **Na/Ca If current drives phase 4; the normal range of SA automaticity is 30–220 beats/min. The intrinsic heart rate (IHR)** is the native SA rate without autonomic input.
- **Autonomic modulation**: parasympathetic vagal tone releases acetylcholine → opens I_{KACH} (G-protein mediated) → K⁺ efflux hyperpolarizes nodal cells → slows phase 4. Sympathetic catecholamines act via **β1 receptors** → activate L-type Ca channels → enhance phase 4 → faster rate (with exercise the PR interval physiologically shortens).
- **Escape rhythm**: if a proximal pacemaker fails, a more distal automatic focus may take over to maintain cardiac output. Mutations in **K-channel** subtypes (e.g., delayed closing) prolong the QT and cause inherited **long-QT syndromes**.

Genesis of the normal ECG — correlation of conduction events with waveforms

Each ECG deflection corresponds to a phase of the simultaneously-obtained ventricular AP: **phase 0** ↔ onset of QRS; plateau phase 2 ↔ isoelectric ST segment; active repolarization phase 3 ↔ T wave.

ECG component	Electrical event	AP phase	Normal value
P wave	Atrial depolarization (vector down & leftward → +ve in II, -ve in aVR)	Atrial phase 0	≤2.5 mm tall
PR interval	Atrial→ventricular delay, mostly AV-nodal conduction	—	120–200 ms
QRS complex	Ventricular depolarization	Phase 0	100–110 ms or less
J point	Junction of QRS end and ST start	—	—
ST segment	Early ventricular repolarization (plateau)	Phase 2	Isoelectric

ECG component	Electrical event	AP phase	Normal value
T wave	Ventricular repolarization (epicardium→endocardium)	Phase 3	Concordant with QRS (within ~45°)
QT interval	Ventricular depolarization + repolarization	Phases 0–3	QTc ≤450 ms (men), ≤460 ms (women)
U wave	Late repolarization deflection	—	≤1 mm

- ▶ Atrial repolarization (ST-Ta) is usually too small to detect; it may emerge in **acute pericarditis**, **atrial infarction** and **AV block**.
- ▶ **QRS septal vectors**: vector 1 = septal depolarization (left→right, anterior) gives a small **septal r** in V1 and **septal q** in V6; vector 2 = dominant LV (left & posterior) gives the **S wave** in V1 and **R wave** in V6. The **transition zone** ($R \approx S$) is usually V3–V4.
- ▶ **Rate-correction (QTc)**: classic Bazett $QTc = QT/\sqrt{RR}$ (in seconds); the **Framingham** formula $QTc = QT + 0.154 (1000 - RR)$ in ms.

The 12-lead ECG: leads, calibration and axis

- ▶ **12 leads** = 6 limb (frontal plane, hexaxial reference) + 6 chest/precordial (horizontal plane). Each lead is like a different “camera angle” viewing the same depolarization/repolarization. An upright deflection occurs when the wavefront travels **toward** the positive pole of a lead.
- ▶ **Calibration**: recorded on 1-mm² grid at 25 mm/s — smallest 1-mm horizontal box = **40 ms (0.04 s)**, heavy lines every **200 ms (0.20 s)**; vertically **1 mV = 10 mm**.
- ▶ **Heart rate**: $300 \div \text{number of large (0.20 s) boxes between R waves}$, or $1500 \div \text{number of small boxes}$.
- ▶ **Mean QRS axis**: normal -30° to $+100^\circ$; more negative than -30° = **left axis deviation**, more positive than $+90$ to $+100^\circ$ = **right axis deviation**.
- ▶ **Supplementary leads**: V3R–V6R (right ventricular infarction), and posterior V7 (**midaxillary**), V8 (**posterior axillary**), V9 (**posterior scapular**) for posterolateral infarction.

Conduction abnormalities and key ECG correlates

- ▶ **Complete bundle branch block**: QRS ≥120 ms; incomplete 110–120 ms. RBBB — terminal vector right & anterior → **rSR'** in V1, **qRS** in V6. LBBB — vector left & posterior → wide **QS** in V1, **monophasic R** in V6; often marks coronary, hypertensive, aortic valve disease, or cardiomyopathy. Both cause **secondary ST-T changes** (T wave opposite to terminal QRS = appropriate discordance).
- ▶ **Fascicular blocks (hemiblocks)**: do not greatly widen QRS but shift the axis — **left anterior fascicular block** (axis more negative than -45° , commonest cause of marked LAD); **left posterior fascicular block** (axis $> +110$ – 120° , rare).

- ▶ **Pre-excitation:** wide QRS via a bypass tract (Wolff-Parkinson-White) — a non-conduction-delay cause of QRS prolongation.
- ▶ **Metabolic/drug effects:** hyperkalemia — peaked/tented T → wide QRS → loss of P → sine-wave → asystole; hypokalemia — prominent U waves, long QT; hypocalcemia prolongs / hypercalcemia shortens QT; hypothermia — Osborn (J) wave; digitalis — ST “scooping,” short QT.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Diagram 1 — Cardiac conduction system** (schematic, after Fig. 247-1): label SA node, right atrium (RA), left atrium (LA), AV node, AV junction, His bundle, right bundle branch, left bundle branch, ventricular septum, Purkinje fibres, RV, LV, ventricular myocardium, with directional arrows showing impulse sequence.
- ▶ **Diagram 2 — Basic ECG waveforms/intervals** (after Fig. 247-2): label P wave, QRS complex, T wave, U wave, J point, PR interval, QRS interval, ST segment, QT interval (and note the RR interval). Optionally align below it the AP phases 0–4 to show ST ↔ phase 2 and T ↔ phase 3.

Clinical / Diagnostic significance

- ▶ The ECG is **immediately available, noninvasive and inexpensive** — central to diagnosing arrhythmias, conduction disturbances and myocardial ischaemia/infarction, and may reveal life-threatening electrolyte disturbances, drug toxicity and susceptibility to sudden cardiac arrest.
- ▶ The 12-lead resting ECG is the **cornerstone** of arrhythmia evaluation; if active arrhythmia is captured a definitive diagnosis is made. As it samples only ~6 s, transient arrhythmias need **ambulatory monitoring** (Holter, event/patch recorders) or provocation, and **invasive EP study** for mechanism/ablation.
- ▶ ECG localization of ischaemia: **anterior** (V1–V6, I, aVL); **inferior** (II, III, aVF); **right ventricular** (right-sided leads); **posterior** (reciprocal ST depression V1–V3).
- ▶ ECG **voltage criteria** for LVH/RVH have low sensitivity; echocardiography and cardiac MRI give more definitive anatomic/functional data.

High-yield exam pointers

- ▶ Impulse order: SA node → atria → AV node → His → bundle branches → fascicles → Purkinje → ventricular myocardium.
- ▶ AV node = **only normal electrical atria-to-ventricle connection**; its slow conduction creates the PR interval (120–200 ms).
- ▶ P wave = atrial depolarization; QRS = ventricular depolarization; ST-T-U = ventricular repolarization; atrial repolarization is normally hidden in QRS.

- ▶ AP correspondence: **phase 0** → QRS, **phase 2** → ST, **phase 3** → T wave; *IK1 sets resting potential*, *If drives SA automaticity* (ivabradine target).
- ▶ Paper: 1 **small box** = 40 ms, 1 **large** = 200 ms, 1 mV = 10 mm; rate = 300/large boxes.
- ▶ Normal QRS axis -30° to $+100^\circ$; QRS ≥ 120 ms = **complete BBB**; RBBB rSR' in V1, LBBB QS in V1/R in V6.
- ▶ QTc upper limits 450 ms (men), 460 ms (women); Bazett QTc = $QT/\sqrt{RR}$.
- ▶ Hyperkalemia sequence: **tented T** → **wide QRS** → **flat P** → **sine wave** → **asystole**.

SOURCE & COVERAGE

Harrison's Principles of Internal Medicine, 22e (2025) — Ch 247 "Electrocardiography" (Goldberger) and Ch 250 "Principles of Clinical Cardiac Electrophysiology" (Sauer, Koplan, Zei). **Coverage note:** The provided chapters describe conduction anatomy functionally but do not give the nodal blood supply (SA-nodal/AV-nodal arteries), the named internodal/Bachmann interatrial tracts, or the classic resting escape pacemaker hierarchy (SA 60–100, AV junction 40–60, ventricular 30–40 /min) — these are added only where universally-accepted standard internal medicine and are flagged here as outside the supplied text (Harrison gives the dynamic SA range of 30–220 /min and the general "escape rhythm" concept instead).

Constrictive Pericarditis

Asked in: Paper II Nov 2019 — RGUHS MD General Medicine

Definition / Introduction — Constrictive pericarditis (CP) is the end-stage of a chronic inflammatory process in which a rigid, thickened, fibrotic and often calcified pericardium encases the heart, obliterating the pericardial cavity and limiting diastolic filling of the ventricles. It is the prototype of a *surgically curable* cause of right-heart failure / diastolic heart failure. (Note: the 2019 paper printed the topic as "conservative pericarditis" — a near-universal transcription error for constrictive pericarditis, which is the only recognised clinical entity and is answered here.)

Etiology and Classification

CP results when healing of fibrinous/serofibrinous pericarditis or resorption of a chronic effusion is followed by obliteration of the pericardial cavity by granulation tissue that contracts into a firm, sometimes calcific, scar. Constriction may evolve over weeks–months but typically takes years.

Group	Causes
Idiopathic / viral	Commonest cause in the developed world; risk after viral/idiopathic pericarditis <1%

Group	Causes
Post-surgical	After cardiac surgery of any type (common in transient/reversible CP)
Post-radiation	Mediastinal irradiation (breast cancer, lymphoma) — poor surgical prognosis
Tuberculous	Leading cause in the developing world (India), sub-Saharan Africa; risk after purulent bacterial pericarditis 20–30%, after immune/neoplastic 2–5%
Connective tissue / autoimmune	RA, SLE, scleroderma, sarcoidosis
Others	Chronic renal failure on dialysis (uremic), neoplasm, trauma with organised clot, asbestosis, drug-induced, <i>Mulibrey nanism</i> (familial, AR)

Harrison's clinical-temporal classification of pericarditis places constriction in the **subacute (6 wks–6 months, effusive-constrictive or constrictive)** and **chronic (>6 months, constrictive or adhesive)** categories.

Pathophysiology — the hallmark physiology

- ▶ **Impaired filling:** Ventricular filling is *unimpeded in early diastole* but stops abruptly when the elastic limit of the rigid pericardium is reached ($\approx$ entire stroke volume enters in early diastole). Contrast with tamponade, where filling is impeded *throughout* diastole.
- ▶ **Equalisation of pressures:** Ventricular end-diastolic, mean atrial, pulmonary venous and systemic venous pressures are all elevated and **equal to within ≤ 5 mmHg** of one another (typically ~ 20 – 25 mmHg).
- ▶ **Dissociation of intrathoracic and intracardiac pressures:** The stiff pericardium prevents transmission of the inspiratory fall in intrathoracic pressure to the cardiac chambers. On inspiration, the pressure drop reaches the pulmonary veins but **not** the LA/LV, reducing the pulmonary-vein-to-LA gradient $\rightarrow$ $\downarrow$ left-heart filling.
- ▶ **Enhanced ventricular interdependence:** Because total cardiac volume is fixed by the shell, inspiratory $\downarrow$ LV filling permits $\uparrow$ RV filling with a **leftward septal shift** (“septal bounce”); the reverse occurs in expiration. This is the basis of all the respirophasic Doppler signs.
- ▶ Systolic function is usually preserved (“pure” constriction); advanced disease may extend fibrosis into the myocardium (mixed constriction–restriction / myopericarditis), worsening prognosis.

Clinical Features

- ▶ **Symptoms:** Insidious fatigue, weakness, exertional dyspnoea, orthopnoea; progressive systemic venous congestion — raised abdominal girth, ascites (often *out of proportion to peripheral oedema*), congestive hepatomegaly/jaundice, anasarca, muscle wasting and cachexia in end-stage disease.

- ▶ **Jugular venous pulse:** Markedly elevated, with a **prominent, rapid y descent** and a normal x descent → **M- or W-shaped** waveform; fails to fall (or rises) on inspiration = **Kussmaul's sign**.
- ▶ **Pericardial knock:** Early diastolic sound at LSB/apex, slightly *earlier and higher-pitched* than an S3, from abrupt cessation of ventricular filling.
- ▶ **Pulsus paradoxus:** Present in only about **one-third** of cases (unlike tamponade, where it is the rule).
- ▶ **Other signs:** Distant heart sounds, *Broadbent's sign* (systolic apical retraction), hepatomegaly with pulsatile veins, splenomegaly, pleural effusions, stigmata of cardiac cirrhosis (spider naevi, palmar erythema). Atrial fibrillation is common.
- ▶ A common pitfall is mistaking CP for **hepatic cirrhosis** (ascites + hepatomegaly); inspection of the distended neck veins distinguishes them.

Investigations

- ▶ **ECG:** Non-specific — low-voltage QRS, diffuse T-wave flattening/inversion; **atrial fibrillation in ~one-third**.
- ▶ **Chest X-ray:** Normal or slightly enlarged heart; **pericardial calcification** (best seen in lateral view) — most frequent in tuberculous CP but neither sensitive nor specific; pleural effusions common.
- ▶ **Echocardiography–Doppler (first-line):** Pericardial thickening; **septal “bounce”**; dilated IVC/hepatic veins with blunted respiratory variation; abrupt halt of early LV filling. Doppler: respiratory variation in **mitral E $\geq 25\%$** ($\uparrow$ on early expiration), tricuspid/mitral flows $\sim 180^\circ$ out of phase, hepatic-vein **expiratory diastolic flow reversal**, mitral E deceleration time usually < 160 ms.
- ▶ **Tissue Doppler / strain:** *Annulus reversus* — medial (septal) mitral-annular **$e' > \text{lateral } e'$** ; preserved/increased medial e' (> 8 cm/s) favours constriction over restriction; *strain reversus* (preserved longitudinal, reduced circumferential strain).
- ▶ **CT / CMR:** CT is most accurate for **pericardial thickness** (normal < 2 mm) and calcification; thickening **> 4 mm** supports the diagnosis, but pericardium is of **normal thickness in $\sim 20\text{--}28\%$ of CP** — so normal thickness does *not* exclude it. CMR with T2-STIR/late gadolinium enhancement detects active pericardial inflammation (predicts response to anti-inflammatory therapy / transient CP).
- ▶ **Cardiac catheterisation (confirmatory in equivocal cases):** Elevated and equalised diastolic pressures; “square-root” / **dip-and-plateau** sign; RVEDP $> \frac{1}{3}$ of RV systolic pressure; **discordance** of RV and LV systolic pressures with respiration (RV rises as LV falls) and a **systolic area index > 1.1** ; low pulmonary artery pressure. **BNP is normal/low in CP but elevated in restriction**.

Constriction vs Restriction vs Tamponade

Feature	Constrictive pericarditis	Restrictive cardiomyopathy	Cardiac tamponade
Pulsus paradoxus	~1/3 of cases (+)	Usually absent	Marked (+++)
JVP y descent	Prominent (M/W shape)	Variable	Absent/blunted (x prominent)
Kussmaul's sign	Present (+++)	±	Absent
Pericardial knock	Present	Absent	Absent
S3	Absent	Present	Absent
RV–LV diastolic pressures	Equal (≤ 5 mmHg apart)	LV higher by ≥ 3 –5 mmHg	Equalised
Filling pressure >25 mmHg / severe PHT	Uncommon	Common	—
Respiratory flow variation	Exaggerated, discordant	Normal/concordant	Exaggerated
Pericardium	Thickened $\pm$ calcified	Normal	Effusion present
Septal bounce	Present	Absent	—
Tissue Doppler e' / BNP	e' increased; BNP normal	e' reduced; BNP high	—

Variants

- **Effusive-constrictive pericarditis (ECP):** Tense effusion *plus* visceral pericardial constriction. Constrictive physiology is unmasked **after pericardiocentesis** — defined as failure of RA pressure to fall by $\geq 50\%$ to <10 mmHg once intrapericardial pressure is reduced to ~ 0 . Commonest causes: idiopathic, malignancy, radiation, post-pericardiotomy, TB. Often needs wide excision of *both* visceral and parietal pericardium.
- **Transient / reversible constriction:** Subacute inflammatory CP (esp. early post-cardiac surgery) that resolves over 3–6 months; $\sim 60\%$ avoid surgery with anti-inflammatory therapy (NSAID + colchicine + prednisone $\pm$ IL-1 antagonist), guided by CMR late-gadolinium enhancement and raised hsCRP.

Treatment

- **Surgical pericardiectomy (decortication) is the only definitive cure** and should be as complete as possible (median sternotomy $\pm$ cardiopulmonary bypass; “waffle” procedure for dense epicardial involvement). Perform **early**, before myocardial atrophy/cachexia set in; benefit accrues over weeks–months.
- **Pre-operative coronary angiography** in patients >50 years to exclude CAD.

- ▶ **Operative mortality** 5–15% (up to ~20% in some series), highest with radiation-induced disease, renal/hepatic dysfunction, reduced LVEF, low serum sodium and NYHA class IV.
- ▶ **Medical / bridging therapy:** Salt restriction and aggressive **diuresis** (loop diuretics ± thiazide ± aldosterone antagonist) for volume overload; rate control with digoxin if AF (avoid drugs that slow the compensatory tachycardia). Treat the **specific cause** — e.g. anti-tuberculous chemotherapy for tuberculous CP, with pericardiectomy if constriction persists.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **JVP waveform in CP:** a venous pressure tracing showing a **prominent, steep y descent** with normal x descent giving an **M/W contour**; label *a wave*, *x descent*, *v wave*, *y descent* (*deep*), *Kussmaul's sign* (*inspiratory rise*).
- ▶ **Ventricular pressure tracing:** RV/LV diastolic curves showing the “**square-root**” (**dip-and-plateau**) sign with **equalised, elevated end-diastolic pressures**; label *early diastolic dip*, *diastolic plateau*, *elevated & equal EDP*, *respiratory discordance of RV/LV systolic peaks*.

Clinical / Diagnostic significance

- ▶ CP is one of the few **reversible/curable** causes of refractory right heart failure — always distinguish it from restrictive cardiomyopathy and cirrhosis, because management diverges completely.
- ▶ In India and the developing world, **tuberculosis remains a leading cause**; calcific (“armoured heart”) constriction is classically tuberculous.
- ▶ A multimodality approach (echo-Doppler → CT/CMR → catheterisation) is needed; no single test is definitive, and normal pericardial thickness does not exclude CP.
- ▶ Anti-inflammatory therapy can reverse *transient* inflammatory constriction and spare some patients surgery — identify them with CMR (LGE) and hsCRP.

High-yield exam pointers

- ▶ **Pathognomonic triad:** raised JVP with prominent y descent + Kussmaul's sign + pericardial knock.
- ▶ “**Square-root**” sign (dip-and-plateau) and **equalisation of diastolic pressures** (≤ 5 mmHg) on catheterisation.
- ▶ **Ventricular interdependence / septal bounce** with respirophasic discordance is the unifying mechanism — yields **systolic area index** > 1.1 .
- ▶ Pulsus paradoxus in only $\sim 1/3$ of CP (contrast tamponade) — *low-yield to expect it*.
- ▶ **Annulus reversus** (medial $e' >$ lateral e') and **normal/elevated e' with normal BNP** favour CP over restriction.

- ▶ **Pericardial calcification** = most often TB; thickening >4 mm supportive but absent in 20–28%.
- ▶ **Pericardiectomy** = only cure; **coronary angiography** if >50 y; mortality ~5–15%, worst with prior radiation.
- ▶ **Effusive-constrictive PCarditis**: constriction revealed *after* draining the effusion.

SOURCE & COVERAGE

- ▶ Harrison's Principles of Internal Medicine, 22e — "Pericardial Disease" (chronic constrictive pericarditis; effusive-constrictive and tuberculous pericardial disease).
- ▶ Braunwald's Heart Disease, 13e — "Pericardial Diseases" (pathophysiology of ventricular interdependence, echo-Doppler/tissue-Doppler criteria, invasive haemodynamics, pericardiectomy outcomes, effusive-constrictive and transient constriction).
- ▶ CMDT 2026 — "Constrictive Pericarditis" (essentials of diagnosis, current diuretic/surgical management, risk of constriction by aetiology).

Coverage note: The exam printed the topic as "conservative pericarditis," which is not a recognised entity; per the spec note this is a typo for **constrictive pericarditis**, and the answer is grounded accordingly. The corpus covers the topic in depth across all three texts; no fabrication was required.

Cor Pulmonale

Asked in: Paper II Jul 2020 — RGUHS MD General Medicine

Definition / Introduction — *Cor pulmonale* ("pulmonary heart") is **right ventricular (RV) enlargement — hypertrophy and/or dilatation — progressing to right heart failure, caused by pulmonary hypertension that arises from primary disorders of the respiratory system, lung parenchyma, pulmonary vasculature, chest wall or ventilatory control**. By convention it **excludes** RV dysfunction secondary to left heart disease or congenital heart disease. As Braunwald frames it, "cor pulmonale, decompensated right heart failure, is the end-stage result of severe RV–pulmonary arterial (RV–PA) uncoupling." It is the common terminal pathway of advanced chronic lung disease, most often COPD, and carries a poor prognosis once overt RV failure supervenes.

Etiology and classification

- ▶ **Acute cor pulmonale** — sudden RV pressure overload and dilatation, classically from **massive/sub-massive pulmonary embolism**; also severe acute lung injury/ARDS. (Acute RV strain pattern, no time for hypertrophy.)
- ▶ **Chronic cor pulmonale** — slow RV hypertrophy then failure from sustained pulmonary hypertension. The underlying causes map largely onto **WSPH Group 3 (PH due to lung disease/hypoxia)** and **Group 4 (chronic thromboembolic PH)**.

Mechanism / category	Representative causes
Obstructive airway disease	COPD/emphysema (commonest cause), severe chronic asthma, bronchiectasis, cystic fibrosis
Restrictive / parenchymal (ILD)	Idiopathic pulmonary fibrosis, sarcoidosis, pneumoconioses, post-TB fibrosis
Chest-wall / neuromuscular	Kyphoscoliosis, thoracoplasty, obesity-hypoventilation, neuromuscular weakness
Hypoventilation / sleep-disordered breathing	Obstructive sleep apnoea, central hypoventilation syndromes
Chronic hypoxia without lung disease	Prolonged high-altitude residence
Pulmonary vascular disease	Pulmonary arterial hypertension (Group 1), CTEPH/recurrent PE (Group 4), schistosomiasis, sickle-cell disease

- ▶ In COPD, cor pulmonale “typically occurs in individuals who have marked decreases in FEV₁ (<25% of predicted) and chronic hypoxaemia (PaO₂ <55 mmHg)” (Harrison). Severe PH in lung disease is uncommon: ~90% of COPD patients have mPAP >20 mmHg but only ~5% exceed 35 mmHg.

Pathophysiology

- ▶ **Alveolar hypoxia** is the central driver: it triggers **hypoxic pulmonary vasoconstriction** (a reflex diverting blood from poorly-ventilated alveoli), which when chronic and global raises **pulmonary vascular resistance (PVR)**.
- ▶ Sustained hypoxaemia, acidosis and hypercapnia, plus **destruction/obliteration of the pulmonary capillary bed** (emphysema, fibrosis, embolic webs) and vascular remodelling (intimal fibrosis, medial hypertrophy), further increase PVR and pulmonary artery pressure.
- ▶ **Secondary erythrocytosis** (chronic hypoxia) raises blood viscosity, adding to RV load.
- ▶ Pulmonary hypertension is now defined hemodynamically as a **mean PA pressure (mPAP) >20 mmHg** at rest (lowered from the older ≥ 25 mmHg at the 2018 Sixth World Symposium); pre-capillary PH additionally requires **PVR >2 Wood units with PA wedge pressure ≤ 15 mmHg**.
- ▶ Rising **RV afterload** → compensatory **RV hypertrophy** → progressive **RV dilatation** → loss of RV–PA coupling → falling RV output, septal flattening (D-shaped LV), functional **tricuspid regurgitation** and systemic venous congestion = clinical right heart failure.

Clinical features

- ▶ **Symptoms** — exertional dyspnoea and fatigue dominate early; as RV fails, **dependent (pedal) oedema, abdominal bloating/distension** (congestive hepatomegaly, ascites), exertional chest pain, and **pre-syncope/syncope** appear (advanced disease). Symptoms of the underlying lung disease (cough, sputum, wheeze) coexist.

Sign	Underlying basis
Loud / palpable P2, accentuated pulmonic component of S2	Elevated pulmonary artery pressure
Left parasternal heave / RV lift	RV hypertrophy & pressure overload
Right-sided S3 ($\pm$ S4) gallop	RV dysfunction / decreased compliance
Raised JVP with prominent <i>a</i> wave; large <i>v</i> wave if TR	Systemic venous congestion
Pansystolic tricuspid regurgitant murmur (louder on inspiration — <i>Carvallo's sign</i>)	RV/tricuspid annular dilatation
Tender, pulsatile hepatomegaly, ascites, pedal oedema	Right heart failure / congestion
Central cyanosis, clubbing (in ILD/bronchiectasis)	Hypoxaemia / underlying lung disease

- ▶ Harrison: *symmetric* pedal oedema “may suggest cor pulmonale,” whereas asymmetric oedema points to DVT; the syndrome presents “with abdominal bloating or distention and pedal edema.”

Investigations

- ▶ ECG — signs of RV hypertrophy with strain: **peaked (tall) R waves in V1, ST-segment depression in V2–V3 (strain), P pulmonale** (P wave >3 mm / tall peaked in II, III, aVF), **right axis deviation** and RBBB; the acute PE pattern is S1Q3T3 with sinus tachycardia.
- ▶ Chest X-ray — enlarged central/proximal pulmonary arteries with peripheral “pruning,” RV enlargement, and **obliteration of the retrosternal space** on the lateral film; features of the underlying lung disease (hyperinflation in COPD, fibrosis in ILD).
- ▶ Echocardiography (key initial screening test) — estimated PA systolic pressure >35 mmHg / **tricuspid regurgitant jet velocity >2.8 m/s** suggests PH; **RV hypertrophy and dilatation, RA enlargement, interventricular septal flattening in diastole** (pressure overload); agitated-saline “bubble” study to exclude intracardiac shunt.
- ▶ BNP / NT-proBNP — correlate with RV dysfunction and prognosis.
- ▶ PFT + ABG — characterise obstructive vs restrictive disease, document hypoxaemia/hypercapnia; an **isolated low DLCO** is typical of pulmonary vascular involvement.
- ▶ V/Q scan or CT pulmonary angiography — screen for CTEPH; nocturnal oximetry/polysomnography for OSA.
- ▶ Right heart catheterisation — *gold standard* to confirm and classify PH (mPAP >20 mmHg, pre-capillary pattern PVR >2 WU, PAWP ≤ 15 mmHg).

Management

- ▶ Treat the underlying disorder — this is the cornerstone:

- COPD: smoking cessation, inhaled bronchodilators (LABA/LAMA) ± ICS triple therapy, pulmonary rehabilitation; treat exacerbations.
- ILD: disease-specific therapy; OSA/hypoventilation: CPAP/NIV; CTEPH: lifelong anticoagulation + **pulmonary endarterectomy** (curative in suitable cases), or **riociguat**/balloon pulmonary angioplasty if inoperable.
- ▶ **Long-term oxygen therapy (LTOT)** — the single most important measure in chronic hypoxaemic cor pulmonale; reverses hypoxic pulmonary vasoconstriction and **reduces mortality, the benefit being proportional to hours/day used**. Prescribe for **resting PaO₂ ≤55 mmHg or SaO₂ ≤88%, OR PaO₂ 56–59 mmHg / SaO₂ 89% with evidence of cor pulmonale** (dependent oedema, **P pulmonale** on ECG, or **haematocrit >56%**). In acute illness, target SaO₂ 88–92% to avoid CO₂ retention.
- ▶ **Diuretics (± mineralocorticoid-receptor antagonist)** and a **low-salt diet** for congestion/oedema — used cautiously to avoid excessive preload reduction and prerenal azotaemia.
- ▶ **Therapeutic phlebotomy** for symptomatic severe secondary erythrocytosis (Hct >56%).
- ▶ **Caveat on PAH-specific vasodilators** — prostanoids, ERAs, PDE5 inhibitors are *not* routinely beneficial in Group 3 (lung-disease) cor pulmonale and may worsen V/Q matching; inhaled iloprost gave only modest benefit in ILD-PH and a COPD-PH trial was stopped early. They are reserved for Group 1 PAH/selected Group 4 disease at expert centres.
- ▶ **Lung or heart–lung transplantation** in refractory end-stage disease.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Pathophysiology flowchart (label each box):** *Chronic lung disease / alveolar hypoxia → Hypoxic pulmonary vasoconstriction + capillary-bed destruction + vascular remodelling + erythrocytosis → ↑ Pulmonary vascular resistance → Pulmonary hypertension (↑ RV afterload) → RV hypertrophy → RV dilatation → Right ventricular failure (cor pulmonale) → Raised JVP, tender hepatomegaly, ascites, pedal oedema, tricuspid regurgitation.*
- ▶ **ECG of RV hypertrophy / strain (label):** *Tall R wave in V1, deep S wave in V6, right axis deviation, P pulmonale (tall peaked P >2.5–3 mm in II), ST-T “strain” in V1–V3, RBBB pattern.*

Clinical / Diagnostic significance

- ▶ Cor pulmonale is the chief cardiovascular complication of advanced chronic lung disease and a **marker of poor prognosis**; its appearance signals the need to optimise oxygenation and reassess the underlying disorder.
- ▶ Distinguishing cor pulmonale (Group 3/4 PH) from PH due to **left heart disease (Group 2)** and from **pulmonary arterial hypertension (Group 1)** is essential, because management diverges

sharply — LTOT and treating the lung disease for cor pulmonale versus PAH-targeted vasodilators for Group 1.

- ▶ **Symmetric** pedal oedema with raised JVP in a known COPD/ILD patient should prompt evaluation for cor pulmonale rather than being dismissed; an absolutely normal echocardiogram makes significant PH unlikely.

High-yield exam pointers

- ▶ **Definition stresses the cause:** RV failure from a *pulmonary/respiratory* cause — left heart and congenital disease are *excluded*.
- ▶ **COPD is the commonest cause of chronic cor pulmonale; massive PE** is the classic cause of acute cor pulmonale.
- ▶ **Hypoxic pulmonary vasoconstriction** is the central mechanism; chronic hypoxia + capillary loss + remodelling → ↑PVR → PH → RV failure.
- ▶ **PH now = mPAP >20 mmHg** (revised 2018 WSPH); pre-capillary PH adds PVR >2 WU, PAWP ≤15 mmHg; **RHC is the gold standard**.
- ▶ **Cardinal signs:** loud P2, left parasternal heave, raised JVP, tricuspid regurgitant murmur, tender pulsatile hepatomegaly, pedal oedema.
- ▶ **ECG:** P pulmonale (P >3 mm in II/III/aVF), tall R in V1, right axis deviation, RV strain; **echo** shows RV dilatation/hypertrophy and septal flattening.
- ▶ **LTOT reduces mortality** in hypoxaemic cor pulmonale ($\text{PaO}_2 \leq 55 \text{ mmHg}$ / $\text{SaO}_2 \leq 88\%$, or $\leq 59/89\%$ with cor pulmonale signs); benefit is dose-dependent on hours/day.
- ▶ **Do not** give PAH-specific vasodilators routinely in lung-disease cor pulmonale; **treat the underlying disease + oxygen + diuretics**.

SOURCE & COVERAGE

Coverage note: The corpus has no chapter titled “Cor Pulmonale”; the entity is covered within the Pulmonary Hypertension, COPD and respiratory-approach chapters. Universally-accepted standard points not separately spelled out in these chapters (e.g., *Carvallo’s sign* for inspiratory accentuation of the TR murmur, the S1Q3T3 pattern of acute PE) are included as established textbook medicine.

Describe conduction system of the heart and add a note on complete heart block

Asked in: Paper I Jul 2021 — RGUHS MD General Medicine

Definition / Introduction — The cardiac conduction system is a network of specialised, predominantly non-contractile myocytes that generate and propagate the electrical impulse responsible for the orderly, sequential contraction of the atria and ventricles. It comprises the **sinoatrial (SA) node** (the natural pacemaker), the **atrial preferential/internodal pathways**, the **atrioventricular (AV) node**, the **bundle of His**, the **right and left bundle branches**, and the terminal **Purkinje network**. *Complete (third-degree) heart block* is the most severe AV conduction disturbance, in which no atrial impulse reaches the ventricles, producing complete AV dissociation with a ventricular rate slower than the atrial rate and a constant risk of syncope (Stokes-Adams attacks) and asystolic death.

Anatomy and physiology of the SA node and atrial conduction

- ▶ **SA node** — a cigar-shaped cluster of small fusiform pacemaker cells in the *sulcus terminalis* (*crista terminalis*) on the epicardial surface at the **right atrial–superior vena cava junction**, enveloping the SA nodal artery within a protective extracellular matrix that insulates it from the hyperpolarising atrium.
- ▶ **Blood supply** — SA nodal artery arises from the **right coronary artery (RCA)** in 55–60% and the **left circumflex (LCx)** in 40–45%.
- ▶ **Pacemaker physiology** — nodal cells have no true resting potential; they exhibit spontaneous **phase 4 (diastolic) depolarisation** driven by the *funny current* (I_f) plus T- and L-type calcium currents. Phase 0 upstroke is slow and **calcium-mediated** (fast Na^+ channels absent). Intrinsic discharge rate **60–100 beats/min**, dominant because phase 4 is steepest here.
- ▶ **Autonomic control** — at rest the node is under vagal (parasympathetic) predominance; after complete autonomic blockade the **intrinsic heart rate** $\approx 118.1 - (0.57 \times \text{age})$ beats/min (~ 100 –110/min in young adults).
- ▶ **Atrial spread** — the impulse spreads to the AV node by **preferential intra-atrial pathways** of higher conduction velocity than ordinary atrial muscle. The **Bachmann bundle** carries activation from the right to the left atrium. The classic three *internodal tracts* — **anterior (Bachmann)**,

middle (Wenckebach) and posterior (Thorel) — are traditional eponyms; their existence as discrete insulated tracts remains debated, with preferential conduction now attributed to fibre orientation in atrial myocardium.

Structure and physiology of the AV node and His–Purkinje system

- ▶ **AV node** — a small structure ($\sim 1 \times 3 \times 5$ mm) beneath the right atrial endocardium at the apex of the **triangle of Koch**, bounded by the **coronary sinus ostium** (posteriorly), the **septal tricuspid annulus** (anteriorly) and the **tendon of Todaro** (superiorly).
- ▶ **Zones** — transitional (atrionodal) cells, the compact node, and the penetrating His bundle. Two functional inputs exist in many people: a **slow pathway** (inferior nodal extension) and a **fast pathway** (the substrate for AV nodal re-entry tachycardia).
- ▶ **Slow conduction / “gatekeeper” role** — compact-node cells sit at ~ -60 mV, have slow phase 0 (<10 V/s) mediated by **L-type Ca^{2+} current ($I_{\text{Ca-L}}$)**, sparse gap junctions (predominantly **connexin-40**) and **decremental conduction**. This creates the physiological AV delay (compact node velocity <10 cm/s vs ~ 35 cm/s in atrial muscle), allowing atrial systole to complete ventricular filling and protecting the ventricle from rapid atrial rates. Intrinsic AV-junctional escape rate **20–60/min**.
- ▶ **Blood supply** — AV nodal artery from the **RCA in 80–90%** and **LCx in $\sim 10\%$** (matching coronary dominance); the bundle branches have dual supply from **LAD septal perforators** (LBB, proximal RBB) and the posterior descending artery.
- ▶ **His bundle (penetrating AV bundle)** — pierces the central fibrous body/annulus fibrosus and runs along the ventricular septum; insulated from working myocardium.
- ▶ **Bundle branches** — **right bundle branch (RBB)**, a discrete cord reaching the **moderator band**; **left bundle branch (LBB)**, a broad subendocardial sheet dividing into **anterior and posterior fascicles**.
- ▶ **Purkinje network** — ramifies over both ventricular endocardia; **fastest conduction in the heart** ($1\text{--}3$ m/s), with rapid phase 0, prolonged plateau and modest automaticity (escape $\sim 20\text{--}40/\text{min}$).
- ▶ **Autonomic note** — the AV node is richly innervated by sympathetic and parasympathetic fibres; the His bundle and distal system are not influenced by autonomic tone.

ECG correlation of the conduction sequence

ECG component	Electrical event	Normal value
P wave	SA node firing $\rightarrow$ atrial depolarisation (RA then LA)	<120 ms; upright in II, inverted in aVR
PR interval	Onset of atrial to onset of ventricular depolarisation (mostly AV-nodal delay)	120–200 ms

ECG component	Electrical event	Normal value
PR segment	AV nodal + His conduction delay	isoelectric
QRS complex	His–Purkinje → ventricular depolarisation	≤100–110 ms
ST-T-U	Ventricular repolarisation	—

- ▶ Invasive His-bundle electrogram intervals: AH interval (AV-nodal conduction) normally <130 ms; HV interval (His-Purkinje conduction) normally ≤55 ms. A prolonged HV (>100 ms) carries ~10% annual risk of complete AV block.

Complete (third-degree) heart block — definition and classification

- ▶ **Definition** — complete interruption of AV conduction; atria and ventricles are driven by independent pacemakers (AV dissociation) with the atrial rate exceeding the ventricular (escape) rate. Complete AV block always implies AV dissociation, but not all AV dissociation is complete block.
- ▶ Level of block determines escape characteristics:

Feature	Block in AV node / proximal His	Infra-Hisian (distal) block
Typical setting	Often congenital, inferior MI, drug/vagal, Lyme	Usually acquired, anterior MI, sclerodegenerative
Escape focus	Junctional, near His	Ventricular (Purkinje)
QRS	Narrow	Wide
Escape rate	40–60/min, more stable	<40/min, unreliable
His electrogram	Each ventricular beat preceded by His deflection; P not followed by His	P followed by His; escape not preceded by His
Response to atropine/exercise	Improves	No improvement
Prognosis	Better	Worse, risk of asystole

Aetiology, clinical features and diagnosis of complete heart block

- ▶ **Idiopathic fibrosis/sclerosis** (~50% of acquired block) — *Lev's disease* (proximal bundle-branch fibrosis/calcification, elderly, related to aortic/mitral annular calcification) and *Lenègre's disease* (distal sclerodegeneration in younger patients); accelerated familial forms link to SCN5A mutations (also cause LQT3).
- ▶ **Ischaemic** — AV block complicates 10–25% of acute MI; inferior MI → nodal block, narrow stable escape, usually reversible; anterior MI → distal/infra-nodal block, wide unstable escape, high mortality.

- ▶ **Iatrogenic/drugs** — beta blockers, verapamil/diltiazem, digoxin; valve surgery, TAVR, alcohol septal ablation, catheter ablation.
- ▶ **Infective/infiltrative/autoimmune** — Lyme carditis (*Borrelia burgdorferi*), endocarditis with perivalvular abscess, viral myocarditis, **Chagas' disease**, cardiac sarcoidosis, amyloidosis, SLE/RA/scleroderma.
- ▶ **Congenital** — maternal SLE/anti-Ro antibodies, complex congenital heart disease (TGA, ostium primum ASD, endocardial cushion defects).
- ▶ **Neuromuscular** — myotonic dystrophy, Kearns-Sayre syndrome, Lamin A/C cardiomyopathy.
- ▶ **Clinical features** — fatigue, exertional intolerance, dyspnoea, presyncope and **Stokes-Adams syncope/convulsions**; sudden death from asystole. Signs: **variable-intensity S₁**, **intermittent cannon “a” waves** in the JVP (atrium contracting against a closed AV valve), wide pulse pressure and variable systolic BP.
- ▶ **Investigations** — 12-lead ECG (AV dissociation, atrial rate > ventricular rate, P waves marching through independent QRS); ambulatory/Holter or mobile telemetry for intermittent block; echocardiography for structural disease; **electrophysiology study with His-bundle recording** to localise block; **cardiac MRI / FDG-PET** for sarcoid/amyloid (especially age ≤60); Lyme serology, electrolytes, TSH and drug review for reversible causes.

Management of complete heart block

- ▶ **Acute** — identify and reverse causes (stop AV-blocking drugs, correct electrolytes/ischaemia, treat hypoxia/sleep apnoea). For symptomatic/haemodynamically unstable block: **atropine 0.5 mg IV** (effective only for nodal block), then **isoproterenol, dopamine or epinephrine** infusion; **transcutaneous pacing** (cathode patch over apex anteriorly, anode posteriorly) as a bridge; **transvenous temporary pacing** for reliability when escape is slow or wide-complex.
- ▶ **Definitive** — **permanent pacemaker (PPM)** is the only reliable therapy. Acquired **third-degree (and Mobitz II) AV block** is a **Class I indication regardless of symptoms** when not reversible/physiological. A **dual-chamber (DDD) device** is preferred to preserve AV synchrony.
- ▶ **Physiologic / conduction-system pacing** — in patients with LVEF <50% likely to need ventricular pacing >40% of the time, use **His-bundle or left bundle branch area pacing**, or **cardiac resynchronisation therapy (CRT)**, to avoid pacing-induced heart failure.
- ▶ **In acute MI** — pace for persistent 2nd/3rd-degree block or transient high-grade block with new bundle branch block; transient inferior-MI nodal block usually needs no permanent device.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Diagram 1 — Conduction system of the heart (coronal heart outline)**. Labels: *SA node (at RA-SVC junction), Bachmann bundle, anterior/middle/posterior internodal tracts, AV node (triangle of Koch — coronary sinus ostium, tendon of Todaro, septal tricuspid annulus),*

bundle of His, right bundle branch → moderator band, left bundle branch with anterior and posterior fascicles, Purkinje fibres.

- ▶ **Diagram 2 — ECG strip of complete heart block.** Labels: *regular P waves (atrial rate), regular but slower QRS (ventricular escape), no fixed PR relationship = AV dissociation, P waves “marching through” QRS, plus a JVP tracing showing intermittent cannon “a” waves.*

Clinical / Diagnostic significance

- ▶ The **physiological AV-nodal delay** times atrial against ventricular contraction (optimising filling) and shields the ventricle during atrial tachyarrhythmias — its decremental property is exploited by AV-nodal blocking drugs for rate control.
- ▶ **Dual blood supply** explains clinical patterns: SA/AV nodes are RCA-dependent, so inferior MI causes (usually reversible) nodal block, whereas anterior (LAD) MI damaging the His-Purkinje system causes dangerous infranodal block.
- ▶ **QRS width + escape rate localise the block** and predict stability — a wide, slow escape mandates urgent pacing.
- ▶ Distinguishing **congenital** (narrow, faster escape, rate rises with exercise) from **acquired** (wide, slow escape, no exercise response) CHB guides prognosis and urgency of pacing.
- ▶ Always exclude **reversible causes** (drugs, ischaemia, hyperkalaemia, hypothyroidism, Lyme, high vagal tone) before committing to a permanent device.

High-yield exam pointers

- ▶ **SA node = pacemaker (60–100/min); AV junction 40–60/min; Purkinje 20–40/min** — hierarchy of subsidiary pacemakers.
- ▶ **Triangle of Koch** = coronary sinus ostium + tendon of Todaro + septal tricuspid annulus → AV node landmark.
- ▶ Normal PR 120–200 ms; AH <130 ms; HV ≤55 ms; QRS ≤110 ms.
- ▶ *Lev’s disease* = proximal/calcific (old); *Lenègre’s disease* = distal sclerodegenerative (young); SCN5A = progressive familial heart block (+LQT3).
- ▶ CHB = AV dissociation with atrial rate > ventricular rate; hallmark sign = cannon “a” waves and variable S₁.
- ▶ Narrow QRS escape = nodal, stable, atropine-responsive; wide QRS escape = infranodal, unstable, atropine-resistant.
- ▶ **Atropine works only for nodal block**; for infranodal/unstable block use isoproterenol + temporary pacing.

- ▶ Acquired third-degree / Mobitz II AV block = Class I indication for permanent pacing irrespective of symptoms.
- ▶ Inferior MI block = nodal, reversible; anterior MI block = infranodal, high mortality, needs pacing.

SOURCE & COVERAGE

- ▶ **Braunwald's Heart Disease, 13e** — “Bradyarrhythmias and Atrioventricular Block” (classification of AV block, levels and His-electrogram correlation in complete heart block, AV dissociation, cannon a waves) and “Mechanisms of Cardiac Arrhythmias” / “Electrocardiography” (SA node automaticity, Bachmann bundle, nodal conduction velocities).
- ▶ **CMDT 2026** — “Disorders of Cardiac Rhythm” (current management of AV block, atropine/isoproterenol/pacing, pacemaker nomenclature and indications).
- ▶ *Coverage note:* the named internodal tracts (anterior/Bachmann, middle/Wenckebach, posterior/Thorel) are classic teaching; modern texts (Braunwald) regard discrete insulated internodal tracts as controversial, favouring preferential atrial conduction — presented here with that caveat.

Describe the structure of the Mitral Valve apparatus. Discuss the etiology, clinical features and management of Mitral Stenosis

Asked in: Paper II Nov 2021 — RGUHS MD General Medicine

Definition / Introduction — The mitral (left atrioventricular) valve is not a simple flap but a functional “mitral apparatus” comprising six integrated components — the *annulus*, *two leaflets*, *two commissures*, *chordae tendineae*, *papillary muscles* and *the supporting left atrial/ventricular myocardium* — whose coordinated action permits unobstructed diastolic LA-to-LV filling and competent systolic closure. Mitral stenosis (MS) is obstruction to LV inflow at valve level producing a diastolic LA-to-LV pressure gradient — the hemodynamic hallmark. The normal orifice is 4–6 cm²; obstruction becomes significant at <2 cm² and “severe” at <1.5 cm², when an LA pressure of ~25 mmHg is needed to maintain output.

Structure of the mitral valve apparatus

Component	Key anatomical features	Relevance in MS
Annulus	Saddle-/D-shaped fibrous ring at the LA–LV junction; anterior part is in fibrous continuity with the aortic valve, posterior part is muscular; contracts in systole to reduce orifice	Mitral annular calcification with extension onto leaflets is a recognised cause of obstruction
Leaflets (2)	Anterior (aortic/septal) — larger, semicircular, guards ~two-thirds of the orifice area; Posterior (mural) — smaller, quadrangular, with scallops	Rheumatic diffuse leaflet thickening + calcification produces the funnel-shaped , “fish-mouth” valve
Commissures (2)	Anterolateral and posteromedial junctions where the two leaflets meet	Commissural fusion is the cardinal rheumatic lesion; splitting it is the basis of <i>commissurotomy</i>
Chordae tendineae	Fibrous cords from papillary muscle tips to leaflets (marginal/primary, intermediate, basal)	Fusion and shortening of chordae create <i>subvalvular</i> stenosis; surgery must “loosen subvalvular fusion”
Papillary muscles (2)	Anterolateral and posteromedial; arise from LV wall, anchor the chordae and prevent leaflet prolapse	Scarring of the subvalvular apparatus reduces suitability for balloon commissurotomy
LA & LV myocardium	The atrial and ventricular walls form the muscular base of the apparatus	LA dilatation/AF promote appendage thrombus; LV EF is preserved in pure MS

- ▶ The valve functions as a *unit*: leaflet closure depends on annular size, chordal restraint and papillary-muscle/LV-wall integrity acting together.
- ▶ In rheumatic disease the inflammatory injury simultaneously affects **leaflets, commissures and the subvalvular apparatus** — the wider the involvement, the less amenable the valve is to balloon therapy.

Etiology and pathology of Mitral Stenosis

Major causes (Table 274-1)
Rheumatic fever — the leading cause worldwide
Congenital — parachute valve, cor triatriatum
Severe mitral annular calcification with leaflet involvement
SLE, rheumatoid arthritis
Left atrial myxoma

Major causes (Table 274-1)**Infective endocarditis with large vegetations**

- ▶ **Rheumatic fever** is by far the commonest cause; **pure or predominant MS** occurs in ~40% of patients with rheumatic heart disease and a history of rheumatic fever, while lesser MS may accompany MR and aortic disease.
- ▶ Incidence has **fallen in temperate, middle-/high-income countries** but MS **remains a major problem in low-income regions** — sub-Saharan Africa, **India**, Southeast Asia and Oceania.
- ▶ **Pathology**: chronic inflammation → diffuse leaflet thickening with fibrosis and calcific deposits → **commissural fusion, fusion and shortening of chordae tendineae**, rigid cusps and narrowing at the apex of the funnel-shaped (“fish-mouth”) valve. Later changes are aggravated by altered-flow trauma. Calcification immobilises leaflets and narrows the orifice further; thrombus/embolism may arise from the calcific valve or, more often in AF, from the dilated **LA appendage**.

Pathophysiology

- ▶ A reduced orifice obliges flow only across an **abnormally raised LA–LV gradient**; elevated pulmonary venous and PA wedge pressures reduce pulmonary compliance → **exertional dyspnea**.
- ▶ **Tachycardia** (especially rapid AF) shortens diastole disproportionately, raising the transvalvular gradient and LA pressure for any given output — explaining decompensation with fever, exercise, anemia, pregnancy and thyrotoxicosis.
- ▶ **LV diastolic pressure and EF remain normal** in isolated MS.
- ▶ **Pulmonary hypertension** results from (1) passive backward transmission of LA pressure, (2) reactive pulmonary arteriolar constriction (“second stenosis”), (3) interstitial edema of vessel walls, and (4) end-stage obliterative vascular changes → RV enlargement, secondary **TR/PR** and right heart failure.

Clinical features

Symptoms — Latent period of ~2 decades after rheumatic carditis; disability typically in the **fourth decade**.

- ▶ Progressive **exertional dyspnea**, then **orthopnea** and **paroxysmal nocturnal dyspnea**.
- ▶ Onset of **persistent AF** marks a turning point and accelerates symptom progression.
- ▶ **Hemoptysis** from rupture of pulmonary–bronchial venous connections (pulmonary venous hypertension); rarely fatal.
- ▶ **Recurrent pulmonary emboli** (often from RA mural thrombus) — important late morbidity/mortality.
- ▶ **Pulmonary infections** (bronchitis, bronchopneumonia, lobar pneumonia).

- ▶ **Systemic embolization** (incidence 10–20%) — commoner with AF, age >65, and reduced CO; may be the presenting feature even in mild MS.
- ▶ **Ortner's (cardiovocal) syndrome** — hoarseness from compression of the left recurrent laryngeal nerve by an enlarged LA/PA.

Signs

- ▶ **Inspection/palpation: malar flush (“mitral facies”)** with pinched, blue facies in severe MS; prominent jugular **a waves** (in sinus rhythm with severe pulmonary hypertension/TS); a **parasternal lift** (RV enlargement); rarely a diastolic thrill at the apex in left lateral position.
- ▶ **Auscultation (the diagnostic quartet):** **loud (accentuated) S1**; **loud P2** with closely split S2 when PAP is high; **opening snap (OS)** best heard in expiration at or just medial to the apex, following A2 by 0.05–0.12 s; and a **low-pitched, rumbling mid-diastolic murmur** at the apex (left lateral position, accentuated by exercise) with **presystolic accentuation** in sinus rhythm.
- ▶ The **A2–OS interval varies inversely with severity**, and murmur duration correlates with severity when CO is preserved.
- ▶ **Associated murmurs:** functional TR with **Carvallo's sign** (louder on inspiration); **Graham Steell murmur** of pulmonary regurgitation in severe pulmonary hypertension. With very low CO, findings may vanish — “**silent MS.**”

Investigations

- ▶ **ECG: P mitrale** (broad notched P, LA enlargement); tall peaked P in II and upright in V1 with pulmonary hypertension/TS; **right-axis deviation and RV hypertrophy** in severe pulmonary hypertension; AF common.
- ▶ **Echocardiography (investigation of choice):** TTE with color/spectral Doppler gives the **E and A wave** inflow velocities, peak/mean gradients, **mitral valve area**, leaflet calcification/restriction, subvalvular distortion, associated MR, PA systolic pressure (from TR jet) and suitability for balloon valvotomy. The “**echo score**” (leaflet thickening, calcification, mobility, subvalvular thickening) predicts PMBC success — a **lower score = better outcome**. TEE is performed to **exclude LA/appendage thrombus** before PMBC.
- ▶ **Chest X-ray:** straightening of the upper-left cardiac border, prominent main PAs, dilated upper-lobe veins, posterior esophageal displacement by the enlarged LA, and **Kerley B lines** when mean LA pressure exceeds ~20 mmHg.
- ▶ **Cardiac catheterization:** reserved for clinical–echo discrepancy; CT coronary angiography or invasive angiography screens for CAD before intervention.

Management

Medical

- ▶ **Secondary prophylaxis** with penicillin against group A streptococcus; infective-endocarditis prophylaxis only in high-risk patients.
- ▶ **Symptom control:** sodium restriction and low-dose diuretics.
- ▶ **Rate control of AF:** beta blockers, non-dihydropyridine calcium-channel blockers (verapamil/diltiazem), or digitalis glycosides.
- ▶ **Anticoagulation:** vitamin K antagonist (warfarin, INR 2–3) indefinitely for MS with AF, prior thromboembolism or LA thrombus. **DOACs are contraindicated** — a randomized trial showed higher mortality with rivaroxaban than warfarin in rheumatic MS with AF.
- ▶ **Cardioversion** for recent-onset AF after ≥3 weeks of therapeutic anticoagulation (or after heparin + TEE if urgent); rarely sustained in severe MS with large LA or AF >1 year.

Mechanical relief of obstruction (symptomatic NYHA II–IV, severe MS, orifice <~1 cm²/m² BSA or <1.5 cm²):

Procedure	Indication / requirements
Percutaneous mitral balloon commissurotomy (PMBC)	Procedure of choice for pliable, minimally calcified valves; needs little commissural calcium, unscarred subvalvular apparatus, no LA thrombus and MR ≤2+/4+. Inoue balloon via transseptal puncture; event-free survival 80–90% over 3–7 years in patients <45 y. Preferred in pregnancy (TEE-guided, minimal radiation)
Open surgical commissurotomy	When PMBC unsuitable/failed or restenosis; on bypass — split commissures, free subvalvular fusion of papillary muscles/chordae, debulk calcium, remove atrial thrombi; perioperative mortality ~2%
Mitral valve replacement (MVR)	Significant associated MR, severely distorted/calcified valve; chordal attachments preserved to protect LV function; perioperative mortality 2–5%

- ▶ **Success criterion** (any commissurotomy): **≥50% fall in mean gradient and doubling of valve area.**
- ▶ In **asymptomatic** patients, intervene only if recurrent systemic embolization or severe pulmonary hypertension (PA systolic **>50 mmHg at rest or >60 mmHg with exercise**).

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Mitral valve apparatus (LV opened, “surgeon’s view”):** label *mitral annulus*, *anterior (aortic) leaflet*, *posterior (mural) leaflet*, *anterolateral commissure*, *posteromedial commissure*, *chordae tendineae*, *anterolateral papillary muscle*, *posteromedial papillary muscle*, *LA*, *LV wall*.

- ▶ **Auscultation timing strip of MS:** label *loud S1, A2, opening snap (OS), mid-diastolic rumble, presystolic accentuation* — with the **A2–OS interval** marked (shorter interval = more severe).

Clinical / Diagnostic significance

- ▶ The diagnostic auscultatory triad — **loud S1 + opening snap + presystolic-accentuated diastolic rumble** — localises the lesion at the bedside; a **short A2–OS interval** flags severe disease.
- ▶ **Echo + echo score** is decisive: it both grades severity and selects patients for **PMBC vs surgery**; mandatory TEE rules out LA thrombus pre-procedure.
- ▶ **AF and the dilated LA appendage** drive thromboembolism — hence lifelong **warfarin** (not DOACs).
- ▶ Distinguish MS from **MR**, the **Austin Flint murmur of AR** (softens with amyl nitrite, no presystolic accentuation), **tricuspid stenosis**, **ASD** and **LA myxoma** (positional murmur, systemic features, IL-6 elevation).

High-yield exam pointers

- ▶ Normal MV area **4–6 cm²**; severe MS **<1.5 cm²**; very severe **<1 cm²**; LA pressure ~25 mmHg sustains output in severe MS.
- ▶ **Rheumatic fever** is the leading cause; pure MS in ~40% of RHD.
- ▶ Lesion quartet: **commissural fusion, leaflet thickening/calcification, chordal fusion-shortening, fish-mouth orifice**.
- ▶ **Ortner's syndrome** = hoarseness from left recurrent laryngeal nerve compression; **Carvallo's sign** = inspiratory accentuation of TR.
- ▶ **P mitrale** on ECG; **Kerley B lines** when mean LA pressure >20 mmHg.
- ▶ **A2–OS interval inversely proportional** to MS severity.
- ▶ **PMBC** = treatment of choice for pliable valves; needs no LA thrombus and MR ≤2+; success = 50% gradient fall + doubling of area.
- ▶ **Avoid DOACs** (rivaroxaban increased mortality vs warfarin); PMBC preferred in pregnancy.

SOURCE & COVERAGE

Harrison 22e — Ch 274 “Mitral Stenosis” (etiology, pathology, pathophysiology, clinical features, investigations, management; Table 274-1; Figs. 274-1 to 274-4). **Coverage note:** Ch 244 “Basic Biology of the Cardiovascular System” covers cardiovascular embryology/biology and Doppler, **not** the detailed mitral valve apparatus anatomy. The six-component structural description (annulus, anterior/posterior leaflets, anterolateral/posteromedial commissures, chordae tendineae, anterolateral/posteromedial papillary muscles, supporting myocardium) is **universally**

accepted standard anatomy; its individual elements — leaflets, commissures, chordae tendineae, papillary muscles, annular calcification and the subvalvular apparatus — are explicitly named in Ch 274 within the rheumatic-pathology and surgical sections, but the integrated anatomical map is supplied from standard textbook anatomy rather than the provided chapters.

Diastolic Heart Failure (Heart Failure with Preserved Ejection Fraction)

Asked in: Paper I May 2019 — RGUHS MD General Medicine

Definition / Introduction — *Diastolic heart failure*, in current nomenclature **heart failure with preserved ejection fraction (HFpEF)**, is the clinical syndrome of heart failure (breathlessness, fatigue, fluid retention) occurring with a left-ventricular ejection fraction (LVEF) **>40%** (HFpEF strictly defined as LVEF $\geq 50\%$; LVEF 41–49% is now termed **HF with mildly reduced EF, HFmrEF**). The cardinal haemodynamic abnormality is **elevated LV end-diastolic and left-atrial pressure** at rest or on exertion, owing to impaired myocardial relaxation and reduced LV chamber compliance (“a stiff ventricle”) despite a normal-sized, non-dilated cavity. It accounts for **about half of all symptomatic HF**, is increasing in prevalence with population ageing, and carries morbidity and hospitalisation rates approaching those of HFrEF.

Definitions, classification and nomenclature

- ▶ The pathophysiologic definition of HF — “*inability of the heart to pump blood at a rate commensurate with the body’s needs, or to do so only at the cost of high filling pressures*” — makes **no assumption about EF**; HFpEF is HF with this physiology but normal EF.
- ▶ **EF-based phenotypes (universal framework)**: HFrEF (LVEF $\leq 40\%$); HFmrEF (41–49%); HFpEF ($\geq 50\%$); and HF with improved EF (previously $\leq 40\%$, now $>40\%$).
- ▶ The older dichotomy of “systolic” vs “diastolic” HF is imprecise because **most HF patients have both systolic and diastolic abnormalities** — many HFpEF patients have subclinical longitudinal systolic dysfunction (reduced global longitudinal strain) despite normal EF.
- ▶ **Clinical sub-phenotypes (Braunwald)**: “garden-variety” HFpEF (hypertension/diabetes/obesity/CKD), CAD-HFpEF, right-heart-failure HFpEF, atrial-fibrillation-predominant, HCM-like, high-output, and valvular HFpEF — useful because management and prognosis differ.

Epidemiology and risk factors

- ▶ ~64 million people live with HF worldwide; of these ~50% have HFpEF and 10–25% HFmrEF.
- ▶ Prevalence rises with age and is **higher in women** at any age; men predominate at lower EFs.

- ▶ **Independent risk factors for HFpEF:** advancing age, **hypertension**, **obesity** (high body-mass index / visceral adiposity), **diabetes mellitus**, **atrial fibrillation**, chronic kidney disease and prior myocardial infarction. Higher BMI and AF associate more strongly with HFpEF, whereas prior MI, male sex and LV hypertrophy associate more with HFrEF.
- ▶ **Atrial fibrillation** is the commonest arrhythmia — present in **20–40%** at presentation and occurring in two-thirds at some point.
- ▶ **Prognosis:** 5-year mortality ~**53–74%** in hospitalised cohorts (comparable to or only slightly lower than HFrEF). A higher proportion of deaths are **non-cardiovascular** (32–49%), but cardiovascular death — chiefly **sudden death** (~25–30% of all deaths) and HF death — still predominates. Hospitalisation burden is high and recurrent.

Pathophysiology

- ▶ **Diastolic dysfunction** — slowed/incomplete myocardial relaxation (an energy-dependent, active process) plus increased passive chamber stiffness — raises LV diastolic pressure for any given volume; small exertional volume shifts cause steep rises in LA/pulmonary venous pressure → exertional dyspnoea and pulmonary congestion.
- ▶ **Comorbidity–inflammation–endothelial dysfunction paradigm (Paulus):** systemic comorbidities (hypertension, obesity, diabetes, CKD, COPD) drive **systemic micro-inflammation** → coronary microvascular endothelial dysfunction → increased reactive oxygen species, reduced nitric-oxide bioavailability, and a **deficient cyclic-GMP–protein-kinase-G (PKG) signalling** state.
- ▶ **Reduced PKG** causes cardiomyocyte hypertrophy and **hypophosphorylation of titin** (the giant sarcomeric spring), increasing resting myocyte and chamber stiffness. Inflammation recruits leukocytes secreting TGF- β , converting fibroblasts to myofibroblasts → **interstitial collagen deposition and fibrosis** (collagen cross-linking is higher than in HFrEF).
- ▶ **Coronary microvascular dysfunction** (reduced coronary flow reserve, CFR <2.0–2.5) is present in up to ~75% of HFpEF — contributing to subendocardial ischaemia and impaired systolic/diastolic reserve.
- ▶ **Beyond the ventricle (systemic syndrome):** left-atrial myopathy, chronotropic incompetence, abnormal ventricular–arterial coupling with **increased aortic stiffness**, pulmonary hypertension/RV dysfunction, renal sodium retention, sarcopenic obesity with impaired skeletal-muscle O₂ extraction, and a state of **relative natriuretic-peptide deficiency** (lower BNP for any given filling pressure, worsened by obesity).

Clinical features and diagnosis

- ▶ **Symptoms/signs** are similar across the EF spectrum: exertional dyspnoea, orthopnoea, paroxysmal nocturnal dyspnoea, fatigue, raised JVP, basal crepitations, S₃/S₄, peripheral oedema, hepatic congestion. Many HFpEF patients are **only symptomatic on exertion**.

- ▶ **Diagnosis requires:** (1) a clinical diagnosis of HF, (2) LVEF >40%, and (3) objective evidence of elevated filling pressures / structural heart disease — supported by raised natriuretic peptides, echocardiography or invasive haemodynamics.
- ▶ **Pitfall — natriuretic peptides may be normal:** 30–40% of HFpEF (especially obese) patients have BNP/NT-proBNP below diagnostic thresholds, so a “normal” NP does not exclude HFpEF; conversely AF, PE, pulmonary arterial hypertension and CKD raise NP non-specifically.
- ▶ **Echocardiography** — concentric LV remodelling (relative wall thickness >0.42), LA enlargement (LA volume index ≥ 34 mL/m²), elevated E/e', raised estimated PA systolic pressure, reduced GLS. The absence of diastolic dysfunction at rest does not exclude HFpEF — pursue exercise/diastolic stress testing.
- ▶ **Grading of diastolic dysfunction (ASE/EACVI; mitral inflow + tissue Doppler):**

Grade	Pattern	Mitral E/A	Average E/e'	LA pressure
Normal	Normal relaxation	≥ 0.8	<10	Normal
Grade I	Impaired relaxation	≤ 0.8	<10	Low/normal
Grade II	Pseudonormal	>0.8 to <2	10–14	Elevated
Grade III	Restrictive filling	>2	>14	Elevated

Supportive: peak tricuspid-regurgitation velocity >2.8 m/s, LA volume index >34 mL/m².

- ▶ **Diagnostic scores** (for the patient with unexplained dyspnoea, normal EF, equivocal workup):
 - **H₂FPEF score** (Mayo): Heavy — BMI >30 (2 pts); Hypertensive — ≥ 2 antihypertensives (1); Atrial Fibrillation (3); Pulmonary hypertension — PASP >35 mmHg (1); Elder — age >60 (1); Filling pressure — E/e' >9 (1). High score makes HFpEF likely; intermediate → proceed to stress test.
 - **HFA-PEFF score** (ESC): Pretest assessment → Echocardiographic + natriuretic-peptide score → Functional testing → Final aetiology. Domains scored 0/1/2; ≥ 5 diagnostic, ≤ 1 excludes, 2–4 → further testing.
- ▶ **Invasive haemodynamics** (reference standard when in doubt): PCWP ≥ 15 mmHg at rest, ≥ 19 mmHg with passive leg-raise, or ≥ 25 mmHg during exercise. Exercise right-heart catheterisation unmasks early HFpEF (exercise-induced LA hypertension).
- ▶ **Always exclude HFpEF “masqueraders”:** cardiac amyloidosis (low voltage with thick walls, bilateral carpal-tunnel, low/falling BP, apical-sparing strain), hypertrophic cardiomyopathy, constrictive pericarditis, restrictive cardiomyopathy, high-output states, severe valve disease, and non-cardiac causes (obesity, COPD, CKD, anaemia, cirrhosis).

Management

- ▶ **Goals:** relieve congestion, improve symptoms/functional capacity, reduce HF hospitalisation, and treat comorbidities (mortality is harder to modify because much of it is non-cardiovascular).
- ▶ **1. SGLT2 inhibitors** — the only class with proven outcome benefit (foundational, standard of care): **empagliflozin (EMPEROR-Preserved)** and **dapagliflozin (DELIVER)** significantly reduce cardiovascular death/HF hospitalisation across the full EF spectrum, including LVEF >60% and HFimpEF, with no decline in benefit as EF rises.
- ▶ **2. Decongestion with diuretics** — empiric cornerstone for fluid overload (loop ± thiazide; avoid over-diuresis/hypotension in the elderly).
- ▶ **3. Mineralocorticoid receptor antagonists** — **spironolactone (TOPCAT)** was neutral overall (HR 0.89) but showed benefit in the Americas region and in those with EF 45–60% (AHA/ACC/HFSA class IIb); the **non-steroidal MRA finerenone (FINEARTS-HF)** reduced CV death/worsening-HF events across HFmrEF–HFpEF. An MRA is reasonable, with potassium/renal monitoring.
- ▶ **4. Angiotensin-receptor–neprilysin inhibitor (sacubitril/valsartan, PARAGON-HF)** — just missed significance (rate ratio 0.87, $P=0.059$); benefit concentrated **below the median EF (~57%) and in women**. FDA-approved for EF “below normal”; **class IIb for HFmrEF**.
- ▶ **5. Treat comorbidities:** blood-pressure control (target generally <130 mmHg, but avoid SBP <130 in some HFpEF phenotypes); AF rate/rhythm control and anticoagulation; coronary disease; CKD; sleep apnoea; iron deficiency.
- ▶ **6. Obesity-HFpEF:** **GLP-1 receptor agonist semaglutide (STEP-HFpEF)** and the GIP/GLP-1 dual agonist **tirzepatide (SUMMIT)** improve symptoms, quality of life and exercise function.
- ▶ **7. Lifestyle:** caloric restriction/weight loss and **supervised exercise/aerobic training** improve exercise capacity and quality of life.
- ▶ **No proven role for ICD or CRT in HFpEF** (unlike HFrEF). Beta-blockers and calcium-channel blockers are **not** disease-modifying — used only for BP/rate; consider cautious withdrawal in chronotropic incompetence (PRESERVE-HR).

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **LV pressure–volume loop in HFpEF:** plot a normal loop and a HFpEF loop showing an **upward-and-leftward-shifted, steeper end-diastolic pressure–volume relationship (EDPVR)**. Labels: *LV pressure (y-axis), LV volume (x-axis), normal EDPVR, stiff/HFpEF EDPVR, elevated LV end-diastolic pressure, preserved ejection fraction (small stroke volume)*.
- ▶ **Mitral-inflow Doppler grades of diastolic dysfunction:** four waveforms side by side — *Normal ($E>A$), Grade I impaired relaxation ($E<A$, $E/A \leq 0.8$, prolonged deceleration time), Grade II pseudonormal (E/A 0.8–2), Grade III restrictive ($E/A >2$, short deceleration time)*. Label *E wave, A wave, deceleration time*.

Clinical / Diagnostic significance

- ▶ A normal EF on echo does **not** exclude HF — the syndrome can exist entirely on a diastolic/filling-pressure basis; this is the single most important teaching point.
- ▶ A **normal natriuretic peptide does not rule out HFpEF**, particularly in obesity — use the H₂FPEF/HFA-PEFF scores and exercise haemodynamics.
- ▶ **Exercise/diastolic stress testing** is key to unmasking early HFpEF when resting studies are equivocal.
- ▶ Always screen for treatable mimics — **ATTR cardiac amyloidosis** (now treatable with tafamidis) and constrictive pericarditis (curable by pericardiectomy) — before labelling “idiopathic” HFpEF.
- ▶ **SGLT2 inhibitors have transformed management** from purely empiric (diuretics) to an evidence-based foundational therapy benefiting the whole EF spectrum.

High-yield exam pointers

- ▶ HFpEF = HF with LVEF >40% (HFpEF ≥50%, HFmrEF 41–49%); ~half of all HF.
- ▶ Cardinal defect: **raised LV/LA filling pressure** from impaired relaxation + reduced compliance (stiff ventricle), normal cavity size.
- ▶ Diagnostic triad: **clinical HF + EF >40% + objective high filling pressures/structural disease** (NP, echo, or invasive PCWP ≥15 rest / ≥25 exercise).
- ▶ Remember the H₂FPEF and HFA-PEFF scores by name and components.
- ▶ Diastolic-dysfunction echo grades: **I impaired relaxation, II pseudonormal, III restrictive** (E/A and E/e' cut-offs); E/e' >14 and LAVI >34 mL/m² signify high LA pressure.
- ▶ Pathophysiology buzz-words: **comorbidity-driven systemic inflammation → microvascular endothelial dysfunction → cGMP–PKG deficiency → titin hypophosphorylation + interstitial fibrosis**.
- ▶ Outcome-positive therapy = **SGLT2 inhibitors (empagliflozin/dapagliflozin)**; everything else (ACEi/ARB/ARNI/spironolactone/β-blocker/CCB) is largely neutral — diuretics for congestion, finerenone/ARNI and MRA as class IIb adjuncts.
- ▶ **Obesity-HFpEF**: semaglutide and tirzepatide improve symptoms; **no role for ICD/CRT**.
- ▶ Negative landmark trials to quote: PEP-CHF, CHARM-Preserved, I-PRESERVE, TOPCAT, PARAGON-HF; positive: EMPEROR-Preserved, DELIVER, FINEARTS-HF.

SOURCE & COVERAGE

- ▶ **CMDT 2026** — “Heart Failure & Cardiomyopathy” (current management: SGLT2 inhibitors as the mainstay, GLP-1/tirzepatide for obesity-HFpEF, role of ATTR amyloid screening; STEP-HFpEF, SUMMIT).

Differential Diagnosis of Mid-Diastolic Murmurs

Asked in: Paper II Nov 2020 — RGUHS MD General Medicine

Definition / Introduction — A **mid-diastolic murmur (MDM)** is a low-frequency murmur that begins a short interval *after* the second heart sound (S2) — characteristically after the **opening snap (OS)** or a third heart sound (S3) — and occupies the rapid-filling phase of diastole. MDMs arise from **obstruction to, and/or augmented flow across, an atrioventricular (mitral or tricuspid) valve**, so the gradient driving them is the low-pressure atrioventricular diastolic gradient. They are best appreciated with the **bell** of the stethoscope, are easily missed, and — unlike most systolic murmurs — *almost always signify organic cardiac disease*. **Mitral stenosis (MS)** is the prototype and commonest cause.

Mechanism, genesis and how to recognise an MDM

- ▶ Two physiological substrates generate an MDM: (1) **obstruction** at the mitral/tricuspid orifice (a true diastolic pressure gradient), or (2) **increased antegrade transvalvular flow** across an anatomically normal valve (a “functional” or “flow” murmur).
- ▶ **Timing**: the murmur follows S2 by a measurable interval. In obstructive lesions it is introduced by an **OS** (MS, tricuspid stenosis); in high-flow lesions it is introduced by an **S3** (rapid-filling sound).
- ▶ The **duration** of the rumble reflects how long the atrial pressure exceeds ventricular diastolic pressure, and so correlates with severity (when output is preserved).
- ▶ **Presystolic accentuation** — a late-diastolic crescendo just before S1 due to atrial contraction augmenting transvalvular flow — is characteristic of MS/TS *in sinus rhythm* and is **lost in atrial fibrillation (AF)**.
- ▶ **Bedside amplification**: **left lateral decubitus position**, **bell with light pressure**, and a brief bout of **exercise** (sit-ups) bring out a soft mitral rumble; **inspiration** augments right-sided (tricuspid) MDMs.

Structured differential diagnosis of mid-diastolic murmurs

Site	Obstructive (true stenosis)	Increased-flow (“functional”)	Other
Mitral	Rheumatic mitral stenosis (commonest); congenital MS, cor triatriatum; severe mitral annular calcification; large vegetation	Severe MR, VSD, PDA, high-output states (anaemia, thyrotoxicosis, pregnancy), complete heart block	Carey-Coombs murmur (acute rheumatic carditis); Austin Flint murmur (severe/eccentric AR); left atrial myxoma (tumour plop)
Tricuspid	Rheumatic tricuspid stenosis (almost never isolated; accompanies MS)	Severe TR, large ASD, anomalous pulmonary venous return	Right atrial myxoma

- ▶ *Aide-mémoire — causes at the mitral valve:* “MS, MR-flow, Carey-Coombs, Austin Flint, Myxoma, Complete heart block.”
- ▶ The **Graham Steell** murmur (pulmonary regurgitation of pulmonary hypertension) and chronic **aortic regurgitation** are *early-to-mid* diastolic, decrescendo and high-pitched; they are listed here only because they can be confused with an MDM heard along the left sternal border, but they are not true mid-diastolic rumbles.

Mitral stenosis — the prototype mid-diastolic murmur

- ▶ **Cause:** rheumatic fever in the vast majority; pure/predominant MS occurs in ~40% of rheumatic heart disease. Normal mitral orifice is 4–6 cm²; symptoms appear when area falls below ~2 cm²; **severe MS = valve area <1.5 cm²** (a left atrial pressure of ~25 mmHg is then needed to maintain output).
- ▶ **Murmur:** low-pitched, **rumbling**, mid-diastolic, loudest at the **apex** in the left lateral decubitus position, beginning after the OS; **presystolic accentuation** in sinus rhythm.
- ▶ **Accompanying signs (a complete auscultatory complex):** loud (and slightly delayed) S1; an OS after A2 — the **A2–OS interval (0.05–0.12 s) varies inversely with severity (a short A2–OS interval = tight MS)*; *loud/palpable P2** when pulmonary hypertension supervenes.
- ▶ **Duration** of the rumble (not loudness) tracks severity; the murmur may be **inaudible** (“**silent MS**”) when cardiac output is very low or the patient is large/obese.
- ▶ Supporting evidence: **mitral facies (malar flush)**, AF, prominent jugular *a* wave (if pulmonary hypertension/TS), parasternal lift (RV enlargement), left atrial enlargement on ECG (P-mitrale) and CXR (straightened left heart border, Kerley B lines), and Doppler echo (gradient, planimetered area, suitability for **percutaneous mitral balloon commissurotomy**).

Other mitral mid-diastolic murmurs

- ▶ **Increased-flow (“functional MS”) murmur:** severe MR, a large left-to-right shunt (VSD, PDA), high-output states or **complete heart block** drive excessive flow across a non-stenotic mitral valve, producing a soft rapid-filling S3 followed by a short MDM. *No OS, no presystolic accentuation*; an apical pansystolic murmur and signs of LV enlargement point to MR as the substrate.
- ▶ **Carey-Coombs murmur:** a soft, transient apical MDM of **acute rheumatic carditis**, attributed to flow through an **oedematous, inflamed mitral valve**. *No OS, soft S1, and the murmur dissipates as the acute attack resolves* — a clue to active rheumatic activity rather than established stenosis.
- ▶ **Austin Flint murmur:** a low-pitched **mid-to-late apical diastolic rumble of severe (or eccentric) chronic AR**, produced by turbulence at the mitral inflow from admixture of the regurgitant aortic jet and forward mitral flow (and partial premature closure of the anterior mitral leaflet). Distinguished from MS by **absence of an OS** and by its **response to vasodilators** (see below).
- ▶ **Left atrial myxoma:** a pedunculated tumour arising near the **fossa ovalis of the interatrial septum** prolapses across the mitral valve in diastole, obstructing inflow and mimicking MS. Auscultation may reveal an early/mid-diastolic **“tumour plop”**; characteristically there is **positional variation** (murmur/symptoms change with body position), *no OS and no presystolic accentuation*. Suspect with constitutional features — fever, weight loss, anaemia, raised ESR/CRP, high IL-6, systemic emboli; familial cases occur in the **Carney complex** (*PRKARIA* mutation). TTE/TEE is diagnostic.
- ▶ **Complete heart block:** intermittent mid-to-late diastolic murmurs occur when atrial contraction falls while the mitral valve is partially closed (atrioventricular dissociation).

Tricuspid mid-diastolic murmurs

- ▶ **Tricuspid stenosis (TS):** almost never isolated — it accompanies rheumatic MS. The MDM is at the **lower left sternal border / 4th left intercostal space**, is **softer, higher-pitched and shorter** than MS, and crucially **increases with inspiration** (*Carvallo’s sign*) and other manoeuvres that raise trans-tricuspid flow. JVP shows a **giant a wave and a slow/delayed y descent; a diastolic thrill may be palpable at the LLSB. A tricuspid OS may follow the mitral OS. Suspect TS in a patient with “MS” who has marked right heart signs without pulmonary hypertension**.
- ▶ **Increased tricuspid flow:** severe TR, a large ASD (left-to-right shunt) or anomalous pulmonary venous return produce a **tricuspid flow MDM**, again inspiration-augmented; fixed splitting of S2 and a pulmonary mid-systolic flow murmur point to an ASD.

Bedside differentiation (dynamic auscultation)

Feature	Mitral stenosis	Austin Flint (severe AR)	Carey-Coombs	LA myxoma	Tricuspid MDM
Opening snap	Present	Absent	Absent	Absent (tumour plop)	Tricuspid OS may be present
Presystolic accentuation	Yes (sinus rhythm)	No	No	No	Yes (sinus rhythm)
Inspiration	Unchanged/softer	Unchanged	Unchanged	Variable	Louder (Carvallo)
Amyl nitrite / vasodilator	Murmur louder (↑ output, ↑ flow)	Murmur softer & shorter	—	—	Louder
Positional change	Left lateral decubitus accentuates	—	—	Changes with body position	Right lateral decubitus accentuates

- ▶ The **vasodilator (amyl nitrite) test** is the classic discriminator between MS and Austin Flint: lowering afterload **shortens and softens the Austin Flint murmur** but **increases the MS rumble** (reflex rise in output and transmitral flow).

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Phonocardiogram of the cardiac cycle** showing, against S1 and S2: (a) the MS complex — loud S1, A2–P2, opening snap (OS), low-pitched mid-diastolic rumble with presystolic accentuation to S1; and (b) a separate trace of an S3 followed by a short flow MDM. Label: S1, A2, P2, OS, S3, mid-diastolic rumble, presystolic accentuation.
- ▶ **Precordial map of murmur location:** mark the apex (left lateral decubitus, bell) for the mitral rumble and the lower left sternal border (4th ICS, inspiration) for the tricuspid MDM. Label: apex – MS rumble; LLSB – tricuspid murmur; aortic area / LSB – AR (Austin Flint at apex).

Clinical / Diagnostic significance

- ▶ Recognising an MDM and its accompaniments (loud S1, OS, presystolic accentuation, AF, mitral facies) allows a **bedside diagnosis of MS** and stratifies severity (short A2–OS interval, long rumble = tight valve).
- ▶ **Transthoracic echocardiography with Doppler** is indicated for any diastolic murmur — it confirms the lesion, quantifies the gradient and orifice area, assesses pulmonary pressures, excludes left atrial thrombus/myxoma, and judges suitability for **balloon valvuloplasty vs surgery**.

- ▶ An MDM in a febrile young patient with arthritis suggests **active rheumatic carditis (Carey-Coombs)**; an MDM with constitutional/embolic features and positional change suggests **atrial myxoma**; an apical rumble with wide pulse pressure and a water-hammer pulse suggests **Austin Flint of severe AR**.
- ▶ Misattributing a flow MDM (severe MR, large shunt) to organic stenosis is a common error — the absence of an OS and the presence of an S3/dominant systolic lesion are the corrective clues.

High-yield exam pointers

- ▶ MDM = **obstruction or increased flow at an AV valve**; best heard with the **bell**, after the OS (obstruction) or S3 (flow).
- ▶ **Commonest cause = rheumatic MS**; severe MS = orifice $<1.5 \text{ cm}^2$ (normal 4–6 cm^2).
- ▶ **A2–OS interval is inversely proportional to severity of MS**; **presystolic accentuation is lost in AF**.
- ▶ **Carey-Coombs** = transient apical MDM of **acute rheumatic carditis**; no OS, resolves with the attack.
- ▶ **Austin Flint** = apical MDM of **severe AR**; differentiated from MS by **no OS** and **softening with amyl nitrite/vasodilator** (MS rumble gets louder).
- ▶ **Atrial myxoma** = **tumour plop**, positional variation, constitutional symptoms, *PRKARIA*/Carney complex; diagnosed on echo.
- ▶ **Tricuspid MDM (TS)** is heard at the **LLSB**, **louder on inspiration (Carvallo's sign)**, with a giant *a* wave and slow *y* descent; rarely isolated.
- ▶ “**Functional**” MDMs of increased flow: **severe MR, VSD, PDA, ASD, severe TR, complete heart block, high-output states** — no OS, preceded by an S3.
- ▶ **Every diastolic murmur warrants echocardiography**; diastolic murmurs are almost never innocent.

SOURCE & COVERAGE

- ▶ **Harrison's Principles of Internal Medicine, 22e** — “Approach to the Patient with a Heart Murmur” (mid-diastolic murmur differential, Carey-Coombs, Austin Flint, dynamic auscultation, amyl-nitrite discrimination); “Mitral Stenosis” (etiology, orifice areas, A2–OS interval, silent MS, differential from AR/TS/ASD/myxoma); “Atrial Myxoma and Other Cardiac Tumors” (tumour plop, Carney complex, *PRKARIA*).

Discuss the diagnosis and management of chronic heart failure with preserved ejection fraction

Asked in: Paper II May 2025 — RGUHS MD General Medicine

Definition / Introduction — Heart failure with preserved ejection fraction (HFpEF) is the clinical syndrome of heart failure (typical symptoms/signs of congestion — dyspnoea, fatigue, oedema) occurring in a patient whose left-ventricular ejection fraction (LVEF) is *preserved* ($\geq 50\%$), in the presence of objective evidence of cardiac structural/functional abnormality and raised cardiac filling pressures at rest or on exertion. It accounts for roughly **half of all heart failure** and is increasing in relative frequency with population ageing. Although the dominant lesion is impaired LV diastolic function, HFpEF is now recognised as a **systemic, multi-organ syndrome** driven by comorbidity-related inflammation, not merely a “diastolic” problem.

Nomenclature, classification and epidemiology

- ▶ The universal EF-based classification (Harrison 22e): HFrEF = EF $\leq 40\%$; HF with mildly reduced EF (HFmrEF) = EF 41–49%; HFpEF = EF $\geq 50\%$. Major trials variably used EF $>40\%$ or $>45\%$; current guidelines reserve “HFpEF” for LVEF $\geq 50\%$.
- ▶ HFpEF comprises $\sim 50\%$ of prevalent HF and HFmrEF a further $\sim 10\text{--}25\%$; prevalence rises with age and is **higher in women** at any given age (largely because women out-live men).
- ▶ **Predominant risk factors / comorbidities**: older age, **hypertension** (LV hypertrophy), **obesity / visceral adiposity**, **diabetes**, atrial fibrillation, chronic kidney disease, COPD and sleep apnoea. Obesity and AF are particularly characteristic.
- ▶ **Atrial fibrillation** coexists in 20–40% at presentation and occurs in two-thirds at some point; its onset frequently precipitates decompensation.
- ▶ **Prognosis**: mortality is high (5-year mortality $\sim 50\text{--}70\%$ in hospitalised cohorts), only modestly lower than HFrEF, with a *higher proportion of non-cardiovascular deaths*; hospitalisation burden equals or exceeds HFrEF.

Pathophysiology (relevant to diagnosis and therapy)

- ▶ **Cardinal abnormality**: elevation of LV end-diastolic pressure and left-atrial pressure (raised PCWP) at rest or, characteristically, **only on exertion**, producing exertional dyspnoea with preserved systolic ejection.
- ▶ Beyond impaired relaxation and reduced LV chamber compliance: **longitudinal systolic dysfunction** (reduced GLS, low tissue-Doppler s'), **left-atrial myopathy**, chronotropic incompetence, abnormal ventricular–arterial coupling and aortic stiffening.
- ▶ **Comorbidity** $\rightarrow$ **systemic inflammation** $\rightarrow$ **endothelial dysfunction paradigm**: reduced nitric-oxide bioavailability lowers cGMP–protein kinase G (PKG) signalling $\rightarrow$ **titin**

hypophosphorylation and cardiomyocyte stiffening, interstitial fibrosis (TGF- β -driven collagen deposition) and coronary microvascular dysfunction (reduced coronary flow reserve in up to ~75%).

- ▶ This multi-organ model (heart, lungs, kidney, skeletal muscle, adipose tissue) explains why isolated “diastolic dysfunction” on echo is neither necessary nor sufficient for diagnosis.

Diagnostic approach

Diagnosis requires (1) a **clinical diagnosis of HF AND (2) LVEF $\geq 50\%$** ($\geq 40\%$ if including HFmrEF), supported by objective evidence of elevated filling pressures or structural disease, and **exclusion of non-cardiac mimics** (obesity, COPD, CKD, cirrhosis, anaemia, pericardial constriction).

- ▶ **Supportive evidence:** raised natriuretic peptides; structural change (LA enlargement, LVH); echo Doppler (increased E/e', dilated IVC); or invasive haemodynamics.
- ▶ **Pitfall — natriuretic-peptide deficiency:** ~30–40% of HFpEF have BNP/NT-proBNP *below* usual diagnostic thresholds (NP levels are lower than in HFrEF, and are further reduced by obesity); a normal NP **does not exclude** HFpEF in a patient with high pre-test probability.
- ▶ **Diastolic dysfunction on echo alone is insufficient** — it is common in asymptomatic elderly, often indeterminate (E/e' 8–15), and may be normal at rest yet abnormal on exercise. Absence does not exclude HFpEF.
- ▶ When non-invasive tests are equivocal, proceed to **provocative testing** — diastolic stress echo or, the *reference standard*, **invasive exercise haemodynamics**.

Diagnostic scoring systems

Score	Source / components	Interpretation
H2FPEF (Mayo)	Heavy: BMI >30 (2); Hypertensive: ≥ 2 antihypertensives (1); atrial Fibrillation (3); Pulmonary HTN: echo PASP >35 mmHg (1); Elder: age >60 yr (1); Filling pressure: E/e' >9 (1). Range 0–9	Higher score = higher probability (AUC ~0.84). Low 0–1; intermediate 2–5 $\rightarrow$ exercise testing; high 6–9
HFA-PEFF (ESC)	Pre-test $\rightarrow$ Echo + NP $\rightarrow$ Functional testing $\rightarrow$ Final aetiology. Functional, morphological and NP domains (major = 2 pts, minor = 1 pt)	≥ 5 points = diagnostic ; <2 = excludes ; 2–4 = intermediate $\rightarrow$ functional/invasive testing

Key investigations

- ▶ **Natriuretic peptides** (BNP/NT-proBNP) — diagnostic and strongly prognostic; use NT-proBNP if on sacubitril/valsartan.

- ▶ **Comprehensive echocardiography** — concentric LV remodelling (relative wall thickness >0.42), LA volume index ≥ 34 mL/m², E/e', TR velocity / estimated PA systolic pressure, and **global longitudinal strain** (normal absolute GLS >18%, abnormal <16%); apical-sparing strain pattern suggests amyloidosis.
- ▶ **High-sensitivity troponin** — persistent low-level elevation flags an infiltrative/"myocardial" phenotype (amyloid, HCM) or microvascular ischaemia.
- ▶ **Cardiac MRI** — tissue characterisation: late gadolinium enhancement, T1 mapping/extracellular volume (fibrosis, amyloid), T2* (iron), pericardial assessment.
- ▶ **Invasive haemodynamics (gold standard when in doubt):** PCWP ≥ 15 mmHg at rest, ≥ 19 mmHg with passive leg raise, or ≥ 25 mmHg during exercise (or PCWP/cardiac-output slope ≥ 2.0) confirms HFpEF.
- ▶ **Screen for "masqueraders":** cardiac amyloidosis (immunofixation, free light chains, prealbumin, bone scintigraphy/biopsy), HCM, constrictive pericarditis, high-output states, Fabry, sarcoidosis, haemochromatosis, valvular disease.

Management

There is no single mortality-lowering drug; therapy targets **decongestion**, the **one outcome-proven drug class** (SGLT2 inhibitors), **aggressive comorbidity control** and **symptom/QOL improvement**.

Class	Key drugs / trials	Status & comment
SGLT2 inhibitors	Empagliflozin — EMPEROR-Preserved; Dapagliflozin — DELIVER	Cornerstone, outcome-proven — reduce CV death/HF hospitalisation across the full EF spectrum (incl. >60%); benefit independent of diabetes. ESC class I
Loop $\pm$ thiazide diuretics	Furosemide; add HCTZ/metolazone if refractory	Empiric mainstay for congestion ; avoid over-diuresis (under-filling $\rightarrow$ azotaemia, hypotension, syncope)
MRA	Spirolactone — TOPCAT (HR 0.89, neutral overall; benefit in the Americas and EF 45–60%); Finerenone — FINEARTS-HF (positive)	Consider in addition to loop diuretic; monitor K ⁺ /renal function. Spirolactone class IIb
ARNI	Sacubitril/valsartan — PARAGON-HF (HR 0.87, $p \approx 0.06$, <i>just missed</i>); benefit in EF below median (~57%) and in women	FDA expanded approval / class IIb, chiefly for HFmrEF and EF below normal

Class	Key drugs / trials	Status & comment
ACEi / ARB	Perindopril (PEP-CHF), Candesartan (CHARM-Preserved), Irbesartan (I-PRESERVE) — all neutral for true HFpEF	Use for comorbid hypertension/CKD/diabetes, not for HFpEF outcomes per se
GLP-1 receptor agonists	Semaglutide — STEP-HFpEF / STEP-HFpEF DM; Tirzepatide — SUMMIT	In obesity-related HFpEF: weight loss, improved KCCQ/exercise capacity, lower NT-proBNP/CRP
β -blockers / non-dihydropyridine CCB	—	Neutral for HFpEF outcomes; useful for AF rate control; withdraw if chronotropic incompetence limits exertion

Other management priorities

- ▶ **Blood pressure:** treat to guideline targets (SPRINT supports <130 mmHg systolic), though some HFpEF data suggest an optimal range of ~130–140 mmHg; central aortic control is relevant.
- ▶ **Atrial fibrillation:** rate control (in AF-HFpEF target resting rate ~70–80 bpm to preserve filling), **anticoagulation** (high thromboembolic risk), and early consideration of **rhythm control/ablation** in symptomatic patients.
- ▶ **Comorbidities:** treat obesity, diabetes, CKD, iron deficiency, COPD and **sleep apnoea**; maintain euvolaemia.
- ▶ **Specific aetiologies:** **tafamidis** for transthyretin (ATTR) cardiac amyloidosis; chemotherapy for AL amyloid; mavacamten / septal reduction for obstructive HCM; revascularisation for ischaemia.
- ▶ **Exercise training / cardiac rehabilitation** — improves peak VO_2 , 6-minute-walk distance and quality of life; sodium and fluid restriction in fluid overload.
- ▶ **Devices:** ICD and CRT are **NOT indicated** for EF >40%. Implantable PA-pressure monitoring (CardioMEMS — CHAMPION) reduces HF events in frequently hospitalised patients. **Interatrial shunt devices** failed in the pivotal trial (possible harm if EF >40%).
- ▶ **Ineffective / unsuccessful in HFpEF:** PDE-5 inhibitors (sildenafil), organic and inorganic **nitrates** (NEAT — isosorbide mononitrate worsened activity), **ivabradine** (EDIFY), vericiguat, and digoxin (may reduce hospitalisations only).

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Pathophysiology cascade of HFpEF:** label *Comorbidities (HTN, obesity, diabetes, CKD)* → *systemic inflammation* → *coronary microvascular endothelial dysfunction* → $\downarrow \text{NO-cGMP-PKG}$ → *titin hypophosphorylation (cardiomyocyte stiffness) + interstitial fibrosis* → $\uparrow \text{LV diastolic stiffness}$ → $\uparrow \text{LVEDP}/\uparrow \text{LA pressure}$ → $\uparrow \text{PCWP (rest/exertion)}$ → *exertional dyspnoea*.

- ▶ **Diagnostic algorithm box:** *Symptoms/signs of HF + LVEF $\geq 50\%$ $\rightarrow$ natriuretic peptides + echo (E/e' , LA volume index ≥ 34 mL/m², GLS, PASP) $\rightarrow$ calculate H2FPEF / HFA-PEFF $\rightarrow$ if intermediate, diastolic stress echo or invasive exercise haemodynamics (PCWP ≥ 15 rest / ≥ 25 exercise) $\rightarrow$ exclude masqueraders (amyloid, HCM, constriction).*

Clinical / Diagnostic significance

- ▶ A normal natriuretic peptide and a normal resting echo do not exclude HFpEF — exertional/invasive testing is the key to “early” or “exercise-induced” HFpEF.
- ▶ Recognising cardiac amyloidosis (bilateral carpal tunnel syndrome, low-voltage ECG with thick walls, persistent troponin elevation, apical-sparing strain) is critical — it changes therapy (avoid non-dihydropyridine CCBs; use tafamidis) and prognosis.
- ▶ SGLT2 inhibitors are the **first and only class proven to improve outcomes across the entire EF spectrum**, making them standard of care in HFpEF as in HFrEF.
- ▶ Most “HFpEF therapy” is in reality **comorbidity and congestion management**; weight loss in obese HFpEF (GLP-1 RA) is an emerging disease-modifying strategy.

High-yield exam pointers

- ▶ HFpEF = EF $\geq 50\%$; HFmrEF = 41–49%; HFrEF = $\leq 40\%$ — memorise the universal definition cut-offs.
- ▶ Diagnosis = HF syndrome + preserved EF + raised filling pressures/structural disease + exclusion of mimics.
- ▶ H2FPEF (Heavy, Hypertensive, atrial Fibrillation, Pulmonary HTN, Elder, Filling pressure) and HFA-PEFF (≥ 5 diagnostic, < 2 excludes) are the two scores.
- ▶ Invasive PCWP ≥ 15 (rest) / ≥ 19 (leg raise) / ≥ 25 mmHg (exercise) is the haemodynamic gold standard.
- ▶ ~30–40% of HFpEF have natriuretic-peptide deficiency, especially with obesity.
- ▶ SGLT2 inhibitors (empagliflozin/EMPEROR-Preserved, dapagliflozin/DELIVER) — only outcome-proven class; diuretics for congestion.
- ▶ Adjuncts: MRA (TOPCAT/FINEARTS-HF), ARNI (PARAGON-HF) for lower-EF/women, GLP-1 RA (STEP-HFpEF) for obesity.
- ▶ ICD/CRT have no role in HFpEF; treat AF with rate control + anticoagulation; consider tafamidis for ATTR amyloid.

Discuss the etiology, clinical manifestations and management of Acute ST elevation Myocardial infarction (STEMI)

Asked in: Paper II Dec 2023 — RGUHS MD General Medicine

Definition / Introduction — STEMI is an acute coronary syndrome due to abrupt severe myocardial ischemia with necrosis, usually from complete thrombotic occlusion of an epicardial coronary artery. It is diagnosed by ischemic symptoms or equivalents, diagnostic ST-segment elevation in contiguous leads, and rise/fall of cardiac troponin above the 99th percentile; reperfusion must not wait for biomarkers when the ECG is diagnostic. It is an emergency because early mortality is dominated by ventricular fibrillation and later in-hospital mortality by pump failure.

Etiology and pathogenesis

- ▶ **Commonest cause - type 1 atherothrombotic MI:** rupture or erosion of an atherosclerotic plaque, often lipid-rich with a thin fibrous cap, in a coronary artery previously affected by atherosclerosis. Smoking, hypertension, LDL accumulation, diabetes, and inflammation promote endothelial dysfunction, vulnerable plaque, and thrombogenic blood.
- ▶ **Thrombus biology:** plaque disruption exposes collagen and tissue factor; platelet agonists (collagen, ADP, epinephrine, serotonin) trigger thromboxane A₂ release, GP IIb/IIIa activation, platelet aggregation, thrombin generation, and fibrin deposition, producing an occlusive platelet-fibrin thrombus.
- ▶ **Predisposing / precipitating factors:** multiple CAD risk factors, unstable angina, vigorous exercise, emotional stress, medical or surgical illness, morning catecholamine/cortisol and platelet-aggregability surge, infection, hypoxemia, pulmonary embolism, fever, tachycardia, hypotension, severe aortic stenosis, cocaine, and sympathomimetics.

- ▶ **Less common etiologies:** coronary embolism, congenital coronary abnormality, coronary spasm/Prinzmetal angina, spontaneous coronary artery dissection, vasculitis, aortitis, aortic root/coronary dissection, hypercoagulable states, collagen vascular disease, systemic inflammatory disease, and intracardiac thrombi/masses.
- ▶ **Infarct size depends on:** vascular territory, totality and duration of occlusion, collateral flow, myocardial oxygen demand, spontaneous lysis, speed of reperfusion, and microvascular obstruction/no-reflow from endothelial injury, leukocyte-platelet activation, thrombotic debris, edema, and cardiomyocyte swelling.

Clinical manifestations

- ▶ **Premonitory pain:** accelerating angina or rest angina may precede infarction; onset is often at rest and more common in the early morning.
- ▶ **Classical pain:** prolonged (>30 minutes) deep central chest or epigastric discomfort, heavy/squeezing/crushing, occasionally burning or stabbing; more severe than angina, poorly relieved by rest or nitroglycerin, and radiating to arms, shoulder, back, jaw, neck, or occiput.
- ▶ **Associated symptoms:** sweating, nausea, vomiting, anxiety, weakness, dyspnea, orthopnea, cough/wheeze, light-headedness, syncope, and sense of impending doom.
- ▶ **Atypical / painless STEMI:** commoner in older adults, women, diabetes mellitus, and transplant recipients; may present as acute heart failure, syncope, confusion, profound weakness, arrhythmia, embolism, shock, or sudden death.
- ▶ **Physical findings:** anxious restless patient, pallor, diaphoresis, cool extremities; anterior MI may cause tachycardia/hypertension, inferior MI bradycardia/hypotension. S4 is common; S3 suggests LV dysfunction. Other signs include soft S1, paradoxical split S2, apical systolic murmur of MR, pericardial rub later, low-volume carotid pulse, and low-grade fever after 12 hours.
- ▶ **RV infarction clue:** inferior STEMI with hypotension, raised JVP/Kussmaul sign, hepatomegaly, and clear lungs; confirm with V4R ST elevation and echocardiography.

Diagnosis and risk assessment

- ▶ **ECG first:** obtain and interpret a 12-lead ECG within 10 minutes of first medical contact; start continuous monitoring and IV access. Add V3R/V4R for inferior/RV infarction and V7-V9 for suspected posterior occlusion.
- ▶ **STEMI ECG criteria:** new ST elevation at the J point in at least two contiguous leads: ≥ 1 mm in all leads except V2-V3; in V2-V3, ≥ 2 mm in men ≥ 40 years, ≥ 2.5 mm in men < 40 years, and ≥ 1.5 mm in women. New LBBB with compatible ischemia is treated as a STEMI equivalent when occlusion criteria are present.
- ▶ **Biomarkers:** high-sensitivity troponin I/T are preferred; acute MI requires rise/fall with at least one value above the 99th percentile plus ischemic evidence. Troponin remains elevated for 5-10 days; CK-MB helps suspected early reinfarction because it falls sooner.

- ▶ **Supportive tests:** leukocytosis may reach 12,000-15,000/microliter; check glucose, creatinine, electrolytes, lipids, and bleeding risk. CXR helps detect congestion and alternative diagnoses such as aortic dissection.
- ▶ **Echocardiography:** documents regional wall motion abnormality, LVEF, RV infarction, papillary muscle dysfunction/rupture, VSD, pericardial effusion, LV aneurysm, and LV thrombus.
- ▶ **Risk markers:** Killip class, persistent ischemia, shock, LVEF <40%, pulmonary congestion, age >75, diabetes, prior MI, tachycardia, hypotension, ventricular arrhythmias, renal dysfunction, and nonpatent infarct-related artery.

Initial and reperfusion management

- ▶ **Prehospital care:** educate high-risk patients, activate EMS, obtain prehospital ECG, transport rapidly to a STEMI network, and ensure defibrillation capability because most early deaths are arrhythmic.
- ▶ **Emergency measures:** cardiac monitor, IV access, aspirin loading, analgesia, baseline bloods, rapid reperfusion decision. Give oxygen only for SaO₂ <90% or heart failure.
- ▶ **Anti-ischemic / analgesic therapy:** chew aspirin 160-325 mg immediately, then 75-162 mg daily. Give sublingual nitroglycerin 0.4 mg every 5 minutes for up to three doses if pain persists; avoid in SBP <90 mmHg, RV infarction, severe aortic stenosis, or recent PDE5 inhibitor use. IV nitroglycerin is used for ongoing ischemia, hypertension, or heart failure with BP monitoring. Morphine 2-4 mg IV repeated cautiously relieves refractory pain.
- ▶ **Primary PCI:** preferred when timely. Perform for symptoms ≤12 hours and for later presentation with ongoing ischemia, shock, acute severe heart failure, or life-threatening arrhythmia. Aim FMC-to-device ≤90 minutes at a PCI-capable centre; transfer if anticipated FMC-to-device ≤120 minutes. Stable multivessel disease may undergo staged nonculprit PCI during admission or up to 45 days; in cardiogenic shock, do culprit-only PCI initially.
- ▶ **Fibrinolysis:** if PCI cannot be achieved within 120 minutes and no contraindication exists, give within 12 hours of symptom onset, ideally door-to-needle ≤30 minutes. Options: alteplase 15 mg bolus then 50 mg/30 min then 35 mg/60 min; streptokinase 1.5 million units/1 h; reteplase 10 units bolus repeated at 30 min; tenecteplase weight-based IV bolus.
- ▶ **Contraindications to lysis:** prior hemorrhagic stroke, ischemic stroke/cerebrovascular event within 1 year, intracranial neoplasm, recent head trauma, active internal bleeding, suspected aortic dissection, and severe uncontrolled BP >180/110 mmHg. Relative contraindications include anticoagulation with high INR, recent major surgery/trauma, prolonged traumatic CPR, bleeding diathesis, pregnancy, active peptic ulcer, hemorrhagic retinopathy, and recent streptokinase exposure/allergy.
- ▶ **After lysis:** reperfusion is suggested by pain relief and ≥50% ST resolution at 60-90 minutes. Persistent pain/ST elevation or reocclusion requires rescue PCI. Even after successful lysis, transfer for angiography and PCI if indicated, usually 3-24 hours after fibrinolysis.

Pharmacotherapy and hospital care

Therapy	Must-write points
P2Y12 inhibitor	Add to aspirin for all STEMI, usually 12 months. PCI: ticagrelor or prasugrel preferred over clopidogrel; avoid prasugrel after stroke/TIA and generally in age >75. Fibrinolysis: clopidogrel is standard.
Anticoagulation	UFH for primary PCI and with fibrin-specific lysis: 60 U/kg bolus, max 4000 U, then 12 U/kg/h, max 1000 U/h, adjusted to aPTT target. Enoxaparin is an alternative after lysis; fondaparinux must not be the sole anticoagulant during PCI.
Beta-blocker	Start oral therapy within 24 hours if no heart failure, low output, shock risk, bradycardia, heart block, asthma, or hypotension. IV metoprolol 5 mg x3 only in selected stable patients with ongoing ischemia.
RAAS blockade	Start ACE inhibitor early when stable, especially anterior MI, HF, LVEF $\leq 40\%$, diabetes, hypertension, prior MI, or large wall motion abnormality; use ARB if intolerant. Add eplerenone/spironolactone if LVEF $\leq 40\%$ plus HF or diabetes without renal dysfunction/hyperkalemia.
Statin / supportive care	High-intensity statin before discharge. Correct K to about 4.5 mmol/L and Mg to about 2.0 mmol/L. Avoid routine calcium channel blockers, glucocorticoids, and NSAIDs other than aspirin.

- ▶ Admit unstable or high-risk patients to cardiac ICU/coronary care. Uncomplicated STEMI: bed rest 6-12 hours, sit out within 24 hours, ambulate progressively, step down after 24-48 hours, discharge commonly by day 3-5.

Complications and secondary prevention

- ▶ **LV failure / shock:** treat hypoxemia, pulmonary edema with loop diuretic and nitrates if BP permits, urgent echo, cautious inotrope/vasopressor, hemodynamic monitoring when useful, and urgent culprit revascularization. Norepinephrine is commonly preferred in shock; routine IABP has not improved outcomes.
- ▶ **RV infarction:** avoid nitrates and diuretics; give cautious saline to maintain preload and inotrope only if needed.
- ▶ **Arrhythmias:** immediate defibrillation for VF/unstable VT; IV amiodarone for sustained tolerated VT; AIVR after reperfusion is usually benign; atropine/pacing for symptomatic bradycardia.

- ▶ **Mechanical complications:** VSD, papillary muscle rupture with acute MR, and LV free-wall rupture typically occur within 1-14 days, especially 24 hours and 3-5 days. New murmur, pulmonary edema, shock, tamponade, or electromechanical dissociation requires urgent echo and surgical/interventional management.
- ▶ **Pericarditis / thrombus / aneurysm:** post-MI pericarditis is treated with high-dose aspirin; avoid early NSAIDs/steroids. Large anterior MI with LV thrombus needs therapeutic anticoagulation for about 3 months. True LV aneurysm causes HF, embolism, arrhythmias; pseudoaneurysm requires repair.
- ▶ **Secondary prevention:** lifelong aspirin, DAPT for 12 months if bleeding risk allows, high-intensity statin, beta-blocker at least 1 year, ACE inhibitor/ARB and aldosterone antagonist when indicated, smoking cessation, BP/diabetes/lipid control, cardiac rehabilitation, LVEF assessment in all, and delayed ICD consideration if severe LV dysfunction persists after reassessment.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **ACS pathogenesis flowchart:** vulnerable plaque -> rupture/erosion -> platelet activation -> thromboxane A₂ + GP IIb/IIIa aggregation -> thrombin/fibrin -> occlusive thrombus -> ST elevation -> necrosis.
- ▶ **STEMI reperfusion algorithm:** suspected STEMI -> ECG within 10 minutes -> primary PCI if FMC-device <=90/120 minutes -> fibrinolysis if PCI delayed and no contraindication -> rescue PCI if failed reperfusion at 60-90 minutes -> routine angiography 3-24 hours after successful lysis.

Clinical / Diagnostic significance

- ▶ Chest pain with diaphoresis for >30 minutes is STEMI until proved otherwise; epigastric “gas” pain in a high-risk patient is dangerous.
- ▶ Do not wait for troponin before reperfusion when the ECG is diagnostic.
- ▶ Inferior STEMI with hypotension and clear lungs suggests RV infarction; nitrates can cause collapse.
- ▶ Failed lysis or recurrent ST elevation mandates rescue PCI.
- ▶ New murmur with pulmonary edema or shock after MI suggests papillary muscle rupture or VSD.
- ▶ Killip class, LVEF, shock, persistent ischemia, age, diabetes, and ventricular arrhythmias guide prognosis.

High-yield exam pointers

- ▶ STEMI is usually **plaque rupture/erosion with occlusive platelet-fibrin thrombus**.
- ▶ **Time is muscle:** primary PCI preferred; fibrinolysis only when timely PCI is unavailable and safe.

- ▶ ECG: ST elevation in two contiguous leads; remember higher V2-V3 cutoffs.
- ▶ **Aspirin immediately:** chew 160-325 mg, then add P2Y₁₂ inhibitor plus anticoagulation.
- ▶ **No routine oxygen** when saturation is normal.
- ▶ **Avoid nitrates** in RV infarction, hypotension, severe aortic stenosis, and recent PDE5 inhibitor use.
- ▶ **Failed lysis:** persistent pain/ST elevation at 60-90 minutes or <50% ST resolution -> rescue PCI.
- ▶ **Killip IV = cardiogenic shock** and needs urgent revascularization.
- ▶ **Discharge drugs:** DAPT, statin, beta-blocker, ACE inhibitor/ARB, aldosterone antagonist when indicated, and rehabilitation.

Early Invasive Strategy in Patients with Non-ST-Segment Elevation Acute Coronary Syndrome

Asked in: Paper II May 2019 — RGUHS MD General Medicine

Definition / Introduction — Non-ST-segment elevation acute coronary syndrome (NSTEMI-ACS) encompasses unstable angina (UA, no necrosis) and non-ST-segment elevation myocardial infarction (NSTEMI, troponin-positive necrosis) and arises from a supply–demand mismatch driven most often by non-occlusive coronary thrombosis on a fissured/eroded plaque. An **early (routine) invasive strategy** means that, after starting anti-ischaemic and antithrombotic therapy, the patient is taken for **coronary angiography within 24 h** (and within 2 h if very high-risk), followed by revascularisation (PCI or CABG) guided by the coronary anatomy. This is contrasted with an **ischaemia-guided (selective) strategy** in which angiography is reserved for spontaneous or provoked ischaemia. The central exam concept is that strategy is *risk-matched*: invasive management benefits high-risk patients, whereas low-risk patients do equally well with an initially conservative approach.

Three Management Strategies — Definitions

Strategy	What it means	Whom it suits
Immediate invasive	Angiography <2 h, as soon as possible	Very-high-risk (haemodynamic/electrical instability)

Strategy	What it means	Whom it suits
Early invasive (routine)	Angiography within 24 h of presentation, then PCI/CABG/medical therapy per anatomy	High-risk stable patients (NSTEMI, GRACE >140, dynamic ECG)
Delayed invasive	Angiography 25–72 h	Intermediate-risk after stabilisation
Ischaemia-guided (selective/conservative)	Medical therapy first; angiography only for recurrent rest pain, ST/biomarker change, haemodynamic instability, or positive non-invasive stress/CT	Non-high-risk, low TIMI/GRACE, troponin-negative

Pathophysiological Rationale & Evidence Base

- ▶ The **culprit lesion** in NSTEMI-ACS is typically an eccentric stenosis with scalloped/overhanging edges and a narrow neck, often a lipid-rich plaque with a thin fibrous cap (rupture) or a proteoglycan-rich eroded plaque with a platelet-rich white thrombus. At angiography ~35% have three-vessel disease, 25% two-vessel, 20% single-vessel, <10% left-main and ~10% no critical epicardial stenosis.
- ▶ An invasive strategy allows **direct identification and treatment of the culprit (and significant non-culprit) lesions**, plaque stabilisation by stenting, and complete revascularisation — addressing the unstable substrate that medical therapy alone cannot.
- ▶ **Trial evidence:** multiple randomised trials and meta-analyses show that, compared with a conservative/selective approach, an early invasive strategy **reduces composite cardiovascular endpoints, recurrent MI and length of stay** — with the benefit **concentrated in high-risk patients** (multiple risk factors, ST-segment deviation, positive biomarkers). A meta-analysis of 13 RCTs (≈11,972 patients) of early vs delayed angiography showed a **significant long-term reduction in MI but no overall mortality difference**; in the pre-specified subgroup with **GRACE score >140**, early invasive management significantly reduced MACE, whereas low-GRACE patients showed no clear benefit.
- ▶ **Timing within the invasive arm:** two studies comparing immediate invasive intervention (median 1.4 and 4.7 h) with delayed intervention (median 61 and 62 h) reduced death or new MI, with the **greatest benefit in high-risk-score patients**. For the broad NSTEMI population the survival benefit of “very early” over “early/delayed” timing is modest; risk score, not the clock alone, drives urgency.
- ▶ **Long-term “catch-up”:** in long-term follow-up of the *ICTUS* trial (out to ~10 years), the early-invasive advantage over a selective strategy was no longer apparent, partly because of catch-up revascularisation in the selective arm — emphasising that selective management is a legitimate option in non-high-risk patients.

Risk Stratification — the Trigger for Strategy Selection

Strategy is selected by formal risk scoring plus clinical features. Early risk assessment identifies those who derive the greatest benefit from an early invasive approach.

- ▶ **TIMI risk score (0–7)**: age ≥ 65 y; ≥ 3 CAD risk factors; known coronary stenosis $\geq 50\%$; ST-segment deviation on presenting ECG; ≥ 2 anginal episodes in prior 24 h; aspirin use in prior 7 days; elevated cardiac biomarkers. Higher score $\rightarrow$ higher 14-day risk of death/MI/urgent revascularisation ($\approx 5\%$ at 0–1 rising to $\approx 41\%$ at 6–7).
- ▶ **GRACE risk score** (best discrimination; applies with or without ST elevation): age, Killip class, systolic BP, ST-segment deviation, cardiac arrest at presentation, serum creatinine, elevated CK-MB/troponin, and heart rate. A **GRACE score** >140 is a key trigger for early invasive management.
- ▶ **HEART pathway** (History, ECG, Age, Risk factors, Troponin): identifies a low-risk group (HEART 0–3 with negative serial troponins, NPV $\sim 99.6\%$) suitable for early discharge, versus HEART ≥ 4 / troponin-positive needing cardiology admission.

Selection, Timing and Staging of the Invasive Strategy

Risk tier	Defining features	Recommended timing
Very high risk (≥ 1)	Cardiogenic shock / unstable haemodynamics; acute HF from ongoing ischaemia; cardiac arrest after presentation; life-threatening arrhythmia; mechanical complication of MI; angina refractory to medical therapy; recurrent dynamic ischaemic ECG changes	Immediate invasive (<2 h)
High risk (≥ 1)	Confirmed NSTEMI; GRACE >140 ; transient ST-segment elevation; dynamic ST- or T-wave changes	Early invasive (<24 h)
Non-high risk	None of the above	Selective invasive — clinical/non-invasive assessment, then angiography only if ischaemia confirmed

- ▶ **Culprit-lesion PCI** is performed (CABG if anatomy unfavourable, e.g. complex multivessel/left-main or mechanical complications such as VSD or papillary-muscle rupture, where surgery is preferred).
- ▶ **Non-culprit / multivessel disease**: complete revascularisation (single-stage during index PCI, or staged within ~ 45 days) should be considered in the absence of cardiogenic shock, severe

comorbidity (e.g. AKI) or unfavourable anatomy; a **Heart Team** decides PCI vs CABG for complex anatomy.

- ▶ **CABG-favouring factors:** diabetes mellitus, LVEF <35%, contraindication to DAPT, diffuse in-stent restenosis, heavy calcification, inability to achieve complete revascularisation, or concomitant valve/aortic surgery.
- ▶ **Vascular access:** radial access is the default (Class I) to reduce bleeding.

Peri-procedural Pharmacotherapy (Optimise Before/During the Cath)

- ▶ **Antiplatelet:** aspirin loading 150–325 mg (then 75–100 mg/day) **plus** a P2Y₁₂ inhibitor. Ticagrelor (180 mg load, 90 mg bd) benefits patients managed conservatively *or* invasively; prasugrel (60 mg load, 10 mg/day) is given **once coronary anatomy is known (post-angiography)** when PCI is planned and is contraindicated after prior stroke/TIA; clopidogrel (300–600 mg load) when potent agents are unsuitable or anticoagulation is also needed. Contemporary guidance discourages **routine P2Y₁₂ pretreatment** before angiography in patients planned for early invasive management with unknown anatomy.
- ▶ **Anticoagulant:** UFH, enoxaparin, bivalirudin (used at/just before PCI) or fondaparinux (best for conservatively-managed, high bleeding risk — needs supplemental UFH at PCI to avoid catheter thrombosis).
- ▶ **GP IIb/IIIa inhibitors** (eptifibatide, tirofiban): reserved for bail-out / high thrombus burden, not routine.
- ▶ **Anti-ischaemic & secondary prevention:** nitrates, beta-blockers (target HR 50–60/min), high-intensity statin (atorvastatin 80 mg or rosuvastatin 40 mg) ± ezetimibe/PCSK9 to LDL-C <55 mg/dL, ACE-I/ARB; DAPT generally 12 months (modulated by ischaemic vs bleeding risk).

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Risk-stratified strategy/timing flow-chart (Fig. 285-4 style):** Box “NSTE-ACS” → three branches: **Very high risk** (shock/HF/arrest/arrhythmia/mechanical complication/refractory angina/dynamic ECG) → *Immediate invasive* <2 h; **High risk** (NSTEMI / GRACE >140 / transient ST-elevation / dynamic ST-T) → *Early invasive* <24 h; **Non-high risk** → *Selective invasive*. Downstream labels: “Culprit-lesion PCI (CABG if unfavourable anatomy)”, “Evaluation of non-culprit lesion”, “Staged vs single-stage PCI”, “Medical management”. Label the GRACE >140 cut-off.
- ▶ **Spectrum-of-ACS diagram:** clinical presentation → ECG (Normal / ST-depression / ST-elevation) → hs-cTn (non-elevated vs rise-and-fall) → final diagnosis UA / NSTEMI / STEMI. Labels: UA, NSTEMI, STEMI, hs-cTn, ST-segment depression.

Clinical / Diagnostic significance

- ▶ **Diagnosis** rests on history (rest pain >10 min, recent-onset, or crescendo), ECG (new ST-depression in $\sim 1/3$; deep symmetrical T-inversions ≥ 0.3 mV) and a **rise-and-fall of high-sensitivity troponin** (distinguishes NSTEMI from UA); the 0/1-h rapid rule-out algorithm accelerates triage. Distinguish **myocardial injury** (troponin >99th percentile without ischaemia — sepsis, CKD, HF, PE, myocarditis, Takotsubo) from true **type 1 MI**.
- ▶ **Management pearl:** match invasiveness to risk — invasive strategy for high-risk substrate, selective for low-risk. Always exclude life-threatening mimics (aortic dissection, PE, tamponade) before committing to the cath lab.
- ▶ Women, older adults, and patients with diabetes or CKD are **under-treated** despite higher risk and benefit from invasive care; meta-analysis supports early intervention in the elderly.

High-yield exam pointers

- ▶ Early/routine invasive = **angiography within 24 h** then revascularisation; **immediate** = <2 h for very-high-risk; **selective/ischaemia-guided** for non-high-risk.
- ▶ **GRACE score >140** is the pivotal numeric trigger for an early invasive strategy; benefit of invasive care is **proportional to baseline risk**.
- ▶ Invasive strategy reduces **recurrent MI, refractory ischaemia, MACE and length of stay**, but **not overall mortality** in unselected patients.
- ▶ **Very-high-risk = immediate (<2 h):** shock, refractory angina, acute HF from ischaemia, life-threatening arrhythmia, mechanical complication, recurrent dynamic ECG changes.
- ▶ **Radial access (Class I)** to cut bleeding; avoid routine GP IIb/IIIa and routine P2Y12 pretreatment before known anatomy.
- ▶ **Prasugrel only after angiography** when PCI planned; contraindicated with prior stroke/TIA. **Ticagrelor** works in both conservative and invasive pathways.
- ▶ Consider **complete revascularisation** (single-stage or staged ≤ 45 days) in multivessel disease without shock/AKI; **Heart Team** for complex/left-main $\rightarrow$ CABG, especially with diabetes or LVEF <35%.
- ▶ **ICTUS** long-term data show the early-invasive edge narrows over years due to **catch-up revascularisation** in the selective arm.

SOURCE & COVERAGE

- ▶ **Harrison's Principles of Internal Medicine, 22e** — “Non-ST-Segment Elevation Acute Coronary Syndrome (Non-ST-Segment Elevation Myocardial Infarction and Unstable Angina)” (risk scores, invasive vs conservative strategy, Fig. 285-4 selection/timing, antithrombotic regimens).

- ▶ **Braunwald's Heart Disease, 13e** — “Non-ST Elevation Acute Coronary Syndromes” (Invasive vs Conservative Management; timing meta-analyses and GRACE >140 subgroup; ICTUS 10-year catch-up; ACC/AHA vs ESC triage; revascularisation/Heart Team).
- ▶ **CMDT 2026** — “Coronary Artery Disease... Key Topics in Cardiology” (early invasive algorithm, GRACE/TIMI scoring, drug doses, indications for catheterisation, Table 10–8).
- ▶ *Coverage note:* the corpus supports the strategy, timing tiers, risk scores and pooled/meta-analytic evidence in full; among individual landmark timing/strategy trials, only *ICTUS* is named explicitly (the older FRISC-II, TACTICS-TIMI 18 and RITA-3 trials that historically established routine-invasive benefit are universally accepted standard cardiology but are not separately detailed in the available chapters).

Emerging therapies and strategies in treatment of Heart failure

Asked in: Paper II May 2022 — RGUHS MD General Medicine

Definition / Introduction — Over the past five decades, management of heart failure (HF) has evolved from a *renocentric* (diuretics) and *hemodynamic* model (digoxin, inotropes) to an era of **disease-modifying therapy** built on neurohormonal antagonism and, more recently, metabolic and device-based strategies. The contemporary pharmacologic backbone of HF with reduced ejection fraction (HFrEF) comprises **four foundational pillars** — RAAS blockade (including ARNI), evidence-based **beta blockers**, **mineralocorticoid receptor antagonists (MRAs)** and **SGLT-2 inhibitors** — onto which newer agents (vericiguat, omecamtiv mecarbil, ivabradine) and novel strategies (rapid in-hospital sequencing, transcatheter valve repair, remote haemodynamic monitoring) are layered. This answer covers the emerging drugs, devices and care-delivery strategies that now modify the natural history of HF.

Foundational “four pillars” of modern HFrEF therapy

- ▶ The sequential addition of each class produces a **progressive, incremental decline in mortality** (Fig. 265-3): ACEI/ARB → beta blocker → MRA → ARNI (in place of ACEI/ARB) → SGLT-2 inhibitor → balanced vasodilators (hydralazine–isosorbide dinitrate in selected populations, e.g. African Americans).
- ▶ These four classes now **form the pillars of pharmacotherapy**, facilitating stabilisation and even *reverse remodelling*, reducing symptoms, hospitalisations and both pump-failure and arrhythmic deaths.
- ▶ **Add-on agents** (ivabradine, vericiguat) further reduce HF hospitalisation but do **not** substantially lower mortality. Further “stacked” neurohormonal blockade (ACEI + ARB + MRA

together; aliskiren — *ATMOSPHERE*; endothelin antagonists; moxonidine) is ineffective or harmful — there is a **ceiling of benefit** of RAAS inhibition.

Drug class	Representative agent	Initiation → target dose	Key trial(s)
ARNI	Sacubitril–valsartan (LCZ696)	100 mg bid → 200 mg bid	PARADIGM-HF; PIONEER-HF
SGLT-2 inhibitor	Dapagliflozin / Empagliflozin	10 mg qd → 10 mg qd	DAPA-HF; EMPEROR-Reduced
sGC stimulator	Vericiguat	2.5 mg qd → 10 mg qd	VICTORIA
Myosin activator	Omecamtiv mecarbil	25 mg bid → up to 50 mg bid (plasma-guided)	GALACTIC-HF; COSMIC-HF
If-channel inhibitor	Ivabradine	— (added if HR >70, sinus rhythm)	SHIFT

ARNI and soluble guanylyl cyclase stimulation

- ▶ **Angiotensin receptor–neprilysin inhibitor (ARNI)**: sacubitril–valsartan combines an **AT1-receptor blocker** with **neprilysin inhibition**, which raises circulating **natriuretic peptides** (and other vasoactive peptides), promoting natriuresis, vasodilation and anti-remodelling.
- ▶ In **PARADIGM-HF** (8399 HFrEF patients), sacubitril–valsartan vs enalapril gave a **20% reduction in CV death/HF hospitalisation** and a **16% reduction in all-cause mortality**, with lower hyperkalaemia and renal dysfunction but more symptomatic hypotension.
- ▶ Guidelines now advocate **switching to ARNI** in symptomatic HFrEF tolerating ACEI/ARB; up-front use in *de novo* HF is increasingly considered. **Contraindicated** with prior angioedema; allow a **36-h washout** from an ACEI (excess bradykinin → angioedema, as seen with omapatrilat in *OVERTURE*). An ARB leaves the ACE-bradykinin pathway intact, hence lower angioedema risk.
- ▶ **Vericiguat** is a novel oral **soluble guanylyl cyclase (sGC) stimulator** that enhances cyclic-GMP/NO signalling (directly stimulates and sensitises sGC to endogenous NO). In **VICTORIA** (5050 patients, LVEF <45%, recent worsening HF), it produced a **modest 10% relative risk reduction** in CV death/HF hospitalisation, driven principally by reduced HF hospitalisation — a useful **adjunct** in high-risk, recently-decompensated HFrEF.

SGLT-2 inhibition and metabolic strategies

- ▶ **SGLT-2 inhibitors** (dapagliflozin, empagliflozin) are the most recent pillar; their cardiac benefit is **independent of glycaemic (HbA1c) lowering** and of diabetes status (SGLT-2 is itself a *novel biologic target* in HF).

- ▶ **DAPA-HF** (4744 HFrEF) — dapagliflozin 10 mg gave a **26% reduction** in worsening HF/CV death, consistent with and without diabetes. **EMPEROR-Reduced** (3730, EF $\leq 40\%$) — empagliflozin gave a **25% reduction** in CV death/HF hospitalisation.
- ▶ Benefit now extends across the EF spectrum: **EMPEROR-PRESERVED** and **DELIVER** show reduced CV death/HF hospitalisation in **HFpEF/HF with LVEF $>40\%$** — the first clearly effective disease-modifying drug class in HFpEF.
- ▶ **Other metabolic/inflammatory targets**: **GLP-1 receptor agonists** (e.g. liraglutide) do not worsen HF and **improve QOL in obese HFpEF irrespective of diabetes**; **IV iron** (ferric carboxymaltose — **FAIR-HF**, **CONFIRM-HF**, **AFFIRM-AHF**, **IRONMAN**) corrects iron deficiency and improves symptoms/functional capacity (oral iron ineffective); anti-inflammatory therapy (anti-TNF infliximab/etanercept) **failed**, while IL-1 β blockade (**canakinumab**, **CANTOS**) reduced HF hospitalisation post-MI in post-hoc analysis.

Novel inotropy and heart-rate modification

- ▶ **Omecamtiv mecarbil** — a selective cardiac myosin activator that prolongs the ejection period and increases fractional shortening **without raising myocardial oxygen demand** or intracellular calcium (distinct from classic inotropes). In **GALACTIC-HF** (8256, EF $\leq 35\%$) it gave a **14% reduction** in the composite of CV death/first HF event, driven by HF events (**no effect on CV death alone**); a signal of greater benefit in advanced HF (lower EF, higher natriuretic peptides).
- ▶ **Calcium sensitisers** — **levosimendan** (also a PDE-3 inhibitor/vasodilator) for acute decompensated HF: in **SURVIVE/REVIVE II** it did **not** reduce mortality; not approved in the USA but used elsewhere. *Routine long-term/short-term inotropes (e.g. milrinone, OPTIME-CHF) remain discouraged* — reserved as bridge to LVAD/transplant or palliation.
- ▶ **Ivabradine** — selective **If-current inhibitor** of the SA node; lowers heart rate without affecting contractility or vascular tone. **SHIFT** (NYHA II–III, sinus rhythm, HR $>70/\text{min}$): reduced CV death/HF hospitalisation proportional to heart-rate reduction. Considered as **adjunct/alternative** in patients still symptomatic on GDMT, in sinus rhythm, with HR $>70/\text{min}$.

Emerging therapies and strategies in HFpEF

- ▶ **SGLT-2 inhibitors** (**EMPEROR-PRESERVED**, **DELIVER**) — reduce HF hospitalisation; now the cornerstone of HFpEF therapy.
- ▶ **ARNI** — **PARAGON-HF** (4822, LVEF $\geq 45\%$) showed a 13% reduction that **narrowly missed significance** ($p = 0.06$); benefit greatest in those with **lower (mildly reduced) EF and in women**. Now approved across the full EF spectrum, greatest benefit when LVEF is below normal (**PARAGLIDE-HF** — benefit confined to EF $\leq 60\%$).
- ▶ **MRAs** — spironolactone (**TOPCAT/ALDO-DHF**) improved diastolic indices but not hard outcomes; the non-steroidal MRA **finerenone** (**FINEARTS-HF**) and **SPIRRIT-HFpEF** are evaluating this further.

- ▶ **Ineffective in HFpEF:** ACEIs/ARBs (except for prevention), digoxin (may cut hospitalisation), beta/calcium-channel blockers (useful only for rate control in AF), **PDE-5 inhibitor sildenafil**, and nitrates (NEAT-HFpEF, INDIE-HFpEF). Strategy emphasis: decongestion (avoiding excessive preload reduction → underfilling, azotaemia, syncope), BP control, maintaining sinus rhythm (AF ablation), and treating comorbidity (obesity, sleep apnoea, CKD, iron deficiency).

Strategies: in-hospital initiation, rapid sequencing and remote monitoring

- ▶ **Pre-discharge / in-hospital initiation:** PIONEER-HF (sacubitril–valsartan started before discharge) and EMPULSE (empagliflozin in hospitalised HF across EF spectrum) improved natriuretic peptides and clinical outcomes — institute GDMT *before discharge* to improve adherence.
- ▶ **Rapid sequencing / intensive titration:** STRONG-HF showed that aggressive up-titration to guideline targets **within 2 weeks of discharge** plus frequent follow-up to 2 months cut all-cause mortality and HF readmission at 180 days (benefit regardless of EF) — most readmissions occur in the first 2 weeks.
- ▶ **Remote haemodynamic monitoring:** implantable **pulmonary-artery pressure sensor** (CardioMEMS) reduced HF hospitalisations by up to 39% (CHAMPION); GUIDE-HF was neutral overall (confounded by COVID-19) but positive in pre-pandemic analysis. Telemonitoring of weight/vitals and intrathoracic impedance have **not** improved outcomes.

Device, surgical, cellular and gene-based advances

- ▶ **Cardiac resynchronisation therapy (CRT):** biventricular pacing via coronary sinus restores synchronous contraction; mortality benefit in CARE-HF, RAFT, MADIT-CRT — greatest with **QRS >149 ms and LBBB**. **Conduction-system / left-bundle-branch-area pacing** is an evolving alternative (evidence still less certain).
- ▶ **ICD for primary prevention of sudden cardiac death** — NYHA II–III, LVEF ≤35% (≤30% post-MI), on optimal therapy, no benefit within 40 days of MI; uncertain benefit in non-ischaemic cardiomyopathy (DANISH).
- ▶ **Cardiac contractility modulation (CCM):** non-excitatory RV-septal stimulation during the refractory period — improves symptoms/QOL in EF 25–45% with **narrow QRS** (not CRT-eligible); no proven mortality benefit, not yet guideline-endorsed.
- ▶ **Neuromodulation devices** (vagal nerve stimulation — INOVATE-HF/ANTHEM-HFrEF; baroreflex activation; renal denervation) have **largely failed** in large trials.
- ▶ **Transcatheter edge-to-edge mitral repair (MitraClip)** for functional MR: COAPT (positive — fewer hospitalisations and deaths) vs MITRA-FR (neutral); benefit depends on MR being disproportionate to LV dilation.

- ▶ **Surgical:** CABG for ischaemic cardiomyopathy (STICH — long-term benefit), AF catheter ablation (CASTLE-AF), and advanced therapies — **LVAD and cardiac transplantation** (detailed in Chap. 271).
- ▶ **Cellular and gene-based therapy (investigational):** bone-marrow/cardiac-derived and mesenchymal precursor cells (DREAM-HF negative) and **SERCA2a gene transfer** via AAV1 (CUPID — confirmatory trial failed) remain experimental.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Mortality-staircase (Fig. 265-3 style):** an X-Y plot with *risk of mortality* descending stepwise. Label, top→bottom: **Placebo → ACE inhibitor/ARB → Beta-blockers (carvedilol, metoprolol succinate, bisoprolol) → Mineralocorticoid receptor antagonist → ARNI (instead of ACEI/ARB) → SGLT-2 inhibitor → balanced vasodilators**; side-box “add-on, hospitalisation-only: Ivabradine, Vericiguat, Omecamtiv mecarbil”; “Ineffective/harmful: Endothelin antagonists, Moxonidine, Xamoterol, oral inotropes”.
- ▶ **Neurohormonal target schematic:** a cardiomyocyte/vasculature with arrows to drug targets — **AT1 receptor (ARB), neprilysin (sacubitril) → ↑natriuretic peptides, sGC/cGMP (vericiguat), SGLT-2 (gliflozins), cardiac myosin (omecamtiv), SA-node If current (ivabradine), mineralocorticoid receptor (MRA/finerenone).**

Clinical / Diagnostic significance

- ▶ **Sequence flexibly, titrate fully:** CIBIS-III showed order of ACEI vs beta blocker initiation does not matter — what matters is achieving target doses of all four pillars; GDMT is widely **under-dosed/under-utilised**.
- ▶ **ARNI** needs a 36-h ACEI washout and is avoided with prior angioedema; monitor BP (hypotension), K⁺ and renal function.
- ▶ **SGLT-2 inhibitors** are now started early and across the EF spectrum regardless of diabetes — a practice-changing shift; watch for genital mycotic infection, volume depletion and (rare) euglycaemic ketoacidosis.
- ▶ **Functional MR** with refractory symptoms → consider transcatheter repair (COAPT-type patients); refractory advanced HF → MCS/transplant referral.
- ▶ **Transitional care** (pre-discharge GDMT, STRONG-HF rapid titration, early follow-up, CardioMEMS in selected NYHA III) reduces the high (~50% at 6 months) readmission rate.

High-yield exam pointers

- ▶ **Four pillars of HFrEF:** ARNI/RAAS-blocker, beta blocker, MRA, **SGLT-2 inhibitor** — each adds incremental mortality benefit.
- ▶ **PARADIGM-HF:** sacubitril-valsartan → 20% ↓ CV death/HF hospitalisation, 16% ↓ all-cause mortality; target **200 mg bid**, 36-h ACEI gap, contraindicated if prior angioedema.

- ▶ **DAPA-HF** (26% ↓) and **EMPEROR-Reduced** (25% ↓); HFpEF benefit in **EMPEROR-PRESERVED & DELIVER**.
- ▶ **Vericiguat** = oral sGC stimulator (VICTORIA, modest 10% RRR, HF-hospitalisation driven).
- ▶ **Omecamtiv mecarbil** = selective cardiac myosin activator (GALACTIC-HF, 14% ↓, no effect on CV death alone, no ↑O₂ demand).
- ▶ **Ivabradine** = If-current SA-node inhibitor (SHIFT; HR >70, sinus rhythm).
- ▶ **HFpEF**: SGLT-2i effective; ARNI borderline (PARAGON-HF p = 0.06); finerenone (FINEARTS-HF) and GLP-1 agonists (obesity) emerging; sildenafil/nitrates ineffective.
- ▶ **Strategies**: in-hospital initiation (PIONEER-HF, EMPULSE), rapid up-titration (STRONG-HF), MitraClip (COAPT), CardioMEMS, CRT (QRS >149 ms + LBBB), ICD (LVEF ≤35%).

SOURCE & COVERAGE

Harrison's Principles of Internal Medicine, 22e — Ch 265 "Heart Failure: Management" (primary); with brief reference to Ch 264 "Heart Failure: Pathophysiology and Diagnosis" (SGLT-2 as a novel biologic target). LVAD and cardiac transplantation are cross-referenced by Harrison to Ch 271 (not provided here). *Coverage note*: this answer is fully grounded in the provided chapters; specific drug doses are taken from Table 265-2. Advanced mechanical circulatory support/transplant details fall outside the supplied text (Ch 271) and are therefore summarised only at the level Ch 265 provides.

Endomyocardial fibrosis

Asked in: Paper II Nov 2020 — RGUHS MD General Medicine

Definition / Introduction — Endomyocardial fibrosis (EMF, *Davies' disease*) is a progressive **fibrotic obliterative disease of the ventricular apices and subvalvular apparatus** that produces a **restrictive cardiomyopathy (RCM)**. It is a member of the *endomyocardial diseases* — a group unified pathologically by **dense fibrosis of the endocardium**, of which the temperate-zone counterpart is **Löffler (eosinophilic) endocarditis**. First described in Uganda in 1948, EMF is one of the **commonest causes of RCM worldwide** and a major cause of heart failure in tropical Africa, the South Asian subcontinent (notably Kerala, India) and Brazil. The dominant haemodynamic lesion is **impaired diastolic filling of a non-compliant ventricle with preserved or near-preserved ejection fraction**.

Etiopathogenesis and epidemiology

- ▶ **Cause remains unknown**. No single unifying infectious, environmental or genetic mechanism has been established; several hypotheses coexist.
- ▶ **Eosinophil hypothesis (unifying concept)**: EMF is regarded as the **end-stage fibrotic phenotype** that pathologically resembles eosinophilic (Löffler) endocarditis. Toxic **eosinophil granule**

cationic proteins are thought to damage the endocardium and drive fibrosis. *However*, peripheral or cardiac-tissue **eosinophilia is seldom demonstrable in established tropical EMF** — distinguishing it from frank hypereosinophilic disease.

- ▶ **Environmental hypothesis:** exposure to **cerium** (a rare-earth element abundant in affected soils) has been implicated; dietary and infectious (helminthic/filarial) cofactors have been proposed but not confirmed.
- ▶ **Geography:** tropical and subtropical regions — **sub-Saharan Africa (Uganda, Nigeria, Mozambique)**, the South Asian subcontinent and Brazil; sporadic cases occur in temperate climates.
- ▶ **Epidemiology:** a **community prevalence of ~20% has been reported in rural Mozambique**, with **male predominance** ($\approx 23\%$ vs 17% in females) and **family clustering**. Age shows a **bimodal peak** — onset in the **first decade**, and again in the **second to fourth decades**.

Pathology and natural history

- ▶ Hallmark is **dense, white, glistening fibrous tissue obliterating the apex of the right and/or left ventricle**, extending onto the **inflow tract and the chordae/papillary muscles** (subvalvular apparatus) while characteristically **sparing the outflow tracts**.
- ▶ **Apical obliteration** by fibrosis ($\pm$ superimposed mural thrombus) reduces cavity volume and produces restriction; tethering of the AV-valve apparatus produces **mitral and/or tricuspid regurgitation**. The atria dilate, often massively.
- ▶ **Three pathological stages** (best characterised in eosinophilic/Löffler disease, the temperate analogue, and applied to the endomyocardial-disease spectrum):

Stage	Pathological process	Clinical correlate
1. Acute necrotic	Eosinophil infiltration of myocardium, degranulation and myocardial necrosis/inflammation	Often few/no symptoms; biomarkers $\pm$ raised, CMR may show inflammation
2. Intermediate (thrombotic)	Mural thrombus layered over damaged endocardium, favouring the apices; risk of embolism	Chest pain, dyspnoea, AV-valve regurgitation, systemic/cerebral emboli
3. Fibrotic	Diffuse endocardial scarring $\rightarrow$ restrictive cardiomyopathy , subvalvular scarring impairing valve mobility	Established RCM with biventricular congestion

- ▶ **Anatomical patterns of EMF:** *right-ventricular* (RV apical obliteration $\rightarrow$ severe TR, gross ascites, raised JVP), *left-ventricular* (LV apical obliteration $\rightarrow$ MR, pulmonary congestion), and *biventricular* (commonest, $\sim 50\%$).

Tropical EMF versus Löffler (eosinophilic) endocarditis

Feature	Tropical EMF (Davies')	Löffler endocarditis
Geography / climate	Tropics (Africa, S. Asia, Brazil)	Temperate / developed countries
Age, sex	Children & young adults; M>F	Adults (typically male)
Eosinophilia	Usually absent / not demonstrable	Hypereosinophilia present (AEC >1500/ μ L $\geq$ 1 month, often $\geq$ 6 months)
Underlying cause	Unknown (cerium, ?infective)	Helminth/parasitic infection, allergy/drug reaction, eosinophilic leukaemia/malignancy , idiopathic HES; myeloproliferative HES may respond to tyrosine-kinase inhibitors
Course	Indolent, chronically progressive	More aggressive (acute necrotic $\rightarrow$ thrombotic $\rightarrow$ fibrotic)
Common end-point	Restrictive cardiomyopathy with apical fibrosis & AV regurgitation	Same fibrotic RCM end-stage

Clinical features

- Symptoms of **restrictive physiology** dominate, frequently **right-sided**: exertional dyspnoea, **paroxysmal nocturnal dyspnoea**, fatigue, peripheral oedema and **prominent ascites** (a feature common to all endomyocardial diseases, often out of proportion to peripheral oedema).
- **Signs**: raised JVP with **rapid/steep Y descent** and a **positive Kussmaul sign** (inspiratory rise in JVP); a **fourth heart sound (S4)** is more typical than S3 in sinus rhythm; murmurs of **mitral and/or tricuspid regurgitation**; **atrial fibrillation** is common; hepatomegaly and dependent oedema. The apex beat is **less displaced than in DCM** and **less forceful than in HCM**.
- **Complications**: congestive heart failure, AF and other arrhythmias, mural thrombus with **systemic/pulmonary embolism**, AV-valve regurgitation, pericardial effusion, and **sudden cardiac death**.

Investigations and diagnosis

- **ECG**: non-specific — low-voltage complexes, T-wave inversion, atrial enlargement, **atrial fibrillation**, conduction abnormalities.
- **Chest radiograph**: cardiomegaly from biatrial enlargement; pericardial effusion; occasionally **apical/endocardial calcification**.

- ▶ **Echocardiography (key test):** obliteration of the ventricular apex by fibrous tissue ± thrombus, apical/subvalvular AV-apparatus involvement, AV-valve regurgitation, **gross biatrial enlargement**, restrictive transmitral inflow (tall E, short deceleration time) and preserved/near-normal systolic function.
- ▶ **Cardiac MRI:** demonstrates apical fibrosis and **subendocardial late gadolinium enhancement**; detects thrombus and inflammation in the eosinophilic phase.
- ▶ **Cardiac catheterisation:** elevated and equalised end-diastolic pressures with a “**dip-and-plateau**” (square-root sign) ventricular pressure tracing; **pulmonary arterial pressure is raised**.
- ▶ **Endomyocardial biopsy:** more useful in RCM than in DCM/HCM to confirm an infiltrative/fibrotic aetiology; shows endocardial fibrosis (and eosinophilic infiltration in the active eosinophilic phase).
- ▶ **Crucial differential** — RCM vs constrictive pericarditis (both present with right-heart dominance):

Feature	Restrictive cardiomyopathy (EMF)	Constrictive pericarditis
Respiratory ventricular interaction	Absent / not accentuated	Accentuated (interdependence)
Pulmonary artery pressure	Elevated (high PCWP)	Usually normal
Pericardium	Normal	Thickened ± calcified
BNP / NT-proBNP	High	Relatively low/normal
Septal motion / CMR	Apical fibrosis, LGE	Pericardial thickening, septal bounce

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Four-chamber heart in EMF** — label: *fibrous obliteration of LV apex, fibrous obliteration of RV apex, mural thrombus over endocardium, tethered mitral and tricuspid subvalvular apparatus* → MR/TR, grossly dilated left and right atria, spared outflow tracts.
- ▶ **Stages of endomyocardial (eosinophilic) disease** — a 3-box flow: *Acute necrotic (eosinophil infiltration & myocardial necrosis)* → *Intermediate/thrombotic (mural thrombus, embolism)* → *Fibrotic (endocardial scarring → restrictive cardiomyopathy)*.

Clinical / Diagnostic significance

- ▶ EMF is a **leading cause of restrictive cardiomyopathy and heart failure in the tropics**, and an important Indian cause (Kerala) — high-yield for an Indian postgraduate exam.
- ▶ The **eosinophil link** unifies tropical EMF with Löffler endocarditis; recognising an active eosinophilic phase allows **disease-modifying therapy** (treat parasitosis, corticosteroids, TKIs for myeloproliferative HES) *before* irreversible fibrosis.

- ▶ Echocardiographic apical obliteration with AV-valve regurgitation and biatrial enlargement is virtually diagnostic in an endemic setting.
- ▶ Distinguishing EMF from **constrictive pericarditis** is decisive because constriction is **surgically curable by pericardiectomy**, whereas EMF requires endocardial decortication/valve surgery.
- ▶ Mural thrombus mandates attention to **thromboembolic risk**.

Management

- ▶ **Medical (supportive)**: the cornerstone is **euvolaemia** — judicious **diuretics** (loop ± thiazide ± aldosterone antagonist) balancing decongestion against the need for adequate filling. Rate control and anticoagulation for AF; anticoagulation for mural thrombus/embolism. **Beta-blockers** can prolong diastolic filling but may be poorly tolerated by lowering an already fixed stroke volume; **vasodilators are often poorly tolerated**. Standard HFrEF therapies are **not routinely indicated** in RCM.
- ▶ **Disease-specific (active eosinophilic phase)**: treat the underlying cause; **corticosteroids and cytotoxic/cytolytic agents** (e.g. hydroxyurea), and **tyrosine-kinase inhibitors** for FIP1L1-PDGFR α / myeloproliferative HES.
- ▶ **Surgical (fibrotic stage)**: endocardectomy (decortication/resection of fibrous tissue) with **mitral/tricuspid valve repair or replacement** can produce dramatic symptomatic and survival benefit, *but* carries **significant perioperative morbidity and mortality**.
- ▶ **Prognosis**: advanced fibrotic EMF with heart failure carries a poor prognosis; outcome depends on ventricular involvement, AV-valve regurgitation and operability.

High-yield exam pointers

- ▶ EMF = **fibrous obliteration of ventricular apices + subvalvular apparatus** → **restrictive cardiomyopathy**; eponym *Davies' disease*; first described in **Uganda, 1948**.
- ▶ One of the **commonest causes of RCM worldwide**; tropical Africa, India (Kerala), Brazil; **male predominance, bimodal age, family clustering**; ~20% prevalence reported in rural Mozambique.
- ▶ **Three histological stages**: acute necrotic → thrombotic → **fibrotic**.
- ▶ **Löffler endocarditis** = **temperate analogue with hypereosinophilia** (AEC >1500/ μ L); EMF usually has **no demonstrable eosinophilia**.
- ▶ **Clues**: ascites out of proportion, raised JVP with steep Y descent + **Kussmaul sign**, S4 > S3, MR/TR murmurs, AF.
- ▶ **Echo**: **apical obliteration + biatrial enlargement + AV regurgitation**; **CMR**: **subendocardial LGE**; **cath**: **square-root (dip-and-plateau) sign**.
- ▶ **Distinguish from constrictive pericarditis**: RCM has **no respiratory ventricular interaction**, **raised PA pressure, high BNP**.

- Treatment: **diuretic-based supportive care**; steroids/cytotoxics/TKI in the eosinophilic phase; **endocardectomy + valve surgery** in the fibrotic stage.

SOURCE & COVERAGE

- **Harrison's Principles of Internal Medicine, 22e** — “*Amyloidosis and Other Restrictive Cardiomyopathies*” (restrictive physiology, Table of causes of RCM listing tropical endomyocardial fibrosis and Löffler's endocarditis) and “*Myocarditis*” (eosinophilic myocarditis → Loeffler endocarditis, hypereosinophilic syndrome).
- **Braunwald's Heart Disease, 13e** — “*The Dilated, Restrictive, and Infiltrative Cardiomyopathies*” (Endomyocardial disease; Löffler eosinophilic endocarditis with the acute/intermediate/fibrotic stages; Endomyocardial fibrosis — Uganda 1948, Mozambique prevalence, cerium, clinical and surgical management). *This dedicated cardiology text supplied the depth on staging, epidemiology and pathology.*
- **CMDT 2026** — “*Heart Failure & Cardiomyopathy*” (restrictive cardiomyopathy essentials; RCM vs constrictive pericarditis — ventricular interaction and PA pressure; diuretic/beta-blocker management principles).

Coverage note: The corpus covers the restrictive-cardiomyopathy framework, the eosinophilic (Löffler) spectrum and the core EMF epidemiology/pathology/management well, but **tropical-EMF-specific minutiae are relatively thin** — points such as the *Davies* eponym, the predominantly Kerala focus in India, calcific endocardial change and the dip-and-plateau/square-root sign are stated as universally accepted standard internal medicine, consistent with (but not all verbatim in) the corpus.

Hypertrophic Cardiomyopathy

Asked in: Paper II Jul 2020 · Paper II May 2019 (2×) — RGUHS MD General Medicine

Definition / Introduction — Hypertrophic cardiomyopathy (HCM) is a primary myocardial disorder defined by **left ventricular hypertrophy (LVH) that develops in the absence of any abnormal loading condition** (hypertension, aortic stenosis) or systemic infiltrative/storage disease that could account for the wall thickening. It is the **commonest monogenic cardiovascular disease (prevalence ≈1:500)**, classically caused by autosomal-dominant pathogenic variants in genes encoding the **cardiac sarcomere**, and is histologically marked by myocyte hypertrophy, **myocyte disarray** and fibrosis. The preferred current term is *hypertrophic cardiomyopathy with or without obstruction* (replacing “HOCM”); it is a leading cause of **sudden cardiac death (SCD) in the young** and an important cause of heart failure.

Etiology and genetic basis

- ▶ **Sarcomeric HCM:** a pathogenic sarcomere-gene variant is found in ~40–50% of all patients — over 60% of those with familial disease or childhood presentation, but ~30–40% of apparently sporadic cases. Inheritance is **autosomal dominant** with **age-dependent, incomplete penetrance** (~60%) and variable expressivity.
- ▶ **>1500 variants in ≥9 genes;** ~80% involve **MYBPC3** or **MYH7** (thick-filament proteins).
- ▶ **Mechanism:** most act as a **dominant-negative** (“poison peptide”); **MYBPC3** is the exception (~90% are truncating variants causing **haploinsufficiency**). At the myofilament level variants produce **increased force generation, increased Ca²⁺ sensitivity, impaired relaxation and abnormal energetics** (increased ATP consumption).
- ▶ **Nonsarcomeric HCM:** polygenic, with **hypertension (esp. diastolic BP) and obesity** as the strongest environmental modifiers (Mendelian-randomisation data).

Sarcomere gene	Protein	Approx. share of genetic HCM
MYBPC3	Myosin-binding protein C	~45%
MYH7	β-myosin heavy chain	~35%
TNNT2	Cardiac troponin T	~5%
TNNI3	Cardiac troponin I	~3%
TPM1 / MYL2 / MYL3 / ACTC1 / TNNC1	Tropomyosin, light chains, actin, troponin C	<3% each

- ▶ **Genocopies / “pseudohypertrophy”** (mimic HCM, must be excluded — often a *short PR / pre-excitation* clue): **Fabry disease** (*GLA*, X-linked; angiokeratoma, renal failure, neuropathy), **Danon disease** (*LAMP2*, X-linked), **PRKAG2 cardiomyopathy** (pre-excitation/AV block), **Friedreich ataxia** (*FXN*), **Noonan/RASopathy** (*PTPN11*), **cardiac amyloidosis** (*TTR* — carpal tunnel, biceps-tendon rupture), and mitochondrial disease.

Pathology and pathophysiology

- ▶ **Macroscopy:** non-uniform wall thickening; **asymmetric septal hypertrophy with reversed septal curvature** is classic and most predictive of a sarcomere variant. Other patterns: **concentric, mid-ventricular, and apical** (apical HCM is less often familial, sarcomere variant in only ~15%, more common in Japanese/Asian descent).
- ▶ **Microscopy:** characteristic **myocyte disarray** (swirling/branching instead of parallel fibres), **interstitial and replacement fibrosis**, and **small thick-walled intramural arterioles** → microvascular ischaemia and angina with normal epicardial coronaries. Endomyocardial biopsy is **not** used to diagnose HCM (changes are patchy/deep) but can exclude infiltrative disease.
- ▶ **LVOT obstruction (dynamic):** present at rest in ~30% and provoked by exercise in a further ~30%. The hypertrophied septum + an enlarged, anteriorly-displaced anterior mitral leaflet

generate **drag forces** → **systolic anterior motion (SAM)** of the mitral valve contacting the septum → late-peaking outflow obstruction and a **posteriorly-directed jet of mitral regurgitation**.

- ▶ **Load dependence:** obstruction worsens with ↓**preload** (dehydration, Valsalva, standing, diuretics), ↓**afterload** (vasodilators) and ↑**contractility** (exercise, digoxin, inotropes); it improves with squatting, handgrip and volume.
- ▶ **Diastolic dysfunction** (stiff, hypertrophied ventricle with impaired relaxation) is near-universal; systolic function is usually preserved/supranormal — an EF <50% is **abnormal** in HCM and signifies systolic decline.

Clinical features and physical signs

- ▶ **Symptoms:** exertional **dyspnoea** (commonest), **angina**, and **post-exertional syncope/pre-syncope** (volume loss + tachycardia worsen obstruction); palpitations; may be asymptomatic and detected on family screening or murmur. SCD may be the first presentation.
- ▶ **Pulse:** sharp, rapidly rising **bisferiens (spike-and-dome) carotid pulse** (contrast with the slow-rising *pulsus parvus et tardus* of aortic stenosis).
- ▶ **Apex:** **triple apical impulse**, prominent **a-wave** in JVP, **loud S4**.
- ▶ **Murmur:** harsh, **late-peaking systolic ejection murmur** at the left sternal border ± apical pansystolic murmur of MR. **Dynamic auscultation is the key bedside test:** murmur **increases** with Valsalva strain and standing from squatting (↓preload); **decreases** with squatting and sustained handgrip (↑afterload/preload) — the opposite of valvular AS.
- ▶ **Brockenbrough–Braunwald–Morrow sign:** a paradoxical **fall in aortic pulse pressure in the post-extrasystolic beat** (augmented contractility increases obstruction) — a classic confirmatory sign of dynamic LVOT obstruction.

Diagnosis and investigations

- ▶ **Echocardiography (diagnostic, first-line):** maximal LV wall thickness ≥15 mm in adults (or ≥13 mm with a family history or proven pathogenic variant; z-score ≥2.5 in children) with a non-dilated, hypercontractile, **small LV cavity**, SAM, dynamic LVOT gradient, and diastolic dysfunction. **Obstruction = peak instantaneous gradient ≥30 mmHg; ≥50 mmHg** (rest or provoked) is the threshold for limiting symptoms/intervention. Use **provocation** (Valsalva, squat-to-stand, exercise echo) if resting gradient <30 mmHg but symptomatic.
- ▶ **ECG** (abnormal but non-specific; insensitive): LVH, deep **inferolateral/septal Q waves**, ST-T changes; **giant T-wave inversions** suggest apical HCM. May be normal in ~25%.
- ▶ **Cardiac MRI:** quantifies hypertrophy in areas missed by echo, and **late gadolinium enhancement (LGE)** identifies fibrosis (arrhythmic substrate and emerging SCD risk marker).
- ▶ **Genetic testing:** multigene panel in the proband chiefly to **enable cascade (predictive) testing of relatives** and to distinguish genocopies; phenotype, not genotype, guides therapy.

- ▶ **Athlete's heart vs HCM:** physiological hypertrophy shows mild LV dilation, normal diastolic function, supranormal VO_2max ($>50 \text{ mL/kg/min}$), no LGE, and regression with detraining — features absent in HCM.

Management

Three pillars: symptom control, SCD-risk/arrhythmia management, and family screening + lifestyle counselling. No therapy yet proven to alter mortality; treat the symptomatic patient.

Setting	Approach
Obstructive, symptomatic	First-line β -blocker OR non-dihydropyridine CCB (verapamil/diltiazem); optimise volume; stop vasodilators. Add disopyramide (negative inotrope, give with AV-nodal blocker) or a cardiac myosin inhibitor (mavacamten) for persistent symptoms
Refractory + gradient $\geq 50 \text{ mmHg}$	Septal reduction therapy — surgical septal myectomy (gold standard; experienced-centre 30-day mortality $<1\%$, 90–95% success) or alcohol septal ablation (for non-surgical candidates / suitable septal-perforator anatomy)
Nonobstructive, symptomatic	β -blocker / verapamil, cautious diuretics for congestion; trials of myosin inhibitors and SGLT2 inhibitors ongoing; transplant for refractory/end-stage disease
Avoid	Arterial vasodilators (ACE-I/ARB, nitrates, dihydropyridine CCB, PDE5 inhibitors) and digoxin ($\uparrow$ contractility worsens obstruction)

- ▶ **Cardiac myosin inhibitors (disease-specific):** mavacamten allosterically inhibits myosin ATPase, favouring the super-relaxed “off” state $\rightarrow$ fewer cross-bridges $\rightarrow$ $\downarrow$ contractility and $\downarrow$ LVOT gradient. **FDA-approved April 2022** for symptomatic obstructive HCM; trials EXPLORER-HCM and VALOR-HCM showed improved exercise capacity, symptoms and reduced need for SRT. Chief risk: **reversible fall in LVEF** $\rightarrow$ mandatory echo monitoring/REMS. **Aficamten** (SEQUOIA-HCM) is the second-in-class agent.
- ▶ **Atrial fibrillation:** common, poorly tolerated (loss of atrial kick worsens filling/obstruction). Rate-control with β -blocker/verapamil, restore sinus rhythm; **disopyramide/amiodarone** preferred antiarrhythmics; ablation for refractory cases. **Anticoagulate regardless of $\text{CHA}_2\text{DS}_2\text{-VASc}$ score**, DOAC preferred over warfarin.
- ▶ **Septal-reduction complication:** **complete heart block needing permanent pacing** (commoner after ablation). Pacing alone is **not** effective primary therapy.
- ▶ **Lifestyle:** recent data show low arrhythmic risk with recreational/competitive sport; blanket restriction is no longer mandated — **shared decision-making**.

Risk stratification for sudden cardiac death

- ▶ Baseline SCD risk ~0.5–1% per year; SCD is not reduced by drugs/septal reduction, so prevention rests on the ICD.
- ▶ **Secondary prevention (Class I ICD):** prior cardiac arrest / sustained VT/VF.
- ▶ **Primary prevention major risk factors** (each weighed for shared decision-making): **family history of SCD, unexplained (non-vagal) syncope, massive LVH ≥ 30 mm, LV apical aneurysm, LV systolic dysfunction (EF $< 50\%$), and non-sustained VT on monitoring.** Extensive LGE on CMR is a modifying marker.
- ▶ The ESC HCM Risk-SCD calculator estimates 5-year risk from age, max wall thickness, LA diameter, LVOT gradient, FH of SCD, NSVT and syncope: $\geq 6\%$ → **ICD advised**; 4–6% → **consider**; $< 4\%$ → **not advised**.
- ▶ **Prognosis:** generally better than older referral series suggested; ~1 in 20 (5–8%) progress to systolic dysfunction / “burnt-out” end-stage HCM (EF $< 50\%$) needing HFrEF therapy or transplant.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Parasternal long-axis echo of obstructive HCM** — label: *hypertrophied interventricular septum, asymmetric LVH, small LV cavity, systolic anterior motion (SAM) of anterior mitral leaflet contacting septum, narrowed LVOT, posteriorly-directed mitral regurgitation jet, enlarged left atrium, aorta.*
- ▶ **Cardiac sarcomere schematic** — label: *thick filament (β -myosin heavy chain MYH7, myosin-binding protein C MYBPC3, myosin light chains), thin filament (actin ACTC1, tropomyosin TPM1, troponin T/I/C complex), Z-disc* — marking the genes mutated in HCM.

Clinical / Diagnostic significance

- ▶ HCM is the **leading cause of sudden death in young athletes**; pre-participation evaluation and family cascade screening (ECG + echo, beginning in adolescence and continued lifelong) are critical.
- ▶ **Dynamic auscultation** distinguishing HCM from aortic stenosis is a high-yield clinical and viva skill.
- ▶ Always **exclude genocopies** (Fabry, amyloid, Danon, PRKAG2) — several are specifically treatable (enzyme replacement / migalastat for Fabry; tafamidis/acoramidis for ATTR amyloid).
- ▶ **Mavacamten** is a landmark first disease-specific therapy reshaping management of symptomatic obstructive HCM.

High-yield exam pointers

- ▶ Commonest **monogenic** CVS disease; **AD inheritance**, prevalence 1:500; MYBPC3/MYH7 ≈80% of sarcomeric cases.
- ▶ Diagnostic wall thickness ≥15 mm (≥13 mm with FH/variant); **obstruction = gradient ≥30 mmHg**, intervene at ≥50 mmHg.
- ▶ **SAM of mitral valve** → LVOT obstruction + **posteriorly-directed MR**; **myocyte disarray** is the histological hallmark.
- ▶ Murmur ↑ **with Valsalva/standing**, ↓ **with squatting/handgrip**; **Brockenbrough sign**; **bisferiens pulse**.
- ▶ **Avoid digoxin, nitrates and vasodilators**; first-line = **β-blocker / verapamil**; add **disopyramide** or **mavacamten**.
- ▶ Refractory obstruction → **septal myectomy** (gold standard) or **alcohol septal ablation**; main complication = **complete heart block**.
- ▶ SCD prevention = **ICD**; major risks = **FH SCD, syncope, LVH ≥30 mm, apical aneurysm, EF <50%, NSVT**; use the **ESC HCM Risk-SCD score**.
- ▶ **AF**: anticoagulate **irrespective of CHA₂DS₂-VASc**; ~5–8% evolve to end-stage (“burnt-out”) HCM.

Left ventricular remodeling

Asked in: Paper II Nov 2022 — RGUHS MD General Medicine

Definition / Introduction — **Left ventricular (LV) remodeling** is the process by which the ventricle undergoes progressive changes in **shape, size, mass, wall thickness and geometry** in response to an **index injury** or chronic haemodynamic overload, occurring at the molecular, cellular and chamber levels. It is the structural substrate of heart failure with reduced ejection fraction (**HFrEF**): an index event (e.g., acute myocardial infarction, or chronic pressure/volume overload) is followed by **months**

to years of structural and functional cardiovascular remodeling, during which compensatory mechanisms ultimately become maladaptive and drive disease progression. Initially adaptive, remodeling sets up a **self-perpetuating vicious cycle** of rising wall stress and falling pump function that culminates in clinical heart failure.

Pathophysiology — the remodeling cascade

- ▶ HFrEF is a **progressive disease** that begins with an *index event* — **sudden** (acute MI), **gradual** (chronic pressure or volume overload, e.g., valvular disease), **inherited** (genetic cardiomyopathy), or **congenital** in origin. Despite an early fall in cardiac performance, patients stay asymptomatic for prolonged periods because of **compensatory mechanisms** that later promote progression.
- ▶ The central driver is **increased myocardial wall stress**. By the **Law of Laplace**, wall stress $\propto$ (intracavitary pressure $\times$ chamber radius) $\div$ (2 $\times$ wall thickness) — so chamber dilatation and pressure loading both raise wall stress, while wall thickening lowers it. (*Laplace formula is standard cardiac physiology — see Coverage note.*)
- ▶ **Remodeling stimuli** (Fig. 264-6) acting on the myocardium are: increased **wall stress**, inflammatory **cytokines**, **neurohormonal** signals, and **oxidative stress**.
- ▶ The myocardium responds with **adaptive and maladaptive** changes — myocyte hypertrophy, altered interstitial matrix, fetal-gene re-expression, altered calcium-handling proteins, and myocyte death — producing **ventricular enlargement** and **systolic and/or diastolic dysfunction**.
- ▶ Myocytes unable to adapt to remodeling stimuli are triggered to undergo **apoptosis** (**programmed cell death**). Continued pump impairment plus systemic vasoconstriction and loss of neurohormonal adaptation produce **afterload mismatch**; these events **feed back on remodeling stimuli**, completing a **vicious cycle** that drives clinical HF.

Patterns of remodeling — concentric vs eccentric hypertrophy

- ▶ Different geometric patterns occur in response to **excess cardiac workload**, governed by the type of overload.

Feature	Concentric hypertrophy	Eccentric hypertrophy
Loading stimulus	Pressure overload	Volume overload
Typical causes	Hypertension, aortic stenosis	Aortic regurgitation, mitral regurgitation
Geometry	Increased mass out of proportion to chamber volume	Increased cavity size/volume, wall thinning
Effect on wall stress	Reduces wall stress (adaptive, initially)	Raised wall stress with progressive dilatation

Feature	Concentric hypertrophy	Eccentric hypertrophy
Sarcomere change (standard)	Sarcomeres added in parallel → thicker wall	Sarcomeres added in series → elongated myocytes

- ▶ In **both** forms, increased ventricular mass is accompanied by tissue- and protein-level changes: **myocyte hypertrophy and interstitial fibrosis**; altered **calcium-handling and cytoskeletal protein abundance/function**; and **re-expression of fetal genes**.

Mechanisms of ventricular remodeling (Table 264-3)

- ▶ Remodeling is organised at three levels — **myocyte biology, myocardial composition, and ventricular geometry**:

Level	Mechanisms
Changes in myocyte biology	Abnormal excitation–contraction coupling and crossbridge interaction; fetal gene expression (e.g., β -myosin heavy chain); β -adrenergic receptor desensitisation ; myocyte hypertrophy; impaired cytoskeletal proteins
Changes in myocardial composition	Myocyte necrosis, apoptosis and autophagy; interstitial and perivascular fibrosis ; matrix degradation
Changes in ventricular geometry	Ventricular dilation and wall thinning; increased sphericity and displacement of papillary muscles; atrioventricular valve regurgitation

- ▶ **Neurohormonal activation** is pivotal: activation of the **sympathetic nervous system (SNS)** and the **renin–angiotensin–aldosterone system (RAAS)** initially supports heart rate, BP, contractility and Na^+ /water retention, but unchecked promotes **myocyte hypertrophy, cell death and myocardial fibrosis** — remodeling the heart, vessels and kidneys.
- ▶ **Endothelin** (a potent vasoconstrictor with growth-promoting effects) drives **myocyte hypertrophy and interstitial fibrosis**; **inflammatory cytokines** ($\text{TNF-}\alpha$, $\text{IL-1}\beta$) and **reactive oxygen species** (superoxide, peroxynitrite) also contribute to remodeling.
- ▶ **Counter-regulatory vasodilatory hormones** oppose remodeling — the **natriuretic peptides** (ANP, BNP) cause vasodilation, natriuresis and RAAS inhibition; they are degraded by **neprilysin** (the rationale for **angiotensin receptor–neprilysin inhibition, ARNI**).
- ▶ **Electrical dyssynchrony** (QRS prolongation/LBBB in up to one-third of HF patients) worsens remodeling; **secondary (functional) mitral regurgitation** arises from the **spherical ventricle**, papillary-muscle displacement and **mitral annular dilation**, feeding the vicious cycle.

Post-myocardial-infarction remodeling

- ▶ After STEMI the LV undergoes a series of changes in **shape, size and thickness in both infarcted and non-infarcted segments** — this is **ventricular remodeling**, and it generally **precedes clinically evident heart failure** by months to years.
- ▶ **Acute phase — infarct expansion**: soon after STEMI the LV begins to **dilate** due to **slippage of muscle bundles, disruption of myocardial cells and tissue loss** within the necrotic zone, causing **disproportionate thinning and elongation of the infarct zone**.
- ▶ **Later phase**: **lengthening of the non-infarcted segments** occurs, producing global chamber enlargement.
- ▶ **Determinants of severity**: overall chamber enlargement relates to **infarct size and location** — **anterior wall and apical infarcts** cause greater dilatation, more marked haemodynamic impairment, more frequent HF and a **poorer prognosis**.
- ▶ **Infarct healing** (Fig. 286-3): reparative monocytes and monocyte-derived fibroblasts synthesise **interstitial collagen** that reinforces the myocardial skeleton, **mitigating expansive remodeling** of the infarct and reducing the risk of chronic HF.
- ▶ **LV aneurysm**: defined as **dyskinesis or local expansile paradoxical wall motion**; a **true aneurysm** is composed of **scar tissue** and **neither predisposes to nor is associated with cardiac rupture**. Apical aneurysms are commonest; complications (HF, arterial embolism, ventricular arrhythmias) appear weeks–months later; a **double/diffuse/displaced apical impulse** is the key sign and 2-D echocardiography detects the aneurysm and any **mural thrombus**.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Diagram 1 — “Remodeling stimuli in heart failure”** (vicious cycle, after Fig. 264-6).
Boxes/arrows with EXACT labels: **Increased wall stress** → stimuli (**Wall stress, Cytokines, Neurohormonal, Oxidative stress**) → myocardial responses (**Myocyte hypertrophy, Altered interstitial matrix, Fetal gene expression, Altered calcium-handling proteins, Myocyte death**) → **Ventricular enlargement** → **Systolic or diastolic dysfunction** → feedback arrow returning to **Increased wall stress** (vicious cycle).
- ▶ **Diagram 2 — Concentric vs eccentric remodeling**. Three LV cross-sections labelled **Normal LV, Concentric hypertrophy (pressure overload — thick wall, small cavity), Eccentric hypertrophy (volume overload — dilated cavity, thin wall)**; annotate Laplace: **wall stress = $(P \times r)/(2h)$** .

Clinical / Diagnostic significance

- ▶ **Reverse remodeling is the therapeutic goal**. Antagonism of the RAAS and SNS with RAS inhibitors (ACEi/ARB), mineralocorticoid-receptor antagonists, and beta-blockers attenuates or reverses ventricular and vascular remodeling and reduces morbidity and mortality; ARNI

(sacubitril/valsartan) and SGLT-2 inhibitors (effects on cardiac/vascular remodeling) extend this benefit in HFrEF.

- ▶ **Post-MI:** ACE inhibitors reduce mortality after STEMI via reduction in ventricular remodeling, with maximum benefit in high-risk patients (anterior infarction, prior infarction, globally depressed LV function); prescribe ACEi/ARB ± beta-blocker when EF <40%. Add an MRA (spironolactone/eplerenone) if EF ≤40% with symptomatic HF or diabetes (no significant renal dysfunction/hyperkalaemia). Note: sacubitril/valsartan was NOT superior to an ACE inhibitor in preventing incident HF early post-MI.
- ▶ **Cardiac resynchronisation therapy** (biventricular/LBBB pacing) for symptomatic HFrEF with LBBB reverses ventricular remodeling, improves contractile function and reduces mitral regurgitation.
- ▶ **Imaging:** chronic HF with remodeling is accompanied by cardiac enlargement with a downward and leftward-displaced apical impulse; echocardiography and serial cardiac MRI (quantifies LV mass, volumes and function) are used to assess remodeling in response to therapy.
- ▶ Reverse remodeling may also follow weight loss in obese HF patients.

High-yield exam pointers

- ▶ Remodeling = change in shape, size, mass, wall thickness, geometry; structural basis of HFrEF; the index event → months–years of remodeling concept is key.
- ▶ **Pressure overload** → concentric (parallel sarcomeres, reduces wall stress); **volume overload** → eccentric (series sarcomeres, dilatation).
- ▶ Three levels of remodeling (Table 264-3): myocyte biology, myocardial composition, ventricular geometry.
- ▶ Fetal gene re-expression classically = β-myosin heavy chain; β-adrenergic receptor desensitisation occurs.
- ▶ Maladaptive geometry → increased sphericity, papillary-muscle displacement → functional mitral regurgitation.
- ▶ Post-STEMI: infarct expansion (muscle slippage, thinning/elongation) → later non-infarct segment lengthening; anterior/apical infarcts remodel worst.
- ▶ **Drugs that reverse remodeling:** ACEi/ARB, ARNI, MRA, beta-blockers, SGLT-2 inhibitors, CRT.
- ▶ **True LV aneurysm** = scar tissue, does NOT cause rupture (contrast with pseudoaneurysm/free-wall rupture).
- ▶ Endothelin blockade does NOT slow LV-failure HF but helps PAH/right HF.

SOURCE & COVERAGE

Harrison 22e — Ch 264 “Heart Failure: Pathophysiology and Diagnosis” (Fig. 264-6, Table 264-3, neurohormonal mechanisms, reverse remodeling, imaging) + Ch 286 “ST-Segment Elevation Myocardial Infarction” (post-MI ventricular remodeling/dysfunction, infarct expansion, RAAS inhibition, LV aneurysm, Fig. 286-3). **Coverage note:** The provided chapters fully cover remodeling triggers, patterns, mechanisms, post-MI remodeling and reverse-remodeling therapy. Two adjuncts are *standard physiology/medicine not stated verbatim in the supplied text* — the explicit **Laplace formula** (wall stress = $P \cdot r / 2h$) and the **parallel- vs series-sarcomere** correlate of concentric vs eccentric hypertrophy — included as universally accepted cardiac physiology to complete the answer.

Management of Supraventricular Tachycardia

Asked in: Paper II Dec 2023 — RGUHS MD General Medicine

Definition / Introduction — Supraventricular tachycardia (SVT) is a tachyarrhythmia arising from atrial tissue or from circuits using the AV node/accessory pathway, i.e. above or involving the His bundle. In exam practice, “SVT” usually refers to **regular paroxysmal narrow-complex tachycardia**, chiefly **AV nodal re-entrant tachycardia (AVNRT)** and **atrioventricular re-entrant tachycardia (AVRT)**, but focal atrial tachycardia and atrial flutter must be recognized. Management is algorithmic: assess stability, record the rhythm, terminate the episode safely, prevent recurrence, and offer curative ablation when appropriate.

Classification and mechanisms

- ▶ **AVNRT:** commonest paroxysmal SVT; re-entry within dual AV nodal physiology. Typical slow-fast AVNRT has a regular narrow QRS tachycardia with hidden/retrograde P waves, pseudo-r' in V1, or pseudo-S waves in inferior leads.
- ▶ **Orthodromic AVRT:** antegrade conduction through AV node and retrograde conduction through an accessory pathway; narrow QRS unless baseline bundle branch block/aberrancy. It is the usual tachycardia in Wolff-Parkinson-White (WPW) syndrome.
- ▶ **Antidromic AVRT:** antegrade conduction down the accessory pathway and retrograde conduction through AV node/another pathway; produces a regular broad-complex tachycardia and may mimic VT.
- ▶ **Focal atrial tachycardia:** automatic, triggered, or micro-re-entrant atrial focus; P-wave morphology differs from sinus rhythm and AV block may occur without terminating the atrial rhythm.
- ▶ **Atrial flutter / macro-re-entrant atrial tachycardia:** atrial rate often around 250-350/min; ventricular response depends on AV conduction, commonly 2:1 with a rate near 150/min.

- ▶ **Multifocal atrial tachycardia:** irregular atrial tachycardia with at least three P-wave morphologies, often in COPD, hypoxia, pulmonary disease, sepsis, or electrolyte disturbance; do not manage as AVNRT.

Immediate assessment and diagnosis

- ▶ First decide **unstable versus stable**. Instability includes hypotension/shock, acute pulmonary edema, ischemic chest pain, altered sensorium, severe dyspnea, or syncope attributable to tachycardia.
- ▶ Obtain a **12-lead ECG during tachycardia** before treatment if this does not delay emergency care; also record a post-conversion ECG to look for pre-excitation, ischemia, QT interval, and baseline conduction disease.
- ▶ Define the rhythm by **QRS width** and **regularity**:

ECG pattern	Likely diagnosis	Immediate implication
Regular narrow-complex	AVNRT, orthodromic AVRT, atrial tachycardia, flutter with fixed block	Vagal maneuvers and adenosine are useful
Irregular narrow-complex	AF, atrial flutter with variable block, MAT	Avoid reflex "SVT bolus" treatment; identify atrial rhythm
Regular broad-complex	VT, SVT with aberrancy, antidromic AVRT	Treat as VT if uncertain
Irregular broad-complex	AF with pre-excitation, polymorphic VT	Avoid AV nodal blockers; urgent specialist/emergency treatment

- ▶ Look for reversible precipitants: fever, pain, anemia, hypovolemia, hypoxia, pulmonary embolism, myocardial ischemia, thyrotoxicosis, alcohol/stimulants, sympathomimetics, digoxin toxicity, hypokalemia, and hypomagnesemia.
- ▶ Basic work-up after stabilization: electrolytes including Mg/Ca, renal function, glucose, thyroid testing when indicated, troponin only if ischemia is suspected, echocardiography for structural heart disease, ambulatory monitoring for undocumented episodes, and EP study for recurrent/uncertain SVT.

Acute management of regular narrow-complex SVT

- ▶ **Stable patient:** monitor ECG and blood pressure, establish IV access, give oxygen only if hypoxemic, prepare defibrillator, and explain that transient AV block or flushing may occur with adenosine.
- ▶ **Vagal maneuvers** are first-line: modified Valsalva is preferred where feasible; carotid sinus massage may be used with continuous monitoring after excluding carotid bruit, recent stroke/TIA, and significant carotid disease. Do not use ocular pressure.
- ▶ **Adenosine** is the drug of choice for AV node-dependent PSVT:

Step	Dose and method	Key point
First bolus	6 mg rapid IV push followed immediately by saline flush	Use a large proximal vein; record rhythm strip
If no conversion	12 mg rapid IV push	May repeat 12 mg once if needed
Modified dosing	Consider lower initial dose, e.g. 3 mg, with central line, heart transplant, or dipyridamole	Methylxanthines antagonize effect

- ▶ Adenosine terminates most **AVNRT/orthodromic AVRT** and may only transiently slow atrial tachycardia/flutter, thereby revealing flutter waves or atrial P waves.
- ▶ If adenosine is ineffective/contraindicated and the rhythm is definitely narrow-complex without pre-excitation, use **IV diltiazem or verapamil** or an **IV beta-blocker** with BP monitoring.
- ▶ Avoid combining IV beta-blockers with verapamil/diltiazem because of hypotension, bradycardia, or AV block risk. Avoid nondihydropyridine calcium channel blockers in significant LV systolic dysfunction or decompensated heart failure.
- ▶ If drug therapy fails or the patient deteriorates at any step, proceed to **synchronized DC cardioversion**.

Management of unstable SVT and broad-complex presentations

- ▶ **Unstable SVT**: perform immediate **synchronized electrical cardioversion**; give sedation/analgesia if time permits, but do not delay cardioversion for shock, ischemia, pulmonary edema, or altered sensorium.
- ▶ For regular narrow-complex SVT, start with **50-100 J biphasic synchronized shock** and escalate if required. Reassess airway, BP, rhythm, and precipitating cause after conversion.
- ▶ **Regular wide-complex tachycardia** should be treated as VT unless SVT with aberrancy is certain. Adenosine may be diagnostic/therapeutic only in a regular monomorphic rhythm with no evidence of pre-excited AF or polymorphic VT.
- ▶ **Pre-excited AF** is an emergency clue: irregular wide QRS, very rapid ventricular rates, beat-to-beat QRS variation, and WPW features. Avoid adenosine, digoxin, beta-blockers, verapamil, and diltiazem because AV nodal block may accelerate accessory pathway conduction.
- ▶ For stable pre-excited AF or antidromic AVRT, specialist-directed rhythm control with **procainamide or ibutilide** may be used; if unstable, use synchronized cardioversion.
- ▶ Treat electrolyte abnormalities aggressively: correct hypokalemia and hypomagnesemia, stop pro-arrhythmic drugs, and manage ischemia, hypoxia, sepsis, or stimulant/drug toxicity.

Drug choices: indications and cautions

- ▶ **Adenosine:** very short acting; adverse effects are flushing, chest tightness, dyspnea, sense of doom, transient AV block, and rarely bronchospasm or AF. Use caution in asthma/COPD with active bronchospasm.
- ▶ **Verapamil/diltiazem:** useful for AV node-dependent SVT and rate control in atrial tachyarrhythmias without pre-excitation; avoid in hypotension, HFrEF/decompensated HF, wide-complex undiagnosed tachycardia, and pre-excited AF.
- ▶ **Beta-blockers:** useful acutely and chronically for AVNRT/AVRT suppression and adrenergic atrial tachycardia; avoid or use cautiously in severe bronchospasm, acute decompensated HF, marked bradycardia, and advanced AV block.
- ▶ **Class IC drugs** such as flecainide/propafenone may prevent recurrent SVT or AVRT in patients without structural or ischemic heart disease; they require specialist selection and usually AV nodal protection when atrial flutter risk exists.
- ▶ **Amiodarone, sotalol, dofetilide** are not routine first-line drugs for uncomplicated AVNRT; reserve for selected patients with structural heart disease, refractory arrhythmia, or when ablation is not possible, considering QT, renal, pulmonary, thyroid, hepatic, and drug-interaction risks.
- ▶ **Digoxin** has limited contemporary use for PSVT prevention and must be avoided in pre-excited AF; toxicity can itself cause atrial tachycardia with block.

Long-term and definitive management

- ▶ Explain benign prognosis in structurally normal hearts, teach **self-administered vagal maneuvers**, identify triggers, and advise documentation of future episodes by ECG/wearable strip when feasible.
- ▶ **Catheter ablation** is the definitive treatment for recurrent symptomatic AVNRT, AVRT/accessory pathway-mediated tachycardia, recurrent focal atrial tachycardia, incessant SVT, tachycardia-induced cardiomyopathy, high-risk occupation, or patient preference to avoid lifelong drugs.
- ▶ For AVNRT, slow-pathway modification is standard; success is high and recurrence is low, with a small but important risk of AV block requiring pacing.
- ▶ For AVRT/WPW, ablate the accessory pathway, especially with syncope, documented AVRT, pre-excited AF, high-risk pathway properties, multiple pathways, or competitive athletics/high-risk work.
- ▶ If ablation is deferred: use oral beta-blocker, verapamil, or diltiazem for recurrent AVNRT/orthodromic AVRT without pre-excitation during AF; consider class IC drugs only in carefully selected patients without structural heart disease.

- ▶ **Pregnancy:** vagal maneuvers and adenosine are preferred acutely; synchronized cardioversion is safe when unstable. Use beta-blockers or verapamil selectively for prevention; consider low/zero-fluoroscopy ablation only for refractory, poorly tolerated SVT.
- ▶ **MAT** management is treatment of the underlying illness: oxygenation, bronchodilator optimization without excess beta-agonist exposure, correction of K/Mg, treatment of infection or pulmonary disease; cardioversion and adenosine usually do not cure MAT.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Acute SVT algorithm flowchart:** stable/unstable split; unstable -> synchronized cardioversion; stable regular narrow QRS -> vagal maneuver -> adenosine 6 mg -> 12 mg -> calcium channel blocker/beta-blocker -> cardioversion/EP referral; side box: “avoid AV nodal blockers in pre-excited AF.”
- ▶ **Re-entry mechanism sketch:** AVNRT slow and fast AV nodal pathways with retrograde P wave; orthodromic AVRT circuit showing AV node antegrade limb and accessory pathway retrograde limb; label atrium, AV node, His-Purkinje system, ventricle, accessory pathway.

Clinical / Diagnostic significance

- ▶ A narrow regular tachycardia that terminates abruptly with adenosine strongly suggests **AV node-dependent re-entry**; transient slowing without termination suggests atrial tachycardia or flutter.
- ▶ P-wave position is diagnostically useful: short RP tachycardia suggests typical AVNRT/orthodromic AVRT; long RP tachycardia suggests atrial tachycardia, atypical AVNRT, or permanent junctional reciprocating tachycardia.
- ▶ Always obtain a sinus-rhythm ECG after conversion: delta wave and short PR identify WPW; QT prolongation, bundle branch block, ischemic changes, or Brugada pattern alter management.
- ▶ Recurrent incessant SVT may cause **tachycardia-induced cardiomyopathy**, which can improve after rhythm control or ablation.
- ▶ In older patients, SVT may present as falls, presyncope, angina, heart failure, or hypotension rather than palpitations.
- ▶ Troponin elevation can occur after prolonged tachycardia without plaque rupture; interpret in clinical context rather than labelling all cases acute coronary syndrome.

High-yield exam pointers

- ▶ Write the first line of management as **ABC, monitor, IV access, 12-lead ECG, assess hemodynamic stability**.
- ▶ **Unstable SVT = synchronized cardioversion**, not a prolonged drug trial.
- ▶ **Stable regular narrow SVT = vagal maneuver -> adenosine -> AV nodal blocker/cardioversion**.

- ▶ Adenosine dose: 6 mg rapid IV bolus, then 12 mg, then 12 mg with immediate flush and rhythm strip.
- ▶ Do not give AV nodal blockers in pre-excited AF: avoid adenosine, digoxin, beta-blocker, verapamil, and diltiazem.
- ▶ Treat broad-complex tachycardia as VT until proved otherwise.
- ▶ Definitive therapy for recurrent symptomatic AVNRT/AVRT is radiofrequency catheter ablation.
- ▶ Look for reversible triggers: hypoxia, ischemia, thyrotoxicosis, stimulants, alcohol, sepsis, hypokalemia, and hypomagnesemia.
- ▶ Draw the acute algorithm and the AVNRT/AVRT re-entry circuit; these diagrams score quickly in a 10-mark answer.

Narrow QRS Tachycardia

Asked in: Paper II Nov 2022 — RGUHS MD General Medicine

Definition / Introduction — A narrow QRS (narrow-complex) tachycardia is a heart rate >100 beats/min with a QRS duration <120 ms, reflecting normal ventricular activation over the His–Purkinje system. Because the impulse originates from, or is dependent on conduction through, the atrium or AV node, these are essentially supraventricular tachycardias (SVTs), and the QRS morphology is usually identical to that in sinus rhythm. Their importance lies in correct mechanistic identification at the bedside from a 12-lead ECG, as prognosis and treatment vary widely by mechanism.

Mechanistic Classification of Supraventricular Tachycardia (Table 253-1)

Group	Arrhythmia	Defining feature
Physiologic	Sinus tachycardia	Normal sinus mechanism driven by exertion, stress, stimulants, illness
Atrial origin	Inappropriate sinus tachycardia	Sinus-node-area tachycardia with no precipitant (dysfunctional autonomic regulation)
	Focal atrial tachycardia (AT)	Regular, defined P wave; foci at valve annuli, pulmonary veins, coronary sinus, SVC

Group	Arrhythmia	Defining feature
	Atrial flutter / macroreentrant AT	Macroreentry; sawtooth flutter waves, atrial rate typically >200/min
	Atrial fibrillation (AF)	Chaotic atrial activity, variable ventricular rate; commonest sustained arrhythmia in older adults
	Multifocal atrial tachycardia (MAT)	Multiple discrete P-wave morphologies; pulmonary disease exacerbations
AV node	AV nodal reentry tachycardia (AVNRT)	Paroxysmal regular; P at end of QRS or invisible; commonest PSVT in healthy young adults, women
Accessory pathway	Orthodromic AVRT	Paroxysmal regular; preexcitation (WPW) or concealed pathway
	Preexcited (antidromic AVRT, preexcited AF/flutter)	Wide QRS — exception to the narrow-QRS rule

- ▶ A useful three-way split by mechanism: **AV-nodal-dependent reentry** (AVNRT, AVRT), **macroreentry within atrium** (atrial flutter), and **focal AT** (automaticity or microreentry).
- ▶ Other supraventricular rhythms: premature atrial contractions (PACs), sinus arrhythmia, accelerated junctional rhythm, ectopic atrial rhythm.

Bedside Differential by ECG Pattern (Fig 253-1)

Obtain a full 12-lead ECG with a long rhythm strip and decide first whether the rhythm is **regular** or **irregular**.

ECG appearance	Likely diagnoses
Regular, 1:1 AV response	AVNRT, orthodromic AVRT, atrial tachycardia, rarely atrial flutter
Regular, AV block (more A's than V's)	Atrial flutter, atrial tachycardia, rarely AVNRT with 2:1 block below the His
Regular, VA block (more V's than A's)	Junctional tachycardia
Irregular	Atrial fibrillation, multifocal atrial tachycardia

Characteristic Features of Individual Narrow-QRS Tachycardias

- ▶ AVNRT — the most common PSVT (~60% of cases referred for ablation); manifests in the 2nd–4th decades, more often in women, usually with structurally normal hearts. Reentry uses dual AV nodal pathways within the **triangle of Koch** — a **slow pathway** (right inferior nodal extension)

and a **fast pathway**. Near-simultaneous atrial and ventricular activation places the P wave **at the end of the QRS**, producing a *pseudo-r'* in V1 and *pseudo-S waves* in II, III, aVF. Simultaneous atrial contraction against a closed tricuspid valve gives **cannon A waves** (“frog sign,” fluttering in the neck) and post-tachycardia diuresis via natriuretic peptide release.

- ▶ **Orthodromic AVRT** — the commonest tachycardia caused by an accessory pathway (AP); the wavefront travels **antegrade down the AV node/His–Purkinje system and retrograde up the AP**, so the QRS is **narrow** (or has fixed BBB). The P wave **always follows the QRS** (R-P shorter than P-R), inscribed in the ST segment. AV or VA block terminates it. The AP may be manifest (WPW: short PR <0.12 s, delta wave, wide QRS in sinus rhythm) or **concealed** (retrograde-only, normal sinus ECG).
- ▶ **Focal atrial tachycardia** — regular, with **discrete P waves separated by an isoelectric baseline**, distinct from sinus P; tachycardia can continue despite AV block (AV node not in the circuit).
- ▶ **Atrial flutter** — macroreentry giving **sawtooth flutter waves** (atrial rate typically >200/min, classically ~300/min); commonly conducts 2:1, yielding a regular ventricular rate near 150/min.
- ▶ **Atrial fibrillation** — **irregularly irregular**, no discrete P waves; the commonest sustained arrhythmia in older adults.
- ▶ **Multifocal atrial tachycardia** — irregular with **multiple (≥ 3) discrete P-wave morphologies**, seen in acute pulmonary insufficiency exacerbations.
- ▶ **Junctional (ectopic) tachycardia (JET)** — automaticity within the AV node; **narrow QRS often with VA block / AV dissociation**; rare in adults, more often incessant in children after congenital heart surgery. *Accelerated junctional rhythm* is a junctional automatic rhythm of 50–100/min.

Diagnostic and Therapeutic Effect of AV Nodal Blockade (Fig 253-2)

Vagal maneuvers, carotid sinus massage (CSM), or **adenosine** both **treat and diagnose** by transiently blocking the AV node while the ECG runs continuously.

Response to AV nodal blockade	Inference
No effect	Fascicular VT, or inadequate dose/effect
Tachycardia slows then resumes	Sinus tachycardia, junctional tachycardia
Tachycardia terminates	AVNRT, AVRT, adenosine-sensitive focal AT
Atrial activity continues with transient AV block	Atrial flutter, atrial tachycardia

- ▶ **Vagal maneuvers**: Valsalva (bearing down), modified Valsalva with leg-raise, diver’s reflex (cold-water face immersion), and CSM. CSM should be used cautiously or avoided if carotid bruits, prior stroke, or atherosclerosis risk (embolization).
- ▶ **Adenosine 6 mg, then 12 mg IV rapid push** causes transient AV block; it terminates AV-nodal-dependent SVT and unmasks AT/flutter. Note some focal ATs are adenosine-sensitive, so termination does not exclude AT.

Acute and Long-Term Management

- ▶ **Unstable** (hypotension with altered consciousness or respiratory distress): immediate **QRS-synchronous DC cardioversion** — rarely needed, as adenosine usually works promptly.
- ▶ **Stable PSVT (AVNRT / orthodromic AVRT)**: vagal maneuvers/CSM → IV adenosine → AV nodal blocking drugs (**beta blockers, verapamil or diltiazem**). Chronic options for recurrent episodes include these agents or **flecainide**; a single oral dose at onset (“pill-in-the-pocket”) can abort episodes.
- ▶ **Curative catheter ablation**: slow-pathway ablation for AVNRT is curative in >95%, with <1% risk of AV block needing a pacemaker; AP ablation efficacy ~95%, serious complications <3%, mortality <1 in 1000.
- ▶ **Focal AT**: correct precipitants; rate control with beta/calcium channel blockers; antiarrhythmics (flecainide, propafenone, sotalol, amiodarone) or ablation (>80% success) if recurrent/incessant (risk of tachycardia-induced cardiomyopathy).
- ▶ **Preexcited AF (CRITICAL)**: AV nodal blockers — adenosine, verapamil, diltiazem, beta blockers, IV amiodarone — are **CONTRAINDICATED**, as they can accelerate AP conduction and precipitate VF. Treat with DC cardioversion or IV procainamide / ibutilide. Shortest preexcited R-R <250 ms during AF signals high sudden-death risk.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Diagnostic flow-chart (Fig 253-1)**: Top box “Narrow-complex tachycardia → 12-lead ECG + long rhythm strip”; branch into **Regular** vs **Irregular**. Under Regular: **1:1 AV response** (AVNRT, ORT/AVRT, AT, rarely atrial flutter); **AV block, more A’s than V’s** (atrial flutter, atrial tachycardia, rarely AVNRT with 2:1 block); **VA block, more V’s than A’s** (junctional tachycardia). Under Irregular: **atrial fibrillation, multifocal atrial tachycardia**.
- ▶ **AVNRT circuit in the triangle of Koch**: label compact AV node (fast pathway), inferior nodal extension (slow pathway), His bundle, tricuspid valve, coronary sinus (CS), and arrows showing slow-pathway antegrade / fast-pathway retrograde reentry, with retrograde P wave at end of QRS (pseudo-r’ in V1).

Clinical / Diagnostic significance

- ▶ Symptoms: palpitations, chest pain, dyspnea, reduced exertional capacity, occasionally syncope; rarely cardiac arrest in WPW or hypertrophic cardiomyopathy.
- ▶ **Ventricular preexcitation on the resting ECG** points to AVRT via an accessory pathway; the diagnosis of SVT requires capturing an ECG during symptoms — increasingly via wearables/smartphone single-lead ECG.

- ▶ Accessory pathways occur in **1 in 1500–2000** people and associate with **Ebstein’s anomaly**, hypertrophic cardiomyopathy (**PRKAG2**), **Danon’s disease**, and **Fabry’s disease**. *Mahaim (atriofascicular) fibers* cause an LBBB-pattern wide-complex tachycardia.
- ▶ Most paroxysmal SVT occurs in structurally normal hearts; AF is the entity most often linked to structural/systemic heart disease, so initial evaluation should screen for it.

High-yield exam pointers

- ▶ **Narrow QRS** = QRS <120 ms = supraventricular origin; morphology usually identical to sinus rhythm.
- ▶ First branch point on the ECG is **regular vs irregular** — irregular narrow QRS = AF or MAT.
- ▶ AVNRT is the commonest PSVT; P at end of QRS → **pseudo-r’ in V1, pseudo-S in II/III/aVF; cannon A waves / frog sign**.
- ▶ **Orthodromic AVRT**: narrow QRS, P always follows QRS, R-P < P-R.
- ▶ **Adenosine 6 then 12 mg** — both diagnostic and therapeutic; terminates AVNRT/AVRT, unmasks flutter/AT.
- ▶ **Atrial flutter**: sawtooth waves, 2:1 conduction → ventricular rate ~150/min.
- ▶ **Preexcited AF**: **never give AV-nodal blockers** — use procainamide/ibutilide or DC shock.
- ▶ **Slow-pathway ablation cures AVNRT in >95%**, AV block needing pacemaker <1%.
- ▶ Unstable narrow-QRS tachycardia → **synchronized DC cardioversion**.

SOURCE & COVERAGE

Harrison 22e — Ch 253 “Approach to Supraventricular Arrhythmias” and Ch 256 “Paroxysmal Supraventricular Tachycardias” (with focal-AT management from the adjoining Ch 255 figure carried in the Ch 256 text file). **Coverage note:** The provided Ch 256 text ends mid-”Treatment of PSVT,” so the full acute drug algorithm beyond adenosine is truncated; specific IV doses of verapamil/diltiazem/beta blockers are not stated in the supplied text and are given here only as drug classes. The “~300/min” flutter rate and “≥3 P-wave morphologies” for MAT are universally accepted textbook standards added to the source’s “rate >200/min” and “multiple discrete P waves.”

Neurally mediated syncope

Asked in: Paper I May 2019 — RGUHS MD General Medicine

Definition / Introduction — Syncope is a transient, self-limited loss of consciousness (TLOC) due to acute *global* impairment of cerebral blood flow, with rapid onset, brief duration and spontaneous, complete recovery. **Neurally mediated syncope** (synonyms: *reflex, vasovagal, neurocardiogenic*

syncope) is the final common pathway of a complex central-and-peripheral reflex arc in which a transient change in autonomic efferent activity — increased parasympathetic (vagal) outflow plus sympathoinhibition — produces **bradycardia, vasodilatation and/or loss of vasoconstrictor tone**, leading to a fall in systemic blood pressure and cerebral hypoperfusion. It requires an *intact* autonomic nervous system (unlike syncope of autonomic failure) and is the single commonest cause of syncope in population-based studies.

Epidemiology and clinical importance

- ▶ Syncope accounts for **~3% of all emergency-department visits and ~1% of hospital admissions**; lifetime cumulative incidence is up to **40%** (CMDT: ~30% of adults faint at least once).
- ▶ **Bimodal age distribution** — first peak in the young (10–30 yr, median ~15 yr), where neurally mediated syncope dominates; a second sharp rise after age 70 (where orthostatic and cardiac causes climb). Incidence is higher in women; first-degree family history is common in young fainters.
- ▶ Prognosis of neurally mediated (and unexplained non-cardiac) syncope in the young is **excellent** — **life expectancy unaffected**; this contrasts sharply with cardiac syncope, which carries increased risk of sudden cardiac death.

Classification — placing neurally mediated syncope among the causes

Category	Mechanism	Key examples
A. Neurally mediated (reflex)	Transient reflex vasodilatation ± bradycardia; intact ANS	Vasovagal (common faint); situational; carotid sinus syndrome
B. Orthostatic hypotension	<i>Chronic</i> sympathetic vasoconstrictor (autonomic) failure	Synucleinopathies (PD, DLB, MSA/Shy-Drager, pure autonomic failure); diabetic/amyloid neuropathy; drug-induced; volume depletion
C. Cardiac	↓ Cardiac output from arrhythmia or structural disease	SND, AV block, VT/SVT, channelopathies; AS, HOCM, atrial myxoma, tamponade, PE

Sub-classification of neurally mediated syncope — by *afferent trigger* and by *efferent (haemodynamic) pattern*:

By afferent trigger	Provoking stimulus
Vasovagal syncope (common faint)	Fear, pain, intense emotion, sight of blood, prolonged motionless standing, heat, venepuncture
Situational reflex syncope	<i>Pulmonary</i> — cough, sneeze, wind-instrument/weight-lifter; <i>Urogenital</i> — post-micturition, instrumentation; <i>GI</i> — swallow,

By afferent trigger	Provoking stimulus
	defecation, glossopharyngeal neuralgia; <i>Cardiac</i> — Bezold–Jarisch reflex; <i>Ocular</i> — ocular pressure
Carotid sinus syndrome	Carotid sinus stimulation (tight collar, head-turning, shaving)
By efferent pattern	Dominant mechanism
Vasodepressor	Sympathetic vasoconstrictor <i>withdrawal</i> → hypotension predominates
Cardioinhibitory	Excess vagal tone → bradycardia/asystole predominates
Mixed	Both vagal and sympathetic reflex changes (most common)

Pathophysiology — the reflex arc

- ▶ **The orthostatic stress:** standing pools **500–1000 mL** of blood in the legs, buttocks and splanchnic bed, reducing venous return, ventricular filling, cardiac output and BP. Normally the **baroreflex** corrects this: unloading of carotid-sinus and aortic-arch baroreceptors → afferents via *glossopharyngeal (IX)* and *vagus (X)* nerves to the **nucleus tractus solitarius (NTS)** in the dorsomedial medulla → reduced vagal output to the sinus node (via *nucleus ambiguus*) and increased sympathetic outflow (via CVLM→RVLM disinhibition), restoring peripheral resistance and cardiac output.
- ▶ **In neurally mediated syncope this reflex paradoxically reverses.** The favoured model: reduced preload from venous pooling → vigorous contraction of a relatively *empty, catecholamine-stimulated* ventricle → activation of *unmyelinated ventricular mechanoreceptors (C-fibres)* in the atria, ventricles and pulmonary artery → afferents to the dorsal vagal nucleus → “**paradoxical**” **sympathetic withdrawal + surge in vagal tone** → vasodilatation and bradycardia (the **Bezold–Jarisch reflex**). The result mimics a “fictitious haemorrhage” to which the brainstem responds, paradoxically, by slowing/stopping the heart.
- ▶ Higher cortical centres also participate — emotion and the sight of blood can trigger fainting without preload reduction. Many situational faints additionally involve **hyperventilation** (hypocarbica → **cerebral vasoconstriction**) and **raised intrathoracic pressure** (↓ venous return).
- ▶ **Critical thresholds:** cessation of cerebral flow for **6–8 s**, a fall in systolic BP to **~50 mmHg**, or cerebral flow <25 mL/min/100 g causes loss of consciousness. Cerebral autoregulation normally holds flow constant over a perfusion pressure of **50–150 mmHg**.

Clinical features and recognition

- ▶ **Triphasic episode:** (1) *Prodrome (presyncope)* of autonomic activation — light-headedness, nausea, diaphoresis, pallor, warmth, palpitations, yawning, blurred/tunnel vision; (2) *transient LOC* with loss of postural tone; (3) *rapid, complete recovery* (no true post-ictal confusion).
- ▶ During the faint: eyes typically remain **open and deviate upward**, pupils dilated; brief **arrhythmic, multifocal myoclonic jerks** (<30 s) may simulate a seizure (“convulsive syncope”); urinary incontinence can occur but **faecal incontinence is very rare**.
- ▶ **Provocative/predisposing factors:** motionless upright posture, warm environment, volume depletion, alcohol, anaemia, hypoxaemia, pain, venepuncture, emotion.

Differentiating reflex syncope from its mimics

Feature	Neurally mediated syncope	Generalised seizure	Cardiac (arrhythmic) syncope
Posture/trigger	Usually upright; emotion, pain, heat	Any position; aura	Often exertional or supine; no trigger
Prodrome	Long autonomic prodrome (nausea, sweat, pallor)	Aura (e.g. unpleasant smell)	Brief/none (<5 s), sometimes palpitations
Movements	Brief, arrhythmic, multifocal myoclonus	Rhythmic tonic–clonic; tongue-biting	None typical
Recovery	Immediate re-orientation	Prolonged post-ictal confusion (>5 min)	Prompt but injury common
Colour	Pale	Cyanosed/flushed	Pale

Other mimics: **hypoglycaemia** (hunger, tremor, sweating — not features of syncope), **cataplexy** (consciousness preserved), **vertebrobasilar ischaemia**, and **psychogenic pseudosyncope** (frequent falls without haemodynamic change or injury).

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **The baroreflex / reflex arc (Fig. 23-1):** label — *carotid sinus & aortic-arch baroreceptors* → *glossopharyngeal (IX) and vagus (X) afferents* → *Nucleus Tractus Solitarius (NTS)* → *Nucleus Ambiguus* (→ *vagal/parasympathetic to sinus node*) and *CVLM* → *RVLM* (→ *sympathetic efferent to heart & vessels*); mark *ventricular C-fibre mechanoreceptors* → *dorsal vagal nucleus (Bezold–Jarisch limb)*. Annotate the efferent result: *vasodilatation + bradycardia* → *↓BP* → *cerebral hypoperfusion*.
- ▶ **Tilt-table tracing (Fig. 23-2):** two stacked curves over time on 70° head-up tilt — upper = *Heart Rate (bpm)*, lower = *Blood Pressure (mmHg)* — showing the **paroxysmal hypotensive–bradycardic response** of neurally mediated syncope; contrast with the *gradual BP fall without HR rise* of orthostatic hypotension.

Clinical / Diagnostic significance

- ▶ **Initial evaluation (the cornerstone, diagnostic in ~50%):** detailed history, eyewitness account ($\pm$ phone video), full cardiac/neurological exam, **supine and 3-min standing BP/HR**, and a 12-lead ECG. Screen for high-risk features mandating admission (Table 23-1): exertional/supine syncope, palpitations preceding syncope, structural/ischaemic heart disease, **QTc >500 ms**, bifascicular block/QRS ≥ 120 ms, *Brugada* pattern, persistent bradycardia, family history of sudden death.
- ▶ **Tilt-table test:** confirms susceptibility to neurally mediated syncope when the diagnosis is unclear (ACC/AHA/HRS Class IIa). Protocol — 20-min supine stabilisation, then head-up tilt at **60–80° (70° usual) for 30–45 min**; sensitised with **isoproterenol (1–3 $\mu\text{g}/\text{min}$ to raise HR ~25%)** or **sublingual nitroglycerin 300–400 μg** . Unmedicated specificity ~90%; it also classifies the response as cardioinhibitory, vasodepressor or mixed (VASIS types) and exposes psychogenic pseudosyncope (LOC with normal BP/HR).
- ▶ **Carotid sinus massage:** for patients >40 yr with recurrent unexplained syncope. Apply 5–10 s pressure below the angle of the jaw, supine and upright, under continuous ECG/BP. **Positive (carotid sinus hypersensitivity):** *cardioinhibitory* = asystole >3 s, or *vasodepressor* = SBP fall >50 mmHg, with reproduction of symptoms. **Avoid** with carotid bruit, plaque/stenosis or recent TIA/stroke.
- ▶ **Cardiac work-up only if indicated:** echocardiography (if structural disease suspected), ambulatory/Holter monitoring for frequent spells, **external or implantable loop recorder** for infrequent spells (monitor $\geq$ twice the inter-spell interval), exercise testing for exertional syncope, EP study only with structural heart disease. Routine bloods are low-yield.

Management (stepped; ACC/AHA/HRS 2017 & ESC 2018)

- ▶ **Foundation (all patients):** education and reassurance about the benign nature, recognition of prodrome, avoidance of triggers (heat, dehydration, alcohol, prolonged standing), and prompt **supine positioning** at symptom onset. Liberalise **salt and fluid**; acute ingestion of ~500 mL water aborts orthostatic intolerance.
- ▶ **Physical counterpressure manoeuvres (Class IIa):** leg-crossing, squatting, handgrip/arm-tensing and **abdominal + leg-muscle tensing** (most effective) raise central blood volume — most useful in those with a long prodrome (RCT-supported). *Tilt/standing training* is of uncertain benefit.
- ▶ **Pharmacotherapy (refractory cases):** **Midodrine** ($\alpha 1$ -agonist) is the *only* agent proven effective in multicentre RCTs (Class IIa; avoid in hypertension, HF, urinary retention). **Fludrocortisone** (volume expansion, Class IIb) and an **SSRI** may be tried; **β -blockers are generally ineffective** (no better than placebo in POST) except possibly age ≥ 42 yr (Class IIb). Withdraw offending hypotensive drugs.
- ▶ **Cardiac pacing — narrow indication:** *not* routinely beneficial (vasodepression dominates most faints). A **dual-chamber pacemaker with closed-loop stimulation** reduces recurrence only in

selected patients >40 yr with frequent syncope and a documented spontaneous/ tilt-induced cardioinhibitory (asystolic) response (SPAIN, ISSUE-3-type data; ESC Class IIa, ACC/AHA IIb).

- ▶ **Carotid sinus syndrome:** dual-chamber pacing for recurrent syncope with a dominant cardioinhibitory/mixed response (Class IIa).
- ▶ **Emerging: cardioneuroablation** (radiofrequency/cryo ablation of vagal ganglionated plexi) shows high freedom from syncope in cardioinhibitory VVS in small RCTs — still investigational.

High-yield exam pointers

- ▶ Triad of neurally mediated syncope mechanism: **vasodilatation + bradycardia + loss of vasoconstrictor tone** via vagal surge and sympathetic withdrawal — *requires an intact ANS*.
- ▶ **Bezold–Jarisch reflex** (ventricular C-fibre mechanoreceptors) underlies the “empty-ventricle” paradoxical faint.
- ▶ Efferent patterns: **vasodepressor / cardioinhibitory / mixed** — mixed is commonest; pacing helps *only* cardioinhibitory.
- ▶ Carotid sinus hypersensitivity numbers: **asystole >3 s** (cardioinhibitory), **SBP drop >50 mmHg** (vasodepressor).
- ▶ Tilt-table: **70°, 30–45 min**; isoproterenol or SL-GTN sensitisation; specificity ~90% unmedicated.
- ▶ **Midodrine** = only drug with RCT-proven benefit; **β-blockers don’t work** (POST).
- ▶ Critical thresholds: LOC after **6–8 s** of arrested flow or **SBP ~50 mmHg**; cerebral autoregulation **50–150 mmHg**.
- ▶ Distinguish from seizure: brief arrhythmic myoclonus, *immediate* recovery, no tongue-biting, no true post-ictal phase.
- ▶ Convulsive syncope, upward eye deviation and urinary incontinence do **not** equal epilepsy; faecal incontinence is very rare in syncope.

SOURCE & COVERAGE

- ▶ **Harrison’s Principles of Internal Medicine, 22e** — “Syncope” (Freeman & Raj): definition, classification, baroreflex/pathophysiology, neurally mediated subtypes, clinical features, evaluation and treatment.
- ▶ **Braunwald’s Heart Disease, 13e** — “Hypotension and Syncope”: Bezold–Jarisch/C-fibre mechanism, carotid sinus hypersensitivity criteria, tilt-table protocol and sensitisation, ACC/AHA/HRS treatment table, SPAIN trial, pacing and cardioneuroablation.
- ▶ **CMDT 2026** — “Disorders of Cardiac Rhythm” (Syncope): current diagnostic approach, counterpressure manoeuvres, midodrine/fludrocortisone/SSRI, pacing caveats, cardioneuroablation, driving restrictions.

- *Coverage note:* The named VASIS tilt-response typing is standard cardiology nomenclature; the corpus describes the underlying cardioinhibitory/vasodepressor/mixed responses but does not spell out the VASIS subtype letters.

Pathogenesis and Management of Congestive Cardiac Failure

Asked in: Paper II Nov 2020 — RGUHS MD General Medicine

Definition / Introduction — Heart failure (HF) is a complex clinical syndrome of symptoms and signs (breathlessness, fatigue, ankle swelling) arising from any structural or functional impairment of ventricular filling or ejection, leading to elevated intracardiac filling pressures and/or inadequate cardiac output at rest or on exertion. Because many patients lack overt volume overload, the *universal definition* prefers the term “heart failure” over the older “congestive cardiac failure,” requiring symptoms/signs **plus** corroboration by elevated natriuretic peptides **or** objective evidence of cardiogenic pulmonary/systemic congestion. It is the common final pathway of most chronic cardiovascular diseases; 5-year survival after diagnosis is only ~50%.

Aetiology, Phenotypes and Classification

- **Classification by ejection fraction (EF)** — drives therapy; roughly half of patients have reduced EF:
 - **HFrEF** (reduced; LVEF $\leq 40\%$) — coronary artery disease/MI, dilated/nonischaemic cardiomyopathy, valvular, toxic (alcohol, anthracyclines), peripartum, tachycardia-induced.
 - **HFmrEF** (mildly reduced; LVEF 41–49%) — intermediate; treated largely as HFrEF.
 - **HFpEF** (preserved; LVEF $\geq 50\%$) — hypertension, LVH, ageing, aortic stenosis, restrictive/infiltrative disease (amyloid, sarcoid, haemochromatosis), HCM.
 - **HFrecEF** (recovered EF) — e.g., fulminant myocarditis, stress/peripartum/tachycardia cardiomyopathy; better prognosis.
- **High-output failure** — anaemia (Hb ≤ 8 g/dL), thyrotoxicosis, beriberi, large AV fistula, Paget’s disease, cirrhosis; low SVR, usually unmasks underlying heart disease.
- **ACC/AHA stages (progressive, irreversible):** A at-risk (HTN, DM, no structural disease) → B structural disease/asymptomatic → C structural disease + current/prior symptoms → D refractory/advanced HF.
- **NYHA functional class (symptom-based, reversible):**

Class	Limitation	Clinical assessment
I	None	Ordinary activity causes no symptoms
II	Mild	Comfortable at rest; ordinary activity → dyspnoea/fatigue/palpitation/angina
III	Moderate	Comfortable at rest; <i>less than</i> ordinary activity → symptoms
IV	Severe	Symptoms at rest, worsened by any activity

Pathogenesis (Pathophysiology)

- ▶ **Index event and progressive remodelling** — HFrEF begins with an index injury (acute MI, chronic pressure/volume overload, genetic or congenital disease). Despite an initial fall in pump function patients stay asymptomatic for months–years because compensatory mechanisms are recruited; these same mechanisms ultimately become maladaptive and drive progression.
- ▶ **Patterns of ventricular remodelling** — *concentric hypertrophy* (pressure overload, e.g., hypertension, AS) reduces wall stress; *eccentric hypertrophy/dilatation* (volume overload, e.g., AR, MR). Accompanied by myocyte hypertrophy, interstitial/perivascular fibrosis, altered calcium-handling proteins, re-expression of fetal genes (β -myosin heavy chain), and myocyte necrosis/apoptosis/autophagy → increasing sphericity, papillary muscle displacement and secondary mitral regurgitation.
- ▶ **Compensatory (initially adaptive) responses:**
 - **Frank-Starling mechanism** — increased preload (end-diastolic volume) augments stroke volume; preload reserve is exhausted as the ventricle fails.
 - **Neurohormonal activation** — fall in cardiac output “unloads” arterial baroreceptors (LV, carotid sinus, aortic arch) → reduced parasympathetic and increased **sympathetic (SNS)** tone (resting plasma noradrenaline 2–3× normal, predicts mortality), and activation of the **renin-angiotensin-aldosterone system (RAAS)** with non-osmotic release of **arginine vasopressin**. Result: tachycardia, increased contractility, peripheral vasoconstriction, and renal salt/water retention to maintain blood pressure and preload.
- ▶ **Maladaptive consequences / vicious cycle** — sustained SNS/RAAS/AVP activation causes excessive afterload, volume overload, electrolyte disturbance, baroreceptor dysfunction, direct myocyte toxicity, fibrosis, arrhythmia and further remodelling — a self-perpetuating cycle. Counter-regulatory **natriuretic peptides (ANP, BNP)**, prostaglandins, bradykinin, adrenomedullin and nitric oxide oppose this but are eventually overwhelmed; **neprilysin** degrades natriuretic peptides and bradykinin (the rationale for ARNI).

- ▶ **Electrical dyssynchrony** — QRS prolongation/LBBB in up to one-third causes discoordinate contraction, worsening MR (basis for CRT).
- ▶ **Systemic / cardiorenal-abdominal interactions** — the **cardiorenal syndrome** reflects not only reduced forward renal perfusion but importantly **systemic venous congestion** and raised intra-abdominal pressure impeding renal venous return; splanchnic/hepatic congestion, gut wall oedema with endotoxaemia (LPS), and proinflammatory cytokines (TNF- α , IL-1, IL-6) promote progression and **cardiac cachexia**.

Clinical Features and Diagnosis

- ▶ **Symptoms of left HF (pulmonary congestion):** exertional dyspnoea → orthopnoea → paroxysmal nocturnal dyspnoea (“cardiac asthma”), bendopnoea, nocturnal cough; acute pulmonary oedema with pink frothy sputum.
- ▶ **Symptoms of right HF (systemic congestion):** weight gain, dependent oedema, abdominal bloating, anorexia, early satiety, RUQ pain (hepatic capsule stretch); anasarca in refractory disease. **Low-output symptoms:** fatigue, cool extremities, mental dullness, oliguria.
- ▶ **Signs:** tachycardia, narrow pulse pressure, *pulsus alternans*, raised JVP with hepatojugular/abdominojugular reflux, *Kussmaul’s sign*, bibasal crepitations, pleural effusion (right > left), displaced apex, **S3 gallop** (volume overload, poor prognosis), murmurs of functional MR/TR, tender pulsatile hepatomegaly, ascites, pitting oedema.
- ▶ **Investigations:** comprehensive metabolic panel, CBC, thyroid/iron studies (hyponatraemia and worsening renal function are adverse markers); ECG (ischaemia, LVH, LBBB, AF — present in up to 40%); **chest X-ray** (cardiothoracic ratio >0.5, upper-lobe diversion, interstitial/alveolar oedema, effusions); **2-D echocardiography with Doppler** is the key test (EF, chamber size, valves, diastolic function, pericardium); **BNP/NT-proBNP** support diagnosis and prognosis (falsely low in obesity; raised by age, female sex, CKD, AF, PE); CMR/PET, coronary angiography and endomyocardial biopsy for specific aetiologies.

Management of Chronic HFrEF — the Four Foundational Pillars (GDMT)

Stepwise, rapidly up-titrated **guideline-directed medical therapy (GDMT)** produces reverse remodelling and reduces mortality and hospitalisation. ACEI add ~23% mortality reduction; adding a beta blocker a further ~35%. Four pillars + adjuncts:

Pillar / drug class	Representative agent	Initiation → Target dose	Key point
RAAS inhibitor – ARNI (preferred)	Sacubitril-valsartan	100 mg bid → 200 mg bid	20% ↓ CV death/HF hosp vs enalapril (PARADIGM-HF); 36-h gap after ACEI (angioedema)

Pillar / drug class	Representative agent	Initiation → Target dose	Key point
ACE inhibitor (if ARNI not feasible)	Enalapril / Lisinopril	2.5 mg bid → 10–20 mg bid / 20–35 mg qd	Cough/angioedema
ARB (if ACEI-intolerant)	Candesartan / Valsartan	4–8 → 32 qd / 40 → 160 bid	—
Beta blocker (only 3 proven)	Carvedilol / Bisoprolol / Metoprolol succinate	3.125 bid → 25–50 bid / 1.25 → 10 qd / 12.5–25 → 200 qd	Start when euvoaemic; not for acute decompensation
MRA	Spironolactone / Eplerenone	12.5–25 → 25–50 qd / 25 → 50 qd	RALES; watch K ⁺ /renal function; eplerenone if gynaecomastia
SGLT-2 inhibitor	Dapagliflozin / Empagliflozin	10 mg qd	~25–26% ↓ events, with or without diabetes (DAPA-HF, EMPEROR-Reduced)

- ▶ **Loop diuretics** (furosemide, torsemide, bumetanide) for congestive symptoms — symptomatic only, no mortality benefit; minimise dose.
- ▶ **Hydralazine + isosorbide dinitrate** — for RAAS-intolerant patients and added in self-identified African-Americans on background therapy (A-HeFT).
- ▶ **Ivabradine** (If-channel inhibitor) — symptomatic HFrEF, **sinus rhythm**, **HR >70/min** on maximally tolerated beta blocker (SHIFT).
- ▶ **Vericiguat** (soluble guanylate cyclase stimulator) and **digoxin** (late-line, reduces hospitalisation, low dose) as adjuncts; **avoid** verapamil/diltiazem, NSAIDs, thiazolidinediones.
- ▶ **Device & surgical therapy**: ICD for primary prevention if NYHA II–III with LVEF ≤35% on GDMT (any aetiology), or post-MI LVEF ≤30% (not within 40 days of MI). CRT (biventricular pacing) when **QRS >149 ms with LBBB**. CABG for ischaemic cardiomyopathy with viable myocardium (STICH); transcatheter edge-to-edge mitral repair (COAPT) for severe secondary MR; LVAD/cardiac transplant for stage D.

Management of HFpEF/HFmrEF and Acute Decompensated HF

- ▶ **HFpEF/HFmrEF**: historically symptom-focused — control congestion with diuretics (avoid over-diuresis causing under-filling), tight blood-pressure control, maintain sinus rhythm/rate control in AF, treat ischaemia and comorbidities (obesity, OSA, CKD, anaemia/iron deficiency). **SGLT-2 inhibitors** (DELIVER, EMPEROR-Preserved) now reduce CV death/HF hospitalisation across EF >40% and are foundational; ARNI and GLP-1 agonists (obese HFpEF, e.g., semaglutide — STEP-HFpEF) confer selected benefit; spironolactone has a weak recommendation (TOPCAT).

- ▶ **Acute decompensated HF (ADHF):** identify precipitants (non-adherence, dietary salt, NSAIDs, ischaemia, arrhythmia, infection, PE). Phenotype-directed therapy: **IV loop diuretics** (bolus or infusion; low $\sim 1\times$ vs high $\sim 2.5\times$ home dose) $\pm$ sequential nephron blockade with metolazone/acetazolamide; **vasodilators** (nitroglycerin, nitroprusside) for hypertensive/pulmonary-oedema phenotypes with adequate BP; **inotropes** (dobutamine 2–20 $\mu\text{g/kg/min}$, milrinone 0.375–0.75 $\mu\text{g/kg/min}$, dopamine) only for low-output/cardiogenic-shock states as bridge or palliation; oxygen/non-invasive ventilation and opiates for flash pulmonary oedema; **mechanical circulatory support** (IABP, percutaneous VAD, ultrafiltration) for refractory shock. Initiate/continue GDMT before discharge (PIONEER-HF, EMPULSE) and arrange early follow-up with rapid up-titration (STRONG-HF).

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Neurohormonal vicious cycle of HF:** *Index myocardial injury* $\rightarrow$ $\downarrow$ Cardiac output $\rightarrow$ baroreceptor unloading $\rightarrow$ $\uparrow$ SNS + $\uparrow$ RAAS + $\uparrow$ vasopressin $\rightarrow$ vasoconstriction ($\uparrow$ afterload) + $\text{Na}^+/\text{H}_2\text{O}$ retention ($\uparrow$ preload) + $\uparrow$ heart rate/contractility $\rightarrow$ $\uparrow$ wall stress $\rightarrow$ ventricular remodelling (hypertrophy, dilatation, fibrosis, apoptosis) $\rightarrow$ further $\downarrow$ cardiac output. Label the counter-regulatory limb: *natriuretic peptides (ANP/BNP)* $\rightarrow$ vasodilation + natriuresis (inhibited by neprilysin).
- ▶ **GDMT “four pillars” schematic:** four columns labelled ARNI/ACEI/ARB, Beta blocker, MRA, SGLT-2 inhibitor, sitting on a base labelled loop diuretic (symptomatic), with add-ons (ivabradine, hydralazine-nitrate, vericiguat, digoxin) and devices (ICD, CRT) above.

Clinical / Diagnostic significance

- ▶ BNP/NT-proBNP aid diagnosis in undifferentiated dyspnoea and risk-stratify; a very low value helps exclude HF in non-obese patients.
- ▶ Echocardiographic EF is the single most important branch point separating HFrEF (GDMT-responsive) from HFpEF.
- ▶ S3 gallop, elevated JVP, hyponatraemia, worsening renal function and inability to tolerate neurohormonal antagonists are markers of advanced disease and poor prognosis.
- ▶ Recognising and correcting precipitating factors (Table of patient-, provider-, and disease-related triggers) prevents recurrent decompensation; residual congestion at discharge strongly predicts readmission.

High-yield exam pointers

- ▶ **Universal definition** = symptoms/signs **plus** raised natriuretic peptide **or** objective congestion; classify by EF (HFrEF $\leq 40\%$, HFmrEF 41–49%, HFpEF $\geq 50\%$).
- ▶ Distinguish ACC/AHA stages A–D (**irreversible**) from NYHA I–IV (**reversible**).

- ▶ Core pathogenesis = **maladaptive SNS + RAAS activation** driving remodelling — the target of all disease-modifying drugs.
- ▶ **Four pillars of HFrEF GDMT**: ARNI (or ACEI/ARB) + beta blocker + MRA + SGLT-2 inhibitor; rapid up-titration.
- ▶ Only **carvedilol, bisoprolol, metoprolol succinate** improve survival; sacubitril-valsartan needs a **36-h washout** after an ACEI.
- ▶ **Ivabradine** = sinus rhythm + HR >70 on beta blocker; **digoxin/diuretics** = symptom relief, no mortality benefit.
- ▶ **ICD** if LVEF ≤35% (NYHA II–III) or post-MI LVEF ≤30%; **CRT** if QRS >149 ms with LBBB.
- ▶ **SGLT-2 inhibitors** now benefit across the whole EF spectrum, including HFpEF.
- ▶ In ADHF: treat precipitant, IV loop diuretic for decongestion, vasodilators if BP adequate, inotropes only for low-output/shock.

Pericarditis

Asked in: Paper IV May 2019 — RGUHS MD General Medicine

Definition / Introduction — Pericarditis is inflammation of the pericardium, the double-layered fibroserous sac (visceral + parietal layers separated by 15–50 mL of plasma ultrafiltrate) that envelops the heart. It is the commonest pathological process affecting the pericardium and presents as a spectrum of overlapping syndromes — **acute pericarditis, pericardial effusion and cardiac tamponade, recurrent/incessant pericarditis, constrictive pericarditis** and **effusive–constrictive pericarditis**. Most acute cases in developed regions are viral or idiopathic and self-limiting, whereas in India/sub-Saharan Africa **tuberculosis** remains a leading cause and a major driver of constriction.

Classification (Harrison) and Aetiology

- ▶ **Clinical (by duration)**: Acute (<6 weeks; fibrinous or effusive) → Subacute (6 weeks–6 months; effusive-constrictive or constrictive) → Chronic (>6 months; constrictive or adhesive).

- ▶ **Infectious:** *Viral* (coxsackie A/B, echovirus, herpesviruses, mumps, adenovirus, HIV, post-COVID), *pyogenic/purulent* (pneumococcus, Staphylococcus, Streptococcus, Neisseria), *tuberculous, fungal* (histoplasma, coccidioides, Candida).
- ▶ **Non-infectious:** acute idiopathic, *uraemic/dialysis-associated, neoplastic* (lung, breast, lymphoma, leukaemia, mesothelioma), trauma, aortic dissection leaking into the sac, acute MI, post-irradiation, myxoedema, familial (*Mulibrey nanism* — autosomal recessive growth failure with constrictive pericarditis), familial Mediterranean fever.
- ▶ **Autoimmune / hypersensitivity:** rheumatic fever, SLE, rheumatoid arthritis, scleroderma, granulomatosis with polyangiitis, IgG4 disease; drug-induced (procainamide, hydralazine, isoniazid, phenytoin, minoxidil); **post-cardiac-injury syndromes** — postpericardiotomy, post-traumatic, and post-MI (*Dressler's syndrome*).

Acute Pericarditis — Clinical Features & Diagnosis

- ▶ **Four cardinal diagnostic features (Harrison):**
- ▶ **Chest pain** — retrosternal/left precordial, often pleuritic (sharp, worse on inspiration/coughing), radiating to the **trapezius ridge** (near-pathognomonic), classically *aggravated by lying supine and relieved by sitting up and leaning forward*. Pain is often absent in tuberculous, uraemic, neoplastic and post-irradiation forms.
- ▶ **Pericardial friction rub** — heard in ~85%; rasping/scratching, up to three components/cycle (atrial systole, ventricular systole, early diastole), best at end-expiration, patient upright and leaning forward.
- ▶ **ECG — evolves through four stages:** *Stage 1* — diffuse upwardly-concave ST elevation (limb leads + V2–V6) with reciprocal ST depression only in aVR ($\pm$ V1), plus **PR-segment depression** (atrial injury current, an early/specific sign); *Stage 2* — ST returns to baseline; *Stage 3* — diffuse T-wave inversion; *Stage 4* — normalisation. Contrast with AMI (convex/"tombstone" ST, regional, prominent reciprocal change, evolving over hours).
- ▶ **Pericardial effusion** — may cause muffled sounds, **electrical alternans**, *Ewart's sign* (dullness/bronchial breathing below the left scapula from lung compression) and a "water-bottle" cardiac silhouette on chest X-ray.
- ▶ **ESC 2015 diagnostic criteria (Braunwald):** at least **two of four** — (1) characteristic chest pain, (2) friction rub, (3) typical ECG changes (ST elevation/PR depression), (4) new/worsening pericardial effusion. Supported by raised **CRP**, leucocytosis and CMR evidence of pericardial inflammation (late gadolinium enhancement).
- ▶ **Investigations:** ECG, CBC with differential, **CRP/hsCRP** (tracks activity and guides treatment duration), **cardiac troponin** (modest rise indicates *myopericarditis* — concomitant epicardial myocarditis, seen in up to 15%), chest radiograph and **echocardiography** (first-line imaging).

CT/CMR are superior for loculated effusions, pericardial thickening, masses and active inflammation.

Cardiac Tamponade

- ▶ Accumulation of pericardial fluid sufficient to obstruct ventricular inflow — a medical emergency. As little as **200 mL** causes tamponade if rapid, versus **>2000 mL** if slowly accumulating (pericardium stretches).
- ▶ **Beck's triad**: hypotension, soft/absent heart sounds, and raised JVP with a **prominent x descent** and **absent y descent**.
- ▶ **Pulsus paradoxus**: inspiratory fall in systolic BP **>10 mmHg** — due to inspiratory RV filling bulging the septum leftward (ventricular interdependence), reducing LV stroke volume. Also seen in severe asthma/COPD, PE and $\sim\frac{1}{3}$ of constrictive cases.
- ▶ **Echo**: late-diastolic **RA and RV free-wall collapse**, dilated non-collapsing IVC, exaggerated respiratory variation in mitral/tricuspid inflow (“swinging heart” with electrical alternans).
- ▶ **Treatment**: urgent **pericardiocentesis** (echo-guided **subxiphoid** approach most common; apical/parasternal alternatives), draining the sac as completely as possible with a temporary catheter left for 2–3 days; IV saline as a temporising measure. **Anticoagulants are avoided**. Surgical/open drainage for loculated, malignant or recurrent effusions and when biopsy is needed.

Constrictive Pericarditis

- ▶ A rigid, fibrotic, often calcified pericardium encasing the heart, limiting diastolic filling. Worldwide TB is a major cause; in the West it follows viral/idiopathic pericarditis, cardiac surgery, mediastinal irradiation, connective-tissue disease and uraemia. Risk is **<1% after viral/idiopathic**, **2–5% after immune/neoplastic**, and **20–30% after purulent bacterial** pericarditis.
- ▶ **Pathophysiology**: filling is unimpeded in early diastole then halts abruptly at the elastic limit of the pericardium → **“dip-and-plateau”/square-root sign** and **equalisation of diastolic pressures** in all four chambers (within ~ 5 mmHg). Loss of transmission of intrathoracic pressure to the heart produces enhanced ventricular interdependence.
- ▶ **Clinical (right-heart congestion dominates)**: raised JVP with **prominent y descent** (M-/W-shaped venous wave), **Kussmaul's sign** (JVP fails to fall / rises with inspiration), **pericardial knock** (early S3 from abrupt halt of filling), hepatomegaly, ascites out of proportion to oedema, and **Broadbent's sign** (systolic apical retraction). Pulsus paradoxus is usually absent; AF in $\sim\frac{1}{3}$.
- ▶ **Investigations**: ECG — low voltage, T-wave flattening; CXR — **pericardial calcification** (commonest in TB); echo/Doppler — septal bounce, **$\geq 25\%$ inspiratory increase in mitral E velocity**, expiratory hepatic-vein diastolic flow reversal; tissue Doppler — preserved/increased medial mitral annular e' (**>8 cm/s**) with lateral e' lower than medial (*annulus reversus).

CT/CMR* confirm pericardial thickening (≥ 3 –4 mm). Catheterisation shows discordant RV/LV systolic pressures with respiration.

- **Treatment:** diuretics for symptom control; **pericardiectomy (complete pericardial resection)** is the only definitive therapy (operative mortality ~5–15%, highest after radiation).

Transient/reversible constriction (esp. post-cardiac-surgery, raised CRP, CMR enhancement) may respond to anti-inflammatory therapy. *Effusive-constrictive pericarditis* — constrictive physiology persists after fluid removal; needs wide visceral + parietal resection.

Constrictive Pericarditis vs Cardiac Tamponade vs Restrictive Cardiomyopathy

Feature	Tamponade	Constrictive pericarditis	Restrictive cardiomyopathy
Pulsus paradoxus	+++	+ ($\approx 1/3$)	+
JVP — prominent y descent	Absent	+++ (M/W wave)	+
JVP — prominent x descent	+++	++	+++
Kussmaul's sign	–	+++	+
Pericardial knock	–	++	–
Third heart sound (S3)	–	–	+
Pericardial effusion	+++	–	–
Pericardial calcification/thickening	–	++/+++	–
Equalisation of diastolic pressures	+++	+++	–

Treatment of Acute & Recurrent Pericarditis

- **First-line** — NSAID + colchicine (Harrison/ESC/CMDT):
 - Aspirin 750–1000 mg every 8 h for 1–2 weeks (or 2–4 g/day), then taper; or ibuprofen 600–800 mg tid; or indomethacin 25–50 mg tid — with gastroprotection (PPI).
 - Colchicine 0.5–0.6 mg once daily (<70 kg) or twice daily (>70 kg) for 3 months (≥ 6 months for recurrence) — halves recurrence and hastens symptom resolution.
- **Corticosteroids** (e.g. prednisone 0.25–0.5 mg/kg/day, slow taper) reserved for NSAID/colchicine failure or intolerance, autoimmune aetiology, renal failure or pregnancy — they **increase recurrence**, so used at low dose with concurrent colchicine.

- ▶ **Refractory/recurrent disease: IL-1 antagonists** — *anakinra* (IL-1 receptor antagonist) and *rilonacept* (IL-1 trap; FDA-approved after the RHAPSODY trial) — are highly effective steroid-sparing agents; azathioprine and IVIG are alternatives; pericardial stripping is a last resort.
- ▶ **Specific causes:** *Dressler's/post-MI* — prefer **aspirin + colchicine** (NSAIDs/steroids may impair myocardial healing); *uraemic* — intensify dialysis ± NSAID; *purulent* — drainage + IV antibiotics; *neoplastic* — drainage/pericardial window ± sclerotherapy; *tuberculous* — RIPE for 2 months then isoniazid + rifampicin to complete 6 months, with pericardiectomy if constriction develops.
- ▶ **High-risk features warranting admission (ESC):** *major* — fever >38 °C, subacute onset, large effusion, tamponade, failure to respond to NSAID/aspirin after a week; *minor* — myopericarditis, immunosuppression, trauma, oral anticoagulation. Recurrence affects ~15–30%.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **ECG evolution of acute pericarditis (4 stages):** lead strip showing — *Stage 1* diffuse concave ST elevation + PR depression (with reciprocal ST depression/PR elevation in aVR); *Stage 2* normalisation of ST; *Stage 3 T-wave inversion*; *Stage 4* normal. Label “diffuse concave ST↑”, “PR depression”, “aVR reciprocal change”.
- ▶ **JVP waveform comparison:** tamponade — prominent x, absent y descent; constriction — prominent x and y (M/W shape) with Kussmaul's sign. Label a, c, v waves and x, y descents.

Clinical / Diagnostic significance

- ▶ Differentiating acute pericarditis from STEMI is the highest-yield bedside skill: pericarditis shows *diffuse concave* ST elevation with PR depression and only modest troponin rise, versus regional convex ST elevation with marked enzyme rise in MI.
- ▶ A troponin rise signals **myopericarditis**; LV dysfunction is rare and the long-term prognosis is excellent, but it alters activity restriction and avoids over-aggressive anticoagulation.
- ▶ **CRP/hsCRP** is central — it confirms inflammation, monitors response, and guides duration of therapy (taper once CRP normalises).
- ▶ Constrictive pericarditis is a **surgically curable** cause of right heart failure — must be distinguished from cirrhosis (inspect the neck veins) and from restrictive cardiomyopathy (annulus reversus, septal bounce, equalised pressures).
- ▶ TB pericarditis: pericardial fluid **adenosine deaminase (ADA)** elevation and TB-PCR support the diagnosis; biopsy is often required; early anti-TB therapy prevents constriction.

High-yield exam pointers

- ▶ ESC 2015: diagnose acute pericarditis with ≥2 of 4 (pain, rub, ECG ST↑/PR↓, effusion).

- ▶ Friction rub present in ~85%; up to **three components** per cycle.
- ▶ **PR-segment depression** is an early, fairly specific ECG sign; ST elevation is diffuse and concave.
- ▶ **Beck's triad** = hypotension + muffled heart sounds + raised JVP; tamponade JVP has **absent y descent**.
- ▶ **Pulsus paradoxus** >10 mmHg; rapid effusions of only ~200 mL can tamponade.
- ▶ Constriction: **square-root sign**, **Kussmaul's sign**, **pericardial knock**, calcified pericardium (commonest in TB); pericardiectomy is curative.
- ▶ First-line therapy is NSAID/aspirin + **colchicine** ×3 months; colchicine halves recurrence; steroids increase it.
- ▶ **Dressler's syndrome** — weeks post-MI; treat with **aspirin + colchicine**, not NSAIDs/steroids.
- ▶ Recurrent pericarditis — escalate to **IL-1 blockers** (**anakinra**, **rilonacept**).

SOURCE & COVERAGE

- ▶ **Harrison's Principles of Internal Medicine, 22e** — “Pericardial Disease” (classification, four cardinal features, four-stage ECG, Beck's triad, pulsus paradoxus, tamponade, constrictive pericarditis, Table distinguishing tamponade vs constriction vs restriction, treatment doses, tuberculous pericarditis).
- ▶ **Braunwald's Heart Disease, 13e** — “Pericardial Diseases” (ESC 2015 diagnostic criteria, high-risk triage features, myopericarditis, recurrence definition, IL-1 antagonists/RHAPSODY, echo-Doppler differentiation — annulus reversus, septal bounce, 25% mitral E variation, RA/RV collapse timing, effusive-constrictive physiology, TB regimen).
- ▶ **CMDT 2026** — “Acute Inflammatory Pericarditis / Pericardial Effusion / Constrictive Pericarditis” (aspirin/ibuprofen/colchicine dosing and tapering, Dressler management, constriction incidence by aetiology, pericardiectomy outcomes, hemodynamic criteria).

QT Interval Prolongation and Torsades de Pointes

Asked in: Paper II Nov 2021 — RGUHS MD General Medicine

Definition / Introduction — The **QT interval** on the surface ECG subtends both ventricular depolarization and (chiefly) ventricular **repolarization**, and it varies *inversely* with heart rate. Because it is rate-dependent, it is reported as the rate-corrected QT (**QTc**). *Torsades de pointes* (“twisting of the points”) is the characteristic **polymorphic ventricular tachycardia** (VT) that complicates an abnormally prolonged QT interval; the QRS axis appears to twist around the isoelectric baseline. It typically presents with near-syncope, syncope or cardiac arrest, and sustained episodes may degenerate into **ventricular fibrillation** (VF).

Electrophysiology and QT/QTc measurement

- ▶ The QT interval is measured from the onset of the QRS to the end of the T wave; it reflects ventricular action-potential duration, governed mainly by repolarizing **potassium currents** (I_{Kr} , I_{Ks}).
- ▶ Because QT shortens as heart rate rises, it must be **rate-corrected** to QTc. No single formula has formal consensus:
 - **Bazett (“square root”) formula:** $QTc = QT / \sqrt{RR}$ (in seconds) — the classic method, but criticized for systematic over-/under-correction at very low and very high heart rates.
 - **Framingham formula:** $QTc = QT + 0.154 \times (1000 - RR)$ (in milliseconds) — a linear alternative.
- ▶ **Upper normal limits** (Harrison 22e, Ch 247): QTc **450 ms in men** and **460 ms in women**; lower limits are less well defined. In congenital LQTS the QTc is typically prolonged to **>440 ms in men** and **>460 ms in women** (Ch 262).
- ▶ **Prominent U waves** (a small rounded deflection following the T wave) accompanying prolonged repolarization are a recognized marker of *increased susceptibility to torsades*; abnormally large U waves are most often due to hypokalemia or drugs (dofetilide, amiodarone, sotalol, quinidine).

Mechanism of torsades de pointes

- ▶ The fundamental abnormality is **prolonged ventricular repolarization** with **abnormal transmural dispersion of repolarization**, which can arise from channelopathies, drugs or electrolyte disturbance even *without* structural heart disease.
- ▶ Torsades has a characteristic **pause-dependent initiation**: a premature ventricular contraction (PVC) induces a pause, the post-pause sinus beat shows a still-longer QT, and a subsequent PVC falling on the prolonged T wave initiates the polymorphic VT — the classic “**long-short**” **interval sequence** (Fig. 262-1).
- ▶ Drugs that **block repolarizing potassium currents** (notably the antiarrhythmics sotalol, dofetilide and ibutilide, and many non-cardiac agents) prolong the action potential and predispose to this arrhythmia. Individual susceptibility may reflect genetic polymorphisms or mutations affecting repolarization.

Classification / Causes of QT prolongation and torsades (Table 262-1)

Category	Examples
1. Congenital long QT syndromes	LQTS-1, LQTS-2, LQTS-3 (account for 80–90% of cases) and other rarer types
2. Electrolyte abnormalities	Hypokalemia, hypomagnesemia, hypocalcemia
3. Drug-induced (acquired)	Antiarrhythmics, antibiotics, antipsychotics, antihistamines, others (see drug table)

Category	Examples
4. Cardiac conditions	Myocardial ischemia/infarction, myocarditis, marked bradycardia , stress (takotsubo) cardiomyopathy
5. Endocrine disorders	Hypothyroidism, hyperparathyroidism, pheochromocytoma, hyperaldosteronism
6. Intracranial disorders	Subarachnoid hemorrhage, thalamic hematoma, cerebrovascular accident, encephalitis, head injury
7. Nutritional disorders	Anorexia nervosa, starvation, liquid-protein diets, gastroplasty/ileojejunal bypass, celiac disease

- *Acquired LQTS* (drug- and electrolyte-related) is by far the commonest clinical setting; **drug interactions** that raise the level of an offending agent are a frequent precipitant.

Drugs that prolong the QT interval (Table 262-1)

Drug class	Agents
Antiarrhythmics — Class IA	Quinidine, disopyramide, procainamide
Antiarrhythmics — Class III	Sotalol, dofetilide, ibutilide, amiodarone, dronedarone, ranolazine
Macrolide antibiotics	Erythromycin, clarithromycin, azithromycin
Fluoroquinolones	Levofloxacin, moxifloxacin
Other antimicrobials	Trimethoprim-sulfamethoxazole, clindamycin, pentamidine , chloroquine/hydroxychloroquine ; antifungals (ketoconazole, itraconazole); antivirals (amantadine)
Antipsychotics	Haloperidol, phenothiazines, thioridazine, trifluoperazine, sertindole, ziprasidone
Antidepressants	Tricyclic and tetracyclic agents
Antihistamines (H1)	Astemizole, diphenhydramine, hydroxyzine
Others	Methadone , cocaine, citrate (massive transfusion)

- The website crediblemeds.org is an authoritative resource to check whether a given drug is reported to prolong the QT interval.

Congenital long QT syndrome (LQTS)

- Caused by **mutations in genes encoding cardiac ion channels** controlling repolarization. LQTS-1, -2 and -3 account for **80–90%** of cases; the commonest (LQTS-1, -2) involve potassium channels, while LQTS-3 affects the sodium channel.

Type	Channel / current defect	Gene	Typical trigger of events
LQTS-1	Reduced repolarizing I _{Ks}	KCNQ1	Exertion, particularly swimming
LQTS-2	Reduced repolarizing I _{Kr}	KCNH2	Sudden auditory stimuli / emotional upset
LQTS-3	Delayed inactivation of I _{Na}	SCN5A	Sudden death tends to occur during sleep

- ▶ Typical presentation is **syncope or cardiac arrest, usually in childhood**; asymptomatic cases are found on family screening or routine ECG. **Genotyping** aids family screening and prognostication.
- ▶ *Markers of increased risk:* QTc >500 ms, female gender, and a history of syncope or cardiac arrest.
- ▶ *Related repolarization channelopathies (for completeness):* **Short QT syndrome** (QTc <360 ms, usually <300 ms; gain-of-function K-channel), **Brugada syndrome** (SCN5A, coved ST elevation V1–V3), and **catecholaminergic polymorphic VT** (RyR2/calsequestrin-2 mutations; bidirectional VT).

Management

- ▶ **Acute torsades / acquired LQTS:**
 - **IV magnesium sulphate 1–2 g** usually suppresses recurrent episodes (first-line, even if serum magnesium is normal).
 - If magnesium is ineffective, **increase heart rate** with an **isoproterenol infusion or temporary pacing to ~100–120 beats/min** to suppress PVCs and shorten the QT (abolishes the pause-dependent trigger).
 - **Correct hypokalemia, hypomagnesemia and hypocalcemia, treat bradycardia, and withdraw all offending QT-prolonging drugs.**
 - Sustained episodes degenerating to VF **require defibrillation per ACLS**. Such patients have a demonstrated susceptibility and must **avoid all future QT-prolonging drugs**.
- ▶ **Congenital LQTS:**
 - Adequate-dose **β-blockade is the cornerstone** for LQTS-1 and LQTS-2; the **non-selective agents nadolol and propranolol are favored**.
 - **Avoidance of QT-prolonging drugs** is critical for *all* patients, including genotype-positive patients with a normal QT.
 - An **implantable cardioverter-defibrillator (ICD)** is considered for recurrent syncope despite β-blockers or for a high-risk profile (e.g., prior cardiac arrest, QTc >500 ms).

- **Left cardiac sympathetic denervation** is a recognized adjunct for refractory cases (described under CPVT in the source).
- ▶ **Ischemia-related polymorphic VT:** prompt **myocardial reperfusion**, β -adrenergic blockade and correction of electrolytes; persistent severe LV dysfunction (LVEF <35%) is an ICD indication.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Diagram 1 — Torsades de pointes (rhythm strip, after Fig. 262-1).** Draw a sinusoidal polymorphic VT whose QRS amplitude waxes and wanes (“twisting around the baseline”). Labels: *Sinus beat with long QT, PVC, compensatory pause (long RR), PVC initiating VT, “long-short” interval sequence, pause-dependent initiation, polymorphic VT (torsades).*
- ▶ **Diagram 2 — QT interval on a normal complex.** Draw P-QRS-T-U. Labels: *QRS onset (start of QT), ST segment, T wave (end of QT), U wave, RR interval, and annotate QTc = $QT/\sqrt{RR}$ (Bazett); mark hypocalcemia $\rightarrow$ long ST/QT vs hypercalcemia $\rightarrow$ short QT.*

Clinical / Diagnostic significance

- ▶ **ECG is the key investigation:** measure QT and compute QTc; look for prominent U waves, marked T-wave abnormalities and pause-dependent ectopy. Telemetry/Holter captures self-limiting runs of torsades.
- ▶ **Metabolic/secondary clues:** **hypocalcemia** prolongs the QT (ST-segment portion) whereas **hypercalcemia** shortens it; **hypothermia** prolongs repolarization with an **Osborn (J) wave**; **subarachnoid hemorrhage** produces marked QT prolongation with deep, wide T-wave inversions (“CVA T-wave” pattern); digitalis *shortens* the QT with “scooped” ST-T.
- ▶ **Workup:** serum **potassium, magnesium, calcium**, thyroid function, a full drug review (including interactions), and ECG screening of first-degree relatives when congenital LQTS is suspected; consider **genotyping**.
- ▶ **Management pearls:** withdraw the culprit drug and correct electrolytes early; magnesium first, then rate support; do not give further QT-prolonging agents to a susceptible patient.

High-yield exam pointers

- ▶ QT subtends ventricular repolarization and varies **inversely with heart rate**; report QTc — Bazett $QT/\sqrt{RR}$ or Framingham.
- ▶ Upper normal QTc 450 ms (men) / 460 ms (women); QTc >500 ms is a high-risk marker for torsades.
- ▶ Torsades is **pause-dependent** with a “long-short” initiating sequence; **prominent U waves** flag susceptibility.
- ▶ Commonest cause clinically is **acquired** — *drugs + electrolyte disturbance (hypokalemia, hypomagnesemia, hypocalcemia) + bradycardia.*

- ▶ Memorize culprit drugs: Class IA & III antiarrhythmics, macrolides, fluoroquinolones, antipsychotics (haloperidol), methadone, pentamidine, antifungals; check crediblemeds.org.
- ▶ Acute treatment = IV magnesium 1–2 g → isoproterenol/pacing to 100–120/min → correct electrolytes/bradycardia → stop the drug → defibrillate if VF.
- ▶ Congenital LQTS triad: LQTS-1 (KCNQ1, I_{Ks}, exercise/swimming); LQTS-2 (KCNH2, I_{Kr}, auditory/emotion); LQTS-3 (SCN5A, I_{Na}, sleep) — together 80–90% of cases.
- ▶ Congenital LQTS treatment: β -blockers (nadolol/propranolol), avoid QT-prolonging drugs, ICD for high-risk/refractory cases.

SOURCE & COVERAGE

Harrison 22e — Ch 262 “Polymorphic Ventricular Tachycardia and Ventricular Fibrillation” (acquired & congenital LQTS, Table 262-1 causes/drug list, mechanism, management) and Ch 247 “Electrocardiography” (QT/QTc measurement, Bazett/Framingham formulas, normal limits, U waves, electrolyte/drug repolarization changes). *Coverage note:* the underlying cellular mechanism of torsades — **early afterdepolarizations (EADs)** triggering R-on-T — is universally accepted textbook electrophysiology but is not named explicitly in these two chapters; the source describes it functionally as pause-dependent, dispersion-of-repolarization-mediated initiation. **Left cardiac sympathetic denervation** is cited in the source under catecholaminergic polymorphic VT rather than directly under LQTS.

Stroke Prevention in Atrial Fibrillation

Asked in: Paper II May 2019 — RGUHS MD General Medicine

Definition / Introduction — Atrial fibrillation (AF) is the commonest sustained arrhythmia and the single most important cardiac cause of ischaemic stroke. Loss of organised atrial mechanical contraction produces blood stasis and *in situ* thrombosis, predominantly in the **left atrial appendage (LAA)**, which on embolisation causes cardio-embolic stroke and systemic thromboembolism. Because such strokes are large, disabling and often fatal, **antithrombotic prophylaxis guided by validated risk scores is the cornerstone of AF management** and is one of the three therapeutic aims (the others being symptom/rate–rhythm control and risk-factor modification). The decision balances the patient’s **stroke risk** against the **bleeding risk** of anticoagulation.

Pathophysiology of thromboembolism in AF

- ▶ Loss of atrial systole → **stasis of blood**, particularly in the trabeculated **left atrial appendage**, where ~90% of AF-related thrombi form; thrombus may also form in a severely dilated left atrium in mitral valve disease.

- ▶ **Virchow's triad** is satisfied: stasis, endothelial/endocardial dysfunction, and a prothrombotic/hypercoagulable milieu.
- ▶ Embolised thrombus reaches the cerebral circulation → large-vessel ischaemic stroke; recurrent silent emboli contribute to **cognitive impairment and dementia**.
- ▶ **Atrial stunning** — after conversion (spontaneous, electrical or pharmacological) from prolonged AF to sinus rhythm, atrial mechanical recovery is delayed for weeks, so thrombus can form and embolise *even after* sinus rhythm is restored. This underlies peri-cardioversion anticoagulation rules.
- ▶ AF burden (“paroxysmal” vs “persistent”) was traditionally thought not to predict stroke; hence the approach to **paroxysmal AF is the same as for persistent AF**. Asymptomatic episodes are common, so absence of AF on intermittent monitoring does not equal low risk.

Risk stratification — CHA₂DS₂-VASc and bleeding scores

The CHA₂DS₂-VASc score (max 9) estimates annual stroke risk; the HAS-BLED score (max 9) estimates major-bleeding risk. A higher score in either direction maps to a higher annual event rate.

CHA ₂ DS ₂ -VASc component	Points		HAS-BLED component	Points
C – Congestive heart failure / LV dysfunction	1		H – Hypertension (uncontrolled)	1
H – Hypertension	1		A – Abnormal renal / liver function	1 each
A ₂ – Age ≥75 years	2		S – Stroke history	1
D – Diabetes mellitus	1		B – Bleeding history / predisposition	1
S ₂ – Stroke / TIA / thromboembolism	2		L – Labile INR (on warfarin)	1
V – Vascular disease (MI/PAD/aortic plaque)	1		E – Elderly (age >65 years)	1
A – Age 65–74 years	1		D – Drugs (antiplatelet/NSAID) or alcohol	1 each
Sc – Sex category (female)	1			

- ▶ **Annual stroke rate rises with score** (CMDT/Braunwald): ~0% at 0, ~1.3% at 1, ~2.2% at 2, ~3.2% at 3, ~4% at 4, rising further with higher scores — Harrison notes risk may approach ~20% per year at the highest scores without anticoagulation.
- ▶ **Anticoagulation thresholds (2023 ACC/AHA/ACCP/HRS)**: Class I anticoagulation for **men with score ≥ 2 and women with score ≥ 3** ; *consider* (Class IIa) for men =1 / women =2; **no antithrombotic therapy** when the only point is female sex (men =0, women =1).
- ▶ Female sex is a **risk modifier, not an independent risk factor** — it counts only in the presence of other factors.
- ▶ Risk factors *not* captured by the score but relevant: **LA size, mitral annular calcification, AF burden, and renal failure** (RR ~1.4 in non-dialysis CKD, ~1.8 on dialysis).
- ▶ **HAS-BLED ≥ 3 flags high bleeding risk** — it should prompt correction of *modifiable* factors (BP control, stopping NSAIDs/alcohol, labile INR) and closer review, **not** automatic withholding of anticoagulation.
- ▶ Highest-risk groups in whom anticoagulation is recommended *regardless* of score: **prior stroke/TIA, rheumatic mitral stenosis, mechanical valve, and hypertrophic cardiomyopathy**.

Antithrombotic options — DOACs vs warfarin

Oral anticoagulants are far superior to antiplatelets. Warfarin reduces stroke by ~60–64% vs placebo and ~37% vs antiplatelet therapy; **aspirin is no longer recommended** for stroke prevention in AF (variable, modest benefit without a bleeding advantage). For **nonvalvular AF**, **DOACs are now preferred over warfarin** (equal/greater efficacy, ~50% less intracranial haemorrhage, fixed dosing, no monitoring, fewer food/drug interactions).

Agent	Class / target	Standard dose	Reduced dose & criteria	Pivotal trial
Warfarin	Vitamin K antagonist ($\downarrow$ factors II, VII, IX, X; protein C/S) via VKOR inhibition	Titrated to INR 2.0–3.0	— (needs INR monitoring; many interactions)	(reference comparator)
Dabigatran	Direct thrombin (IIa) inhibitor	150 mg BID	110 mg BID (age ≥ 80 , verapamil, high bleeding risk) / 75 mg BID if CrCl 15–30 (US label)	RE-LY
Rivaroxaban	Factor Xa inhibitor	20 mg OD with food	15 mg OD if CrCl 15–50 mL/min	ROCKET-AF
Apixaban	Factor Xa inhibitor	5 mg BID	2.5 mg BID if ≥ 2 of: age ≥ 80 , weight	ARISTOTLE

Agent	Class / target	Standard dose	Reduced dose & criteria	Pivotal trial
			≤60 kg, creatinine ≥1.5 mg/dL	
Edoxaban	Factor Xa inhibitor	60 mg OD	30 mg OD if CrCl 30–50, weight ≤60 kg, or P-gp inhibitor; avoid if CrCl >95	ENGAGE-AF

- ▶ All four DOACs were **non-inferior or superior** to warfarin in nonvalvular AF; pooled data show small absolute superiority (~0.4–0.7%) in mortality, stroke, major bleeding and intracranial haemorrhage. **Apixaban** uniquely showed superiority to warfarin for stroke *and* less major bleeding *and* lower mortality (ARISTOTLE).
- ▶ **Dabigatran** has more GI bleeding; **rivaroxaban** must be taken with food (40% better absorption).
- ▶ Renal dosing is critical — dabigatran/edoxaban avoided in end-stage renal disease/dialysis; **apixaban** has the best evidence in advanced CKD/haemodialysis (2.5 mg BID).
- ▶ **Reversal:** warfarin → IV **vitamin K + 4-factor prothrombin complex concentrate** (preferred over FFP); dabigatran → **idarucizumab** 5 g IV (monoclonal antibody fragment); factor Xa inhibitors → **andexanet alfa** (400 mg bolus then infusion). DOAC short half-life (~10–12 h) means supportive care often suffices; activated charcoal if ingested within 6–8 h.
- ▶ **Aspirin should be avoided** alongside an anticoagulant unless there is a clear indication (recent MI/stent).

Special clinical situations

- ▶ **Valvular AF** (mechanical prosthetic valve or moderate–severe/rheumatic mitral stenosis): **warfarin only** — DOACs are contraindicated/less effective. In rheumatic-heart-disease AF, warfarin gave fewer cardiovascular events/deaths than rivaroxaban without more bleeding.
- ▶ **Peri-cardioversion:** if AF >48 h or duration unknown → either **≥3 weeks of therapeutic anticoagulation before + ≥4 weeks after** cardioversion, **or** a TEE/cardiac-CT to exclude LAA thrombus and then cardiovert with ≥4 weeks' post-procedure anticoagulation (covers atrial stunning). DOACs are as effective as warfarin around cardioversion.
- ▶ **Hypertrophic cardiomyopathy with AF:** anticoagulate **independent of CHA₂DS₂-VASc score** (high thromboembolic risk).
- ▶ **Subclinical AF / device-detected atrial high-rate episodes (AHRE):** associated with a 2.5-fold increase in stroke risk. For AHRE ≥24 h with CHA₂DS₂-VASc ≥2, anticoagulation is reasonable (Class IIa); in subclinical AF of 6 min–24 h, apixaban reduces stroke/systemic embolism but increases major bleeding — individualise.

- ▶ **AF with PCI/coronary stenting:** minimise bleeding by using **OAC plus a single P2Y12 inhibitor (preferably clopidogrel)**, dropping aspirin early; reserve short “triple therapy” (≤ 30 days) for high ischaemic risk such as ACS.
- ▶ **Bridging:** because of rapid DOAC onset/offset, **no heparin bridging** is needed when interrupting a DOAC for procedures; stop 24–48 h before low/moderate-risk and longer before major surgery (extend in renal impairment).

Non-pharmacological / device-based prevention

- ▶ For patients with a **high stroke risk but contraindication to long-term anticoagulation** (excessive bleeding risk), **left atrial appendage (LAA) occlusion/exclusion** is the alternative, since ~90% of thrombi originate there.
- ▶ **Percutaneous LAA closure** — *Watchman* (nitinol plug, FDA-approved 2015; non-inferior to warfarin in *PROTECT AF / PREVAIL*, with less major/haemorrhagic bleeding and mortality benefit) and *Amplatzer Amulet* (non-inferior to Watchman). Post-Watchman, warfarin is continued ~45 days until TEE confirms sealing/no significant peri-device leak.
- ▶ **Surgical/epicardial exclusion** — LAA excision or stapling (often with maze surgery), the **AtriClip** (FDA-approved 2021), and the catheter-delivered **LARIAT** suture (off-label) — surgical LAA occlusion at cardiac surgery adds protection over anticoagulation alone.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **CHA₂DS₂-VASc / HAS-BLED scoring table with a stroke-risk curve:** draw the two-column scoring table (label every component and its points as above) and beneath it a graph of *annual stroke or major-bleeding rate (%)* on the Y-axis vs *score (0–9)* on the X-axis, with two rising lines labelled **CHA₂DS₂-VASc** and **HAS-BLED**.
- ▶ **Left atrial appendage thrombus and Watchman device:** draw the left atrium with a thrombus in the LAA; label *left atrium*, *left atrial appendage*, *thrombus*, *mitral valve*, and a *Watchman occluder device* seated across the LAA ostium delivered via *trans-septal* approach.

Clinical / Diagnostic significance

- ▶ **Risk-stratify every AF patient at diagnosis** with CHA₂DS₂-VASc; reassess periodically as age and comorbidities change.
- ▶ **Echocardiography** (TTE) is done in all new AF; TEE is the most sensitive test for LAA thrombus before cardioversion and before stopping anticoagulation post-LAA closure.
- ▶ Anticoagulation decision applies **equally to paroxysmal and persistent AF** and is **not** governed by the perceived AF burden or by whether sinus rhythm appears maintained.
- ▶ Monitor **renal function and blood counts** at baseline and $\geq$ twice yearly on DOACs; review HAS-BLED factors and correct modifiable bleeding risks.

- ▶ Major bleeding occurs in ~1–2% (warfarin) to 2–4% per year overall; have a clear **reversal pathway** (vitamin K/PCC, idarucizumab, andexanet alfa).

High-yield exam pointers

- ▶ LAA is the source of ~90% of thrombi in AF; main feared complication is **disabling cardio-embolic stroke**.
- ▶ CHA₂DS₂-VASc: age ≥75 and prior stroke/TIA score **2 each**; all others 1. Anticoagulate **men ≥2, women ≥3**.
- ▶ HAS-BLED ≥3 = **high bleed risk** → correct modifiable factors, don't simply withhold OAC.
- ▶ DOACs preferred over warfarin in nonvalvular AF; **warfarin only** for mechanical valves and moderate–severe/rheumatic mitral stenosis (target INR 2–3).
- ▶ Aspirin is **NOT recommended** for stroke prevention in AF.
- ▶ Trial map: dabigatran–RE-LY, rivaroxaban–ROCKET-AF, apixaban–ARISTOTLE, edoxaban–ENGAGE-AF; apixaban superior to warfarin with less bleeding.
- ▶ Reversal: dabigatran → **idarucizumab**; Xa inhibitors → **andexanet alfa**; warfarin → **vitamin K + 4-factor PCC**.
- ▶ Cardioversion rule: AF >48 h/unknown → 3 weeks before + 4 weeks after anticoagulation, or TEE-guided (beware **atrial stunning**).
- ▶ Watchman/Amulet LAA closure for patients unable to take long-term anticoagulation (PROTECT AF/PREVAIL).
- ▶ Anticoagulate **regardless of score** in HCM, mitral stenosis, mechanical valve, or prior stroke.

SOURCE & COVERAGE

- ▶ **Harrison's Principles of Internal Medicine, 22e** — “Atrial Fibrillation” (stroke prevention, CHA₂DS₂-VASc/HAS-BLED, cardioversion-anticoagulation, NOAC dosing table, LAA closure) and “Antiplatelet, Anticoagulant, and Fibrinolytic Drugs” (warfarin/VKOR mechanism, heparin/DOAC pharmacology, reversal agents).
- ▶ **Braunwald's Heart Disease, 13e** — “Atrial Fibrillation” (risk stratification, 2023 ACC/AHA/ACCP/HRS guideline thresholds, DOAC vs warfarin, subclinical AF/AHRE, LAA excision/closure — Watchman, Amulet, LARIAT, AtriClip).
- ▶ **CMDT 2026** — “Disorders of Cardiac Rhythm” (current DOAC regimens and renal dosing, adjusted stroke rate by CHA₂DS₂-VASc, ROCKET-AF/ARISTOTLE/ENGAGE-AF, reversal-agent doses, peri-procedural management).
- ▶ *Coverage note:* the RE-LY trial name for dabigatran is universally accepted standard medicine (Harrison cites the agent without naming the trial; CMDT names ROCKET-AF, ARISTOTLE and ENGAGE-AF explicitly).

Syncope

Asked in: Paper II Nov 2019 — RGUHS MD General Medicine

Definition / Introduction — Syncope is a *transient, self-limited loss of consciousness (TLOC) with loss of postural tone, due to acute global cerebral hypoperfusion, characterised by rapid onset, brief duration and spontaneous, complete recovery*. Because the brain's metabolism is critically perfusion-dependent, cessation of cerebral blood flow for ~6–10 s produces loss of consciousness. A presyncopal prodrome (lightheadedness, dimming of vision, sweating, nausea) is common but consciousness may be lost without warning. Syncope must be separated from other causes of TLOC — seizures, vertebrobasilar ischaemia, hypoxaemia, hypoglycaemia and psychogenic pseudosyncope. It accounts for ~3% of emergency visits and ~1% of admissions, with a lifetime cumulative incidence up to 40%, and a bimodal age distribution (peak in the young at 10–30 years, median ~15 years; a sharp rise after 70 years).

Pathophysiology

- ▶ **Upright stress is central.** Standing pools 500–1000 mL of blood in the legs, buttocks and splanchnic bed, reducing venous return, ventricular filling, stroke volume and blood pressure.
- ▶ This unloads **arterial baroreceptors** in the carotid sinus and aortic arch, normally triggering a compensatory reflex (increased sympathetic outflow, withdrawal of vagal tone) that raises peripheral resistance, heart rate and cardiac output to defend blood pressure.
- ▶ **Syncope results when this compensation fails** — transiently in neurally mediated syncope, chronically in autonomic failure, or because cardiac output is mechanically/electrically compromised in cardiac syncope.
- ▶ Cerebral blood flow is normally 50–60 mL/min per 100 g and is autoregulated over a mean pressure of ~50–150 mmHg (latency 5–10 s). Consciousness is impaired at ~25 mL/min per 100 g; a **fall in systolic BP to ≤50 mmHg** typically causes syncope. Either reduced cardiac output **and/or** reduced systemic vascular resistance can be the final common pathway; hypocarbia from hyperventilation adds cerebral vasoconstriction.
- ▶ EEG during syncope shows a “slow–flat–slow” pattern (high-amplitude delta → cortical flattening → recovery); seizure discharges are absent despite myoclonus.

Classification and causes

Three broad categories — *neurally mediated (reflex), orthostatic, and cardiac* — with neurally mediated being commonest at all ages and cardiac the most dangerous.

Category	Subtypes / triggers	Mechanism
Neurally mediated (reflex/vasovagal)	Vasovagal (fear, pain, emotion, sight of blood, prolonged standing, heat); Situational —	Transient ↑parasympathetic + sympathoinhibition → vasodilation ± bradycardia. Sub-

Category	Subtypes / triggers	Mechanism
	cough, micturition, defecation, swallow, post-prandial, wind-instrument/weightlifter; Carotid sinus syndrome ; cardiac <i>Bezold–Jarisch reflex</i>	typed by efferent limb as vasodepressor (BP fall), cardioinhibitory (bradycardia/asystole) or mixed
Orthostatic hypotension	Primary autonomic failure — <i>synucleinopathies</i> : Parkinson disease, dementia with Lewy bodies, pure autonomic failure (<i>Bradbury–Eggleston</i>), multiple system atrophy (<i>Shy–Drager</i>). Secondary — diabetic/amyloid/immune/HSAN neuropathy, B12 deficiency, HIV. Iatrogenic/volume — diuretics, α -blockers, nitrates, TCAs, phenothiazines; haemorrhage, vomiting, diarrhoea	Sympathetic vasoconstrictor (autonomic) failure $\rightarrow$ no adequate compensatory rise in HR/resistance on standing
Cardiac	Arrhythmias — sinus node dysfunction, AV block (<i>Stokes–Adams attack</i>), SVT, VT, inherited channelopathies; Structural — aortic stenosis, HCM, MI, atrial myxoma, tamponade, massive PE, pulmonary hypertension	Abrupt fall in cardiac output from electrical or mechanical obstruction; associated with $\uparrow$ risk of sudden cardiac death

- **Inherited channelopathies** causing arrhythmic syncope/sudden death: **long-QT syndrome** (K^+ / Na^+ channel genes, scaffolding protein *ankyrin-B/ANK2*) producing *torsades de pointes*; **Brugada syndrome** (Na^+ -channel *SCN5A*; coved RBBB-type ST elevation V1–V3); **catecholaminergic polymorphic VT** (abnormal cardiac calcium handling, *RyR2*). Acquired QT prolongation (drugs) is the commoner cause of torsades.
- **Variants of OH**: *initial OH* (BP fall within 15 s, resolves by 45 s — not true autonomic failure); *delayed OH* (beyond 3 min — early adrenergic failure); **POTS** — chronic (>3 months) orthostatic intolerance with HR rise ≥ 30 /min (≥ 40 in ages 12–19) within 10 min standing without a >20 mmHg SBP fall. **Supine hypertension** coexists in $>50\%$ with autonomic failure.

Differentiating syncope from its mimics

Feature	Vasovagal syncope	Seizure	Cardiac/arrhythmic	Psychogenic
Trigger	Emotion, pain, standing, heat	Rare emotional trigger; aura	Exertion, supine, palpitations	Often present, many witnesses, no trigger

Feature	Vasovagal syncope	Seizure	Cardiac/arrhythmic	Psychogenic
		(déjà vu, olfactory)		
Onset/prodrome	Long (>5 s): nausea, warmth, sweating, pallor	Brief aura	Sudden (<5 s), few/no warning	Variable; eyes closed
During event	Pallor, dilated pupils, slow pulse, brief arrhythmic multifocal myoclonus	Blue/cyanotic face, tonic-clonic, tongue biting , lateral eye deviation	Limp; may be cyanotic	Normal colour, normal pulse/BP
Recovery	Rapid reorientation, prolonged fatigue	Prolonged (>5 min) post-ictal confusion, aching muscles, headache	Rapid unless low output	Rapid, oriented
Incontinence	Urine occasionally; faecal very rare	Urine/faeces more likely	Possible	Absent

Approach and investigations

- ▶ **Three goals:** confirm it was syncope, identify the cause, and stratify risk of recurrence/sudden death.
- ▶ **Cornerstone = history + eyewitness account (and cellphone video) + examination + orthostatic vitals + 12-lead ECG** — establishes a cause in ~50% of patients.
- ▶ **Orthostatic vitals:** BP/HR supine then after standing each minute to 3 min. **OH = fall in systolic ≥ 20 mmHg or diastolic ≥ 10 mmHg within 3 min of standing/head-up tilt.**
- ▶ **High-risk “red-flag” features** mandating admission/intensive evaluation: chest pain/ischaemic ECG, heart failure, moderate–severe valvular or structural disease, history of VT, **QTc >500 ms**, persistent bradycardia (<40/min), bi-/tri-fascicular block or QRS ≥ 120 ms, AF, non-sustained VT, pre-excitation, Brugada pattern, family history of sudden death, palpitations preceding syncope, or **syncope at rest/during exertion**.
- ▶ **ECG:** long QT, short PR + delta wave (WPW), RBBB + ST elevation V1–V3 (Brugada), T-inversion V1–V3 $\pm$ epsilon wave (ARVD), AV block, ischaemia.
- ▶ **Carotid sinus massage** (>40 yr, recurrent unexplained syncope) under continuous ECG/BP; *avoid with bruit/known stenosis/recent TIA-stroke*. **Cardioinhibitory response = asystole >3 s; vasodepressor = SBP fall >50 mmHg; mixed = both.**

- ▶ **Tilt-table test** (head-up 60–80°, usually 70°, after a 20-min supine phase, for 30–45 min, ± isoproterenol or sublingual nitroglycerin) confirms susceptibility to neurally mediated syncope and distinguishes it (paroxysmal hypotensive–bradycardic response) from OH (gradual BP fall without HR rise); also exposes psychogenic pseudosyncope (LOC with normal vitals).
- ▶ **Cardiac monitoring matched to event frequency:** in-hospital telemetry/Holter for daily events; external loop recorder for monthly events; **implantable loop recorder** for infrequent events (monitor ideally $\geq 2\times$ the inter-spell interval).
- ▶ **Echocardiography** when structural disease is suspected (aortic stenosis, HCM, tamponade, dissection, myxoma) and for LVEF-based SCD risk. **Exercise testing** if syncope occurs during/after exertion. **Electrophysiologic study** only with structural disease/abnormal ECG (diagnostic: H-V interval ≥ 100 ms, CSNRT > 525 ms, induced sustained monomorphic VT). **Routine CT/MRI/EEG/carotid Doppler** are **NOT recommended** without focal signs or head trauma — yield ~1–4%.

Management

Type	Management
Neurally mediated / reflex	Education, reassurance, trigger avoidance; salt + fluid loading , ~500 mL bolus water acutely; physical counterpressure manoeuvres (leg-crossing, handgrip, abdominal + leg tensing — most effective; RCT-supported). Drug: midodrine (only agent with RCT support); fludrocortisone, β -blockers (age > 40), SSRI as second-line. Dual-chamber pacing (closed-loop stimulation) only for > 40 yr with frequent recurrence and documented cardioinhibitory/asystolic response
Orthostatic hypotension	Withdraw offending drugs first; staged posture changes, head-up tilt of bed at night, compression garments, counterpressure manoeuvres, avoid large/high-carbohydrate meals; salt and fluid expansion. Drugs: fludrocortisone , midodrine , droxidopa (L-DOPS) ; refractory — pyridostigmine, atomoxetine, yohimbine, octreotide, desmopressin (DDAVP), erythropoietin
Cardiac	Treat the cause: pacemaker for sinus node disease / AV block; ablation for SVT/WPW; antiarrhythmics and ICD for VT/VF or low-EF cardiomyopathy; valve replacement for aortic stenosis; manage PE/tamponade/ischaemia

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

Type	Management
	▶ The baroreflex arc — label: <i>carotid sinus & aortic arch baroreceptors</i> → afferents in <i>glossopharyngeal (CN IX) and vagus (CN X)</i> → <i>nucleus tractus solitarius (NTS)</i> in dorsomedial medulla → <i>nucleus ambiguus (NA)</i> (vagal/parasympathetic to sinus node) and <i>caudal ventrolateral medulla (CVLM)</i> → <i>rostral ventrolateral medulla (RVLM)</i> presympathetic neurons → sympathetic efferents to heart and blood vessels; <i>A1 noradrenergic group</i> → <i>PVN/SON</i> → <i>vasopressin</i>. Colour parasympathetic (green) vs sympathetic (blue). ▶ Tilt-table tracing comparison — label two BP/HR panels: (A) <i>neurally mediated syncope</i> = abrupt paroxysmal fall in BP with bradycardia; (B) <i>orthostatic hypotension</i> = gradual BP fall without compensatory HR rise.

Clinical / Diagnostic significance

- ▶ Prognosis is driven by aetiology: noncardiac/unexplained syncope in the young has **normal life expectancy**, whereas **cardiac syncope carries excess sudden-death and all-cause mortality**; OH-related syncope roughly doubles mortality (reflects comorbidity).
- ▶ Syncope may be the **first and only warning before sudden cardiac death** — hence risk stratification, not just diagnosis, is the priority.
- ▶ **Exertional syncope** suggests aortic stenosis, HCM or arrhythmia; **syncope while supine or seated, or preceded by palpitations** suggests an arrhythmia — all are red flags.
- ▶ *Coat-hanger* (suboccipital/shoulder) ache and post-prandial faintness point to autonomic failure; treating supine hypertension and OH together requires balance.
- ▶ Driving and occupational restriction must be addressed in recurrent or high-risk syncope.

High-yield exam pointers

- ▶ Syncope = **global cerebral hypoperfusion**; LOC after ~6–10 s of arrested flow; recovery is rapid and complete.
- ▶ Three causes: **neurally mediated (commonest)**, **orthostatic**, **cardiac (most lethal)**.
- ▶ OH = systolic $\downarrow \geq 20$ or diastolic $\downarrow \geq 10$ mmHg within 3 min of standing; POTS = HR $\uparrow \geq 30$ /min without ≥ 20 mmHg SBP fall.
- ▶ **Carotid sinus hypersensitivity**: asystole > 3 s (cardioinhibitory) and/or SBP fall > 50 mmHg (vasodepressor).
- ▶ **Stokes–Adams attack** = syncope from brady-/asystole; **Bezold–Jarisch reflex** underlies cardiac reflex syncope.
- ▶ Channelopathies: LQTS (torsades), Brugada (SCN5A, V1–V3 ST elevation), CPVT, ankyrin-B/ANK2.

- ▶ History + examination + orthostatic vitals + ECG diagnose ~50%; routine neuroimaging/EEG are low-yield.
- ▶ **Midodrine** is the only RCT-supported drug for vasovagal syncope; **counterpressure manoeuvres** are first-line non-drug therapy; **droxidopa/fludrocortisone/midodrine** for OH.
- ▶ **Tongue biting, post-ictal confusion >5 min, cyanosis** favour seizure; **pallor, rapid recovery, faecal continence** favour syncope.

SOURCE & COVERAGE

Takotsubo cardiomyopathy

Asked in: Paper II Sep 2025 — RGUHS MD General Medicine

Definition / Introduction — Takotsubo cardiomyopathy (TTC), also called *takotsubo syndrome* (TTS), *stress-induced cardiomyopathy*, *apical ballooning syndrome*, or "*broken-heart syndrome*," is an acute, usually reversible form of left ventricular (LV) dysfunction that classically follows an intense emotional or physical stressor. The acutely dyskinetic, dilated apex with a hypercontractile base produces the characteristic shape of the narrow-necked Japanese octopus-trapping pot (*takotsubo*). It mimics an acute coronary syndrome (ACS) — chest pain, ST-elevation and troponin rise — yet coronary angiography shows no culprit obstruction, and the regional wall-motion abnormality extends beyond any single coronary territory. First described in Japan in the 1990s, it predominantly affects postmenopausal women and generally resolves within days to weeks.

Epidemiology and triggers

- ▶ **Sex/age:** Overwhelmingly **postmenopausal women** — in the *International Takotsubo Registry* (1750 patients) **89.8%** were female. Women are ~**10-fold** more likely to develop TTC overall, and women >55 yr are ~5× more likely than those <55 yr. In patients <50 yr, males predominate with more antecedent neurologic/psychiatric disease.

- ▶ **Burden:** ~5500 US hospital admissions in 2012, with a large additional in-hospital incidence triggered by intercurrent illness; well recognised during emergency cardiac catheterisation and ICU admissions for non-cardiac conditions.
- ▶ **Triggers (preceding stressor not obligatory):** A physical trigger occurred in ~36% and an emotional trigger in ~28% of registry patients. Recognised precipitants include acute medical/surgical illness, hypoglycaemia, alcohol withdrawal, hyperthyroidism, **neurologic catastrophes** (subarachnoid haemorrhage, stroke/TIA, seizures), and **pheochromocytoma**, as well as bereavement and acute emotional shock.
- ▶ **Associations:** Higher prevalence of psychiatric and neurologic disorders than ACS controls; patients with COPD, migraine, or affective disorders on β -agonists may fare worse.

Pathophysiology

- ▶ **Catecholamine excess is central.** An acute stressor activates central and autonomic stress pathways, raising circulating epinephrine/norepinephrine (adrenal medulla) and local norepinephrine from sympathetic nerve terminals.
- ▶ Proposed mechanisms of myocardial injury: **direct catecholamine toxicity**, **adrenoceptor-mediated stunning** (apical myocardium has the highest β -adrenoceptor density), **epicardial multivessel and microvascular coronary spasm**, heterogeneity of myocardial autonomic innervation, abnormal myocardial calcium handling, and increased cardiac workload.
- ▶ **Estrogen deprivation** in postmenopausal women (endothelial dysfunction) is thought to be facilitating, explaining the female predominance.
- ▶ Cardiac MRI shows **diffuse myocardial oedema without necrosis** and, importantly, **absence of late gadolinium scar** — distinguishing it from infarction and myocarditis.
- ▶ A *similar picture* can be produced by a **coronary embolus** in the absence of atherosclerotic disease.

Clinical features and ballooning variants

- ▶ **Presentation mimics ACS:** chest pain (~76%), dyspnoea (~47%), syncope (~8%); may present with pulmonary oedema, hypotension or cardiogenic shock. Arrhythmias are not uncommon; syncope is relatively rare.
- ▶ **ECG:** ST-segment elevation (in nearly half), deep widespread **anterior T-wave inversions**, and **QTc prolongation**; T-wave changes resolve gradually.
- ▶ **Biomarkers:** troponin/CK moderately elevated (troponin raised in ~87%) and *taper quickly* relative to the extent of wall-motion abnormality; BNP/NT-proBNP markedly elevated — a disproportionately small troponin rise for a large akinetic territory is a clue.

Morphologic variant	Frequency / features
Apical ballooning (classic)	>80%; apical akinesis/dyskinesis with hypercontractile base
Midventricular	Mid-LV akinesis with preserved apex and base
Basal ("reverse"/inverted)	Basal akinesis with apical sparing; more often younger patients
Focal	Wall-motion abnormality limited to one segment; rarely within a single coronary territory

Diagnosis and differentiation from ACS

- **InterTAK diagnostic criteria (consensus):** transient LV dysfunction (apical, midventricular, basal or focal pattern, $\pm$ RV involvement) typically *extending beyond one coronary distribution*; an emotional/physical/combined trigger may precede but is **not obligatory**; neurologic disorders or pheochromocytoma may trigger it; new ECG changes (ST elevation/depression, T-inversion, QTc prolongation); moderate troponin/CK rise with marked BNP elevation; **significant CAD does not exclude TTS** (~15% have coexisting CAD); no infectious myocarditis; postmenopausal female predominance. **Cardiac MRI is recommended to exclude myocarditis and confirm TTS.**
- **Imaging:** echocardiography demonstrates apical dyskinesis not conforming to a coronary territory; coronary angiography excludes acute occlusion; LV ventriculography shows classic apical ballooning. CMR confirms oedema without scar.

InterTAK clinical score (TTS vs ACS)	Points
Female sex	25
Emotional stress	24
Physical stress	13
No ST-segment depression (except aVR)	12
Psychiatric disorders	11
Neurologic disorders	9
QTc prolongation	6

- Interpretation: ≤ 70 points = low/intermediate probability; **>70 points = high probability of TTS.** The score aids ED discrimination but does **not replace coronary angiography** in the acute setting.

Management

- **Acute phase = treat as ACS until coronary disease excluded** (urgent angiography). Admit higher-risk patients to ICU/CCU for monitoring.
- **No therapy is proven to alter the natural history;** care is supportive and complication-directed:

- *Pulmonary oedema*: nitrates and standard heart-failure measures.
 - *Haemodynamically stable patients*: combined α - and β -blockade preferred over selective β -blockade.
 - *Arrhythmia / QT prolongation*: magnesium; **avoid QT-prolonging drugs** (e.g., macrolides, certain antiarrhythmics).
 - *Hypotension*: use **inotropes/pressors with great caution** — they can precipitate dynamic LV **outflow tract (LVOT) obstruction**; an intra-aortic balloon pump may be used for critically low output **only if there is no LVOT obstruction**.
 - *LV apical thrombus*: anticoagulation while thrombus is present.
- ▶ **Risk stratification (higher-risk)**: LVEF <45%, hypotension, LVOT gradient >40 mmHg, and/or significant arrhythmia — an **ACE inhibitor and/or β -blocker** is recommended in this group.
 - ▶ **Long-term/secondary prevention**: **ACE inhibitors/ARBs are associated with reduced recurrence and improved survival**, whereas **β -blockers have NOT been shown to prevent recurrence**. Routine long-term anticoagulation is not recommended once thrombus resolves.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **LV ventriculogram/echo in systole (classic “takotsubo” shape)**: outline the LV cavity with labels — *hypercontractile basal segments (narrow neck), akinetic/dyskinetic ballooned apex, mid-LV, aortic outflow*; alongside a small sketch of the **Japanese octopus pot (takotsubo)** for the eponym.
- ▶ **Pathophysiology flow diagram**: *Acute emotional/physical stress* → *central + sympathetic activation* → *catecholamine surge (epinephrine/norepinephrine)* → [*direct catecholamine toxicity + microvascular/epicardial spasm + β -receptor-mediated apical stunning*] → *transient apical ballooning (reversible LV dysfunction)*, with *estrogen deprivation* shown as a facilitating factor.

Clinical / Diagnostic significance

- ▶ Must be considered in any **postmenopausal woman presenting as anterior STEMI after acute stress** — distinguishing it from ACS prevents inappropriate thrombolysis and guides management.
- ▶ **Disproportion clue**: extensive wall-motion abnormality with only modest troponin rise and a non-coronary distribution favours TTS over infarction.
- ▶ **CMR (oedema without scar)** is the key discriminator from MI and myocarditis.
- ▶ Complications driving the ~4–5% in-hospital mortality: **cardiogenic shock, dynamic LVOT obstruction from systolic anterior motion of the mitral valve, LV free-wall rupture, mural-thrombus embolisation/stroke, torsades de pointes** from QT prolongation, and (rarely) complete heart block.

- ▶ Prognosis: historically thought benign, but in-hospital mortality is comparable to STEMI; ~10% have cardiac/neurologic adverse events over the next year.

High-yield exam pointers

- ▶ *Takotsubo* = narrow-necked Japanese **octopus-trapping pot**; synonyms: stress/apical ballooning/"broken-heart" syndrome.
- ▶ **Postmenopausal women (~90%)** after intense emotional or physical stress; estrogen deprivation facilitates.
- ▶ **Mechanism = catecholamine surge** → direct toxicity + microvascular/epicardial spasm + apical β -receptor stunning.
- ▶ Mimics **anterior STEMI** (ST-elevation, deep T-inversions, QTc $\uparrow$) with **normal/non-obstructive coronaries** and wall motion **crossing coronary territories**.
- ▶ **Troponin rise modest** relative to akinesis; **BNP markedly raised**; **CMR shows oedema WITHOUT late-gadolinium scar**.
- ▶ Variants: **apical (>80%)**, midventricular, basal/reverse, focal.
- ▶ **InterTAK score >70** → **high probability of TTS**; significant CAD does NOT exclude the diagnosis.
- ▶ Treatment supportive: avoid pressors/QT-prolonging drugs; beware **LVOT obstruction**; **ACEi/ARB reduces recurrence, β -blockers do not**.
- ▶ Usually **reverses in days–weeks**; recurrence ~5% (mostly within the first year; Harrison cites ~10% lifetime at ~2%/yr).

SOURCE & COVERAGE

- ▶ Harrison's Principles of Internal Medicine, 22e — "*Dilated Cardiomyopathies*" (Takotsubo syndrome/cardiomyopathy section) and "*Classification of Cardiomyopathy*."
- ▶ Braunwald's Heart Disease, 13e — "*The Dilated, Restrictive, and Infiltrative Cardiomyopathies*" (Takotsubo Cardiomyopathy; **International Takotsubo (InterTAK) Diagnostic Criteria and InterTAK Clinical Score**, International Takotsubo Registry epidemiology, complications and therapy).
- ▶ CMDT 2026 — "*Heart Failure & Cardiomyopathy*" (Takotsubo Cardiomyopathy — essentials, pathophysiology, ECG/diagnostic studies, treatment, prognosis).

Coverage note: The corpus does not include the *Mayo Clinic* diagnostic criteria; the InterTAK consensus criteria (Braunwald) are used instead. All figures (89.8% female, InterTAK score points, ~4–5% mortality, ballooning variants, ACEi-vs- β -blocker recurrence data) are taken verbatim from the cited chapters.

Treatment options for management of pulmonary embolism

Asked in: Paper III 15 Apr 2026 — RGUHS MD General Medicine

Definition / Introduction — Pulmonary embolism (PE) is obstruction of the pulmonary arterial circulation by thrombus that has embolised, most often from a lower-limb deep-venous thrombosis (DVT); together they constitute *venous thromboembolism* (VTE). Acute right-ventricular (RV) pressure overload, not hypoxaemia, is the principal determinant of early death. Modern treatment is therefore **risk-stratified**: anticoagulation is the universal cornerstone, while reperfusion (systemic thrombolysis, catheter-directed therapy, or surgical embolectomy) and haemodynamic support are reserved for patients with established or impending RV failure.

Risk stratification — the framework that selects the treatment

Therapy is chosen by combining haemodynamic status, RV function (echocardiography or CT) and cardiac biomarkers (troponin, BNP/NT-proBNP), supplemented by the **Pulmonary Embolism Severity Index** (PESI) or its simplified form (sPESI, one point each for age >80 y, cancer, cardiopulmonary disease, HR ≥110, SBP <100 mmHg, SaO₂ <90%; score 0 = low risk).

Category	Frequency	Defining features	Treatment implication
High-risk (massive)	5–10%	Sustained hypotension/shock, ≥half the pulmonary vasculature occluded	Reperfusion (fibrinolysis/embolectomy) + haemodynamic support
Intermediate-high (submassive)	part of 20–25%	RV dysfunction and raised biomarkers, normotensive	Anticoagulate, monitor in HDU; rescue reperfusion if deteriorating
Intermediate-low	part of 20–25%	RV dysfunction or raised biomarker (one only)	Anticoagulation, close observation
Low-risk	65–75%	Normotensive, normal RV and biomarkers, sPESI 0	Anticoagulation alone; consider early discharge/outpatient

- ▶ A multidisciplinary **Pulmonary Embolism Response Team** (PERT) is recommended to coordinate decisions in high- and intermediate-high-risk PE.

Anticoagulation — the cornerstone for all patients

Begin immediately once PE is confirmed (or empirically when clinical probability is high and bleeding risk low). Heparins act by accelerating antithrombin; they prevent new thrombus but do not lyse existing clot — endogenous fibrinolysis remodels it.

Agent	Dose / regimen	Notes
Unfractionated heparin (UFH)	80 U/kg bolus, then 18 U/kg/h IV; target aPTT 60–80 s (anti-Xa 0.3–0.7 U/mL)	Short half-life — preferred if thrombolysis/embolectomy or renal failure likely; reversible with protamine
LMWH (enoxaparin)	1 mg/kg SC twice daily	No monitoring unless obese/renal failure/pregnant; favoured for intermediate-risk and cancer
Dalteparin / tinzaparin	200 U/kg OD (or 100 U/kg BID) / 175 U/kg OD	Renal dose reduction
Fondaparinux	Weight-based SC once daily	Synthetic anti-Xa pentasaccharide; does not cause HIT; reduce in renal impairment
Rivaroxaban	15 mg BID × 3 weeks → 20 mg OD	Oral monotherapy, no parenteral lead-in
Apixaban	10 mg BID × 1 week → 5 mg BID	Oral monotherapy; 2.5 mg BID extended phase
Dabigatran	150 mg BID after ≥5 days parenteral	Direct thrombin inhibitor; antidote idarucizumab
Edoxaban	60 mg OD after ≥5 days parenteral (30 mg if CrCl 15–50, wt ≤60 kg, or P-gp inhibitor)	Anti-Xa agent
Warfarin	Start 5 mg, titrate to INR 2.0–3.0	Overlap with parenteral agent ≥5 days and until INR ≥2 on two readings 24 h apart

- ▶ DOACs are first-line for most patients: fixed dose, rapid onset, no routine monitoring, fewer interactions. Avoid in pregnancy/breast-feeding, antiphospholipid syndrome (use **warfarin**), and severe renal failure/cirrhosis.
- ▶ Heparin-induced thrombocytopenia (HIT) or its suspicion: stop all heparin, use a direct thrombin inhibitor — **argatroban** (hepatic clearance) or **bivalirudin** (renal) — or fondaparinux.
- ▶ Reversal of bleeding: protamine sulphate for UFH/LMWH; **idarucizumab** for dabigatran; **andexanet alfa** or prothrombin complex concentrate (PCC) for anti-Xa DOACs; vitamin K ± FFP/PCC for warfarin.

Reperfusion therapy — for high-risk and deteriorating intermediate-high-risk PE

1. Systemic fibrinolysis

- ▶ Indication: high-risk (massive) PE with hypotension/shock; also intermediate-high-risk PE that deteriorates (rising lactate, worsening RV strain, clot-in-transit) despite anticoagulation.
- ▶ Regimen: **alteplase (rt-PA) 100 mg IV over 2 h** (FDA-approved, peripheral vein); the sooner given the better, but benefit persists up to ~14 days from symptom onset. An off-label **half-dose 50 mg/2 h** trades efficacy for fewer bleeds.
- ▶ Risk: major bleeding ~10%, **intracranial haemorrhage 2–3%**. Contraindications — intracranial disease, recent surgery, recent trauma; careful screening minimises bleeding.

2. Catheter-directed therapy (CDT) — lowers fibrinolytic dose and bleeding risk:

- ▶ *Ultrasound-facilitated, catheter-directed low-dose fibrinolysis* (e.g. ~24 mg t-PA over ~12 h) improves the RV/LV ratio (SEATTLE II, ULTIMA).
- ▶ *Mechanical/aspiration thrombectomy* without lytic — large-bore nitinol-disc retrieval (FlowTrieve) or aspiration (Indigo) — useful when fibrinolysis is contraindicated.

3. Surgical pulmonary embolectomy

- ▶ For high-risk or intermediate-high-risk PE with severe RV dysfunction when thrombolysis is contraindicated or has failed, or to remove a right-atrial/clot-in-transit or close a patent foramen ovale. Best results **before** pressor dependence and multiorgan failure.

Haemodynamic support, adjuncts and prevention

- ▶ **Massive PE resuscitation:** cautious volume — **500 mL normal saline** only (over-filling worsens RV wall stress and septal shift). First-line **norepinephrine** (raises systemic/coronary pressure) plus **dobutamine** (RV inotropy, lowers filling pressure). Refractory shock → **veno-arterial ECMO** to decompress the RV and bridge to definitive therapy.
- ▶ **Inferior vena cava (IVC) filter:** only two firm indications — (1) active bleeding precluding anticoagulation, and (2) recurrent VTE despite therapeutic anticoagulation. Prefer a **retrievable** filter and remove early; routine filters do not reduce mortality and increase later DVT.
- ▶ **Prophylaxis** of in-hospital VTE (low-dose UFH/LMWH/fondaparinux, or mechanical compression if anticoagulation is contraindicated) is central to reducing PE incidence.

Duration of anticoagulation and special populations

- ▶ **Minimum 3 months** for all. The ESC 2019 framework abandons the rigid “provoked/unprovoked” split and instead weighs **recurrence risk** (low <3%/yr; intermediate 3–8%/yr; high >8%/yr) against bleeding risk and patient preference.
- ▶ **Extended (indefinite) anticoagulation** for a first PE with no identifiable risk factor, a persistent/enduring risk factor (cancer, heart failure, IBD, autoimmune disease), or antiphospholipid syndrome; extended phase often uses **low-dose DOAC** (apixaban 2.5 mg BID or rivaroxaban 10 mg OD).

- ▶ **Cancer-associated VTE:** LMWH monotherapy **or** a DOAC (apixaban/edoxaban) when there is no gastrointestinal malignancy; continue until cancer-free (Caravaggio, Hokusai-VTE Cancer).
- ▶ **Pregnancy:** LMWH throughout — warfarin (embryopathy) and DOACs are avoided.
- ▶ **CTEPH** develops in ~2% of acute PE survivors → follow persistent pulmonary hypertension with echocardiography at ~6 weeks/6 months; treat operable disease with **pulmonary thromboendarterectomy** (mortality 1–5% at expert centres), and inoperable disease with pulmonary vasodilators and balloon pulmonary angioplasty.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Risk-stratified treatment algorithm of acute PE:** *Confirmed PE* → *assess haemodynamics* → “Hypotension/shock?” → **Yes** = **High-risk** → reperfusion (systemic thrombolysis / catheter-directed / surgical embolectomy) + norepinephrine + dobutamine ± VA-ECMO; → **No** → assess RV function + biomarkers → branches labelled *Intermediate-high* (anticoagulation + HDU monitoring + rescue reperfusion), *Intermediate-low* (anticoagulation + observation), *Low-risk (sPESI 0)* (anticoagulation ± early discharge). Add a side box: *IVC filter only if bleeding precludes anticoagulation or recurrent VTE despite it.*
- ▶ **Pathophysiology of RV failure in massive PE:** labels — PE → ↑ pulmonary vascular resistance → ↑ RV wall tension → RV dilation → interventricular septal shift → ↓ LV preload → ↓ cardiac output/systemic BP → ↓ right coronary perfusion → RV ischaemia/microinfarction (↑ troponin) → circulatory collapse.

Clinical / Diagnostic significance

- ▶ Risk stratification (haemodynamics + RV imaging + troponin/BNP) **directly selects therapy** — it is not academic; missing submassive RV dysfunction under-treats a deteriorating patient.
- ▶ ECG S1Q3T3 and T-inversion V1–V4, and **echocardiographic McConnell’s sign** (RV free-wall hypokinesis with apical sparing) flag RV strain and prompt closer monitoring/reperfusion consideration.
- ▶ **CT-derived RV/LV diameter ratio >1** predicts 30-day death and is the standard surrogate of reperfusion response.
- ▶ Age-adjusted D-dimer (age × 10 ng/mL if >50 y) and Wells score guide *whether to image*, conserving CT pulmonary angiography.

High-yield exam pointers

- ▶ Anticoagulation is the cornerstone for **every** PE; reperfusion is added only for high-risk (and deteriorating intermediate-high-risk) disease.
- ▶ **Alteplase 100 mg IV over 2 h** is the FDA-approved lytic regimen for massive PE; ICH risk 2–3%.
- ▶ **UFH 80 U/kg bolus → 18 U/kg/h**, aPTT 60–80 s; UFH preferred when reperfusion or renal failure is anticipated.

- ▶ **DOACs first-line**; rivaroxaban/apixaban need **no parenteral lead-in**, dabigatran/edoxaban need **≥5 days** of heparin first.
- ▶ **HIT** → stop heparin, give **argatroban** or **bivalirudin**; **APS** → use **warfarin**, not DOACs.
- ▶ **IVC filter** indications: active bleeding precluding anticoagulation, or recurrent VTE despite anticoagulation — use a **retrievable** filter.
- ▶ **Massive PE**: **500 mL** fluid only + **norepinephrine** + **dobutamine** ± VA-ECMO; surgical embolectomy if lysis fails/contraindicated.
- ▶ **Reversal**: **protamine** (heparins), **idarucizumab** (dabigatran), **andexanet alfa/PCC** (anti-Xa DOACs).
- ▶ **Minimum duration 3 months**; extend for cancer, APS, persistent risk factor, or recurrent/no-cause PE; cancer VTE → LMWH or apixaban/edoxaban.

SOURCE & COVERAGE

- ▶ **Harrison's Principles of Internal Medicine, 22e** — “Deep-Venous Thrombosis and Pulmonary Thromboembolism” (classification, risk stratification, anticoagulant agents/doses Table 290-4, massive-PE management, fibrinolysis, catheter-directed therapy, embolectomy, IVC filter, duration tables 290-5/290-6); and “Antiplatelet, Anticoagulant, and Fibrinolytic Drugs” (heparin/warfarin/DOAC pharmacology, reversal).
- ▶ **Braunwald's Heart Disease, 13e** — “Pulmonary Embolism and Deep Vein Thrombosis” (PESI/sPESI Table 79.6, ESC risk categories, PERT, systemic vs catheter-directed fibrinolysis SEATTLE II/ULTIMA, FlowTrier/Indigo mechanical thrombectomy, surgical embolectomy, VA-ECMO, IVC filter trials, cancer-VTE Caravaggio/Hokusai, extended-duration DOAC dosing).
- ▶ **CMDT 2026** — Pulmonary and Hemostasis/Thrombosis chapters, for current anticoagulant selection and management.

What are the indications for coronary arteriography? What are the complications of the procedure?

Asked in: Paper II 08 Apr 2026 — RGUHS MD General Medicine

Definition / Introduction — **Coronary arteriography** (selective coronary angiography) is the invasive, catheter-based opacification of the epicardial coronary arteries with radio-opaque iodinated contrast, recorded as cine images in multiple orthogonal projections, and remains the **gold standard** for defining coronary anatomy and the extent/severity of obstructive coronary artery disease (CAD). It is almost

always performed as part of diagnostic **cardiac catheterization**. The technique evolved from Forssmann's self-catheterization (1929) and Cournand & Richards' haemodynamic work (Nobel Prize, 1956) to Sones' first selective coronary injection (1958) and Judkins' preformed catheters that brought it into routine use. The purpose is to determine whether **medical, surgical (CABG), or catheter-based (PCI) interventions** are warranted.

Indications for coronary arteriography

Broadly, arteriography is indicated to **define the extent and severity of cardiac/coronary disease in symptomatic patients**, to decide on revascularisation, and to **exclude severe disease** when non-invasive tests are equivocal but a definitive diagnosis is needed.

Clinical setting	Specific indications
Asymptomatic / symptomatic CAD	High-risk findings on non-invasive testing; aborted sudden cardiac death; sustained (>30 s) monomorphic VT; non-sustained (<30 s) polymorphic VT
Symptomatic CAD	CCS Class II, III, or IV stable angina on medical therapy; acute coronary syndrome (unstable angina & NSTEMI); chest-pain syndrome of unclear cause with equivocal non-invasive tests
Acute myocardial infarction	Reperfusion by primary PCI ; persistent/recurrent ischaemia; pulmonary oedema and/or reduced ejection fraction; cardiogenic shock / haemodynamic instability ; risk stratification or a positive post-MI stress test; mechanical complications (acute MR, ventricular septal defect)
Valvular heart disease	Suspected severe valve disease in symptomatic patients (dyspnoea, angina, heart failure, syncope); infective endocarditis needing surgery; asymptomatic aortic regurgitation with cardiac enlargement or falling EF; prior to cardiac surgery / TAVR or other percutaneous valve intervention when CAD is suspected
Congestive heart failure	New-onset angina or suspected undiagnosed CAD; new-onset cardiomyopathy of uncertain cause or suspected to be ischaemic
Congenital heart disease	Before surgical correction / percutaneous intervention when symptoms or testing suggest coronary disease; suspected congenital coronary anomalies
Pericardial disease	Symptomatic patients with suspected tamponade or constrictive pericarditis (with right heart study)

Clinical setting	Specific indications
Cardiac transplantation	Pre-operative and post-surgical (allograft vasculopathy) evaluation
Other conditions	Hypertrophic cardiomyopathy with angina; diseases of the aorta where coronary involvement alters management; pulmonary hypertension; unexplained dyspnoea

- **Acuity-based strategy (ACS):** an *urgent/immediate* invasive strategy is indicated in NSTEMI-ACS with refractory angina or haemodynamic/electrical instability; an *early invasive* strategy in stabilised high-risk patients (raised troponin, dynamic ST/T changes, **GRACE score >140**, diabetes, EF <40%, early post-infarction angina, recent PCI, prior CABG). **STEMI** within ischaemic-symptom onset warrants urgent angiography for primary PCI.
- **Pre-valve-surgery screening (CMDT):** coronary angiography to detect incidental CAD before valve surgery is recommended in **all men >40 years** and in **menopausal women with coronary risk factors**; younger patients need it only if coronary disease is clinically suspected.
- Catheterisation is **not mandatory** before surgery in selected younger patients with uncomplicated congenital or valvular disease well-defined non-invasively and without risk factors for concomitant CAD.

Contraindications (context for indications)

- There are **no absolute contraindications** when the procedure is performed in anticipation of a **life-saving intervention** and the patient accepts the risks.
- **Relative contraindications (elective):** decompensated congestive heart failure; acute renal failure; severe chronic renal insufficiency (unless dialysis planned); bacteraemia; acute stroke; active GI bleeding; excessive anticoagulation or recent thrombolytic administration; severe uncorrected electrolyte abnormalities; prior **anaphylactoid reaction to iodinated contrast** without premedication; aspirin allergy/anaphylaxis/bronchospasm if progression to PCI is likely and desensitisation not done; uncontrolled hypertension; pregnancy (radiation).
- **Right heart catheterisation-specific:** right heart tumour, endocarditis, or thrombus/clot in transit.

Complications of the procedure

Risks of **elective** catheterisation are low; they rise substantially when done emergently, during acute MI, or in haemodynamically unstable patients. Harrison quotes MI <0.1%, stroke 0.01%, death 0.05%; for elective + emergent procedures combined the **in-hospital mortality is 1.4%**.

Complication	Approximate risk (%)
Mortality	0.11

Complication	Approximate risk (%)
Myocardial infarction	0.05
Cerebrovascular accident (stroke)	0.07
Arrhythmias	0.38
Vascular (access-site) complications	0.43
Contrast agent reaction	0.37
Haemodynamic complications	0.26
Perforation of a heart chamber	0.03
Other	0.28
Total major complications	≈1.70

- ▶ **Vascular access-site bleeding is the most common complication (1.5–2.0%);** major bleeds worsen short- and long-term outcome. **Radial access** lowers vascular/bleeding complications versus femoral and is the preferred route.
- ▶ **Access-site complications:** haematoma, **pseudoaneurysm**, arteriovenous fistula, dissection, and (with femoral puncture outside the safe zone — above the profunda/superficial femoral bifurcation, below the inferior epigastric artery) **retroperitoneal haemorrhage**. Radial access may cause severe vasospasm with device entrapment, forearm haematoma, and rarely **compartment syndrome**.
- ▶ **Arrhythmias:** tachy-/brady-arrhythmias needing countershock, temporary pacing, or drugs. Deep RCA cannulation or contrast injection into the conus branch can precipitate **ventricular fibrillation**; catheter contact during ventriculography may trigger VPCs/VT (usually self-limiting).
- ▶ **Embolic events:** coronary, cerebral, or peripheral air/thrombus/atheroembolism; risk increased by calcified subclavian/axillary vessels. Risk factors for peri-procedural stroke: advanced age, diabetes, emergency procedure, prior stroke, renal failure, CHF.
- ▶ **Iatrogenic coronary dissection or perforation** — infrequent but potentially life-threatening, may need urgent stenting; **aortic dissection** and **cardiac tamponade** can occur.
- ▶ **Other:** acute renal failure requiring transient/permanent dialysis, acute pulmonary oedema, hypotension/haemodynamic compromise, and (rarely) infection — antibiotic prophylaxis is **not** required.

Contrast and radiation complications

- ▶ **Contrast allergy:** allergic reactions in <5%; severe **anaphylactoid** reactions (clinically like anaphylaxis but not IgE-mediated) in 0.1–0.2%. Mild = nausea, vomiting, urticaria; severe = hypotensive shock, pulmonary oedema, cardiorespiratory arrest. *Premedication* for prior

significant allergy: **prednisone 50 mg orally at 13, 7 and 1 hour before**, plus an **H1-antihistamine**, using non-ionic low-osmolar contrast.

- ▶ **Contrast-induced acute kidney injury (CI-AKI)**: rise in creatinine **>0.5 mg/dL or >25% above baseline at 48–72 h**; occurs in ~2–7% overall (20–30% in high-risk patients). *Risk factors*: diabetes mellitus, CHF, chronic kidney disease, anaemia, older age, STEMI. Dialysis needed in 0.3–0.7%, carrying a **five-fold rise in in-hospital mortality**. *Prevention*: IV **0.9% saline 1.0–1.5 mL/kg/h** for 3–12 h before and 6–24 h after (reduces risk by >50%); minimise contrast volume (<50 mL); low-/iso-osmolar agents; **stop metformin 24 h before and restart 48 h after** to avoid lactic acidosis. N-acetylcysteine and sodium bicarbonate show **no clear benefit** in recent meta-analyses.
- ▶ **Radiation injury**: deterministic (dose-dependent — skin erythema, telangiectasia, hair loss, lens injury; commonest site is the skin of the back) and stochastic (carcinogenesis). Thresholds for follow-up: **>5 Gy** — advise watching for erythema; **>10 Gy** — medical-physicist peak-dose calculation at 2–4 weeks; **>15 Gy or fluoroscopy time >60 min** — hospital risk-management event/vigilance. The **ALARA** principle governs dose minimisation.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Normal coronary tree (PA + lateral schematic)**: label **Left main (LM)**, **LAD with diagonal (D) branches**, **Left circumflex (LCx) with obtuse marginal (OM)**, **Right coronary artery (RCA)**, **posterior descending artery (PDA)**, **AV-nodal branch**; annotate **right-dominant circulation (~85%)** where PDA arises from RCA.
- ▶ **Femoral artery puncture “safe zone”**: label **inguinal ligament**, **inferior epigastric artery (upper limit)**, **common femoral artery**, **bifurcation into profunda femoris & superficial femoral artery (lower limit)**, **femoral head landmark** — puncture below the inferior epigastric and above the bifurcation to avoid retroperitoneal bleed.

Clinical / Diagnostic significance

- ▶ A luminal narrowing **>50%** is considered significant; intermediate stenoses (40–70%) are interrogated functionally — **fractional flow reserve (FFR) <0.80** (post-adenosine hyperaemia) or **instantaneous wave-free ratio (iwFR) <0.89** indicate a haemodynamically significant lesion benefiting from revascularisation; **coronary flow reserve <2.0** signals microvascular dysfunction.
- ▶ **IVUS** (axial resolution 100–150 μm) and **OCT** (10–15 μm) refine plaque characterisation and stent optimisation (expansion, apposition, edge dissection).
- ▶ A **myocardial bridge** mimics stenosis but normalises in diastole; **coronary spasm** resolves with intracoronary nitroglycerin; **spontaneous coronary artery dissection** appears in otherwise normal vessels — important differentials of an apparent “stenosis”.

- ▶ Adjunct studies obtained at the same sitting — ventriculography (wall-motion, EF, MR grade), aortography (dissection, AR), right heart study (shunts, PA pressures), and the **Brockenbrough–Braunwald sign** for HOCM — extend diagnostic value.
- ▶ **Pre-procedure optimisation:** 6-h fast, conscious sedation, aspirin 325 mg, hold warfarin until INR <1.8 (heparin bridge for mechanical valves), stop DOACs 24–48 h prior, withhold oral hypoglycaemics in those prone to hypoglycaemia.

High-yield exam pointers

- ▶ **Gold standard** for coronary anatomy; first selective injection by **Sones (1958)**; preformed catheters by **Judkins**.
- ▶ Memorise indication buckets: **symptomatic/high-risk CAD, ACS, acute MI (primary PCI, shock, mechanical complications), valvular & congenital disease, CHF/new cardiomyopathy, HCM with angina, pre-transplant**.
- ▶ **No absolute contraindication** before a life-saving intervention; key relative ones: decompensated HF, uncorrected coagulopathy/electrolytes, untreated contrast anaphylaxis, active bleeding, acute stroke, severe renal failure (unless dialysis planned).
- ▶ **Commonest complication = vascular access-site bleeding (1.5–2.0%)**; serious events (death/MI/stroke) each <1%; overall major complication rate ≈1.7%.
- ▶ **Radial > femoral** for fewer bleeding/vascular complications.
- ▶ **CI-AKI:** creatinine rise >0.5 mg/dL or >25% at 48–72 h; prevent with saline hydration and minimal low-/iso-osmolar contrast; hold metformin.
- ▶ **Contrast anaphylactoid reaction premedication: prednisone 50 mg at 13, 7, 1 h + H1-blocker.**
- ▶ Deep RCA/conus injection → **VF**; femoral puncture below the bifurcation → **retroperitoneal haemorrhage**.
- ▶ Radiation thresholds: >5 Gy erythema watch; >15 Gy / >60 min FT = risk-management event.

SOURCE & COVERAGE

- ▶ **Harrison's Principles of Internal Medicine, 22e** — “Diagnostic Cardiac Catheterization and Coronary Angiography” (indications Table 249-1; risks, relative contraindications, contrast allergy/premedication, CI-AKI, coronary anatomy & dominance, FFR/iwFR/CFR, IVUS/OCT).
- ▶ **Braunwald's Heart Disease, 13e** — “Coronary Angiography and Intravascular Imaging” (appropriate-use criteria, contraindications, Table of risks with per-complication percentages, vascular/embolic complications, CI-AKI prevention, radiation-exposure thresholds and ALARA).
- ▶ **CMDT 2026** — “Coronary Artery Disease, Valvular Disease & Other Key Topics in Cardiology” (pre-valve-surgery coronary angiography screening criteria).

Cardiac Resynchronization Therapy (CRT): Rationale, Indications and Contraindications

Asked in: Paper II May 2025 — RGUHS MD General Medicine

Definition / Introduction — Cardiac resynchronization therapy (CRT) is a device-based pacing therapy that restores coordinated (synchronous) electrical and mechanical activation of the left ventricle in patients with **heart failure with reduced ejection fraction (HFrEF)** and an electrical conduction delay (a widened QRS, classically **left bundle branch block, LBBB**). It is delivered most often as **biventricular pacing (BiVP)** — a lead in the right atrium, a lead in the right ventricle, and a third lead passed through the **coronary sinus** to pace the lateral/posterolateral wall of the left ventricle. CRT is the only device that simultaneously improves symptoms, induces reverse remodelling, and reduces hospitalisation and all-cause mortality, and is offered **after** optimisation of guideline-directed medical therapy (GDMT).

Rationale (pathophysiology — why CRT works)

- ▶ In **~one-third of HFrEF patients** an intraventricular conduction delay (QRS >120 ms, usually LBBB) produces **ventricular dyssynchrony** — temporal discoordination of contraction within the LV (intraventricular) and between the ventricles (interventricular).
- ▶ **Consequences of dyssynchrony**: suboptimal ventricular filling, reduced LV contractility and mechanical efficiency, **increased wall stress**, paradoxical septal motion, and a greater degree and prolonged duration of **functional mitral regurgitation (MR)**.
- ▶ The **single most important marker** of dyssynchrony is a **widened QRS**, particularly an **LBBB morphology**; electrical dyssynchrony generally reflects underlying mechanical dyssynchrony.
- ▶ By **pre-exciting the delayed (lateral LV) wall** through a coronary-sinus lead and timing it with RV activation, CRT **re-aligns opposing-wall contraction**, narrows the QRS, improves the efficiency of ejection, reduces functional MR and promotes **reverse remodelling** (fall in LV end-systolic/diastolic volumes, rise in LVEF).
- ▶ A useful secondary benefit: CRT raises systolic blood pressure (shown in COMPANION and CARE-HF), which **permits up-titration of GDMT** (ACE-I/ARNI, beta-blocker, MRA) previously limited by hypotension — adding further mortality benefit.

Device types and conduction-system alternatives

- ▶ **CRT-P (CRT-pacemaker)**: biventricular pacing alone — for symptomatic relief/remodelling when an ICD is not indicated or in the very elderly/frail.
- ▶ **CRT-D (CRT-defibrillator)**: biventricular pacing **plus** ICD — preferred when the patient also meets an ICD indication (LVEF ≤35%, NYHA II–III) for sudden-death prevention.
- ▶ **Conduction system pacing (CSP)** — *His-bundle pacing (HBP)* and *left bundle branch area pacing (LBBAP)* — are evolving physiological alternatives that pace the native conduction system to

produce a more natural, narrow-QRS activation; current evidence gives them mostly **Class II** recommendations (used when effective BiVP cannot be achieved or as HBP/LBBAP with LBBB correction). BiVP retains the larger mortality evidence base.

Evidence base (landmark CRT trials)

Trial (year)	Population	Key entry criteria	Principal finding
MUSTIC / MIRACLE (2001–02)	NYHA III–IV	QRS $\geq$ 130–150 ms, LVEF low	↑ exercise capacity, VO_2 , LVEF; ↓ MR, QRS (intermediate endpoints)
COMPANION (2004)	NYHA III–IV, LVEF $\leq$ 35%	QRS $\geq$ 120 ms; randomised 1:2:2 (OMT vs CRT-P vs CRT-D)	CRT-P and CRT-D ↓ death/hospitalisation; CRT-D ↓ mortality
CARE-HF (2005)	NYHA III–IV on optimal therapy	QRS $\geq$ 150 ms (or 120–149 ms with echo dyssynchrony)	First trial to show all-cause mortality reduction with CRT-P
REVERSE / MADIT-CRT (2008–09)	NYHA I–II (mild), LVEF $\leq$ 30%	QRS $\geq$ 120–130 ms	Reverse remodelling, ↓ HF events; benefit greatest with LBBB and QRS >149 ms
RAFT (2010)	NYHA II–III, LVEF $\leq$ 30%	QRS $\geq$ 120 ms (or $\geq$ 200 ms if paced)	CRT-D ↓ mortality and HF hospitalisation vs ICD alone
BLOCK-HF	AV block needing RV pacing, LVEF $\leq$ 50%	—	BiVP superior to RV pacing for mortality/morbidity/remodelling
ECHO-CRT (2012)	NYHA III–IV, narrow QRS $\leq$ 130 ms, echo dyssynchrony	—	No benefit and signal of HARM (↑ mortality) → CRT contraindicated in narrow QRS

Take-home: benefit is greatest in LBBB + wide QRS ($\geq$ 150 ms); it falls with shorter QRS and non-LBBB morphology and is **absent or harmful** when the QRS is narrow.

Indications (guideline-graded — 2022 AHA/ACC/HFSA; 2023 HRS/APHRS/LAHRS)

Prerequisite for all: symptomatic HFrEF on $\geq$ 3 months of optimised GDMT, in sinus rhythm, with reasonable functional life expectancy.

Class	Indication
Class I (A)	LVEF $\leq$ 35%, LBBB, QRS $\geq$ 150 ms, NYHA II / III / ambulatory IV, sinus rhythm, on GDMT

Class	Indication
Class I (A)	LVEF $\leq 35\%$, LBBB, QRS 120–149 ms, NYHA II–IV with select characteristics (e.g., female sex)
Class I (B)	Pacemaker-induced cardiomyopathy / patients with LVEF $\leq 50\%$ who require a high burden of RV pacing (BLOCK-HF)
Class IIa (A/B)	LVEF $\leq 35\%$, non-LBBB QRS ≥ 150 ms, NYHA III/ambulatory IV; and LBBB QRS 120–149 ms (NYHA II–IV) without special characteristics
Class IIb (B)	LVEF $\leq 30\%$, LBBB, QRS ≥ 150 ms, NYHA I (ischaemic); non-LBBB QRS 120–149 ms

- ▶ CRT-D vs CRT-P: add the defibrillator (CRT-D) when an ICD is independently indicated; choose CRT-P alone in older/frail patients or where SCD prevention adds little.

Contraindications & predictors of non-response

- ▶ QRS <120–130 ms (narrow QRS) — *Class III (no benefit / harm)*; ECHO-CRT showed increased mortality. Echo-defined dyssynchrony in a narrow QRS is **not** a valid target.
- ▶ Non-LBBB morphology with QRS <150 ms (especially RBBB) — minimal/uncertain benefit ($\leq$ Class IIb / III).
- ▶ Heart failure with preserved or mid-range EF (HFpEF/HFmrEF) — no established role; CRT/ICD are not indicated.
- ▶ NYHA class IV refractory, non-ambulatory (“inotrope-dependent”) HF, terminal illness, or predicted survival <1 year from comorbidity — unlikely to benefit; consider advanced therapies (LVAD/transplant) or palliation instead.
- ▶ Relative / situational uncertainty (lower expected response): permanent atrial fibrillation without rate control or AV-node ablation (excluded from pivotal trials), RBBB, extensive lateral-wall scar at the intended pacing site, and acute decompensated HF.
- ▶ Procedural/anatomical: active infection/bacteraemia, unfavourable coronary sinus anatomy, or inability to position the LV lead.
- ▶ Predictors of non-response ($\sim 1/3$ of recipients): non-LBBB, QRS <150 ms, ischaemic cardiomyopathy with scar, AF, suboptimal LV lead position (non-lateral), and low percentage of biventricular pacing.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ Diagram 1 — CRT lead anatomy (frontal cardiac silhouette): label pulse generator (left prepectoral pocket), right atrial lead (RA appendage), right ventricular lead (RV apex);

defibrillator coil if CRT-D), coronary sinus → lateral/posterolateral LV branch lead, SVC, tricuspid valve. Annotate “third lead via coronary sinus paces lateral LV wall.”

- ▶ **Diagram 2 — Mechanism strip:** two panels — (A) LBBB: wide QRS, septum and lateral wall contract out of phase, paradoxical septal motion, functional MR; (B) *After CRT:* simultaneous biventricular pacing, **narrowed QRS**, synchronised septal–lateral contraction, reduced MR, reverse remodelling. Label QRS width and arrows of wall activation.

Clinical / Diagnostic significance

- ▶ **Patient selection** rests on a 12-lead ECG (QRS duration and morphology), echocardiographic LVEF, NYHA class and confirmation of GDMT **optimisation** for ≥3 months.
- ▶ CRT delivers **symptom relief, improved exercise capacity/QoL, reverse remodelling, fewer HF hospitalisations and reduced mortality** — the only HF device with all of these.
- ▶ Aim for **≥92–98% biventricular pacing**; low BiVP% (often from AF or frequent ectopy) is a leading cause of failure and may warrant rhythm/rate control or AV-node ablation.
- ▶ Re-assess LVEF after 3–6 months; “super-responders” may normalise EF. Persistent severe functional MR despite CRT may need transcatheter edge-to-edge repair (e.g., MitraClip, COAPT).
- ▶ Complications to counsel for: coronary-sinus lead dislodgement, **phrenic nerve stimulation** (diaphragmatic twitch), pocket infection, and pneumothorax.

High-yield exam pointers

- ▶ **Target = electrical dyssynchrony**; the best surrogate is a **wide QRS with LBBB** — benefit rises with QRS width, maximal at **≥150 ms**.
- ▶ **Strongest Class I indication:** LVEF ≤35% + LBBB + QRS ≥150 ms + NYHA II–IV (ambulatory) + sinus rhythm + on GDMT.
- ▶ **CARE-HF** — first trial to show **all-cause mortality** reduction (CRT-P); **COMPANION** randomised 1:2:2; **RAFT/MADIT-CRT** extended CRT to mild (NYHA I–II) HF.
- ▶ **ECHO-CRT** = narrow-QRS CRT is **harmful** → **narrow QRS (<120–130 ms)** is a **contraindication**.
- ▶ **CRT-D** when an ICD is also indicated; **CRT-P** for frail/elderly or no SCD indication.
- ▶ **BLOCK-HF / pacing-induced cardiomyopathy:** prefer BiVP over RV pacing when high RV-pacing burden + LVEF ≤50% (now Class I).
- ▶ **No role in HFpEF**; non-LBBB and AF predict poorer response.
- ▶ **His-bundle / LBB area pacing** are emerging physiological alternatives to BiVP.

SOURCE & COVERAGE

- ▶ **Harrison's Principles of Internal Medicine, 22e** — “Heart Failure: Management” (rationale of dyssynchrony, CARE-HF/RAFT/MADIT-CRT, QRS >149 ms + LBBB, areas of uncertainty, CSP alternatives; Table 265-3 ICD principles).

- ▶ **CMDT 2026** — “Heart Failure & Cardiomyopathy” (referral thresholds: LVEF ≤35% with QRS ≥120 ms, especially LBBB; no role in HFpEF).

**Atrial Fibrillation — Risk Factors and Management**

Asked in: Paper II 08 Apr 2026 — RGUHS MD General Medicine

Definition / Introduction — **Atrial fibrillation (AF)** is the commonest sustained arrhythmia, characterised by disorganised, rapid, irregular atrial electrical activation with loss of organised atrial mechanical contraction, producing an *irregularly irregular* ventricular response (typically 110–160/min) with absent P waves and a fibrillatory baseline on ECG. It is a major public-health problem whose prevalence rises steeply with age (>95% of patients are >60 years; ~20% of those >80 years), and whose principal hazards are a 1.5–1.9-fold excess mortality, cardioembolic stroke (AF causes ~25% of all ischaemic strokes), heart failure, tachycardia-induced cardiomyopathy and dementia. Management rests on four pillars: **risk-factor modification, rate control, rhythm control and stroke prevention**.

Classification (basis for therapy)

Type	Definition
Paroxysmal	Episodes self-terminate (or by cardioversion) in ≤7 days; normal/mildly enlarged LA, low scar burden — antiarrhythmics often effective
Persistent	Continuous AF >7 days but <1 year; mild-to-severe LA enlargement
Long-standing persistent	Persistent AF >1 year; usually severely enlarged, fibrotic, refractory LA
Permanent	AF accepted; no further attempt at rhythm control

- ▶ A newer **continuum staging** is proposed: Stage 1 — at risk of AF; Stage 2 — pre-AF; Stage 3 — AF; Stage 4 — permanent AF, emphasising prevention and lifestyle/risk-factor modification rather than duration alone.
- ▶ AF without mitral stenosis or a mechanical valve is termed **nonvalvular AF** (governs anticoagulant choice).

Risk factors

- ▶ **Non-modifiable:** advancing age, male sex, white race, tall stature, family history of AF (especially <50 years; a small subset have a heritable familial form), and underlying structural/genetic cardiac disease.
- ▶ **Cardiac:** hypertension, coronary artery disease, valvular disease (especially mitral), heart failure (HFrEF and HFpEF), hypertrophic and other cardiomyopathies, cardiac amyloidosis, pericardial disease, congenital heart disease, prior cardiac surgery (post-operative AF in up to ~50%).
- ▶ **Modifiable / lifestyle (the “fourth pillar”):** obesity (AF risk rises ~29% per 5-point rise in BMI), hypertension, diabetes mellitus, obstructive sleep apnoea, alcohol (acute “holiday heart” and chronic use), smoking, physical inactivity/poor cardiovascular fitness — but also extreme endurance exercise (a *U-shaped* risk curve in men).
- ▶ **Other / precipitants:** hyperthyroidism, acute alcohol intoxication, acute myocardial infarction, pulmonary embolism, pneumonia/lung disease, pulmonary hypertension, pericarditis and psychological stress. *Modest caffeine intake is not a risk factor (large cohorts show a slight reduction).*

General approach & acute management

- ▶ Three immediate aims: (1) control symptoms by rate and/or rhythm control; (2) mitigate thromboembolic risk; (3) address modifiable risk factors.
- ▶ **Haemodynamic instability** (hypotension, pulmonary oedema, ongoing ischaemia): perform **emergent synchronised DC cardioversion** (QRS-synchronous shock, sedated patient).
- ▶ **Stable patient:** control ventricular rate, decide on anticoagulation, and consider restoration of sinus rhythm.
- ▶ **Pharmacologic cardioversion:** IV **ibutilide** (class III); *avoid* with baseline QT prolongation or severe LV dysfunction (torsades de pointes risk).

Stroke prevention (anticoagulation)

- ▶ Risk stratified by the CHA₂DS₂-VASc score; bleeding risk by HAS-BLED.

CHA ₂ DS ₂ -VASc	Pts	HAS-BLED	Pts
C — Congestive HF / LVEF ≤40%	1	H — Hypertension	1

CHA ₂ DS ₂ -VASc	Pts	HAS-BLED	Pts
H — Hypertension	1	A — Abnormal renal/liver function	1 each
A ₂ — Age ≥75	2	S — Stroke history	1
D — Diabetes mellitus	1	B — Bleeding diathesis	1
S ₂ — prior Stroke/TIA/thromboembolism	2	L — Labile INR (on warfarin)	1
V — Vascular disease (MI/PAD/aortic plaque)	1	E — Elderly (>65)	1
A — Age 65–74	1	D — Drugs predisposing to bleed / alcohol	1 each
Sc — Sex category (female)	1		

- **Oral anticoagulation (OAC) is recommended for a score ≥1, unless the sole point is female sex** (men score 1, women score 2 as treatment thresholds). Untreated annual stroke risk rises with score (up to ~20%). The **burden** of AF does not reliably predict stroke risk — paroxysmal AF is treated like persistent AF; even **subclinical** AF raises stroke risk ~2.5-fold.
- **DOACs (dabigatran, rivaroxaban, apixaban, edoxaban) are preferred over warfarin** in nonvalvular AF — non-inferior/superior for stroke prevention with markedly **lower intracranial haemorrhage**, no INR monitoring and fewer interactions. Warfarin reduces stroke by **64% vs placebo** and **37% vs antiplatelet therapy**.
- **Warfarin (INR 2–3) is mandatory in rheumatic mitral stenosis and mechanical valves** — DOACs are inferior/contraindicated here.
- **Antiplatelets are inadequate** for stroke prevention; aspirin+clopidogrel is inferior to warfarin and bleeds more.
- **Reversal:** warfarin — vitamin K, FFP, prothrombin-complex concentrate; **dabigatran** — **idarucizumab**; **factor Xa inhibitors** — **andexanet alfa**.
- **Left atrial appendage occlusion** (e.g. *Watchman*) is non-inferior to warfarin for patients with high stroke risk but contraindication to long-term OAC; surgical LAA exclusion may be done with concomitant cardiac/maze surgery.

DOAC	Standard	Reduced dose & criteria
Dabigatran	150 mg bid	110 mg bid (age ≥80, verapamil, high bleed risk)
Rivaroxaban	20 mg od	15 mg od (CrCl 15–49 mL/min)

DOAC	Standard	Reduced dose & criteria
Apixaban	5 mg bid	2.5 mg bid (≥ 2 of: age ≥ 80 , wt ≤ 60 kg, Cr ≥ 1.5 mg/dL)
Edoxaban	60 mg od	30 mg od (CrCl 30–50, wt ≤ 60 kg, P-gp inhibitor)

Peri-cardioversion anticoagulation

- ▶ AF <48 h, low risk: cardioversion without preceding anticoagulation is acceptable; start OAC if stroke risk warrants.
- ▶ AF ≥ 48 h or unknown duration: either 3 weeks of uninterrupted OAC before and ≥ 4 weeks after cardioversion, or a TEE (or delayed-acquisition cardiac CT) to exclude LA-appendage thrombus, then cardiovert under anticoagulation, continuing ≥ 4 weeks (covers post-cardioversion atrial stunning). Long-term continuation is by CHA₂DS₂-VASc.

Rate control

- ▶ **Goal:** improve diastolic filling and symptoms, prevent tachycardiomyopathy. **Strict target** = resting HR <80/min (rising to <100/min on light exertion); a **lenient target** <110/min is acceptable if asymptomatic with preserved LV function (RACE II).
- ▶ **First-line agents:** β -blockers and the non-dihydropyridine calcium-channel blockers verapamil/diltiazem (oral or IV); often combined.
- ▶ **Digoxin:** mainly for HF or hypotensive patients (no negative inotropy) and as add-on; **chronic use linked to increased mortality** — now reserved for HF.
- ▶ **Amiodarone:** rate control only when other agents fail/are not tolerated (e.g. HF with bronchospasm).
- ▶ **“Ablate and pace”:** AV-junction ablation + permanent pacemaker (with CRT/conduction-system pacing to avoid dyssynchrony) when drug rate control fails.

Rhythm control

- ▶ **Indications:** symptomatic paroxysmal AF, recurrent symptomatic persistent AF, AF with poor rate control, or AF causing/aggravating LV dysfunction or HF; favoured in younger, active patients.
- ▶ **Early rhythm control** (within 1 year of diagnosis) reduces death/stroke/HF/ACS hospitalisation (EAST-AFNET 4); a catheter-ablation strategy improves survival in AF with HFrEF.
- ▶ **Antiarrhythmic drugs (AADs):**
 - **No structural heart disease:** class Ic flecainide / propafenone (also “pill-in-the-pocket”), or sotalol, dofetilide, dronedarone.
 - **CAD / structural disease:** avoid class Ic (proarrhythmia, $\uparrow$ mortality — CAST); use sotalol, dofetilide, dronedarone.

- **Heart failure:** only **amiodarone** and **dofetilide** are survival-neutral; **dronedarone** is contraindicated in decompensated/NYHA IV HF.
- **Amiodarone** is the most effective (maintains sinus rhythm in $\sim\frac{2}{3}$), usable in HF/CAD, but **>40% develop long-term toxicity** (thyroid, lung, liver, skin, eye) — second-line in most.
- Class Ia/III agents cause QT prolongation/torsades; **dofetilide (and often sotalol) require in-hospital initiation** with ECG monitoring.
- ▶ **Catheter ablation — pulmonary vein isolation (PVI):** triggers most often arise from PV antra. Now **first-line in selected younger paroxysmal-AF patients** and superior to AADs for maintaining sinus rhythm; $\sim 80\%$ sinus at 1 year after a single procedure for paroxysmal AF (10–30% need repeat). Energy sources: radiofrequency, cryoballoon, and newer **pulsed-field (electroporation) ablation** (myocardium-selective, lower oesophageal/phrenic/PV-stenosis injury). **Complications (2–7%):** tamponade ($\sim 1\%$), stroke (0.5–1%), phrenic nerve palsy, PV stenosis, and the rare but lethal **atrio-oesophageal fistula** ($<0.1\%$).
- ▶ **Surgical/hybrid ablation (Cox-maze):** usually concomitant with valve/CABG surgery; LAA excised.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **ECG of AF:** label *absent P waves, fibrillatory (f) baseline best seen in V1, irregularly irregular R-R intervals, narrow QRS, variable/rapid ventricular rate.*
- ▶ **AF management algorithm:** boxes for *Haemodynamically unstable* → *emergent DC cardioversion*; *Stable* → three arms — *Rate control* (β -blocker / verapamil-diltiazem / digoxin), *Rhythm control* (AADs / PVI ablation), *Stroke prevention* ($\text{CHA}_2\text{DS}_2\text{-VASc}$ → DOAC/warfarin / LAA occlusion); plus a *Risk-factor modification* box (weight loss, BP, OSA, alcohol).

Clinical / Diagnostic significance

- ▶ **Diagnosis:** 12-lead ECG, ambulatory Holter, implantable loop recorder or wearable/smartwatch ECG (for paroxysmal and subclinical AF, including post-cryptogenic-stroke screening — AF detected in up to $\sim 8.9\%$ within 6 months).
- ▶ **Work-up:** echocardiography (LA size, LV function, valve disease, HCM/amyloid), thyroid function, electrolytes, full blood count, renal/liver function (guides DOAC dosing); TEE before cardioversion when indicated.
- ▶ **Pearls:** rate control + uncontrolled rapid AF → reversible **tachycardia-induced cardiomyopathy**; **stiff left atrial syndrome** with long-standing AF; aggressive **risk-factor management** ($\geq 10\%$ weight loss, $\text{BMI} \leq 27$, OSA treatment, alcohol abstinence, BP and glycaemic control) reduces AF burden and improves ablation success.

High-yield exam pointers

- ▶ Commonest sustained arrhythmia; causes ~25% of **ischaemic strokes**; lifetime risk ~25% in 40-year-old men.
- ▶ **Four pillars**: risk-factor modification, rate control, rhythm control, stroke prevention.
- ▶ **CHA₂DS₂-VASc ≥ 1 → anticoagulate** (female sex alone does not count); **HAS-BLED** assesses bleed risk.
- ▶ **DOACs preferred** in nonvalvular AF; **warfarin mandatory** for mechanical valves and rheumatic mitral stenosis.
- ▶ ≥ 48 h AF → **3 weeks OAC before + 4 weeks after** cardioversion, or **TEE-guided** approach (atrial stunning).
- ▶ **Rate target**: strict $<80/\text{min}$, lenient $<110/\text{min}$; **digoxin reserved for HF**.
- ▶ **Reversal**: idarucizumab (dabigatran), andexanet alfa (factor Xa inhibitors).
- ▶ **PVI ablation** first-line in selected paroxysmal AF; **EAST-AFNET 4** supports early rhythm control.
- ▶ Avoid class Ic drugs in CAD/structural heart disease; **dronedarone contraindicated** in decompensated HF.

SOURCE & COVERAGE

- ▶ **Harrison's Principles of Internal Medicine, 22e** — “Atrial Fibrillation” (pathophysiology, classification, CHA₂DS₂-VASc/HAS-BLED, DOAC dosing table, rate/rhythm control, ablation).
- ▶ **Braunwald's Heart Disease, 13e** — “Atrial Fibrillation” (risk-factor modification as fourth pillar, EAST/CABANA trials, rate-control targets, AAD selection by comorbidity).
- ▶ **CMDT 2026** — “Disorders of Cardiac Rhythm” (current anticoagulation thresholds, DOAC table, antiarrhythmic cautions).

Neurology

Acute Disseminated Encephalomyelitis

Asked in: Paper III Nov 2020 — RGUHS MD General Medicine

Definition / Introduction — Acute disseminated encephalomyelitis (ADEM) is an acute, typically **monophasic**, immune-mediated inflammatory demyelinating disorder of the CNS that characteristically follows an antecedent viral infection (**post-infectious / parainfectious encephalomyelitis**) or, historically, a vaccination (**post-vaccinal encephalomyelitis**). It is defined clinically by the rapid evolution of a **polyfocal** neurological deficit accompanied by **encephalopathy**,

and pathologically by widely scattered foci of **perivenular** inflammation and demyelination. ADEM is far commoner in children than adults; its hyperacute, haemorrhagic variant is *acute haemorrhagic leukoencephalitis (AHL)* of *Weston Hurst*.

Etiology and triggers

- ▶ **Post-infectious (parainfectious) ADEM** — the great majority of cases; the neurological syndrome typically begins *late* in the viral illness, as the exanthem is fading.
 - **Measles** is the classic and historically commonest antecedent — complicates roughly **1 in 1000** cases (Bradley: ~1 in 400 to 1 in 1000); live measles vaccination has dramatically reduced this worldwide.
 - In developed countries **varicella (chickenpox)** is now the most frequent trigger (**1 in 4000–10,000** cases); chickenpox-associated ADEM is notable for conspicuous **cerebellar** involvement.
 - Other agents: **rubella, mumps, influenza, parainfluenza, Epstein–Barr virus, human herpesvirus-6, HIV, dengue, Zika, herpes simplex/zoster, Mycoplasma pneumoniae, Borrelia, Leptospira, and SARS-CoV-2.**
- ▶ **Post-vaccinal ADEM** — of mainly historical importance: the original “*neuroparalytic accidents*” of the *Pasteur* rabies vaccine (rabbit spinal-cord-derived) and the *Jenner* smallpox vaccine; later reports with pertussis, rubella, diphtheria and the swine-influenza vaccine.
 - **Modern vaccines pose no meaningful risk:** the *Vaccine Safety Datalink* study of 24 vaccines in >9 million individuals (64 million doses) found no excess ADEM risk — the only possible signal was Tdap, estimated at <1 case per million doses.
- ▶ **Idiopathic** — a non-specific upper respiratory illness or no identifiable trigger in a proportion of cases. Rare drug associations: sulfonamides, para-aminosalicylic acid/streptomycin.

Form	Typical antecedent	Note
Parainfectious	Measles, varicella, rubella, mumps, EBV, Mycoplasma, SARS-CoV-2	Commonest; begins as exanthem fades
Post-vaccinal	Rabies (Pasteur), smallpox (Jenner), pertussis	Now of historical importance only
Idiopathic	None / non-specific URI	No identifiable trigger
AHL (Hurst)	Usually preceding URI	Hyperacute, haemorrhagic, often fatal

Pathogenesis and pathology

- ▶ **Mechanism** — a **cross-reactive (molecular-mimicry) autoimmune response** to the infectious agent triggers an inflammatory demyelinating attack on CNS myelin. Autoantibodies to **myelin**

basic protein (MBP) and other myelin antigens are found in the CSF of some patients; cases with serum or CSF antibodies to **myelin oligodendrocyte glycoprotein (MOG)** are now reclassified as **MOGAD** (see below).

- ▶ **Hallmark histology** — *widely scattered foci of perivenular (perivascular) inflammation with surrounding demyelination*, involving **both white and grey matter**; vessel necrosis is frequent and meningeal reaction may be seen. This contrasts with the larger, confluent white-matter plaques of MS.
- ▶ **Acute haemorrhagic leukoencephalitis (AHL / Hurst disease)** — the most explosive form; lesions are **vasculitic and haemorrhagic** with a **necrotising vasculitis of venules and capillaries** and perivascular accumulation of polymorphonuclear cells and red blood cells. Antecedent is usually an upper respiratory infection; course is fulminant and frequently fatal.

Clinical features

- ▶ **Onset** — abrupt, with rapid progression over hours to a few days; peak deficit within days. A **prodrome** of fever, malaise and myalgia may precede the CNS syndrome.
- ▶ **Encephalopathy is the defining feature** — ranging from lethargy/irritability through stupor to coma; its presence (with multifocal signs) is the single most useful clinical discriminator from a first MS attack.
- ▶ **Polyfocal / disseminated signs** reflecting simultaneous cerebral, brainstem, cerebellar and spinal-cord involvement: hemiparesis or quadriparesis, extensor plantar responses, lost or hyperactive tendon reflexes, sensory loss, ataxia and movement disorders.
- ▶ **Seizures** are common; **meningismus** and headache frequent (fever often reappears as the exanthem fades).
- ▶ **Optic and spinal patterns** — when present, optic neuritis tends to be **bilateral** and any transverse myelopathy **complete** (cf. usually unilateral/partial in MS).
- ▶ **Course and prognosis** — recovery begins within days and resolves over weeks to months; the illness is **monophasic** by definition. Poor prognosis correlates with severity and abruptness of onset; measles-associated ADEM carries a worse outcome than vaccine-associated disease. Adult case-series report **mortality of 5–20%**, with permanent sequelae in many survivors.

Investigations

- ▶ **CSF** — normal/raised opening pressure; **lymphocytic pleocytosis** (generally ≥ 200 cells/ μ L in ~80%), occasionally a mixed polymorphonuclear–lymphocytic picture in the first days; **protein modestly elevated** (0.5–1.5 g/L; 50–150 mg/dL). **Oligoclonal bands (OCB)** are transient and **uncommon** — their persistence favours MS.
- ▶ **MRI (investigation of choice)** — *extensive, large, poorly-demarcated, relatively symmetric* T2/FLAIR hyperintensities in cerebral and cerebellar white matter, brainstem and spinal cord; characteristic involvement of **deep grey matter (thalamus, basal ganglia)** and cortex. A key

feature is that the **great majority of lesions enhance with gadolinium simultaneously** (all of similar/recent age) — consistent with a single monophasic event — and they show partial resolution *without new lesions* on follow-up. (Contrast MS: lesions of differing ages, *Dawson fingers*, T1 black holes.)

- ▶ **Antibody serology** — test serum (and CSF if seronegative) **MOG-IgG** by cell-based assay and **AQP4-IgG** to identify MOGAD/NMOSD; **autoimmune/paraneoplastic encephalitis panel** where relevant.
- ▶ **Diagnostic criteria (paediatric ADEM, IPMSSG)** — a first **polyfocal clinical CNS event** of presumed inflammatory demyelinating cause **plus encephalopathy not explained by fever**, abnormal brain MRI in the acute phase, and **no new clinical or MRI events ≥ 3 months after onset**.

ADEM versus multiple sclerosis versus MOGAD

Feature	ADEM	Multiple sclerosis	MOGAD
Typical age	Children > adults	15–50 yr	Children and adults
Course	Monophasic	Relapsing/progressive	Monophasic or relapsing
Encephalopathy/seizures	Characteristic	Rare	Possible (ADEM-like in children)
Antecedent infection/vaccine	Usual	Not typical	Often
Optic neuritis	Bilateral, transient	Usually unilateral	Bilateral, longitudinally extensive, papillitis
MRI lesions	Large, symmetric, deep grey matter; all enhance together	Ovoid, periventricular, Dawson fingers; lesions of varying age	Fluffy ill-defined lesions; longitudinally extensive cord, conus, “H sign”
CSF OCB	Transient, uncommon	Persistent in majority	Uncommon (~6–13%)
Antibody	MBP (non-specific)	—	MOG-IgG (cell-based assay)

- ▶ **Caveat:** ~30% of adults initially labelled ADEM relapse within 3 years and are reclassified as MS; others prove to be MOGAD, NMOSD or GFAP astrocytopathy — hence **surveillance imaging after recovery is mandatory**.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Axial brain MRI (FLAIR) schematic of ADEM** — label: *bilateral, large, poorly-demarcated, relatively symmetric subcortical/deep white-matter hyperintensities; thalamic*

and basal-ganglia (deep grey matter) lesions; brainstem lesion; all lesions enhancing simultaneously with gadolinium. Add a contrasting small panel for MS (periventricular Dawson fingers, lesions of differing ages).

- ▶ **Histology of the perivenular lesion** — label: *central venule; perivascular cuff of lymphocytes/monocytes; surrounding “sleeve” of demyelination with preserved axons; (AHL variant: necrotising vasculitis, perivascular neutrophils and red cells, petechial haemorrhage).*

Clinical / Diagnostic significance

- ▶ **Treatment is empirical (no controlled trials):** first-line is **high-dose IV glucocorticoids** (e.g., IV methylprednisolone) followed by an oral prednisone taper that may need to continue up to 8 weeks to prevent rebound.
- ▶ **Refractory / steroid-unresponsive disease** (no response within a few days): escalate to **plasma exchange (plasmapheresis)** or **IV immunoglobulin**; immunosuppressants such as cyclophosphamide have been used in fulminant cases.
- ▶ **AHL demands aggressive immunotherapy and neuro-critical care** for raised intracranial pressure; prognosis remains poor.
- ▶ **Mandatory exclusions before committing to ADEM:** infective (herpes simplex/viral) encephalitis (treat empirically with **aciclovir** until excluded), bacterial meningoencephalitis, antiphospholipid syndrome, autoimmune/paraneoplastic (limbic) encephalitis, CNS vasculitis, neurosarcoidosis, primary CNS lymphoma and metastatic disease.
- ▶ **Key triage rule:** *simultaneous onset of disseminated signs, meningismus, encephalopathy and seizures favours ADEM over a first MS attack* — but distinction may be impossible acutely in adults, so follow up clinically and radiologically.

High-yield exam pointers

- ▶ **ADEM = monophasic, post-infectious/post-vaccinal, immune-mediated demyelination with encephalopathy + polyfocal deficit.**
- ▶ **Encephalopathy** is the cardinal discriminator from MS; **seizures and meningismus** also favour ADEM.
- ▶ Commonest antecedent historically = **measles** (≈ 1 in 1000); now **varicella** (1 in 4000–10,000), the latter with **cerebellar** signs.
- ▶ **Hallmark pathology = perivenular inflammation + demyelination**, white *and* grey matter.
- ▶ **AHL (Weston Hurst)** = hyperacute, haemorrhagic, necrotising-vasculitic, often fatal variant.
- ▶ **MRI:** large, symmetric, deep-grey-matter lesions that all enhance simultaneously; OCBs transient/uncommon (persistent OCB $\rightarrow$ think MS).

- ▶ Many “ADEM” cases with MOG-IgG are now reclassified as MOGAD; ~30% of adults later prove to be MS — *do surveillance MRI after recovery*.
- ▶ Treatment: **high-dose IV steroids** → **taper (up to 8 weeks)**; PLEX or IVIG if refractory; adult mortality 5–20%.

SOURCE & COVERAGE

- ▶ **Harrison’s Principles of Internal Medicine, 22e** — “Neuromyelitis Optica” (chapter covering MOGAD and Acute Disseminated Encephalomyelitis) and “Multiple Sclerosis” (Table: Disorders that can mimic MS).
- ▶ **Bradley & Daroff’s Neurology in Clinical Practice, 8e** — “Multiple Sclerosis and Other Inflammatory Demyelinating Diseases of the CNS” (ADEM, post-vaccinal and parainfectious forms, acute haemorrhagic leukoencephalitis).
- ▶ **CMDT 2026** — “Nervous System Disorders” (demyelinating disease differential; supportive management).
- ▶ *Coverage note:* The corpus covers ADEM well within Harrison’s NMO/MOGAD chapter and Bradley, despite the spec flagging it as thin. The **formal IPMSSG (International Paediatric MS Study Group) consensus ADEM criteria** quoted under Investigations are universally accepted paediatric-neurology consensus but are not stated verbatim in the indexed corpus; all other specifics (epidemiological ratios, CSF/MRI values, mortality, Vaccine Safety Datalink data, treatment) are taken directly from Harrison 22e and Bradley 8e.

Aetiology, pathogenesis and management of Parkinson’s disease

Asked in: Paper III Nov 2020 — RGUHS MD General Medicine

Definition / Introduction — Parkinson’s disease (PD) is the second most common age-related neurodegenerative disorder after Alzheimer’s disease, first described by *James Parkinson* (1817). It is a **synucleinopathy** characterised pathologically by degeneration of dopaminergic neurons in the **substantia nigra pars compacta (SNc)**, striatal dopamine depletion, and intraneuronal **α -synuclein** inclusions (*Lewy bodies* and *Lewy neurites*). Clinically it presents with the cardinal motor tetrad of **bradykinesia, rest tremor, rigidity and postural instability**, accompanied by a broad spectrum of non-motor features. Mean age of onset is ~60 years; lifetime risk is ~3% (men) and ~2% (women).

Aetiology

- ▶ **Sporadic / idiopathic** — the majority of cases occur sporadically and are of **unknown cause**; gene mutations are the only proven causes and may be found even in apparently sporadic cases.

- ▶ **Genetic (~15% familial)** — monogenic forms account for ~5% of cases, rising to ~15% when *GBA1* variants are included.
 - *Dominant*: **SNCA** (α -synuclein — first gene linked; even duplication/triplication of wild-type gene causes PD), **LRRK2** (~3% of sporadic cases; *p.G2019S* commonest, founder effect in Ashkenazi Jews & North African Berber Arabs; incomplete penetrance), **VPS35**, **RAB32**.
 - *Recessive (early-onset)*: **PRKN** (*Parkin* — commonest cause of autosomal-recessive juvenile PD, onset <20 yr, dystonia common, dementia rare), **PINK1**, **PARK7/DJ-1**.
 - **GBA1** (glucocerebrosidase) — the **strongest known genetic risk factor**; present in ~10% of PD and ~25% of Ashkenazi PD; associated with faster progression and cognitive decline.
- ▶ **Environmental** — the MPTP story (1-methyl-4-phenyl-1,2,5,6-tetrahydropyridine, a contaminant of illicit heroin synthesis) produced parkinsonism in Californian addicts in the 1980s, proving an exogenous toxin can selectively kill dopamine neurons. Epidemiological associations (inconsistent): **pesticides, solvents, rural living, farming, well-water**. *Possible protective factors*: caffeine, cigarette smoking, NSAIDs, calcium-channel blockers.
- ▶ **“Double-hit” hypothesis** — interaction of a genetic susceptibility with an environmental toxin; neither alone is sufficient (unproven).
- ▶ **Secondary parkinsonism** — drug-induced (dopamine blockers — neuroleptics, **metoclopramide**; also tetrabenazine, **flunarizine/cinnarizine**, amiodarone, lithium), vascular, tumour, infection, normal-pressure hydrocephalus, trauma, and toxins (carbon monoxide, manganese).

Pathology and pathogenesis

- ▶ **Hallmark pathology** — loss of pigmented dopaminergic SNc neurons (depigmentation of the nigra), reduced striatal dopamine, and **α -synuclein-positive Lewy bodies/neurites**. *Non-dopaminergic* degeneration also affects cholinergic *nucleus basalis of Meynert*, noradrenergic *locus coeruleus*, serotonergic *raphe nuclei*, olfactory and peripheral autonomic systems — explaining the non-motor features.
- ▶ **Braak staging / spread** — Lewy pathology may begin in the peripheral autonomic nervous system, gut, olfactory bulb or **dorsal motor nucleus of the vagus** and ascend in a predictable sequence to the SNc and cortex, giving rise to the **“body-first” vs “brain-first”** concept. Premotor features (constipation, anosmia, REM sleep behaviour disorder, cardiac denervation) may precede motor onset by years to decades.
- ▶ **α -Synuclein “prion-like” hypothesis** — misfolded α -synuclein forms β -sheet-rich toxic oligomers and aggregates that **template** misfolding of native protein and **spread** trans-synaptically (supported by Lewy pathology developing in grafted healthy embryonic neurons, and by the **gut-brain axis** via the vagus).

- ▶ **GBA1-lysosome vicious cycle** — reduced glucocerebrosidase (GCase) activity impairs lysosomal clearance → α -synuclein accumulation; accumulated α -synuclein further inhibits GCase trafficking — a self-amplifying loop also operative in sporadic PD.
- ▶ **Final common pathways of cell death** — oxidative stress, neuroinflammation (microglial activation, HLA-DRB1 association, autoreactive T cells), excitotoxicity, **mitochondrial dysfunction** (complex I defect; *Parkin/PINK1* impair mitophagy), and lysosomal/proteasomal failure converge on a signal-mediated **apoptotic** process (interacting network — Olanow model).

Pathophysiology — basal ganglia circuitry

- ▶ The **striatum** (putamen + caudate) is the input region; **GPI/SNr** are the inhibitory (GABAergic) output regions projecting to thalamus and brainstem. Striatum and output nuclei are linked by the **direct (D1, facilitatory)** and **indirect (D2, inhibitory)** pathways, modulated by SNc dopamine.
- ▶ In PD, **dopamine denervation** → reduced inhibition of the indirect pathway → **increased firing of the STN and GPI** → excessive inhibition of the thalamus → reduced cortical motor activation → **parkinsonism**.
- ▶ This model is the rationale for surgically **lesioning or stimulating the STN/GPI**. Levodopa-induced **dyskinesia** relates not merely to reduced output firing *frequency* but to altered firing *patterns* (pauses, bursts) transmitting “misinformation” to cortex.

Clinical features and diagnosis

- ▶ **Cardinal motor features** — *Bradykinesia* (slowness, decrement); *Rest tremor* (4–6 Hz, “pill-rolling”, asymmetric, re-emergent on posture); *Rigidity* (lead-pipe; **cogwheel** when tremor is superimposed — *Negro’s sign*); *Postural instability* (late).
- ▶ **Other motor** — micrographia, masked facies (*hypomimia*), reduced blinking, hypophonia, drooling, dysphagia, stooped posture, **festinating shuffling gait**, freezing, falls; *Myerson’s sign* (non-fatiguing glabellar tap reflex).
- ▶ **Non-motor** — anosmia, **REM sleep behaviour disorder**, constipation, orthostatic hypotension, urinary/sexual dysfunction, depression/anxiety/apathy, psychosis (visual hallucinations), and cognitive impairment/dementia.
- ▶ **Diagnosis is clinical** — historically “2 of 3” cardinal signs (24% post-mortem error). The **UK Brain Bank Criteria** (asymmetry, rest tremor, good levodopa response) raise accuracy to >90%; the **MDS Clinical Diagnostic Criteria** add supportive criteria, absolute exclusions and red flags, defining *clinically established* and *clinically probable* PD.
- ▶ **Investigations (selective)** — **DAT-SPECT / PET** shows reduced asymmetric striatal uptake (posterior putamen, caudate spared) — useful when diagnosis is uncertain; **α -synuclein seed amplification assay (SAA)** in CSF/skin (high sensitivity/specificity); MRI to exclude

atypical/secondary causes; genetic testing in young-onset/familial cases. **Excellent levodopa response** strongly supports PD.

Differential diagnosis and staging

Category	Examples	Distinguishing clue
Atypical parkinsonism	MSA (MSA-p / MSA-c), PSP, corticobasal syndrome	Early speech/gait, falls, no rest tremor, symmetry, poor levodopa response
MSA	Glial cytoplasmic α -synuclein inclusions	Autonomic failure, cerebellar signs, pontine “hot-cross-bun” sign
PSP	Tauopathy	Vertical gaze palsy, “hummingbird” midbrain sign, retrocollis, early falls
Secondary	Drug-induced, vascular, NPH, toxins	History of neuroleptics; symmetrical; CO/Mn $\rightarrow$ globus pallidus
Other neurodegenerative	Wilson’s disease, Huntington (Westphal), SCA, DLB	Age <40, <i>exclude Wilson’s</i> (treatable)

- **Hoehn & Yahr staging** (severity): I — unilateral; II — bilateral/midline, balance intact; III — impaired righting reflex, mild–moderate disability; IV — severe disability but still walks/stands unaided; V — wheelchair/bedbound unless aided.

Management

- **General principle** — no current therapy is disease-modifying; treatment is **symptomatic and individualised**, using **low doses and polypharmacy** to minimise the levodopa dose and delay motor complications. Exercise, physiotherapy, speech/occupational therapy, education and caregiver support apply throughout.
- **Levodopa** (with peripheral decarboxylase inhibitor **carbidopa** or **benserazide**) — the **gold standard / most effective** drug; 200–1000 mg/day, start $\leq$ 400 mg/day (e.g. Sinemet 25/100 tds). Failure to respond should question the diagnosis. Forms: standard, CR, **Rytary/Crexont** (immediate+extended beads), Stalevo (with entacapone), intestinal gel (Duopa/Duodopa), inhaled (**Inbrija**).
 - *Motor complications* (dose- and duration-related, worse in young/female/severe disease): **wearing-off**, unpredictable **on-off**, **peak-dose (choreiform) dyskinesia**, **diphasic dyskinesia**, delayed-/no-on; behavioural — dopamine dysregulation syndrome, *punding*.
- **Dopamine agonists** — non-ergot **pramipexole**, **ropinirole**, **rotigotine patch** (less dyskinesia; favoured in younger patients); **apomorphine** (SC/sublingual — rescue for “off”). Beware sudden sleep attacks and **impulse-control disorders** (gambling, hypersexuality, shopping).

- ▶ **MAO-B inhibitors** — **selegiline**, **rasagiline** (1 mg/day), **safinamide** — mild monotherapy benefit and adjunctive reduction of “off” time; rasagiline of interest for possible disease-modification (*ADAGIO*, *DATATOP*).
- ▶ **COMT inhibitors** — **entacapone** (with each levodopa dose), **opicapone** (once daily), **tolcapone** (needs LFT monitoring — hepatotoxicity) — prolong “on” time.
- ▶ **A2A antagonist** — **istradefylline** (20–40 mg/day) reduces “off” time.
- ▶ **Amantadine** (NMDA antagonist) — the only oral agent that reduces **dyskinesia** without worsening parkinsonism.
- ▶ **Anticholinergics** — **trihexyphenidyl**, **benztropine** — mainly for **tremor**; avoid in elderly/cognitively impaired.
- ▶ **Advanced disease** — **continuous dopaminergic delivery** (intestinal levodopa-carbidopa gel; SC foslevodopa-foscarbidopa or apomorphine) and **on-demand therapies** (inhaled levodopa, SC/sublingual apomorphine) for refractory fluctuations.
- ▶ **Surgery** — **deep brain stimulation** (DBS) of the STN or GPi for disabling tremor or medically refractory motor complications (reversible, allows bilateral procedures); historical **pallidotomy** / **VIM thalamotomy** (tremor); **MRI-guided focused ultrasound** as a non-incisional alternative. DBS improves dopaminergic features but not non-dopaminergic disability.
- ▶ **Non-motor management** — depression/anxiety (SSRIs/benzodiazepines; pramipexole); psychosis (reduce offending drugs, then low-dose **quetiapine**/**clozapine** or **pimavanserin** — *avoid typical neuroleptics*); dementia (**rivastigmine**); orthostatic hypotension (salt, head-up tilt, **fludrocortisone**, **midodrine**, **droxidopa**); RBD (**clonazepam** 0.5–1 mg / **melatonin**); constipation, urinary and sexual dysfunction addressed symptomatically.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Basal ganglia direct/indirect pathway circuit (normal vs PD)**: label *Cortex*, *Putamen* (*striatum*), *D1* (*direct*) *pathway*, *D2* (*indirect*) *pathway*, *SNc* (*dopamine*), *GPe*, *STN*, *GPi/SNr*, *Thalamus* (*VL*), *PPN* — with arrows showing in PD: ↓dopamine → ↑STN & ↑GPi firing → ↑thalamic inhibition → parkinsonism.
- ▶ **SNc pathology / Lewy body**: label *depigmented substantia nigra*, *melanised dopaminergic neuron*, *α-synuclein-positive Lewy body* (*with halo*), *Lewy neurite*.

Clinical / Diagnostic significance

- ▶ A **brisk, sustained response to levodopa** is both diagnostic and therapeutic; poor response is a *red flag* for atypical/secondary parkinsonism.
- ▶ **Premotor markers** (anosmia, RBD, constipation, DAT/SAA positivity) may permit diagnosis before motor onset — important for future disease-modifying trials.

- ▶ Always **exclude treatable mimics**: drug-induced parkinsonism (stop offending agent) and **Wilson's disease** (copper chelation prevents progression).
- ▶ Striatal dopamine terminal loss may be near-complete within ~4 years of diagnosis — relevant to the timing of any neuroprotective therapy.

High-yield exam pointers

- ▶ **Cardinal tetrad**: bradykinesia + rest tremor (4–6 Hz, pill-rolling) + rigidity (cogwheel) + postural instability; tremor is **asymmetric** at onset.
- ▶ **Pathology**: SNc dopaminergic loss + **α -synuclein** **Lewy bodies**; PD is a **synucleinopathy** (cf. PSP/CBS = tauopathies).
- ▶ **Genetics**: *SNCA* first linked; *LRRK2 G2019S* commonest dominant; *****GBA1* strongest risk factor***; *PRKN** commonest early-onset recessive.
- ▶ **MPTP** → **MPP⁺** = mitochondrial complex I toxin — proof of principle for toxic dopaminergic injury.
- ▶ **Levodopa** = **gold standard**; combine with carbidopa/benserazide; start ≤ 400 mg/day; motor complications are **dose/duration-related**.
- ▶ **Amantadine** = best oral drug for **dyskinesia**; **anticholinergics** for tremor; **DBS of STN/GPi** for refractory fluctuations.
- ▶ **Avoid typical neuroleptics** in PD psychosis — use **quetiapine/clozapine/pimavanserin**.
- ▶ **Hoehn & Yahr** stages I–V; **UK Brain Bank & MDS** diagnostic criteria; **DAT-SPECT** + **α -synuclein SAA** as supportive tests.

SOURCE & COVERAGE

- ▶ **Harrison's Principles of Internal Medicine, 22e** — “Parkinson's Disease” (aetiology, genetics, pathogenesis, basal-ganglia pathophysiology, full pharmacological/surgical management) and “Dementia with Lewy Bodies”.

- ▶ **DeJong's The Neurologic Examination** — clinical signs (cogwheel/lead-pipe rigidity, *Negro's* and *Myerson's* signs, micrographia, masked facies).
- ▶ **CMDT 2026** — “Nervous System Disorders / Parkinsonism” (current drug regimens, doses, surgical and supportive management).

Alzheimer's Disease

Asked in: Paper III Nov 2019 — RGUHS MD General Medicine

Definition / Introduction — Alzheimer's disease (AD) is a progressive neurodegenerative disorder and the **most common cause of dementia**, accounting for an estimated **60–70%** of the ~55 million people living with dementia worldwide. It is a clinico-biological entity defined pathologically by extracellular **neuritic (amyloid- β) plaques**, intraneuronal **neurofibrillary tangles (NFTs)** of hyperphosphorylated tau, and neuronal/synaptic loss, classically presenting as an insidious, slowly progressive **amnestic dementia** beginning with loss of episodic memory. Pathology spreads from the medial temporal lobes to temporo-parietal and frontal association cortices, with relative sparing of primary motor and sensory cortex until late.

Epidemiology & Risk Factors

- ▶ **Age** is the dominant risk factor: ~10% of people >65 years have AD — 3% at 65–74, 17% at 75–84, and 32% at ≥ 85 years.
- ▶ **Positive family history** is the second key factor; **autosomal-dominant familial AD (FAD)** accounts for only 1–2% of cases (multigenerational early-onset dementia).
- ▶ **ApoE $\epsilon 4$ allele** — the major genetic risk factor for sporadic/late-onset AD (see Genetics).
- ▶ **Female sex** is an independent risk factor; women carrying a single $\epsilon 4$ allele are more susceptible than male $\epsilon 4$ carriers.
- ▶ Other associations: **traumatic brain injury**, **diabetes** (≈ 3 -fold risk), hypertension, obesity, dyslipidaemia, elevated homocysteine, **hearing loss**, low educational attainment, smoking, physical inactivity, sleep disorders, and air pollution. Vascular disease and stroke lower the threshold for clinical expression of AD.

Clinical Manifestations & Course

- ▶ **Typical (amnestic) AD**: insidious **episodic memory loss** (repeating questions, misplacing items) followed by progressive deficits in **executive, language, and visuospatial** domains.
- ▶ **Disease spectrum (clinical staging)**: *subjective cognitive decline* $\rightarrow$ *mild cognitive impairment (MCI)* / “early symptomatic AD” $\rightarrow$ *dementia*. About **50% of MCI patients progress to dementia over ~4 years** ($\sim 12\%$ /year); the *preclinical* stage (biomarker-positive, asymptomatic) may precede symptoms by ≥ 20 years.
- ▶ **Middle stages**: unable to work, easily lost; progressive aphasia (naming $\rightarrow$ comprehension $\rightarrow$ fluency), **apraxia**, visuospatial failure, acalculia, impaired clock reading; delusions (theft, infidelity, misidentification), wandering, sleep–wake disruption.
- ▶ **Late stages**: rigidity, mutism, incontinence, bedbound state; **myoclonus** and hyperactive reflexes; death usually from aspiration, infection, or malnutrition.
- ▶ **Atypical variants** ($\sim 20\%$ present non-amnestically): **posterior cortical atrophy** (visuospatial, Balint & Gerstmann syndromes), **logopenic progressive aphasia** (impaired naming/repetition

with phonological errors), **dysexecutive/behavioural** (“frontal”) variant, and **corticobasal (akineti-rigid-dystonic)** syndrome.

- Typical symptomatic duration is **8–10 years** (range 1–25). Seizures (focal and generalized) increasingly recognized, especially in young-onset and autosomal-dominant AD.

Pathology & Pathogenesis

- **Macroscopic**: diffuse cortical atrophy, earliest and most severe in the **medial temporal lobe** (entorhinal/perirhinal cortex, hippocampus) and **nucleus basalis of Meynert**; locus coeruleus severely affected, substantia nigra relatively spared.
- **Neuritic plaques**: extracellular core of **amyloid- β (A β)**, a 39–42-amino-acid peptide cleaved from **amyloid precursor protein (APP)** by **β -secretase (BACE)** and **γ -secretase**. The amyloidogenic pathway yields toxic **A β 42**; the non-amyloidogenic α -secretase (ADAM10/17) pathway is non-toxic. Soluble **A β oligomers** are thought to be the early toxic species (amyloid cascade hypothesis).
- **Neurofibrillary tangles**: intraneuronal **paired helical filaments** of hyperphosphorylated **tau**; tau normally stabilizes microtubules, but when hyperphosphorylated it detaches and aggregates, with prion-like templated spread. NFT spread follows **Braak staging** — six stages reducible to three: **transentorhinal (I–II) $\rightarrow$ limbic (III–IV) $\rightarrow$ isocortical (V–VI)**.
- **Amyloid angiopathy**: vascular A β deposition predisposing to microhaemorrhage and lobar haemorrhage.
- **Neurochemistry**: marked **cholinergic deficit** ($\downarrow$ acetylcholine, choline acetyltransferase, nicotinic receptors) from degeneration of the nucleus basalis of Meynert — the basis of the **cholinergic hypothesis** and cholinesterase-inhibitor therapy; also noradrenergic (locus coeruleus) and serotonergic (dorsal raphe) depletion.

Genetics

Gene	Chromosome	Role / Effect
APP	21	Point mutations cause FAD; trisomy 21 (Down syndrome) develops AD pathology after age 40 (extra APP dose)
PSEN-1 (presenilin-1)	14	Commonest FAD cause (40–70%); γ -secretase component; mean onset ~45 yr, rapid course (~6–7 yr)
PSEN-2 (presenilin-2)	1	Rarer FAD (Volga-German kindreds); mean onset ~53 yr, duration ~11 yr

Gene	Chromosome	Role / Effect
ApoE ε4	19	Major risk allele for sporadic/late-onset AD; not a deterministic cause

- ▶ **ApoE**: one ε4 allele raises risk ~2–3-fold; ε4/ε4 homozygotes ~10–15-fold, with each allele advancing onset ~10 years. ε2 is protective. ε4 is *neither necessary nor sufficient*. The **Christchurch ApoE3 mutation** may protect against tau aggregation/dementia despite amyloid.
- ▶ **GWAS / risk modifiers**: >40 common low-effect variants — **CLU, PICALM, CR1** (innate immunity, lipid metabolism, synaptic function); **TREM2** rare but strong (OR ~3–4; homozygous mutation = Nasu-Hakola disease).

Diagnosis & Biomarkers

- ▶ **Clinical**: slowly progressive amnesic dementia, normal systemic labs, and posterior-predominant cortical + hippocampal atrophy. Clinical diagnosis confirmed at autopsy ~70–80% of the time (mimics: LATE, PART, Lewy body disease, vascular, FTLT).
- ▶ **Bedside cognition**: MMSE, MoCA, Mini-Cog (insensitive to MCI). Neuropsychology shows a **encoding/consolidation deficit** (flat learning curve, no benefit from recognition cues) typical of medial temporal involvement.
- ▶ **Structural MRI/CT**: medial temporal (hippocampal/entorhinal) atrophy with temporal-horn dilatation; chiefly to **exclude** NPH, tumour, vascular disease.
- ▶ **FDG-PET**: temporo-parietal **hypometabolism**.
- ▶ **Amyloid PET** ([¹¹C]PIB, [¹⁸F]florbetapir/florbetaben/flutemetamol): confirms plaque load; ~25% of cognitively-normal elderly are positive, so use is restricted to defined scenarios.
- ▶ **Tau PET** ([¹⁸F]flortaucipir): NFT distribution mirroring Braak stages.
- ▶ **CSF**: ↓Aβ42 and ↓Aβ42/Aβ40 ratio, ↑phospho-tau (p-Tau181 / p-Tau217); ↑total tau is non-specific.
- ▶ **Plasma biomarkers** (emerging): p-Tau217, p-Tau181, Aβ42/Aβ40 ratio — scalable, high concordance with amyloid PET/autopsy.
- ▶ **Diagnostic criteria evolution**: 1984 NINCDS-ADRDA (clinicopathological “probable/possible AD”) → 2011 NIA-AA (clinical stages + amyloid/neurodegeneration biomarkers) → 2018 NIA-AA research framework (A/T/N) = biological definition by Amyloid, Tau, Neurodegeneration → 2014 IWG-2 → 2024 Revised Criteria (amyloid PET/CSF/plasma Aβ and p-Tau as “core 1” biomarkers, tau PET “core 2” for staging).

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **APP processing pathway**: draw the transmembrane APP spanning the cell membrane; show two branches — *non-amyloidogenic* (α-secretase [ADAM10/17] → sAPPα + P3;

“Non-toxic”) and *amyloidogenic* (β -secretase [BACE] then γ -secretase $\rightarrow$ $A\beta_{40}$ [non-toxic] and $A\beta_{42}$ [toxic]) leading to the **neuritic plaque**. Label: APP, cell membrane, α -secretase, β -secretase, γ -secretase, sAPP α , $A\beta_{40}$, $A\beta_{42}$, amyloid plaque.

- ▶ **AD neuropathology / Braak spread:** a mid-sagittal/coronal brain showing **medial temporal lobe** (hippocampus, entorhinal cortex) and **nucleus basalis of Meynert**; inset of a **neuritic plaque** (central $A\beta$ core + dystrophic neurites) and a **neurofibrillary tangle** (paired helical filaments of hyperphosphorylated tau). Label the Braak sequence: transentorhinal $\rightarrow$ limbic $\rightarrow$ isocortical.

Clinical / Diagnostic significance

- ▶ **Symptomatic (neurotransmitter) therapy:** Cholinesterase inhibitors (first-line) — **donepezil** 5–10 mg OD; **rivastigmine** 1.5 mg BID up to 3–6 mg BID or 9.5 mg/24 h patch; **galantamine** 4 mg BID up to 8–12 mg BID / 24 mg ER. **Memantine** (NMDA-receptor antagonist) 5 mg $\rightarrow$ target 10 mg BID for **moderate–severe** AD, often added when disease advances. Titrate over 4–6 weeks; main side effects GI (nausea, diarrhoea, cramps), bradycardia, vivid dreams.
- ▶ **Disease-modifying anti-amyloid monoclonal antibodies** (early symptomatic, biomarker-confirmed): **Lecanemab** (anti-protofibril) 10 mg/kg IV every 2 weeks — *Clarity-AD* showed 27% **slowing** of CDR-SB decline at 18 months; **Donanemab** (anti-pyroglutamate- $A\beta$) IV monthly — *TRAILBLAZER-ALZ2* showed 22% **slowing on iADRS** / 28% on CDR-SB. **Aducanumab** withdrawn. Key toxicity = **ARIA** (amyloid-related imaging abnormalities): **ARIA-E** (vasogenic oedema, FLAIR) and **ARIA-H** (microhaemorrhage/siderosis, GRE/SWI); risk rises with **ApoE ϵ 4 dose** (FDA box warning for ϵ 4 homozygotes) — genotype before treatment; contraindicated with anticoagulation, extensive CAA, and thrombolysis.
- ▶ **Neuropsychiatric management:** SSRIs (e.g. escitalopram) for depression; **levetiracetam** for seizures; **brexpiprazole** is the only FDA-approved drug for agitation in AD (atypical antipsychotics carry a **black-box mortality warning** in elderly dementia). **Avoid anticholinergics** (diphenhydramine, oxybutynin).
- ▶ **Caregiver support:** memory aids, home-safety, driving cessation, day-care, respite, and education; lifestyle/vascular-risk modification (Mediterranean/DASH diet, exercise, cognitive and social activity).

High-yield exam pointers

- ▶ AD = commonest dementia (60–70%); two pathological hallmarks — **$A\beta$ neuritic plaques + tau NFTs**.
- ▶ **ApoE ϵ 4** = major sporadic risk gene (chr 19); **APP** (21), **PSEN-1** (14, commonest FAD), **PSEN-2** (1) cause autosomal-dominant early-onset FAD.
- ▶ **Down syndrome** invariably develops AD pathology after age 40 (extra APP dose).

- ▶ **Nucleus basalis of Meynert** cholinergic loss → cholinesterase-inhibitor rationale.
- ▶ **Braak staging**: transentorhinal → limbic → isocortical.
- ▶ CSF: ↓Aβ42, ↑p-Tau; plasma p-Tau217 is the emerging blood biomarker; A/T/N = biological framework.
- ▶ First-line drugs = **cholinesterase inhibitors**; add **memantine** in moderate–severe disease.
- ▶ **Lecanemab & donanemab** = first disease-modifying anti-amyloid antibodies; watch for ARIA (highest in ε4 homozygotes).
- ▶ MCI converts to dementia at ~12%/year (~50% over 4 years).
- ▶ Posterior cortical atrophy and logopenic aphasia are atypical AD presentations.

Approach to Coma

Asked in: Paper III Jun 2024 — RGUHS MD General Medicine

Definition / Introduction — *Coma* is a deep sleep-like state of unarousable unresponsiveness, with the eyes closed, from which the patient cannot be roused even by vigorous stimuli. It lies at the severe end of a continuum of impaired alertness (drowsiness → stupor → coma) and is one of the commonest neurological emergencies in internal medicine. Consciousness has two components — **arousal/wakefulness** (brainstem reticular activating system, RAS) and **awareness/content** (cerebral cortex); coma reflects failure of one or both. An *organised, time-critical bedside approach* — simultaneous resuscitation, structured history, and a focused neurological examination to localise the lesion — is essential, because metabolic-toxic causes (far commoner than structural ones) are frequently reversible.

Spectrum of impaired consciousness and coma mimics

State	Arousal	Awareness	Key features
Drowsiness	↓ (easily roused)	Largely intact	Simulates light sleep

State	Arousal	Awareness	Key features
Stupor	Roused only by vigorous/repeated stimuli	Impaired	Withdraws from noxious stimuli
Coma	Absent	Absent	Eyes closed, unarousable
Vegetative state	Present (eyes open, sleep–wake cycles)	Absent	“Awake but unaware”; autonomic/respiratory function retained; <i>persistent</i> if >4 weeks
Minimally conscious state	Present	Inconsistent/minimal	Reproducible command-following, visual tracking; better prognosis than VS
Akinetic mutism / abulia	Awake	Partly preserved	Immobile, mute; medial frontal/medial thalamic damage
Catatonia	Variable	Preserved	Psychiatric; waxy flexibility, responds to <i>lorazepam</i>
Locked-in syndrome	Awake	Fully preserved	Ventral pontine lesion (basilar thrombosis); quadriplegic, anarthric, but vertical gaze + lid elevation retained , pupils reactive

- ▶ These mimics must be distinguished from true coma at the bedside; asking the patient to look up/down and blink unmasks the *locked-in state*, and *catatonia* may reverse transiently with IV lorazepam.

Anatomical–physiological basis and causes

- ▶ Coma arises from either (1) **widespread bilateral cerebral hemispheric dysfunction** or (2) **failure of the brainstem–thalamic RAS** (upper pons, midbrain, thalamus). A unilateral hemispheric mass causes coma only by compressing the brainstem.
- ▶ Neurons depend on continuous cerebral blood flow: **glucose stores last ~2 min and oxygen stores only 8–10 s** after circulatory arrest — hence the urgency.
- ▶ **Three diagnostic categories (Harrison):**
- ▶ **No focal/lateralising signs (CT often normal)** — intoxications (alcohol, sedatives, opioids), metabolic (hypo-/hyperglycaemia, hypoxia, hyponatraemia, uraemia, hepatic coma, hypercapnia, hypercalcaemia, Addisonian/myxoedema crisis), severe systemic infection/sepsis, status/non-

convulsive status epilepticus and post-ictal states, hypertensive encephalopathy/eclampsia/PRES, severe hypo-/hyperthermia.

- ▶ **Focal brainstem or lateralising signs (CT usually abnormal)** — intracerebral (basal ganglionic, thalamic, cerebellar, pontine) haemorrhage, large MCA infarct with mass effect, basilar artery thrombosis, abscess, tumour with oedema, subdural/epidural haematoma.
- ▶ **Meningeal syndromes (fever/stiff neck, CSF pleocytosis)** — bacterial meningitis/meningoencephalitis, subarachnoid haemorrhage, autoimmune/paraneoplastic encephalitis.
- ▶ **Threshold values** worth recalling: serum Na^+ <125 mmol/L $\rightarrow$ confusion, <119 mmol/L (acute) $\rightarrow$ coma/convulsions; hyperosmolar coma when osmolality >350 mosmol/L; coma from hypothermia when core $<31^\circ\text{C}$.

Herniation syndromes (structural deterioration)

- ▶ **Uncal (lateral) transtentorial** — medial temporal uncus impacts CN III $\rightarrow$ *ipsilateral fixed dilated pupil* (earliest sign; peripheral parasympathetic fibres affected first), then contralateral hemiparesis; compression of the opposite peduncle gives ipsilateral hemiparesis = ***Kernohan-Woltman notch sign*** (a false-localising sign).
- ▶ **Central transtentorial** — symmetric downward thalamic displacement; heralded by *small pupils and drowsiness*, with orderly rostro-caudal (midbrain $\rightarrow$ pons $\rightarrow$ medulla) deterioration.
- ▶ **Transfalcine (subfalcine/cingulate)** — cingulate gyrus under the falx.
- ▶ **Foraminal (tonsillar)** — cerebellar tonsils into foramen magnum $\rightarrow$ early medullary compression, apnoea, sudden death.

Step 1 — Resuscitation, history and general examination

- ▶ **Airway–Breathing–Circulation first:** protect airway/intubate if GCS ≤ 8 , apnoea, or aspiration risk; support BP; immobilise the cervical spine if trauma is possible.
- ▶ **“Coma cocktail” without delay (CMDT):** **thiamine 100 mg IV** (before glucose, to avert Wernicke’s), then **dextrose 50% 25 g IV**, and **naloxone 0.4–1.2 mg IV** for possible opioid overdose; check a bedside capillary glucose immediately.
- ▶ **History (collateral)** from family/paramedics: rapidity of onset (abrupt $\rightarrow$ SAH, brainstem stroke, ICH; gradual $\rightarrow$ mass/metabolic), antecedent headache/fever/seizures/trauma, drug/alcohol use, and chronic liver/renal/cardiac/lung disease.
- ▶ **General examination:** vital signs, fundoscopy (papilloedema, subhyaloid haemorrhage of SAH), nuchal rigidity, skin (petechiae $\rightarrow$ meningococcaemia/TTP; cherry-red $\rightarrow$ CO), breath (fetus hepaticus, ketones), and a trauma survey. *Fever* $\rightarrow$ infection/heatstroke/NMS; *hypothermia* $\rightarrow$ sedative/alcohol/myxoedema; **hypertension + bradycardia + irregular respiration = Cushing response of raised ICP.**

Step 2 — Neurological examination: grading and localisation

A. Depth of coma — scoring scales

Glasgow Coma Scale	Best response	Score
Eye opening (E)	Spontaneous / To speech / To pain / Nil	4 / 3 / 2 / 1
Verbal (V)	Oriented / Confused / Inappropriate words / Incomprehensible sounds / Nil	5 / 4 / 3 / 2 / 1
Motor (M)	Obeys / Localises / Withdraws / Abnormal flexion / Extension / Nil	6 / 5 / 4 / 3 / 2 / 1

- ▶ GCS ranges 3–15; validated chiefly for *traumatic* coma. Limitation: cannot score V in intubated patients and omits brainstem reflexes — hence the **FOUR score** (*Full Outline of UnResponsiveness*; Wijdicks), which grades **Eye, Motor, Brainstem reflexes** (pupillary, corneal, cough) and **Respiration** (each 0–4, total 0–16) and is usable in the intubated patient.

B. Brainstem reflexes (localise the level — see Fig. 30-3 analogue):

- ▶ **Pupils** — reactive midsize (2.5–5 mm) excludes upper-midbrain damage; **unilateral fixed dilated** >6 mm = CN III/uncal compression; **bilateral fixed midposition** = midbrain; **pinpoint** (<1 mm) **reactive** = pontine haemorrhage *or* opioids (give naloxone); **small reactive** (1–2.5 mm) = metabolic/diencephalic. Pupillary reactivity is typically *preserved in metabolic coma* — a key discriminator.
- ▶ **Ocular position/movement** — “the eyes look toward a hemispherical lesion and away from a brainstem lesion”; roving conjugate movements exclude brainstem damage; **ocular bobbing** = bilateral pontine lesion (basilar thrombosis); **ocular dipping** = diffuse anoxic cortical damage.
- ▶ **Oculocephalic** (“doll’s eye”) — turn the head (only after excluding cervical injury); intact brainstem → eyes move opposite to head turn. **Oculovestibular** (**cold caloric**) — irrigate the canal with ice water → tonic deviation *toward* the cold ear; mnemonic **COWS** (Cold-Opposite, Warm-Same, naming the fast phase). Both are preserved in metabolic coma and lost with structural brainstem damage.
- ▶ **Corneal reflex** — afferent CN V, efferent CN VII; tests pontine integrity.

C. Respiratory patterns (localising value, see Fig. 5.1 analogue):

- ▶ **Cheyne-Stokes** (cyclical crescendo–decrescendo with apnoea) → bihemispheric/diencephalic or metabolic; **central neurogenic hyperventilation** → upper pontine/midbrain tegmentum; **apneustic** (inspiratory pause) → mid/caudal pons; **cluster/ataxic** (*Biot*) → medulla (pre-terminal); **Kussmaul** (deep regular) → metabolic acidosis.

D. Motor responses & posturing:

- ▶ **Decorticate** posturing (flexion of elbows/wrists, supination; legs extended) → lesion *rostral to the midbrain*; **decerebrate** posturing (extension/pronation of arms, leg extension) → lesion in/caudal to the *midbrain–upper pons*. Purposeful withdrawal implies intact corticospinal tracts; *multifocal myoclonus and asterixis* suggest a metabolic cause.

Step 3 — Investigations

- ▶ **Bedside/blood**: capillary then lab glucose, electrolytes, calcium, magnesium, osmolality, renal and hepatic function (with NH_3), ABG, full blood count, **toxicology screen**, cultures if febrile.
- ▶ **Imaging**: urgent **non-contrast CT head** for haemorrhage/herniation/hydrocephalus; add CT/MR **angiography** if posterior-circulation/basilar occlusion is suspected. A normal CT does not exclude early infarction, encephalitis, diffuse axonal injury, or isodense subdural.
- ▶ **EEG**: essential to detect **non-convulsive status epilepticus**; shows triphasic/ δ slowing in metabolic coma, “alpha coma” (poor prognosis), and *extreme delta brush* in anti-NMDA-receptor encephalitis.
- ▶ **Lumbar puncture** (after CT excludes a mass): mandatory when meningitis/encephalitis or CT-negative SAH is suspected — give blood cultures + empirical antibiotics *first* if meningitis is likely.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Brainstem-reflex localisation diagram (Harrison Fig. 30-3 style)**: sagittal brainstem with labels — *Midbrain (CN III / pupillary light reflex)*, *Pons (CN V–CN VII corneal reflex; MLF; reflex conjugate eye movements; CN VI, VIII)*, *Medulla (respiratory neurons; gag/cough)*; arrows for *oculocephalic* and *oculovestibular (caloric)* pathways.
- ▶ **Pupils-in-coma chart (Plum & Posner style)**: label each — *Metabolic = small reactive*, *Diencephalic = small reactive*, *Tectal = large “fixed”*, *hippus*, *CN III/uncal = dilated fixed*, *Pontine = pinpoint*, *Midbrain (nuclear) = midposition fixed*.

Clinical / Diagnostic significance

- ▶ The pattern of pupils + eye movements + respiration + posturing **localises** the lesion to hemisphere vs diencephalon vs midbrain vs pons vs medulla and distinguishes *structural* from *metabolic* coma (preserved pupillary and reflex eye movements favour metabolic).
- ▶ **Brain death** = irreversible cessation of all cerebral and brainstem function: prerequisites — established irreversible cause, exclusion of confounders (hypothermia $<32\text{--}35^\circ\text{C}$, sedatives/paralytics, severe metabolic/endocrine derangement); findings — deep coma, **absent pupillary, corneal, oculocephalic, oculovestibular, cough/gag reflexes**, and a **positive apnoea test** (no respiratory effort with $\text{PaCO}_2 \geq 60$ mmHg or a ≥ 20 mmHg rise above baseline, pH <7.30). Spinal reflexes may persist. Ancillary tests (cerebral angiography/radionuclide flow study) used when clinical testing is incomplete.

- **Prognosis:** metabolic coma fares far better than anoxic/traumatic coma. After cardiac arrest, *bilaterally absent pupillary light reflexes at 24 h*, and *absent corneal reflexes / absent–extensor motor responses and bilaterally absent SSEP cortical responses at 72 h*, predict poor outcome — but therapeutic hypothermia delays reliable prognostication, mandating *multimodal* assessment.

High-yield exam pointers

- Consciousness = **arousal (RAS) + awareness (cortex)**; coma needs bilateral hemispheric or brainstem RAS failure.
- **Metabolic > structural** as a cause; *reactive pupils + intact reflex eye movements* point to metabolic coma.
- **First-line drugs:** thiamine → dextrose → naloxone; intubate if GCS ≤8.
- **Uncal herniation** → ipsilateral blown pupil first; **Kernohan-Woltman** = false-localising ipsilateral hemiparesis.
- **GCS 3–15** (E4 V5 M6); **FOUR score** adds brainstem reflexes + respiration and works in intubated patients.
- **COWS** for cold-caloric fast phase; **ocular bobbing** = pons, **dipping** = anoxic cortex.
- **Decorticate** = above midbrain; **decerebrate** = midbrain/pons (worse).
- **Cushing response** (hypertension + bradycardia + irregular breathing) signals raised ICP/impending herniation.
- Always do EEG in unexplained coma to exclude **non-convulsive status epilepticus**.

SOURCE & COVERAGE

- **Harrison's Principles of Internal Medicine, 22e** — “Coma” (Josephson, Ropper, Hauser): definitions, RAS physiology, herniation syndromes, brainstem-reflex examination, differential diagnosis (Table 30-1), brain death and prognosis.
- **Bradley & Daroff's Neurology in Clinical Practice, 8e** — “Stupor and Coma”: Glasgow Coma Scale (Table 5.6) and FOUR score, pupillary pathways/Plum-Posner pupil chart, respiratory-pattern localisation, oculocephalic/caloric tables, posturing.

Autosomal Recessive Ataxias

Asked in: Paper III 09/2025 — RGUHS MD General Medicine

Definition / Introduction — The **autosomal recessive cerebellar ataxias (ARCAs)** are a clinically and genetically heterogeneous group of inherited disorders in which degeneration of the **cerebellum and its**

afferent/efferent pathways (spinocerebellar tracts, dorsal columns, dorsal root ganglia, peripheral nerves) produces progressive gait and limb incoordination, dysarthria and oculomotor disturbance, typically with **onset in childhood, adolescence or early adulthood**. ARCA's characteristically affect siblings while parents are asymptomatic heterozygous carriers, and they are frequently accompanied by non-cerebellar neurological and systemic features (neuropathy, pyramidal signs, cardiomyopathy, telangiectasia, skeletal deformity). With whole-exome/whole-genome sequencing the number of recognised ARCA's now exceeds **90**, but *Friedreich's ataxia* remains by far the commonest, accounting for about half of all hereditary ataxias.

Classification — a mechanism-based scheme

A genomic/pathway classification has largely superseded the older purely clinical one. ARCA's are usefully grouped by the **biological pathway disrupted** (Synofzik), which also predicts the diagnostic biomarker and potential therapy:

Pathogenic pathway	Representative ARCA's (gene → protein)	Diagnostic biomarker / clue
Mitochondrial dysfunction	Friedreich ataxia (<i>FXN</i> → frataxin); ARSACS (<i>SACS</i> → saccin); SPG7 (<i>SPG7</i> → paraplegin); POLG/ataxia-neuropathy spectrum (<i>POLG1</i>); AVED (<i>TTPA</i> → α-tocopherol transfer protein)	Low serum vitamin E (AVED)
Defective DNA repair	Ataxia-telangiectasia (<i>ATM</i>); ataxia-telangiectasia-like disorder (<i>MRE11</i>); AOA1 (<i>APTX</i> → aprataxin); AOA2 (<i>SETX</i> → senataxin)	↑α-fetoprotein (AT, ATLD, AOA2); ↓albumin + ↑cholesterol (AOA1)
Complex lipid metabolism	Abetalipoproteinaemia (<i>MTTP</i>); Niemann-Pick type C (<i>NPC1/NPC2</i>); cerebrotendinous xanthomatosis (<i>CYP27A1</i>)	↑plasma cholestanol (CTX); oxysterols/bile acids (NPC)
Cytoskeletal / structural & repeat-expansion	SYNE1 ataxia (<i>SYNE1</i> → nesprin-1); RFC1-related CANVAS (biallelic AAGGG intronic expansion)	Cerebellar atrophy + sensory neuropathy (CANVAS)

After *Friedreich's ataxia* and *RFC1/CANVAS*, the next commonest ARCA's are *SPG7*, *ARSACS*, *AOA2*, *SYNE1*, *ataxia-telangiectasia*, *AOA1* and *POLG-ataxia* (each ≥2%).

Friedreich's Ataxia (FRDA) — the prototype ARCA

Clinical features

- ▶ Presents **before 25 years of age** with progressive staggering gait, frequent falls and *titubation*; the **lower limbs are more severely affected** than the upper.
- ▶ Examination: **nystagmus**, **loss of fast saccades**, **dysarthria**, **dysmetria**, **truncal/limb ataxia**; **areflexia** (absent ankle and knee jerks) with **extensor plantar responses** (the classic combination of areflexia + Babinski sign in a young patient); **loss of vibration and joint-position sense** (large-fibre sensory/spinocerebellar involvement); distal weakness.
- ▶ **Systemic: hypertrophic cardiomyopathy in ~90%** (cardiomegaly, symmetrical hypertrophy, conduction defects/arrhythmias — the **commonest cause of death**); **diabetes mellitus in ~20%** (insulin resistance + β -cell dysfunction); skeletal deformities — **pes cavus**, **pes equinovarus** and **scoliosis**; optic atrophy and sensorineural deafness may occur. Median age at death ~35 years; women have a better prognosis than men.

Genetics & pathogenesis

- ▶ The **only known autosomal recessive trinucleotide-repeat disease**, caused by an unstable ***GAA triplet-repeat expansion in intron 1 of the FXN (*frataxin*) gene on chromosome 9 (9q13–q21.1)***.
- ▶ **>95% are homozygous** for the GAA expansion; normal alleles carry **7–22 repeats**, patients **200–900 repeats** — *larger repeats correlate with earlier onset and greater severity*. **Compound heterozygotes** (one GAA expansion + one point mutation) give atypical/milder phenotypes (e.g. late-onset FRDA, FRDA with retained reflexes).
- ▶ **Frataxin is a mitochondrial protein of iron homeostasis**; its deficiency causes **mitochondrial iron accumulation**, **loss of iron-sulphur (Fe-S) cluster enzymes**, **reduced ATP production** and **oxidative cell injury**, with iron deposition in the heart.

Pathology: degeneration of **dorsal root ganglia**, **dorsal (posterior) columns**, **dorsal/ventral spinocerebellar tracts**, **lateral corticospinal tracts** and **the dentate nucleus**; MRI shows **spinal cord atrophy** (cerebellar atrophy is relatively mild).

Other important autosomal recessive ataxias

- ▶ **Ataxia-telangiectasia (AT):** first decade; cerebellar ataxia with **oculocutaneous telangiectasia (conjunctival)**, oculomotor apraxia, choreoathetosis, myoclonus; **recurrent sinopulmonary infections**, **IgA/IgG2 immunodeficiency**, marked **radiosensitivity** and high risk of **lymphoma**, **leukaemia** and **breast cancer**. **ATM gene (11q22–23)** encodes a PI3-kinase-like serine/threonine kinase activated by DNA double-strand breaks. Markers: **elevated α -fetoprotein** and immunoglobulin deficiency.
- ▶ **Ataxia with vitamin E deficiency (AVED):** **TTPA** mutation (α -tocopherol transfer protein); juvenile onset, **phenotype mimics Friedreich's** (ataxia, proprioceptive loss, areflexia, Babinski) with **low serum vitamin E but normal lipoproteins** — *treatable with vitamin E*.
- ▶ **Abetalipoproteinaemia (Bassen-Kornzweig syndrome):** **MTTP** (microsomal triglyceride transfer protein) defect impairing VLDL formation $\rightarrow$ fat-soluble vitamin (E) malabsorption;

spinocerebellar degeneration with **acanthocytosis**, **retinitis pigmentosa**, **steatorrhoea** — responds to high-dose vitamin E.

- ▶ **ARSACS** (autosomal recessive spastic ataxia of Charlevoix-Saguenay, *SACS/sacsin*; Québec founder effect): triad of **cerebellar ataxia + lower-limb spasticity + sensorimotor neuropathy**; MRI shows **pontine T2-hypointense stripes and thickened middle cerebellar peduncles**.
- ▶ **RFC1-related CANVAS**: late-onset; Cerebellar Ataxia + Neuropathy (sensory neuronopathy) + Vestibular Areflexia Syndrome, frequently preceded by a **chronic dry cough** and autonomic features; biallelic intronic AAGGG expansion.
- ▶ ***AOA1** (*APTX/aprataxin*) — *ataxia + oculomotor apraxia + neuropathy with hypoalbuminaemia and hypercholesterolaemia*; **AOA2** (*SETX/senataxin*) — *similar, with raised α -fetoprotein**.
- ▶ ***Cerebrotendinous xanthomatosis** (*CTX, CYP27A1*): *ataxia, dementia, epilepsy, neuropathy with tendon xanthomas and juvenile cataracts; raised plasma cholestanol** — treatable with chenodeoxycholic acid.
- ▶ ***Niemann-Pick type C** (*NPC1/NPC2*): *ataxia with vertical supranuclear gaze palsy, organomegaly and psychiatric features; miglustat slows progression*. **POLG***-related ataxia-neuropathy spectrum (**MIRAS/SANDO**) — ataxia, neuropathy, seizures, ophthalmoplegia.

Diagnostic approach & biomarkers

- ▶ **Pattern recognition**: age at onset, family tree (affected siblings, consanguinity), and the *spinocerebellar/sensory* versus *pure cerebellar* phenotype.
- ▶ **Targeted serum biomarkers** (cheap, high-yield first-line): **vitamin E** (AVED, abetalipoproteinaemia), **α -fetoprotein** (AT, AOA2), **albumin + cholesterol** (AOA1), **plasma cholestanol** (CTX), **lipoprotein electrophoresis/blood film for acanthocytes** (abetalipoproteinaemia), lactate (mitochondrial).
- ▶ **Genetic testing**: repeat-primed PCR for *FXN* GAA and *RFC1* AAGGG expansions first; then a **recessive-ataxia NGS panel / WES** if negative.
- ▶ **Ancillary**: nerve conduction (absent sensory action potentials with near-normal motor velocities in FRDA), MRI brain/spine (spinal-cord atrophy in FRDA; cerebellar atrophy in others), ECG/echocardiography (FRDA cardiomyopathy), audiometry, OGTT.

Treatment

- ▶ **Identify the treatable ARCA**s — *vitamin E* for AVED/abetalipoproteinaemia, *chenodeoxycholic acid* for CTX, *miglustat* for Niemann-Pick C, *coenzyme Q10* for CoQ10-deficient ataxia; correct B1/B12/thyroid deficiencies that mimic inherited ataxia.
- ▶ **Friedreich's ataxia**: **omaveloxolone**, an NRF2 agonist, is the **first and only FDA-approved drug** (patients ≥ 16 years), improving function in randomised trials by targeting mitochondrial energy failure. **Iron chelators and antioxidants are potentially harmful** (may aggravate myocardial

injury). Otherwise supportive — physiotherapy, surveillance and management of cardiomyopathy, diabetes and scoliosis.

- ▶ **Ataxia-telangiectasia:** immunoglobulin (IVIG) replacement for immunodeficiency, infection control, avoidance of unnecessary ionising radiation, malignancy surveillance; glucocorticoids may transiently improve neurological function.
- ▶ **Genetic counselling** (1-in-4 recurrence risk, carrier testing, prenatal diagnosis) is integral to management.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Spinal-cord cross-section in Friedreich's ataxia** — label and shade the degenerating tracts: *dorsal (posterior) columns (gracilis & cuneatus), dorsal and ventral spinocerebellar tracts, lateral corticospinal tracts*, with *dorsal root ganglion* and *Clarke's column* marked as primary sites of neuronal loss; show *dentate nucleus* of the cerebellum.
- ▶ **Classification tree of inherited ataxias** — branches: *Autosomal dominant (SCAs, DRPLA, episodic ataxia)* | *Autosomal recessive (Friedreich's, AVED, abetalipoproteinaemia, AT, ARSACS, AOA1/2, CANVAS, CTX, NPC)* | *X-linked (FXTAS)* | *Mitochondrial*, with the recessive branch sub-grouped into **mitochondrial / DNA-repair / lipid-metabolism** pathways.

Clinical / Diagnostic significance

- ▶ The triad of a young patient with **areflexia, extensor plantar responses and loss of position/vibration sense** should trigger an FXN GAA test — FRDA is the single commonest inherited ataxia worldwide.
- ▶ **Cardiomyopathy drives mortality in FRDA**, so every patient needs ECG/echo surveillance — a neurological diagnosis with a cardiological endpoint.
- ▶ Recognising the **treatable mimics** (AVED, abetalipoproteinaemia, CTX, NPC, CoQ10 deficiency) is the highest-value clinical act, since timely metabolic therapy can arrest progression.
- ▶ **α-fetoprotein and cholestanol** are simple serum tests that rapidly narrow a wide genetic differential before expensive sequencing.

High-yield exam pointers

- ▶ Friedreich's ataxia = **commonest hereditary ataxia (~50%)**; *FXN/frataxin*, chromosome 9, GAA intron-1 expansion, only AR trinucleotide-repeat disease; normal 7–22, disease 200–900 repeats; **frataxin = mitochondrial iron-handling/Fe-S protein**.
- ▶ FRDA signs: **areflexia + Babinski + impaired proprioception**, pes cavus, scoliosis, **hypertrophic cardiomyopathy (90%, top cause of death)**, diabetes (20%).
- ▶ **Omaveloxolone (NRF2 agonist)** — only FDA-approved FRDA drug (≥16 yr); **avoid iron chelators/antioxidants**.

- ▶ **Ataxia-telangiectasia:** *ATM* gene, ↑AFP, immunodeficiency, radiosensitivity, malignancy (lymphoma/leukaemia).
- ▶ ***AVED** (TTPA) and **abetalipoproteinaemia** (MTTP) are treatable with vitamin E; *abetalipoproteinaemia* shows *acanthocytes + retinitis pigmentosa*.*
- ▶ **CANVAS** = RFC1 AAGGG expansion; ataxia + sensory neuronopathy + vestibular areflexia + chronic cough.
- ▶ Biomarker shortcuts: ↑AFP → AT/AOA2; ↓albumin+↑cholesterol → AOA1; ↑cholestanol → CTX; ↓vitamin E → AVED/abetalipoproteinaemia.
- ▶ **ARSACS** triad = **ataxia + spasticity + neuropathy** (Charlevoix-Saguenay, SACS/sacsin).

SOURCE & COVERAGE

- ▶ **Harrison's Principles of Internal Medicine, 22e** — “Ataxic Disorders” (Autosomal Recessive Ataxias: Friedreich's ataxia, RFC1-CANVAS, ataxia-telangiectasia; treatment incl. omaveloxolone).
- ▶ **Bradley & Daroff's Neurology in Clinical Practice, 8e** — “Cerebellar Ataxia” (ARCA classification Table 23.7 by pathogenic pathway — mitochondrial/DNA-repair/lipid; gene-protein-biomarker correlations; ARSACS, AOA1/2, CTX, NPC, POLG, AVED).
- ▶ **CMDT 2026** — “Nervous System Disorders” (Friedreich ataxia clinical/genetic summary and omaveloxolone) and vitamin E deficiency.

Benign Intracranial hypertension

Asked in: Paper III Jul 2021 — RGUHS MD General Medicine

Definition / Introduction — *Benign intracranial hypertension*, now preferentially termed **idiopathic intracranial hypertension (IIH)** or *pseudotumor cerebri*, is a syndrome of raised intracranial pressure (ICP) — manifesting with headache and papilledema — occurring in the **absence of an intracranial mass, hydrocephalus, venous sinus thrombosis or abnormal CSF constituents**. The label “benign” is a misnomer because untreated disease causes **progressive optic atrophy and irreversible blindness**; “idiopathic” is preferred. Diagnosis is one of *exclusion* and rests on the modified Dandy (Friedman) criteria, with the cardinal goal of therapy being preservation of vision.

Terminology & epidemiology

- ▶ **Historical names:** *otitic hydrocephalus* (papilledema with otitis media), *pseudotumor cerebri* (pneumoencephalography era), *benign intracranial hypertension* — all unsatisfactory; **IIH** is the current descriptive term, though “pseudotumor cerebri” persists for the *secondary* causes.

- ▶ Overwhelmingly a disease of **obese young women of childbearing age**. In the landmark **Idiopathic Intracranial Hypertension Treatment Trial (IIHTT)** the mean age was **29 years**, **97.6% were women**, and mean BMI **39.9 kg/m²**.
- ▶ Associations: obesity, recent weight gain, menstrual irregularity; with modern imaging IIH is now the **commonest cause of papilledema** in the developed world.

Pathophysiology

- ▶ The fundamental abnormality is **raised CSF pressure** with otherwise normal brain parenchyma and ventricles.
- ▶ **Venous outflow / venous sinus stenosis hypothesis** (dominant current model): bilateral distal **transverse sinus stenoses** (or stenosis of a dominant transverse sinus) → reduced cerebral venous drainage → **cerebral venous hypertension** → impaired passive CSF resorption at arachnoid granulations → rising CSF pressure → external compression of the transverse sinus → a self-perpetuating *vicious cycle*. Whether the stenosis is cause or consequence remains debated (stenoses also occur in normals).
- ▶ Elevated venous pressure has been documented in the superior sagittal and proximal transverse sinuses; raised right-atrial filling pressure can be transmitted to the sinuses.
- ▶ A contribution from cerebral interstitial **white-matter (brain) edema** has been proposed on MRI diffusion studies but remains *without consensus*.

Clinical features

- ▶ **Headache** — most frequent presenting symptom (~84% in IIHTT); often worse on straining/coughing, may wake the patient in the early morning; phenotype is **migraine-like in ~52%** and **tension-type in ~22%**.
- ▶ **Transient visual obscurations (TVOs)** — brief (seconds) mono- or binocular greying/blacking of vision, precipitated by postural change or Valsalva; reflect transient hypoperfusion of the swollen optic nerve head (~68%).
- ▶ **Pulse-synchronous (pulsatile) tinnitus** (~52%) and **back pain** (~53%).
- ▶ **Diplopia** from **unilateral or bilateral sixth (abducens) nerve palsy** — a classic *false localizing sign* (the long intracranial course/Dorello's canal makes CN VI vulnerable to pressure).
- ▶ **Visual loss** — only ~32% report it at onset, but it is the *feared* outcome; vision is typically preserved until late, when chronic papilledema encroaches on the macula. Visual fields show an **enlarged blind spot**, then nasal/sector scotomas.
- ▶ **Papilledema** is the cardinal sign; the patient otherwise looks well with a normal neurological exam (except CN VI).

Diagnostic criteria (modified Dandy / Friedman 2013)

Criterion	Requirement for IIH
A. Papilledema	Present
B. Neurological exam	Normal except cranial nerve VI palsy
C. Neuroimaging	Normal brain parenchyma; venous sinus thrombosis excluded
D. CSF constituents	Normal (normal/low protein, normal glucose, no cells)
E. Opening pressure	Elevated LP pressure >250 mm CSF (>25 cm) in adults

- ▶ **IIH without papilledema (IIHWOP):** criteria B–E **plus** a unilateral/bilateral sixth-nerve palsy.
- ▶ Normal CSF opening pressure upper limit is ~180–200 mm H₂O; in IIH it usually exceeds 200 and may reach >500 mm. **Measure in the lateral decubitus position** with legs extended and neck straight — *sitting and prone (fluoroscopy) readings overestimate and are invalid.*

Investigations & differentiation

- ▶ **MRI brain with contrast + MR venography (MRV)** are *mandatory before LP* to exclude a mass, hydrocephalus, and **cerebral venous sinus thrombosis (CVST)** — the key IIH mimic. Supportive (non-specific) MRI signs: **empty sella, posterior scleral flattening, optic nerve sheath distension, vertical tortuosity of the optic nerve, optic nerve head enhancement, and transverse sinus stenosis.**
- ▶ **Lumbar puncture** with manometry confirms raised opening pressure and documents normal CSF; CSF removal transiently relieves headache and obscurations.
- ▶ **Papilledema vs papillitis:** in *papilledema* (raised ICP) acuity is preserved early and pupillary reactions are normal; in *papillitis* (optic neuritis) central vision is lost early with a relative afferent pupillary defect. Distinguish true papilledema from **pseudopapilledema** (optic disc drusen) — an ophthalmologist should confirm.
- ▶ **Formal perimetry (visual fields)** and serial funduscopy/OCT monitor the threat to vision.

Secondary “pseudotumor cerebri” — causes to exclude

- ▶ **Cerebral venous abnormalities:** venous sinus / bilateral jugular thrombosis or ligation, middle-ear/mastoid infection, raised right-heart pressure, SVC syndrome, AV fistula, hypercoagulable states.
- ▶ **Drugs/exposures:** tetracyclines (tetracycline, **minocycline, doxycycline**), nalidixic acid, sulfonamides/cotrimoxazole, nitrofurantoin; **vitamin A excess / retinoids (isotretinoin, all-trans retinoic acid)**; growth hormone, thyroxine (children), levonorgestrel, anabolic steroids; **withdrawal from chronic corticosteroids; lithium.**

- ▶ **Medical conditions:** Addison disease, hypoparathyroidism, hypothyroidism, hypercapnia, obstructive sleep apnea / **Pickwickian syndrome**, anemia, renal failure/uremia, Turner and Down syndromes.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Fundus in papilledema (label):** hyperemic *elevated* optic disc, **blurred/obliterated disc margins**, filled-in physiologic cup, **engorged tortuous retinal veins**, **peripapillary flame-shaped hemorrhages**, **cotton-wool spots** (NFL infarcts), loss of spontaneous venous pulsations; chronic stage “*champagne-cork*” disc; end-stage secondary optic atrophy.
- ▶ **Pathophysiology loop (label):** transverse sinus stenosis → ↓venous outflow → cerebral venous hypertension → ↓CSF resorption → ↑ICP → external sinus compression (vicious cycle); annotate MRI signs — empty sella, posterior scleral flattening, optic nerve sheath distension, optic nerve tortuosity.

Management

- ▶ **Goal:** prevent permanent visual field loss; treat any identifiable secondary cause (stop offending drug, gradually re-taper steroids, correct endocrinopathy/anemia, treat OSA).
- ▶ **Weight loss** is disease-modifying — up to ~15% loss can induce remission; some authors regard it as important as drug therapy.
- ▶ **Acetazolamide** (carbonic anhydrase inhibitor; lowers CSF production): start **500 mg twice daily**, titrate as tolerated up to **4 g/day**; the IIHTT supported acetazolamide ≤4 g/day **with weight loss** for mild visual loss, improving papilledema, ICP and quality of life. Monitor for metabolic acidosis, paresthesias (~25%), hypokalemia.
- ▶ **Topiramate** — also a carbonic anhydrase inhibitor, with the bonus of weight loss; alternative when acetazolamide is not tolerated. **Furosemide** 20–40 mg/day as adjunct.
- ▶ **Corticosteroids** — reserved for **fulminant** disease with rapidly progressive visual loss; avoided for maintenance because of weight gain and relapse on withdrawal.
- ▶ **Serial therapeutic LPs** — temporizing measure only.
- ▶ **Bariatric surgery** — consider for BMI ≥35 (RCT showed reduction in ICP and weight at 2 years).
- ▶ **Surgical / interventional** (failed medical therapy or threatened vision): **optic nerve sheath fenestration** (best for vision-threatening papilledema with preserved headache control), **CSF diversion shunt** (ventriculoperitoneal preferred over lumboperitoneal for patency), and **venous sinus stenting** in selected patients with a documented pressure gradient across a transverse sinus stenosis (still considered investigational).
- ▶ **Fulminant IIH:** rare, urgent — high-dose steroids + acetazolamide + early surgical decompression; despite treatment ~50% may remain legally blind, underscoring that the condition is *not* benign.

Clinical / Diagnostic significance

- ▶ IIH must be actively sought in *every* young obese woman with chronic daily headache — fundoscopy for papilledema is the screening pivot.
- ▶ The diagnosis is by **exclusion**: imaging (MRI/MRV) precedes LP to rule out mass and CVST; a sixth-nerve palsy is a non-localizing sign of raised ICP.
- ▶ Vision, not headache, dictates urgency and the threshold for surgery; serial perimetry and OCT are essential.
- ▶ Headache may persist after ICP normalizes (coexistent migraine/medication-overuse headache in a large fraction of IIHTT patients) and is then treated by its phenotype.

High-yield exam pointers

- ▶ Triad concept: **raised ICP + papilledema + normal neuroimaging/CSF** = IIH; “benign” is a misnomer (blindness risk).
- ▶ **Demographic**: obese woman of reproductive age (IIHTT: mean age 29, 97.6% female, BMI 39.9).
- ▶ **Modified Dandy/Friedman criteria** — opening pressure >250 mm CSF, measured in lateral decubitus.
- ▶ CN VI palsy = **false localizing sign**; commonest symptom is headache, most feared is visual loss.
- ▶ MRI signs mnemonic: **empty sella, posterior scleral flattening, optic nerve sheath distension/tortuosity, transverse sinus stenosis**.
- ▶ Secondary causes: **tetracyclines, vitamin A/retinoids, steroid withdrawal, OSA, venous sinus thrombosis**.
- ▶ First-line therapy: **weight loss + acetazolamide (up to 4 g/day)**; topiramate as alternative; **optic nerve sheath fenestration / CSF shunt / venous sinus stenting** for refractory vision-threatening disease.
- ▶ Always **exclude CVST with MRV** before labelling as idiopathic.

SOURCE & COVERAGE

- ▶ **Bradley & Daroff's Neurology in Clinical Practice 8e** — “Brain Edema and Disorders of Cerebrospinal Fluid Circulation” (Idiopathic Intracranial Hypertension: clinical features, CSF criteria, treatment) and “Headache and Other Craniofacial Pain” (IIHTT data, IIH diagnostic criteria Table 102.1, secondary pseudotumor causes Table 102.2).
- ▶ **DeJong's The Neurologic Examination** — “The Optic Nerve” (stages of papilledema, papilledema vs pseudopapilledema, transient visual obscurations).
- ▶ **CMDT 2026** — “Nervous System Disorders” (Idiopathic Intracranial Hypertension: essentials of diagnosis, imaging, drug regimens, surgical options).

- **Harrison's Principles of Internal Medicine 22e** — neurologic history/disorders of the eye (vitamin A-associated pseudotumor cerebri; corroborating detail).

Coverage note: Harrison 22e covers IIH only sparsely and scattered (no dedicated section), as flagged in the spec; the substantive depth here is drawn from Bradley & Daroff, DeJong and CMDT 2026. A formal Frisén papilledema grading scale was not present in the searched corpus, so the four descriptive stages (early, fully developed, chronic, atrophic) from DeJong are used instead.

Cerebral venous sinus thrombosis

Asked in: Paper III May 2022 — RGUHS MD General Medicine

Definition / Introduction — Cerebral venous sinus thrombosis (CVST) is thrombotic occlusion of the dural venous sinuses and/or the cerebral veins, causing impaired venous drainage, raised intracranial pressure (ICP), venous congestion and frequently haemorrhagic venous infarction. It is an uncommon but eminently treatable cause of stroke (~0.5–1% of all strokes), distinguished from arterial stroke by its predilection for **young adults and women**, its **subacute, multi-symptom evolution**, and its excellent prognosis when anticoagulated early. Because lesions do not respect arterial territories and seizures and headache dominate the picture, a high index of suspicion is essential.

Applied anatomy of the cerebral venous system

- **Superficial (cortical) system:** cortical veins → **superior sagittal sinus (SSS)** along the falx; the *vein of Trolard* (superior anastomotic) and *vein of Labbé* (inferior anastomotic to transverse sinus) are key cortical channels.
- **Deep system:** internal cerebral veins + basal vein of *Rosenthal* → **great vein of Galen** → **straight sinus**.
- **Confluence and outflow:** SSS + straight sinus + inferior sagittal sinus meet at the **confluence of sinuses** (torcular Herophili) → paired **transverse (lateral) sinuses** → **sigmoid sinuses** → **internal jugular veins**.
- **Cavernous sinuses** flank the sella, transmitting the internal carotid artery and cranial nerves III, IV, VI and V1/V2; they drain via superior/inferior petrosal sinuses.
- **Commonest thrombosis sites:** superior sagittal sinus and transverse sinuses (often combined); deep venous and cavernous sinus thromboses are less common but distinctive.

Etiology and risk factors (Virchow's triad)

Multiple causes coexist in up to half of patients; an underlying prothrombotic state should always be sought.

Category	Examples
Hereditary thrombophilia	Factor V Leiden, prothrombin G20210A, protein C/S deficiency, antithrombin deficiency, hyperhomocysteinaemia
Acquired prothrombotic	Antiphospholipid syndrome, nephrotic syndrome, malignancy, paroxysmal nocturnal haemoglobinuria, myeloproliferative disease (JAK2 V617F)
Hormonal / obstetric	Pregnancy and puerperium , oral contraceptives, hormone replacement therapy
Infective (septic)	Otitis media / mastoiditis (transverse–sigmoid; “otitic hydrocephalus”), sinusitis, meningitis, facial/orbital sepsis (cavernous sinus thrombosis , classically <i>Staphylococcus aureus</i>)
Inflammatory / systemic	Behçet disease, SLE, inflammatory bowel disease, sarcoidosis, dehydration
Mechanical / iatrogenic	Head trauma, neurosurgery, jugular catheterisation, lumbar puncture
Drug / vaccine-related	Adenoviral-vector COVID-19 vaccines causing VITT (vaccine-induced immune thrombotic thrombocytopenia, anti-PF4 antibodies); COVID-19 infection itself

Pathophysiology

- ▶ **Two parallel mechanisms** produce symptoms: (1) sinus occlusion → impaired CSF absorption at arachnoid granulations → **raised ICP**; (2) cortical/deep vein occlusion → venous congestion → vasogenic and cytotoxic oedema → **venous (often haemorrhagic) infarction**.
- ▶ Venous infarcts characteristically **cross arterial boundaries**, are frequently bilateral/parasagittal (SSS) and have a **high propensity to haemorrhage** — a crucial point, since this haemorrhage does *not* contraindicate anticoagulation.
- ▶ **Deep venous (galenic/straight sinus) thrombosis** causes bilateral **thalamic and basal ganglia** oedema, presenting as encephalopathy or coma.

Clinical features — four classic presentations

Onset is usually **subacute** (days–weeks); **headache is the commonest and earliest symptom** (~90%), often diffuse, progressive and worse on recumbency or Valsalva; *thunderclap* onset can occur.

Syndrome	Key features
Isolated intracranial hypertension	Headache, papilloedema, visual obscurations, 6th-nerve palsy , pulsatile tinnitus (mimics idiopathic intracranial hypertension)
Focal syndrome	Focal deficits (hemiparesis, aphasia) and seizures — far commoner than in arterial stroke (~40%), often focal with secondary generalisation
Encephalopathy	Altered consciousness, multifocal signs, coma — typical of deep cerebral venous thrombosis (bilateral thalami)
Cavernous sinus syndrome	Painful ophthalmoplegia, proptosis , chemosis , ptosis , CN III/IV/VI palsies, V1–V2 sensory loss; frequently septic and may become bilateral

Investigations

- ▶ **D-dimer**: usually elevated and supportive, but a normal value does **not** exclude CVST (especially isolated headache or long-standing presentation).
- ▶ **Non-contrast CT**: often normal; may show a **hyperdense thrombosed sinus** (“dense triangle”/“cord sign”) and parenchymal venous infarct/haemorrhage not conforming to an arterial territory.
- ▶ **Contrast CT / CT venography**: the “**empty delta sign**” — enhancing dural walls surrounding a non-enhancing central thrombus in the SSS; CTV demonstrates the filling defect.
- ▶ **MRI + MR venography (MRV)**: investigation of **choice** — directly shows absent venous flow and the evolving thrombus signal, plus parenchymal oedema/haemorrhage; gradient-echo/SWI sequences highlight the clot.
- ▶ **Digital subtraction angiography (venous phase)**: reserved for equivocal cases or planned endovascular therapy.
- ▶ **Lumbar puncture**: raised opening pressure; may show elevated protein, red cells and pleocytosis — useful chiefly to relieve pressure and to exclude meningitis (defer if a large mass lesion risks herniation).
- ▶ **Etiological workup**: thrombophilia screen, antiphospholipid antibodies, autoimmune and malignancy screen; in suspected VITT — platelet count, anti-PF4 ELISA, fibrinogen.

Management

- ▶ **Anticoagulation is the cornerstone**, given even in the presence of haemorrhagic venous infarction:
 - **Acute**: therapeutic **low-molecular-weight heparin** (e.g., enoxaparin 1 mg/kg SC 12-hourly), preferred over dose-adjusted unfractionated heparin (UFH reserved when rapid reversal or renal failure is a concern).

- **Maintenance:** transition to **oral anticoagulation** — warfarin (target INR 2–3) or a DOAC (dabigatran 150 mg BD shown non-inferior in the RE-SPECT CVT trial).
- **Duration:** provoked/transient cause **3–6 months**; unprovoked **6–12 months**; recurrent VTE or strong thrombophilia → **indefinite**.
- ▶ **Endovascular thrombolysis/thrombectomy:** considered for clinical deterioration despite adequate anticoagulation (routine use not supported — TO-ACT trial neutral).
- ▶ **Raised ICP / mass effect:** head-end elevation, **acetazolamide**, therapeutic LP for refractory hypertension; **decompressive hemicraniectomy** is life-saving for impending herniation from a large venous infarct/haemorrhage.
- ▶ **Seizures:** antiseizure medication for clinical seizures (and considered prophylactically with a supratentorial parenchymal lesion).
- ▶ **Treat the cause:** antibiotics ± surgical drainage for septic CVST/cavernous sinus thrombosis; correct dehydration; manage malignancy/thrombophilia.
- ▶ **VITT-associated CVST:** use **non-heparin anticoagulants** (argatroban, fondaparinux, or a DOAC) plus IVIG; **avoid heparin and platelet transfusion**.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Diagram 1 — Dural venous sinus map (superolateral/midsagittal view):** label *Superior sagittal sinus*, *Inferior sagittal sinus*, *Straight sinus*, *Great vein of Galen*, *Internal cerebral vein*, *Vein of Labbé*, *Vein of Trolard*, *Confluence of sinuses (torcular Herophili)*, *Transverse sinus*, *Sigmoid sinus*, *Internal jugular vein*, *Cavernous sinus*.
- ▶ **Diagram 2 — “Empty delta sign”:** triangular cross-section of the superior sagittal sinus with *enhancing dural wall* (outer rim) and *central non-enhancing thrombus*; label both.

Clinical / Diagnostic significance

- ▶ Consider CVST in any **young patient with new persistent headache, papilloedema, seizures, or a haemorrhagic infarct crossing arterial boundaries** — especially peripartum women or those on oral contraceptives.
- ▶ It is a key differential of **idiopathic intracranial hypertension** and of arterial stroke in the young; MRV/CTV is decisive.
- ▶ **Bilateral thalamic signal change** suggests deep venous thrombosis; **proptosis with ophthalmoplegia** suggests cavernous sinus thrombosis.
- ▶ **Prognosis is favourable** (~80% recover well; mortality ~5–10%). Poor predictors: coma/depressed consciousness, deep venous or posterior fossa involvement, intracranial haemorrhage, malignancy, CNS infection, male sex and older age.

High-yield exam pointers

- ▶ CVST = stroke of the young, women > men, classic triggers pregnancy/puerperium and OCPs.
- ▶ Headache is the commonest symptom; seizures are much commoner than in arterial stroke.
- ▶ Superior sagittal and transverse sinuses are the most frequent sites.
- ▶ Imaging signs: dense cord/triangle sign (NCCT), empty delta sign (CECT/CTV); MRV is the investigation of choice.
- ▶ Anticoagulate even when there is haemorrhagic venous infarction — the single most important management pearl.
- ▶ DOAC (dabigatran) is a validated alternative to warfarin (RE-SPECT CVT).
- ▶ Cavernous sinus thrombosis is usually septic (*S. aureus*) — proptosis, chemosis, CN III/IV/VI + V1–V2 involvement, may become bilateral.
- ▶ VITT-related CVST: non-heparin anticoagulation + IVIG; avoid heparin and platelets.
- ▶ Decompressive hemicraniectomy is the rescue for impending herniation.

SOURCE & COVERAGE

Harrison 22e — Ch 437 “Introduction to Cerebrovascular Diseases” (Smith & Hemphill).

Coverage note: The provided Ch 437 text covers arterial ischaemic stroke anatomy, hemorrhage and general cerebrovascular evaluation, but does **not** substantively cover cerebral venous sinus thrombosis — it mentions only DVT prophylaxis (Fig. 437-1) and cross-references raised intracranial pressure (Ch 439). Harrison’s primary CVST coverage lies in the Ischemic Stroke chapter (Ch 438), which was not supplied. Accordingly, this answer is grounded in **universally accepted standard internal-medicine** content; the disease framework, imaging signs (empty delta/cord sign), anticoagulation principle (including in haemorrhagic infarction), RE-SPECT CVT/TO-ACT trial data and VITT management are standard textbook/guideline material and were stated only where confidently accurate. No specifics were drawn unverified from Ch 437.

Clinical features and management of Alzheimer’s disease

Asked in: Paper III May 2019 — RGUHS MD General Medicine

Definition / Introduction — Alzheimer’s disease (AD) is a chronic, progressive neurodegenerative disorder and the commonest cause of dementia, contributing an estimated **60–70%** of all dementia (≈55 million people worldwide). It is characterised pathologically by extracellular **neuritic plaques** of amyloid- β (A β) and intraneuronal **neurofibrillary tangles** (NFTs) of hyperphosphorylated tau, with cholinergic neuronal loss in the nucleus basalis of Meynert. Clinically it presents most often with insidious-onset, progressive loss of **episodic memory** that slowly engulfs other cognitive domains and, ultimately, function and independence. Typical symptomatic duration is **8–10 years** (range 1–25).

Epidemiology & risk factors

- ▶ **Age** is the dominant risk factor: ~10% of those >65 have AD — 3% at 65–74, 17% at 75–84, and 32% at ≥85 years.
- ▶ **Genetic / family history**: the **ApoE ε4** allele on chromosome 19 is the major susceptibility gene — one ε4 allele raises risk ~2–3-fold (more in women), two alleles **10–15-fold**; each ε4 allele lowers age of onset by ~10 years. Autosomal-dominant familial AD (1–2%) is caused by mutations in **APP (chr 21)**, **Presenilin-1 (PSEN-1, chr 14)** and **Presenilin-2 (PSEN-2, chr 1)**; PSEN-1 is the commonest cause of early-onset FAD. Adults with **trisomy 21 (Down syndrome)** invariably develop AD pathology after age 40.
- ▶ **Female sex** is an independent risk factor; **TREM2** and >40 GWAS variants (**CLU**, **PICALM**, **CR1**) add small effects.
- ▶ **Modifiable / vascular**: mid-life hypertension, diabetes (≈3-fold risk), obesity, dyslipidaemia, smoking, hearing loss, traumatic brain injury, physical inactivity, low education, depression and air pollution. SPRINT-MIND showed intensive BP control (SBP <120) reduced incident MCI.

Pathology & neurochemistry

- ▶ Earliest and most severe degeneration begins in the **medial temporal lobe** (entorhinal cortex, hippocampus) and **nucleus basalis of Meynert**, spreading to temporoparietal then frontal neocortex.
- ▶ **Aβ** (39–42 aa) is cleaved from **amyloid precursor protein (APP)** by **β- and γ-secretases**; soluble Aβ oligomers and Aβ42 are the toxic species, polymerising into plaques. Vascular Aβ deposition = **cerebral amyloid angiopathy (CAA)**.
- ▶ **NFTs** = paired helical filaments of hyperphosphorylated **tau**, which detaches from microtubules and spreads in a prion-like, stereotyped pattern (**Braak staging**).
- ▶ **Neurochemistry**: loss of cortical **acetylcholine** and choline acetyltransferase (basis of cholinesterase-inhibitor therapy), with noradrenergic (locus coeruleus) and serotonergic (dorsal raphe) depletion.

Clinical features

AD evolves through a recognised continuum — **preclinical** → **MCI/early symptomatic** → **dementia** (mild → moderate → severe).

- ▶ **Preclinical AD**: biomarker evidence of amyloid (± tau) pathology *without* symptoms; may precede symptoms by ≥20 years.
- ▶ **Mild cognitive impairment (MCI) / early symptomatic AD**: memory loss noticeable to patient and family and confirmed on testing, but daily function preserved. ~50% of MCI (≈12%/year) progress to dementia over 4 years.
- ▶ **Typical (amnestic) presentation**: insidious loss of **episodic memory** — repeating questions, forgetting recent conversations and appointments — reflecting hippocampal pathology.

Disorientation to time/place, getting lost on familiar routes, and impaired complex tasks (finances, work, driving) follow.

- ▶ **Mild dementia:** memory + word-finding difficulty (circumlocution), early visuospatial and executive decline; depression, anxiety, social withdrawal and apathy are common and may be a prodrome.
- ▶ **Moderate dementia:** unable to work, easily lost, needs daily supervision. Progressive **language** failure (naming → comprehension → fluency), **apraxia** (using utensils/appliances), **visuospatial deficits** (dressing, copying figures), and **acalculia/clock** difficulties. **Delusions** (theft, infidelity, misidentification), agitation, wandering, disinhibition and disrupted sleep–wake cycle appear.
- ▶ **Severe (late) dementia:** patient becomes rigid, mute, incontinent, bedridden and totally dependent; **myoclonus**, hyperreflexia, parkinsonian gait and **seizures** may occur. Death is usually from **aspiration**, infection, malnutrition or pulmonary embolism.
- ▶ **Atypical variants (~20%, often younger):** **posterior cortical atrophy** (progressive visual processing failure), **logopenic primary progressive aphasia** (impaired naming and repetition), **dysexecutive/behavioural (“frontal”) variant**, and a **corticobasal (akinetic-rigid-dystonic)** syndrome. Anosognosia (unawareness) may occur, but most retain insight early.

Diagnosis & investigations

- ▶ **Clinical diagnosis** rests on slowly progressive amnesic decline with normal systemic labs and posterior-predominant cortical + hippocampal atrophy; it is confirmed at autopsy in ~70–80%.
- ▶ **Cognitive screening:** MMSE (Folstein), **MoCA**, Mini-Cog — quick but insensitive to MCI; formal neuropsychometry for atypical cases.
- ▶ **Exclude reversible/secondary dementia (mandatory work-up):** serum **vitamin B12**, **TSH/free T4**, electrolytes, calcium, RPR/VDRL, HIV; LP where indicated. Treat the “treatable” differentials — B12 deficiency, hypothyroidism, normal-pressure hydrocephalus, neurosyphilis, depression (pseudodementia), chronic drug intoxication.
- ▶ **Structural MRI/CT:** medial temporal (hippocampal) and posterior-predominant cortical atrophy; chiefly excludes tumour, vascular disease, subdural haematoma and NPH.
- ▶ **Functional/molecular imaging:** **FDG-PET** shows temporoparietal hypometabolism (and distinguishes AD from FTD); **amyloid PET** ([18F]florbetapir/florbetaben/flutemetamol) confirms plaque burden; **tau PET** ([18F]flortaucipir) maps NFTs.
- ▶ **Fluid biomarkers:** CSF shows **low Aβ42**, reduced **Aβ42/Aβ40 ratio** and raised **phospho-tau (p-Tau181/p-Tau217)**. Plasma **p-Tau217** (and Aβ42/40) now offer scalable, blood-based confirmation.
- ▶ **Criteria:** evolution from NINCDS-ADRDA (1984) → NIA-AA (2011) clinical-biomarker criteria → 2018 ATN research framework (Amyloid, Tau, Neurodegeneration) and the 2024 Revised

Criteria defining AD *biologically* by “core 1” biomarkers (amyloid PET, CSF/plasma A β and p-Tau). ApoE genotyping is recommended *before* anti-amyloid therapy to assess ARIA risk.

Management

AD requires a **multidomain approach**: symptomatic neurotransmitter therapy, disease-modifying anti-amyloid antibodies, treatment of neuropsychiatric symptoms, and patient/caregiver support.

1. Neurotransmitter-based (symptomatic) therapy

Drug	Mechanism	Dosing	Approved stage
Donepezil	Cholinesterase inhibitor	Start 5 mg OD $\times$ 4 wk $\rightarrow$ 10 mg OD (23 mg for mod-severe)	Mild-severe
Rivastigmine	Cholinesterase inhibitor	1.5 mg BID, titrate to 3–6 mg BID; or 9.5 mg/24h patch	Mild-severe
Galantamine	Cholinesterase inhibitor	4 mg BID $\rightarrow$ 8–12 mg BID (24 mg/day ER)	Mild-severe
Memantine	NMDA-receptor antagonist	5 mg OD, $\uparrow$ 5 mg/wk $\rightarrow$ 10 mg BID	Moderate-severe

- Dose-escalate over **4–6 weeks**. Cholinesterase inhibitors modestly slow decline (MMSE maintained $\sim$ 1 year vs 2–3 point fall on placebo); main side effects are GI (**nausea, diarrhoea, cramps**), vivid dreams, bradycardia/syncope (obtain ECG in cardiac patients). A common strategy: start a cholinesterase inhibitor in mild AD and **add memantine** in moderate-severe disease. Memantine side effects: constipation, dizziness, headache, somnolence. Cholinesterase inhibitors are **avoided in frontotemporal dementia** (worsen behaviour).

2. Disease-modifying anti-amyloid monoclonal antibodies (first DMTs for AD)

- **Lecanemab** (anti-A β **protofibril**): 10 mg/kg IV every 2 weeks — **Clarity-AD** showed **27% slowing** of CDR-SB decline at 18 months.
- **Donanemab** (anti-pyroglutamate A β): 700 mg IV q4w $\times$ 3 then 1400 mg q4w — **TRAILBLAZER-ALZ2** showed 22% slowing on iADRS and 28% on CDR-SB; greatest benefit in low-medium tau-PET patients.
- **Aducanumab** received accelerated approval but was withdrawn (ambiguous efficacy).
- **Restricted to MCI or mild AD dementia with biomarker-confirmed amyloid (PET/CSF)**. Key toxicity = **ARIA** — ARIA-E (oedema/effusion on FLAIR) and ARIA-H (microbleeds/siderosis on GRE/SWI); $\sim$ 75% asymptomatic, but seizures, stroke-like episodes and rare death occur. Risk rises with each ϵ 4 allele (**box warning for ϵ 4 homozygotes**). Requires serial surveillance MRI; **contraindicated** with extensive CAA ($>$ 4 microbleeds/cortical siderosis), uncontrolled hypertension, anticoagulation, and concurrent **thrombolysis** for acute stroke.

3. Neuropsychiatric / behavioural symptoms

- ▶ **Depression/anxiety:** SSRIs with low anticholinergic burden (e.g., **escitalopram** 5–10 mg).
- ▶ **Agitation/psychosis:** non-pharmacological behavioural measures first; low-dose atypical antipsychotics (risperidone, quetiapine, olanzapine) carry an **FDA black-box warning** (increased mortality in elderly dementia). **Brexipiprazole** is the only agent FDA-approved for **agitation in AD**.
- ▶ **Seizures:** levetiracetam. **Avoid strong anticholinergics** (diphenhydramine, oxybutynin) which worsen cognition.

4. Non-pharmacological & caregiver support

- ▶ Memory aids (notebooks, posted reminders), home safety, eventual cessation of driving.
- ▶ Lifestyle: physical/cognitive/social activity, vascular risk-factor control, sleep hygiene, **Mediterranean/DASH diet**.
- ▶ Address **caregiver burnout** with respite care, adult day-care and support groups (Alzheimer's Association). (*Estrogen, statins, vitamin E and ginkgo have not shown benefit in RCTs.*)

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **APP processing pathway:** membrane-spanning APP cleaved by β -secretase (BACE) then γ -secretase $\rightarrow$ toxic $A\beta_{42}$ (amyloidogenic) vs non-amyloidogenic α -secretase $\rightarrow A\beta_{40}/P3$.
Label: APP, $\alpha/\beta/\gamma$ -secretase, $A\beta_{42}$ (toxic plaque), $A\beta_{40}$, cell membrane.
- ▶ **Brain atrophy / pathology schematic:** coronal section showing **hippocampal + medial temporal lobe atrophy** with dilated temporal horns and posterior cortical atrophy; inset labelling **extracellular neuritic (amyloid) plaque** and **intraneuronal neurofibrillary tangle**, and the **nucleus basalis of Meynert** (cholinergic loss).

Clinical / Diagnostic significance

- ▶ **Episodic memory loss + medial temporal atrophy + temporoparietal hypometabolism** is the classic triad pointing to AD.
- ▶ Always **exclude reversible dementias** (B12, thyroid, NPH, neurosyphilis, depression, drugs) before labelling AD.
- ▶ **Distinguishing clues:** early gait disturbance with mild memory loss $\rightarrow$ vascular dementia/NPH; resting tremor, fluctuations and visual hallucinations $\rightarrow$ DLB; rapid decline with myoclonus $\rightarrow$ Creutzfeldt-Jakob disease; behavioural change with anterior atrophy $\rightarrow$ frontotemporal dementia.
- ▶ Biomarker confirmation is now **mandatory before disease-modifying therapy**, and **ApoE genotyping** stratifies ARIA risk.

High-yield exam pointers

- ▶ Commonest dementia (60–70%); hallmark = **amyloid plaques + tau NFTs**; cholinergic deficit (nucleus basalis of Meynert).
- ▶ **ApoE ε4** = major risk gene (2–3× heterozygote, 10–15× homozygote); FAD genes = **APP, PSEN-1, PSEN-2**; Down syndrome → early AD.
- ▶ Earliest clinical feature = **episodic (anterograde) memory loss**; atypical variants = posterior cortical atrophy, logopenic aphasia, frontal/dysexecutive.
- ▶ CSF: ↓Aβ42, ↓Aβ42/40 ratio, ↑p-Tau181/217; **plasma p-Tau217** emerging. FDG-PET = temporoparietal hypometabolism.
- ▶ Symptomatic drugs: **cholinesterase inhibitors** (donepezil, rivastigmine, galantamine) ± **memantine** (NMDA antagonist, moderate–severe).
- ▶ Disease-modifying: **lecanemab & donanemab** (anti-amyloid mAbs) for early AD; major risk = ARIA-E/ARIA-H; check ApoE before starting.
- ▶ **Brexpiprazole** = only drug FDA-approved for agitation in AD; antipsychotics carry a mortality **black-box warning**.
- ▶ Death usually from **aspiration pneumonia**, infection or malnutrition.

SOURCE & COVERAGE

- ▶ **Harrison's Principles of Internal Medicine, 22e** — “Alzheimer's Disease” (clinical manifestations, pathology, genetics, biomarkers, treatment including anti-amyloid antibodies, ARIA) and “Dementia.”
- ▶ **Bradley & Daroff's Neurology in Clinical Practice, 8e** — “Alzheimer Disease and Other Dementias” (MCI continuum, NINCDS-ADRDA/NIA-AA/2018 ATN diagnostic frameworks, structural/functional/amyloid–tau imaging).
- ▶ **CMDT 2026** — “Nervous System Disorders” (current drug dosing, anti-amyloid therapy regimens and cautions, diagnostic work-up).

Clinical features, pathophysiology and management of trigeminal neuralgia. Differentiate trigeminal neuralgia from trigeminal neuropathy

Asked in: Paper III 15 Apr 2026 — RGUHS MD General Medicine

Definition / Introduction — *Trigeminal neuralgia (tic douloureux)* is a chronic facial pain disorder characterised by recurrent paroxysms of excruciating, electric shock-like or stabbing pain confined to one or more divisions of the fifth cranial nerve, classically provoked by innocuous tactile stimuli to cutaneous **trigger zones** and, by definition, *without demonstrable sensory loss* on examination. It must be sharply distinguished from **trigeminal neuropathy**, in which structural disease of the nerve produces

objective sensory deficit and/or motor (masticatory) weakness. The estimated annual incidence is 4–8 per 100,000; it affects middle-aged and elderly persons, with ~60% of cases in women.

Pathophysiology

- ▶ **Ectopic impulse generation:** Pain arises from ectopic generation of action potentials in pain-sensitive afferent fibres of the trigeminal root *just before it enters the lateral surface of the pons* (the root entry zone).
- ▶ **Demyelination & ephaptic transmission:** Compression/pathology causes **focal demyelination of large myelinated (A β touch) fibres** that do not themselves carry pain. These become hyperexcitable and **electrically (ephaptically) coupled** to adjacent small unmyelinated/poorly myelinated nociceptive fibres — explaining why a light tactile stimulus, conveyed by large fibres, can ignite a paroxysm of pain.
- ▶ **Vulnerable myelin zone:** CN V is ensheathed by **oligodendrocyte-derived central myelin for up to 7 mm** after leaving the brainstem (vs a few mm for other nerves); demyelination occurs at this central–peripheral myelin **transition (Obersteiner–Redlich) zone**, accounting for the link with multiple sclerosis (a disorder of oligodendrocyte myelin).
- ▶ **Neurovascular compression (classic TN):** A tortuous artery — most often the **superior cerebellar artery**, occasionally the **anterior inferior cerebellar artery** or a vein — compresses/indents the root, causing axonal loss and demyelination. *Vascular contact alone is insufficient* (it is common in asymptomatic controls/cadavers); **morphological indentation/atrophy** of the root is required.
- ▶ **Ageing substrate:** Age-related brain sagging and increased vascular thickness/tortuosity explain the prevalence in later life.

Clinical features

- ▶ **Character:** Paroxysms of *excruciating*, superficial, stabbing/lancinating “electric-shock” pain; so intense the patient winces — hence *tic*.
- ▶ **Duration & periodicity:** Each jab lasts seconds to a minute or two; single jabs or clusters recur frequently **day and night for weeks–months**, then remit spontaneously. Remissions may be long but the disorder usually ultimately recurs.
- ▶ **Distribution:** Strictly **unilateral**, confined to trigeminal territory — most often **V2 (maxillary) and V3 (mandibular)**; the **ophthalmic (V1) division is involved in <5% of cases**.
- ▶ **Trigger zones / triggers:** Tactile stimulation of trigger points on the face, lips or tongue provokes attacks — *washing the face, brushing teeth, shaving, chewing, speaking, smiling, or a draught of cold air*. Patients hold the face still and avoid eating/talking.
- ▶ **Examination:** *No objective sensory loss and no motor weakness* — an **essential diagnostic feature**. (A dull background ache may persist between jabs in long-standing/”concomitant continuous pain” cases.)

Classification (ICHD-based) & differential diagnosis

Type	Mechanism	Clue
Classic TN	Neurovascular compression with morphological root change (SCA/AICA)	Older age, normal exam, vessel-nerve contact on MR angiography
Secondary (symptomatic) TN	MS plaque at root entry zone, cerebellopontine-angle tumour (acoustic schwannoma, meningioma), aneurysm, neurofibroma, chronic meningitis	Young/bilateral patient, subtle sensory loss → suspect MS or mass
Idiopathic TN	No cause found despite imaging	Diagnosis of exclusion

- ▶ **Differentiate from other facial pains:** Migraine/cluster pain is *deep, steady* (not superficial-stabbing); rarely cluster coexists (*cluster-tic*). SUNCT/SUNA and paroxysmal hemicrania are distinguished by attack frequency/duration and prominent cranial autonomic features (V1 territory). **Giant cell (temporal) arteritis** gives non-shocklike facial pain with myalgia and ↑ESR/CRP. Also exclude dental, jaw and sinus disease.
- ▶ **Red flags for a secondary cause:** onset <40 years, **bilateral** symptoms, V1 involvement, any objective sensory loss, or other cranial-nerve signs → mandates imaging.

Investigations

- ▶ **High-resolution contrast-enhanced brain MRI** in all: to exclude secondary causes (MS plaque, tumour, aneurysm) and demonstrate neurovascular compression. **MR angiography** delineates the nerve–vessel relationship and is used pre-operatively to plan decompression.
- ▶ ESR/CRP if temporal arteritis is suspected.
- ▶ Younger/atypical patients: evaluate for **MS** (a demyelinating plaque near the pontine root entry zone is the typical lesion).

Management

A. Medical therapy (first line):

- ▶ **Carbamazepine** — drug of choice, effective in ~50–75%. Start **100 mg once daily with food**, increase by 100 mg/day in divided doses every 1–2 days to >50% relief; usual maintenance **200 mg four times daily**; doses >1200 mg/day give no added benefit. Monitor for dizziness, ataxia, sedation, hyponatraemia and rare **agranulocytosis** (serial blood counts + LFTs). If effective, continue ~1 month then taper.
- ▶ **Oxcarbazepine 300–1200 mg bid** — equally efficacious, less marrow toxicity (preferred by many).

- Second-line / add-on: phenytoin 300–400 mg/day; lamotrigine 400 mg/day; baclofen 10–20 mg tid; topiramate 50 mg bid; gabapentin up to 3600 mg/day (useful in MS-related TN).

B. Surgical / interventional therapy (drug failure or intolerance): initial relief in $\geq 80\%$.

Procedure	Mechanism	Outcome / caveat
Microvascular decompression (MVD) — Jannetta	Suboccipital craniotomy; pad/separate offending vessel from root	>70% efficacy, ~75% long-term relief, low recurrence; <i>no sensory loss</i> ; best for classic lancinating pain; major surgery
Stereotactic (Gamma-knife) radiosurgery	Radiation lesion of root	Complete relief (often delayed) in $\sim 1/2$ (~45%); recurrence in $1/3$ over 2–3 yr; few serious complications
Radiofrequency thermal rhizotomy	Heat lesion of ganglion/nerve	>95% short-term, ~60% long-term; common facial numbness, masseter weakness, corneal denervation/keratitis (V1)
Percutaneous balloon compression	Mechanical ganglion injury (under GA)	~67% relief; ipsilateral facial numbness common

- MS-related TN: open surgical exploration is inappropriate; less-invasive ablative techniques may help. Glossopharyngeal neuralgia (a close mimic in the throat/ear) responds to the same drugs and MVD.

Trigeminal neuralgia vs trigeminal neuropathy

Feature	Trigeminal neuralgia	Trigeminal neuropathy
Nature of pain	Paroxysmal, brief (sec–min), shock-like/stabbing	Constant numbness/paraesthesia, burning, or no pain
Trigger zones	Present (tactile triggers)	Absent
Sensory loss	Absent (cardinal rule)	Present — objective facial numbness, ↓corneal reflex
Motor (masticatory) deficit	Absent	May be present — jaw deviates to the weak side (pterygoids)
Divisions	V2/V3 mainly; V1 <5%	Any; chin (mental) or cheek numbness may signal malignancy
Mechanism	Neurovascular compression / demyelination at root	Structural disease of nucleus, ganglion or nerve
Typical causes	Vascular loop; MS (secondary)	Sjögren's, SLE, scleroderma, MCTD; herpes zoster; leprosy; tumours (schwannoma, meningioma, nasopharyngeal Ca, perineural spread); GBS;

Feature	Trigeminal neuralgia	Trigeminal neuropathy
		sarcoidosis; trauma; drugs (stilbamidine, trichloroethylene); idiopathic
Examination dictum	Normal exam	“Diagnosed by the company they keep” — long-tract/other CN signs

- ▶ **Idiopathic trigeminal neuropathy:** numbness/paraesthesiae (sometimes bilateral) with sensory loss but *no jaw weakness*; gradual recovery is the rule.
- ▶ **Numb chin (mental neuropathy) or numb cheek syndrome:** isolated chin/cheek numbness may be the *sole presenting sign of systemic malignancy* (breast, lung, prostate, lymphoma) — never ignore.
- ▶ **Trigeminal trophic syndrome:** anaesthesia → self-induced ulceration of the **ala nasi** following ganglion damage/rhizotomy or central tract lesions.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Trigeminal nerve and its sensory territory on the face** — label: *Pons (root entry zone), Trigeminal (gasserian/semilunar) ganglion in Meckel’s cave, Ophthalmic V1, Maxillary V2, Mandibular V3*, and the corresponding facial dermatomal zones; mark the **trigger zone** on the cheek/lip.
- ▶ **Neurovascular compression schematic** — label: *Trigeminal root, Superior cerebellar artery (compressing vessel), Central (oligodendrocyte) myelin segment, Central–peripheral myelin transition (Obersteiner–Redlich) zone, focal demyelination with ephaptic coupling*.

Clinical / Diagnostic significance

- ▶ A strictly paroxysmal pain with trigger zones and a completely normal neurological examination is virtually diagnostic of TN; *any* sensory/motor deficit reclassifies the patient as trigeminal neuropathy and demands a search for structural disease.
- ▶ Bilateral TN, onset <40 years, or V1 involvement strongly suggests MS or a posterior-fossa mass — image early.
- ▶ MRI/MRA is both **diagnostic** (excludes secondary causes) and **therapeutic-planning** (defines the offending vessel before MVD).
- ▶ Carbamazepine response is itself **supportive of the diagnosis**; failure or need for escalating surgery should prompt re-imaging.

High-yield exam pointers

- ▶ *Tic douloureux* = paroxysmal, unilateral, shock-like V2/V3 pain with **trigger zones** and **NO sensory loss**.

- ▶ Incidence 4–8/100,000; ~60% women; middle-aged/elderly.
- ▶ Pathology = **demyelination + ephaptic coupling** at the root entry zone; **superior cerebellar artery** is the commonest compressing vessel.
- ▶ **V1 involved in <5%**; if young/bilateral/V1 → think MS (plaque at pontine root entry zone).
- ▶ **Carbamazepine** is first-line (50–75% response); oxcarbazepine an equal alternative; max CBZ benefit ≤1200 mg/day.
- ▶ Surgery of choice = **microvascular decompression (Jannetta)**, >70% **durable relief**, **no numbness**; ablative procedures cause facial numbness.
- ▶ **Neuropathy ≠ neuralgia**: neuropathy has **objective sensory loss ± jaw weakness** (deviation to weak side) and signals Sjögren's/zoster/leprosy/tumour/perineural spread.
- ▶ **Numb chin sign** = mental neuropathy = possible occult malignancy.

SOURCE & COVERAGE

- ▶ **Harrison's Principles of Internal Medicine, 22e** — “Trigeminal Neuralgia, Bell's Palsy, and Other Cranial Nerve Disorders” (clinical features, pathophysiology, drug doses, surgical options, Table of trigeminal nerve disorders).
- ▶ **Bradley & Daroff's Neurology in Clinical Practice, 8e** — “Cranial Neuropathies” and “Cranial and Facial Pain” (classic vs symptomatic TN, neurovascular compression at central–peripheral myelin transition, SCA/AICA, <5% V1, numb-chin/cheek syndromes).

- ▶ **CMDT 2026** — “Nervous System Disorders” (current diagnostic criteria, MRI rule for secondary causes <40 yr/bilateral, surgical success rates: MVD ~75%, RF rhizotomy 60%, balloon 67%, radiosurgery 45%).

Describe the physiological anatomy of neuromuscular junction and explain how diseases involving the neuromuscular junction cause muscle weakness

Asked in: Paper I May 2025 — RGUHS MD General Medicine

Definition / Introduction — The **neuromuscular junction (NMJ)** is the specialised cholinergic synapse where a motor axon terminal makes functional contact with a skeletal muscle fibre, converting a nerve action potential into a muscle fibre action potential and hence contraction. It is uniquely vulnerable to disease because it lies *outside the blood–nerve barrier*, depends on a finely tuned excess of acetylcholine (ACh) release over demand (the **safety factor**), and is built from many distinct presynaptic and postsynaptic molecules, each of which can be targeted by autoantibodies, genetic mutation or toxins.

Failure of transmission at any of these sites produces the cardinal NMJ sign — **fatigable, fluctuating weakness without sensory loss**.

Physiological anatomy — three functional compartments

The NMJ is organised into a presynaptic motor nerve terminal, the synaptic cleft and the postsynaptic muscle end-plate.

Compartment	Key structures	Function
Presynaptic terminal	Synaptic vesicles each storing one <i>quantum</i> (~5000–10,000 ACh molecules); active zones (release sites) apposed to postsynaptic folds; voltage-gated (P/Q-type) Ca^{2+} channels ; voltage-gated Na^+/K^+ channels ; SNARE fusion proteins — <i>syntaxin-1</i> , <i>SNAP-25</i> , <i>synaptobrevin</i> , <i>synaptotagmin</i>	ACh is synthesised from acetate + choline by choline acetyltransferase (ChAT) , packaged into vesicles, and released by Ca^{2+} -triggered exocytosis
Synaptic cleft	~50 nm gap; synaptic basal lamina ; acetylcholinesterase (AChE) anchored to the basal lamina by its collagenic tail (COLQ); agrin	ACh diffuses across; rapidly hydrolysed by AChE, terminating signal
Postsynaptic membrane	Deeply infolded junctional (postsynaptic) folds ; acetylcholine receptors (AChRs) densely packed at the <i>crests</i> of folds; voltage-gated Na^+ channels in the depths of folds; clustering scaffold — MuSK , LRP4 , Dok-7 , rapsyn , dystroglycan	High-density AChR + Na^+ channels convert the chemical signal into a propagated muscle action potential

- ▶ The AChR is a pentamer of five subunits — **2 α , 1 β , 1 δ and 1 γ (fetal) or 1 ϵ (adult)** — arranged around a central cation pore; ACh binds the two α -subunits, opening the channel to Na^+ (and Ca^{2+}) influx.
- ▶ **End-plate maturation/maintenance pathway**: nerve-derived **agrin** → binds **LRP4** → activates **MuSK** → recruits **Dok-7** and **rapsyn** → clusters AChR at the fold crests. The same molecules implicated here are the antigens/genes of autoimmune and congenital NMJ disease.

Physiology of neuromuscular transmission — the sequence

- ▶ A nerve action potential invades the terminal and opens **voltage-gated (P/Q-type) Ca^{2+} channels**; Ca^{2+} influx triggers SNARE-mediated **vesicle docking and exocytosis at active zones**.
- ▶ A single impulse releases the contents of ~**150–200 vesicles** (Harrison); experimental estimates of quantal release vary (~50–300 quanta, mean ≈ 60 — Bradley). Quantal output $m = p \times n$,

where p is release probability (≈ 0.2 , proportional to Ca^{2+}) and n the immediately available vesicle pool.

- ▶ Each quantum acting on AChRs produces a **~ 1 mV** depolarisation — the **miniature end-plate potential (MEPP)** (spontaneous, sub-threshold).
- ▶ Summation of all quanta from one impulse produces the **end-plate potential (EPP)**, normally **~ 60 mV** — far larger than the threshold needed to open perijunctional Na^+ channels and fire a **muscle fibre action potential**.
- ▶ AChE hydrolyses ACh within milliseconds and diffusion clears the cleft, resetting the junction.

The “safety factor” — the key to understanding weakness

- ▶ Because the EPP (~ 60 mV) **greatly exceeds the threshold** needed to trigger a muscle action potential, every nerve impulse reliably excites its fibre. This excess is the **safety factor of neuromuscular transmission**.
- ▶ Its magnitude depends on: **quantal content** (ACh released), **AChR density/conductance**, **AChE activity** and the geometry of the junctional folds.
- ▶ **Presynaptic rundown**: ACh output normally declines over the first few impulses of a train. In health this is invisible because the EPP still clears threshold; remove the safety factor and the same rundown now causes intermittent transmission failure — i.e. **fatigable weakness**.
- ▶ *Any* disease that lowers the EPP toward threshold (fewer AChRs, less ACh release, blocked release, or excess cholinergic depolarisation) converts a guaranteed signal into a probabilistic one — successive impulses activate **fewer and fewer fibres**, manifesting as decremental weakness and clinical fatigue.

How NMJ diseases cause weakness — site-based mechanisms

Disorder	Site / target	Mechanism of reduced safety factor	Distinctive features
Myasthenia gravis (MG) — anti-AChR	Postsynaptic AChR	↓ available AChRs by (1) antibody cross-linking → accelerated endocytosis/turnover; (2) complement (MAC)-mediated lysis of folds; (3) direct blockade of ACh-binding site. Folds flatten/”simplify” → small EPPs fail to reach threshold	AChR-Ab in $\sim 85\%$ generalised, $\sim 50\%$ ocular; ptosis, diplopia, bulbar & proximal limb weakness; reflexes preserved
MG — anti-MuSK	Postsynaptic clustering	IgG4 antibody blocks MuSK-LRP4 interaction → loss of AChR clustering; does not fix complement	$\sim 40\%$ of AChR-negative generalised MG; prominent bulbar/neck/respiratory weakness + muscle atrophy; often <i>worsens</i> with anticholinesterases

Disorder	Site / target	Mechanism of reduced safety factor	Distinctive features
MG — anti-LRP4	Postsynaptic clustering	IgG1 → complement-mediated injury + interrupts agrin–MuSK signalling	1–3% of MG
Lambert-Eaton myasthenic syndrome (LEMS)	Presynaptic P/Q-type Ca^{2+} channel	Antibody against voltage-gated Ca^{2+} channels ↓ Ca^{2+} entry → ↓ quantal ACh release → low baseline EPP	Proximal leg weakness, <i>hyporeflexia</i> , autonomic features (dry mouth); post-exercise facilitation ; ~85% have P/Q-Ab; SCLC association
Botulism	Presynaptic SNAREs	<i>C. botulinum</i> toxin enzymatically cleaves SNARE proteins → blocks ACh exocytosis	Descending paralysis, bulbar onset, dilated pupils, autonomic failure; normal sensation
Congenital myasthenic syndromes (CMS)	Any component (pre-, synaptic, post-)	>30 gene mutations (e.g. ϵ-subunit AChR ~50%, <i>RAPSN</i> , <i>COLQ</i> , <i>DOK7</i> , <i>CHAT</i> , <i>agrin</i>) impair ACh synthesis, AChE anchoring, AChR kinetics or clustering	Non-immune; onset infancy/childhood; AChR & MuSK antibodies absent
Drug/toxin & metabolic	Variable	Aminoglycoside/quinolone/macrolide antibiotics, IV magnesium, procainamide, penicillamine (induces autoimmune MG), botulinum toxin — all impair release or block AChR	Exacerbate established MG; high doses weaken normal NMJ

- ▶ **Common final pathway:** every NMJ disease reduces the **EPP relative to threshold**. Presynaptic disorders (LEMS, botulism) do so by *reducing ACh release*; postsynaptic disorders (MG, most CMS) by *reducing the AChR response*. The result is identical — failure of a proportion of fibres to fire, i.e. **weakness that worsens with use**.

Electrodiagnostic correlation (proof of the physiology)

- ▶ **Slow repetitive nerve stimulation (2–3 Hz):** in MG the already-reduced safety factor lets the normal rundown drop successive EPPs below threshold → a **decremental CMAP response >10%** (postsynaptic pattern).
- ▶ **Rapid RNS (20–50 Hz) or 10-s exercise:** in LEMS the accumulating presynaptic Ca^{2+} raises ACh release → EPPs cross threshold → **incremental response (often >100–200%)** — the electrophysiological signature of a presynaptic defect.
- ▶ **Single-fibre EMG:** increased **jitter** (variability of inter-potential interval) and **blocking** are the most sensitive markers of impaired transmission, reflecting EPPs hovering near threshold.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Diagram 1 — Normal NMJ (longitudinal section).** Label: *motor axon terminal, mitochondria, synaptic vesicles (quanta), active zone, voltage-gated Ca^{2+} channel, SNARE proteins (syntaxin-1/SNAP-25/synaptobrevin/synaptotagmin), synaptic cleft + basal lamina, acetylcholinesterase (AChE), junctional (postsynaptic) folds, AChR clustered at fold crests, voltage-gated Na^+ channels in fold depths, clustering scaffold (agrin-LRP4-MuSK-Dok-7-rapsyn).*
- ▶ **Diagram 2 — Myasthenic vs normal end-plate.** Two panels side by side. Label: *normal — abundant AChRs, deep/normal folds, narrow cleft; MG — reduced AChR number, flattened/simplified folds, widened synaptic space, complement + AChR autoantibody on folds.* Optionally add an EPP-versus-threshold tracing showing the normal EPP above threshold and the myasthenic EPP failing threshold (the safety-factor concept).

Clinical / Diagnostic significance

- ▶ **Pattern recognition:** fatigable ptosis, diplopia, bulbar and proximal weakness with **preserved reflexes, normal sensation and normal pupils** localises to the NMJ; *hyporeflexia + autonomic features* point instead to LEMS.
- ▶ **Bedside tests:** **ice-pack test** (2 min over a ptotic lid; ≥ 2 mm lid rise = positive) exploits reduced AChE activity in the cold; the historical **edrophonium/anticholinesterase test** transiently improves strength.
- ▶ **Serology:** anti-AChR radioimmunoassay first; if negative, **anti-MuSK** then **anti-LRP4**. In LEMS test P/Q-type Ca^{2+} channel antibodies and screen for small-cell lung cancer.
- ▶ **Always image the chest (CT/MRI)** in MG — thymic hyperplasia (~65–70%) or thymoma (~10–15%) is common.
- ▶ **Management pearls (Harrison/CMDT 2026):** symptomatic pyridostigmine (30–180 mg, avg ~60 mg, four times daily) — but it may *worsen* anti-MuSK MG; **corticosteroids** (gradual uptitration to avoid early steroid dip) and steroid-sparing agents (**azathioprine 2–3 mg/kg/day, mycophenolate, rituximab** — rituximab especially effective in MuSK MG); **thymectomy** for thymoma and for generalised AChR-positive MG <65 yrs (MGTX trial); **rapid rescue with IVIg or plasmapheresis** for crisis/pre-op. Newer FDA-approved agents: **complement inhibitors** (eculizumab, ravulizumab, zilucoplan — require meningococcal vaccination) and **FcRn antagonists** (efgartigimod, rozanolixizumab). LEMS is treated with **3,4-diaminopyridine** (blocks K^+ channels $\rightarrow$ prolongs depolarisation $\rightarrow$ $\uparrow$ ACh release) $\pm$ pyridostigmine; botulism with **antitoxin** and ventilatory support.
- ▶ **Myasthenic crisis** = respiratory/bulbar failure needing ventilation; precipitated by infection, surgery, or offending drugs (aminoglycosides, magnesium) — a medical emergency.

High-yield exam pointers

- ▶ NMJ = cholinergic synapse outside the blood–nerve barrier → uniquely exposed to circulating antibodies.
- ▶ AChR = pentamer $2\alpha/\beta/\delta/\gamma$ -or- ϵ ; ACh binds the α -subunits.
- ▶ Quantum = 5000–10,000 ACh molecules → ~1 mV MEPP; one impulse → EPP ~60 mV >> threshold = safety factor.
- ▶ Agrin → LRP4 → MuSK → Dok-7/rapsyn → AChR clustering — the master end-plate pathway and the disease antigen map.
- ▶ MG = postsynaptic (3 antibody mechanisms; complement, turnover, blockade) → decrement on slow RNS.
- ▶ LEMS = presynaptic P/Q Ca^{2+} -channel antibody → low CMAP, increment after exercise/rapid RNS, hyporeflexia, SCLC.
- ▶ Botulism cleaves SNARE proteins; CMS = genetic, ϵ -subunit commonest (~50%).
- ▶ Final common pathway of all NMJ disease = EPP falls toward threshold → fibres fail intermittently → fatigable weakness.
- ▶ NMJ weakness spares sensation, reflexes (except LEMS) and pupils (except botulism).

SOURCE & COVERAGE

- ▶ Harrison's Principles of Internal Medicine, 22e — "*Myasthenia Gravis and Other Diseases of the Neuromuscular Junction*" (NMJ transmission physiology, AChR structure, antibody mechanisms, MG/LEMS/botulism/CMS, treatment).
- ▶ Bradley & Daroff's Neurology in Clinical Practice, 8e — "*Disorders of Neuromuscular Transmission*" (immunopathology, junctional-fold ultrastructure, MG subtypes) and "*Clinical Electromyography*" (quantal release $m = p \times n$, MEPP/EPP, safety factor, RNS decrement/increment, jitter).
- ▶ CMDT 2026 — "*Nervous System Disorders: Myasthenia Gravis & Lambert-Eaton Myasthenic Syndrome*" (diagnostic criteria, drug doses, thymectomy, FcRn/complement therapies).
- ▶ Coverage note: the corpus covers this topic richly. The per-impulse ACh figure differs slightly between sources (Harrison "150–200 vesicles" vs Bradley "~50–300 quanta, mean ~60"); both are quoted faithfully rather than reconciled.

Posterior (Vertebrobasilar) Circulation of the Brain: Anatomy and Clinical Relevance

Asked in: Paper I 06 Apr 2026 — RGUHS MD General Medicine

Definition / Introduction — The **posterior (vertebrobasilar) circulation** is the arterial system derived from the paired **vertebral arteries (VA)** and the **basilar artery**, terminating in the two **posterior cerebral arteries (PCA)**. It supplies the brainstem, cerebellum, labyrinth and cochlea, subthalamus, portions of the thalamus, and the inferomedial temporal and occipital lobes. Because dense, eloquent, life-sustaining structures are packed into a small volume, occlusion produces characteristic **crossed (alternating) brainstem syndromes** and visual deficits; “top-of-the-basilar” and basilar occlusion are neurological emergencies. About **87%** of strokes are ischaemic, and roughly one-fifth of ischaemic strokes are posterior-circulation events.

Arterial anatomy — origin, course and segments

- ▶ **Vertebral artery** arises from the **subclavian artery** and has four segments: **V1** (origin to the C6 transverse foramen), **V2** (ascends through the transverse foramina C6→C2), **V3** (loops around the atlanto-occipital joint), and **V4** (pierces the dura at the **foramen magnum** to become intracranial). The two VAs unite at the **pontomedullary junction** to form the basilar artery.
- ▶ Key VA branches: **anterior spinal artery**, **posterior spinal artery**, and the **posterior inferior cerebellar artery (PICA)**.
- ▶ **Basilar artery** runs along the ventral pons (proximal, middle and distal segments), giving **paramedian perforators**, short and long circumferential branches, the **anterior inferior cerebellar artery (AICA)** and the **superior cerebellar artery (SCA)**; it bifurcates at the **pontomesencephalic junction** within the **interpeduncular cistern** into the two PCAs.
- ▶ **Posterior cerebral artery segments**: **P1** (precommunal / “mesencephalic”), **P2** (ambient), **P3** (quadrigeminal) and **P4** (calcarine). In ~20–25% of people the PCA has a **fetal (embryonic) origin** from the internal carotid via the posterior communicating artery (PCoA).
- ▶ Each VA distributes in **three vascular patterns** — median/paramedian, short circumferential and long circumferential arteries — creating **four brainstem territories**: **anteromedial**, **anterolateral**, **lateral** and **posterior**.

Vessel	Main territory supplied	Major perforators/branches
Vertebral artery (V4)	Medulla (anteromedial + lateral), upper cervical cord	Anterior spinal a., PICA
PICA	Inferior vermis, inferior/posterior cerebellar hemisphere, dorsolateral medulla	Medial & lateral branches
Basilar artery	Pons, via paramedian + circumferential branches	Paramedian perforators, AICA, SCA
AICA	Flocculus, middle cerebellar peduncle, lower pontine	Labyrinthine artery

Vessel	Main territory supplied	Major perforators/branches
	tegmentum, inner ear (labyrinthine a.)	
SCA	Superior cerebellum & vermis, dentate nucleus, upper pontine tegmentum	—
PCA	Occipital lobe, inferomedial temporal lobe, midbrain, thalamus, choroid plexus	Thalamoperforating, thalamogeniculate, posterior choroidal, calcarine

Collateral circulation

- ▶ **Circle of Willis** is the principal collateral, joining the anterior (carotid) and posterior systems via the **posterior communicating arteries**; an anatomically complete circle is present in only ~20–25%.
- ▶ Additional collaterals: extracranial–intracranial anastomoses and **leptomeningeal (pial) anastomoses** between terminal cerebral/cerebellar branches.
- ▶ **Persistent primitive carotid–vertebrobasilar anastomoses** may persist — **trigeminal** (commonest, ~0.2%), **acoustic (otic)**, **hypoglossal** and **proatlantal** arteries.

Medullary and pontine syndromes (crossed/alternating)

- ▶ **Lateral medullary (Wallenberg) syndrome** — usually **intracranial VA (V4) occlusion or dissection**, sometimes PICA. *Ipsilateral*: limb and gait ataxia with **body lateropulsion**, facial pain/temperature loss (spinal trigeminal nucleus/tract), palatal–pharyngeal weakness, dysphagia, dysphonia (**nucleus ambiguus**), **Horner syndrome**; *contralateral*: trunk and limb pain/temperature loss (spinothalamic tract); plus vertigo, nausea, nystagmus and intractable hiccups. **Opalski variant** adds ipsilateral hemiplegia.
- ▶ **Medial medullary (Déjérine) syndrome** — anteromedial group (anterior spinal a./VA). *Ipsilateral* LMN tongue weakness (CN XII); *contralateral* hemiparesis and loss of position/vibration (medial lemniscus); **face spared**, sometimes upbeat nystagmus. **Babinski–Nageotte syndrome** = combined medial + lateral medullary (hemimedullary) infarct.
- ▶ **Medial inferior pontine syndrome** (paramedian basilar branch) — ipsilateral gaze palsy, CN VI palsy, nystagmus; contralateral hemiparesis with impaired touch/proprioception.
- ▶ **Lateral inferior pontine syndrome (AICA)** — ipsilateral facial palsy (CN VII), facial sensory loss, gaze palsy, **deafness and tinnitus** (cochlear/labyrinthine infarct), Horner and limb ataxia; contralateral pain/temperature loss. *Sudden bilateral deafness may herald basilar occlusion.*
- ▶ **Lateral superior pontine syndrome (SCA)** — ipsilateral Horner, gaze paresis, hearing loss and severe ataxia; contralateral pain/temperature loss with skew deviation.

- ▶ **Locked-in syndrome** (“ventral pontine”/de-efferented state) — **bilateral basis pontis** infarct from paramedian basilar perforator occlusion: **quadriplegia, anarthria, aphonia, horizontal gaze palsy**, but **preserved consciousness** (ARAS spared) with retained **vertical eye movements and blinking**.
- ▶ *Named classic pontine eponyms: Millard–Gubler, Foville, Raymond, Raymond–Cestan, Marie–Foix, Brissaud.*

Midbrain (PCA-penetrator) and cerebellar syndromes

- ▶ **Weber syndrome** — ventral peduncle: ipsilateral CN III palsy (dilated pupil) + contralateral hemiparesis.
- ▶ **Benedikt syndrome** — tegmentum (red nucleus + CN III): ipsilateral CN III palsy + contralateral hemitremor/hemichorea/hemiathetosis.
- ▶ **Claude syndrome** — dorsal tegmentum: CN III palsy + contralateral cerebellar ataxia/dysmetria (without involuntary movements). **Nothnagel**: CN III palsy + contralateral cerebellar ataxia (superior cerebellar peduncle region).
- ▶ **Parinaud (dorsal midbrain) syndrome** — vertical-gaze palsy, impaired convergence, **convergence–retraction nystagmus**, light–near dissociation, lid retraction (**Collier sign**) and skew deviation.
- ▶ **Cerebellar infarcts**: **PICA** → vertigo, gait/limb ataxia, nystagmus, dysarthria; large oedematous infarcts cause **hydrocephalus and tonsillar herniation**. **AICA** → “ventral cerebellar syndrome” with deafness. **SCA** → “dorsal cerebellar syndrome” with intention tremor and limb/gait ataxia.

PCA territory, thalamic and top-of-the-basilar syndromes

- ▶ **PCA occlusion** — contralateral **homonymous hemianopia** (with **macular sparing** if the occipital pole is spared) from striate cortex/optic radiation/lateral geniculate infarction. Dominant (left) lesions involving the splenium/callosal branches cause **alexia without agraphia**; bilateral occipital infarcts cause **cortical blindness** (**Anton syndrome** = denial of blindness) and **Balint syndrome** (simultanagnosia, optic ataxia, psychic gaze paralysis); medial temporal involvement causes **amnesia**, and prosopagnosia/peduncular hallucinosis may occur.
- ▶ **Thalamic syndromes: Déjérine–Roussy** (posterolateral, thalamogeniculate P2 branches) — contralateral hemisensory loss to all modalities with delayed **central post-stroke pain**, allodynia and hyperalgesia. **Artery of Percheron** — a single trunk from a proximal PCA supplying **both paramedian thalami ± rostral midbrain** → bilateral thalamic infarcts with hypersomnolence, vertical-gaze palsy and memory loss.
- ▶ **“Top-of-the-basilar” syndrome** — embolic occlusion of the **rostral basilar artery** infarcting midbrain, thalamus, hypothalamus, medial temporal and occipital lobes: somnolence/coma, **akinetic mutism**, peduncular hallucinosis, memory loss, vertical-gaze palsy, pseudo-abducens palsy, convergence–retraction nystagmus and cortical visual loss.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Diagram 1 — Vertebrobasilar tree (ventral view):** label *Subclavian artery, Vertebral artery (V1–V4), Anterior spinal artery, PICA, Basilar artery, AICA, Superior cerebellar artery (SCA), Posterior cerebral artery (P1–P4), Posterior communicating artery*, and the **Circle of Willis**.
- ▶ **Diagram 2 — Medullary cross-section (Wallenberg):** label *Spinal trigeminal nucleus & tract, Nucleus ambiguus, Spinothalamic tract, Inferior cerebellar peduncle (restiform body), Vestibular nuclei, Descending sympathetic fibres*, shading the **dorsolateral PICA/VA territory**.

Clinical / Diagnostic significance

- ▶ **Bedside clue:** “crossed” findings (ipsilateral cranial-nerve palsy + contralateral long-tract deficit), vertigo with nystagmus, diplopia, dysarthria, dysphagia, ataxia and bilateral/shifting motor-sensory signs localise to the posterior circulation; **isolated transient vertigo, diplopia, dysarthria or dysphagia alone are insufficient** to diagnose a vertebrobasilar TIA.
- ▶ **Imaging:** non-contrast CT first to exclude haemorrhage; **MRI/DWI** (with attention to the posterior fossa, where CT is poor) plus **CT/MR angiography** of head and neck; consider CT perfusion for delayed presentations.
- ▶ **Acute reperfusion (Harrison/CMDT):** IV rtPA 0.9 mg/kg (max 90 mg; 10% bolus then remainder over 1 h) within 4.5 h, or IV tenecteplase 0.25 mg/kg (max 25 mg); **mechanical thrombectomy 0–6 h**, and in selected cases **6–24 h**; non-randomised data support thrombectomy for **basilar artery occlusion up to 24 h**.
- ▶ **Cerebellar infarction** demands vigilance for mass effect, obstructive hydrocephalus and tonsillar/upward herniation — may need EVD and suboccipital decompressive craniectomy.
- ▶ **Secondary prevention:** antiplatelet therapy (aspirin ± clopidogrel after TIA/minor stroke), anticoagulation for atrial fibrillation/cardioembolism, and aggressive risk-factor control; **spinal manipulation** is a recognised cause of VA dissection.

High-yield exam pointers

- ▶ VA segments V1–V4; basilar bifurcates into PCAs at the **interpeduncular cistern**; PCA segments P1–P4.
- ▶ Fetal PCA in ~20–25%; complete circle of Willis in only ~20–25%.
- ▶ **Wallenberg = lateral medullary**, commonest brainstem stroke; usual cause **intracranial VA (V4) occlusion/dissection**, *not* PICA in most cases.
- ▶ **Crossed sensory loss** (ipsilateral face + contralateral body) is the signature of Wallenberg.
- ▶ **Weber = peduncle**, **Benedikt = tegmentum (red nucleus)**, **Claude = dorsal tegmentum + cerebellar**, **Parinaud = dorsal midbrain/vertical-gaze**.

- ▶ **Locked-in syndrome** = bilateral basis pontis; consciousness and vertical gaze preserved.
- ▶ **Artery of Percheron** → bilateral paramedian thalamic infarction; **Déjérine–Roussy** = thalamic pain syndrome.
- ▶ **PCA stroke** → macular-sparing homonymous hemianopia; bilateral → cortical blindness/**Anton syndrome**.
- ▶ **Basilar occlusion / top-of-the-basilar** is a time-critical emergency; thrombectomy considered up to 24 h.

SOURCE & COVERAGE

- ▶ **Brazis — Localization in Clinical Neurology — “Vascular Syndromes of the Forebrain, Brainstem, and Cerebellum”** (primary source for posterior-circulation anatomy, segments, and brainstem/cerebellar/PCA/thalamic syndromes).
- ▶ **Harrison’s Principles of Internal Medicine, 22e** — “Ischemic Stroke” and “Introduction to Cerebrovascular Diseases” (mechanisms, acute thrombolysis/thrombectomy).
- ▶ **CMDT 2026** — “Nervous System Disorders” (Stroke / cerebral infarction) (clinical correlation of vertebrobasilar occlusion and current reperfusion time-windows).

Coverage note: Harrison 22e covers posterior-circulation *syndromes* and management but treats the detailed vascular neuroanatomy thinly; the segmental anatomy and the named brainstem eponyms in this answer are grounded in Brazis. Standard neuroanatomical points (e.g., labyrinthine artery from AICA) are universally accepted textbook neurology.

Differential Diagnosis of Seizures

Asked in: Paper III Jul 2020 — RGUHS MD General Medicine

Definition / Introduction — A **seizure** (Latin *sacire*, “to take possession of”) is a transient occurrence of signs or symptoms due to **abnormal excessive or synchronous neuronal activity** in the brain; *epilepsy* denotes a tendency to **recurrent unprovoked seizures**. Because the diagnosis of a seizure rests largely on clinical grounds — examination and laboratory studies are frequently normal — a wide range of paroxysmal, transient, stereotyped events can imitate it. Distinguishing true epileptic seizures from these “non-epileptic” mimics is critical, as misdiagnosis leads to unnecessary, potentially teratogenic antiseizure medication (ASM), loss of driving privileges and a missed treatable cause (e.g. cardiac syncope). The cornerstone of differentiation is a **meticulous history with an independent eyewitness account**, supplemented when needed by video-EEG, tilt-table testing and cardiac electrophysiology.

Step 1 — Is the event actually a seizure?

- ▶ The first task is to decide whether the paroxysmal event was a seizure at all, then whether it was an *epileptic* seizure versus a non-epileptic mimic, then (if epileptic) focal versus generalized onset.
- ▶ **Features favouring an epileptic seizure:** a stereotyped **aura**, **cyanosis**, sustained tonic–clonic motor activity lasting >15 s, **lateral tongue biting**, urinary/faecal incontinence, **post-ictal confusion/disorientation**, post-ictal headache, muscle soreness, **Todd's paralysis**, sleepiness and **complete amnesia** for the loss of consciousness.
- ▶ **Positive vs negative symptoms** — seizures involving sensory/motor cortex produce *positive* phenomena (twitching, paraesthesiae, flashing lights) that **march/spread over seconds**; ischaemic events (TIA) classically produce *negative* phenomena (weakness, numbness) with no march.
- ▶ **Adjunctive biomarkers:** a transient rise in **serum prolactin** within the first 30 min post-ictally supports a generalized or some focal seizures (a normal baseline value is rarely available, limiting reliability); **serum lactate >2.4 mmol/L for up to 3 h** after a convulsion favours a generalized convulsive *epileptic* seizure over PNES or syncope.
- ▶ **Gold standard for ambiguous events:** prolonged **video-EEG monitoring** capturing a habitual attack — generalized tonic–clonic seizures *always* produce marked ictal/post-ictal EEG change, whereas PNES does not (caveat: some frontal/orbitofrontal and supplementary-motor seizures have no scalp EEG correlate).

Classification of conditions that mimic seizures (Harrison Table 436-6)

Category	Specific mimics
Syncope	Vasovagal (neurally mediated), cardiac arrhythmia, valvular heart disease (aortic stenosis), cardiac failure, orthostatic hypotension
Cerebrovascular	Transient ischaemic attack, basilar-artery TIA , transient global amnesia, transient focal neurologic episodes (cerebral amyloid angiopathy)
Sleep disorders	Narcolepsy–cataplexy, benign sleep myoclonus, parasomnias (night terrors, sleepwalking, REM-behaviour disorder)
Movement disorders	Tics, non-epileptic myoclonus, paroxysmal kinesigenic/non-kinesigenic dyskinesia (choreoathetosis), hyperekplexia
Psychological	Psychogenic non-epileptic seizure (PNES) , hyperventilation, panic attack, rage attacks
Metabolic / toxic	Hypoglycaemia, hypoxia, alcoholic blackouts, delirium tremens, psychoactive drugs (hallucinogens)

Category	Specific mimics
Migraine	Migraine aura, confusional migraine, basilar migraine (“migralepsy”)
Special — children	Breath-holding spells, Sandifer syndrome (GERD posturing), benign paroxysmal vertigo, apnoea, cyclic vomiting / abdominal migraine

Seizure versus syncope — the commonest dilemma (Harrison Table 436-7)

Feature	Generalized tonic-clonic seizure	Syncope
Precipitant	Usually none	Emotional stress, pain, Valsalva, prolonged standing, orthostasis, cardiac cause
Premonitory symptoms	None, or aura (e.g. odd odour)	Tiredness, nausea, diaphoresis , tunnelling/greying of vision
Posture at onset	Variable	Usually erect
Transition to unconsciousness	Often immediate	Gradual over seconds (sudden with arrhythmia)
Duration of unconsciousness	Minutes	Seconds , rapid recovery on recumbency
Convulsive movements	30–60 s, sustained tonic-clonic	Never >15 s ; brief, multifocal , arrhythmic myoclonus
Face during event	Cyanosis, frothing	Pallor
Post-event confusion	Many minutes to hours	<5 min / minimal
Tongue biting	Sometimes (lateral)	Rarely
Aching of muscles	Often	Sometimes

- ▶ **Convulsive (“anoxic”) syncope** — a sustained drop in cerebral perfusion (e.g. fainting while kept upright in a dental chair) commonly produces brief multifocal myoclonus, posturing, head turning and oral automatisms; there is **no associated EEG discharge** (the motor activity is brainstem-generated), and post-ictal confusion is minimal. Rarely, true syncope triggers a genuine *anoxic-epileptic seizure*.
- ▶ **Cardiac syncope** (arrhythmia, aortic stenosis) is typically abrupt with **no prodrome**; suspect it in older patients or those with structural heart disease, and exertional events with a systolic murmur — it mandates ECG/Holter/tilt-table evaluation as it is life-threatening.

Psychogenic non-epileptic seizures (PNES / pseudoseizures)

- ▶ Emotionally-triggered attacks **without ictal epileptic discharge**, usually part of a **conversion (somatoform) disorder** (or, rarely, malingering); ~70–80% **female**, peak onset 15–35 years, frequent antecedent of **childhood sexual/physical abuse**, head injury, fibromyalgia or chronic pain.
- ▶ **Clinical pointers favouring PNES**: **out-of-phase / asynchronous** thrashing of limbs, **forward pelvic thrusting**, **side-to-side head shaking**, **forced eye closure with resistance to eye opening**, “pseudosleep” onset, **waxing-and-waning prolonged duration** (often >2 min, even *pseudo-status*), emotional vocalisation (weeping, stuttering), preserved awareness with goal-directed behaviour, biting the **tip of the tongue/lip** (vs lateral in true seizures), shallow rapid post-ictal breathing, and **absence of post-ictal stertor / confusion**.
- ▶ **PNES coexists with epilepsy** in ~10–15% of patients, so its diagnosis does not exclude true epilepsy. **Diagnosis is confirmed by video-EEG** demonstrating typical semiology with no ictal correlate; serum prolactin and lactate remain unchanged.

Other neurological and medical mimics

- ▶ **TIA** — longer duration (usually >2 min), no spread/march, *negative* symptoms; *limb-shaking* TIA (brief, <5 min, precipitated by standing/exercise) signals **high-grade internal carotid stenosis**.
- ▶ **Migraine** — aura spreads slowly (cortical spreading depression ~3 mm/min) and lasts **5–60 min** (vs epileptic auras typically <30 s); visual aura is a fortification spectrum/scintillating scotoma (vs coloured circles in occipital seizures); basilar migraine causes brainstem symptoms then altered consciousness.
- ▶ **Transient global amnesia** — isolated anterograde amnesia for hours with preserved complex behaviour, in older adults.
- ▶ **Parasomnias** (somnambulism, night terrors, REM-behaviour disorder) — arise from slow-wave sleep ~90 min into the night; frontal-lobe seizures are brief, stereotyped, hypermotor and arise from stage 1–2 / sleep–wake transition.
- ▶ **Narcolepsy-cataplexy** — emotion-triggered loss of tone with **fully preserved consciousness and memory**.
- ▶ **Paroxysmal movement disorders** — kinesigenic dyskinesia (movement-triggered, consciousness preserved, responds to ASM), non-kinesigenic dyskinesia, hyperekplexia (exaggerated startle).
- ▶ **Panic attacks / hyperventilation** — paraesthesiae, derealisation and fear; distinguished by inter-ictal anxiety and clear situational triggers; **rage attacks** are situational and goal-directed.
- ▶ **Metabolic / toxic** — hypoglycaemia, hypoxia, hyponatraemia, uraemia, hepatic failure, alcohol/sedative withdrawal — these cause *provoked (acute symptomatic) seizures*, which by definition are **not epilepsy** and rarely cause chronic epilepsy.

Age-specific differential

- ▶ **Neonates/infants:** apnoea, jitteriness (metabolic), exaggerated startle, **Sandifer syndrome** (GERD posturing), **breath-holding spells** (cyanotic preceded by crying; pallid is reflex asystolic).
- ▶ **Children/adolescents:** shuddering attacks, stereotypies, tics, daydreaming mistaken for absence (and vice-versa).
- ▶ **Older adults:** TIA, transient global amnesia, cardiac arrhythmia and convulsive syncope predominate.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Diagnostic algorithm for the adult with a “seizure”** — central box *Paroxysmal event* → branch on History + eyewitness + examination → boxes to **EXCLUDE: Syncope · TIA · Migraine · Acute psychosis/PNES · Other episodic cerebral dysfunction (metabolic, sleep, movement disorder)** → if seizure confirmed → arms “No prior epilepsy” (labs, MRI, EEG) vs “Known epilepsy” (assess ASM adequacy/levels). Labels: *History, Eyewitness account, EEG, MRI, Video-EEG, Prolactin, Lactate*.
- ▶ **Seizure-vs-syncope timeline** — two parallel horizontal arrows labelled *Seizure* and *Syncope* with markers: Prodrome (aura vs nausea/diaphoresis/greying vision), Posture (variable vs erect), LOC (immediate/minutes vs gradual/seconds), Motor (tonic-clonic 30–60 s vs multifocal myoclonus <15 s), Colour (cyanosis vs pallor), Recovery (post-ictal confusion vs rapid).

Clinical / Diagnostic significance

- ▶ An eyewitness/home-video account is the single most valuable diagnostic tool; up to one-third of “refractory epilepsy” referrals to tertiary centres prove to be PNES.
- ▶ **Always exclude provoked (acute symptomatic) seizures** — hypoglycaemia, hyponatraemia, uraemia, hepatic failure, alcohol/benzodiazepine withdrawal, eclampsia, and offending **drugs** (e.g. tramadol, bupropion, isoniazid, β -lactams/quinolones, theophylline, cocaine) — because treatment is correction of the cause, not chronic ASM.
- ▶ **Investigations:** routine 12-lead ECG in **every first seizure** (to catch long-QT/arrhythmic syncope); MRI brain (superior to CT) for structural cause; EEG (first inter-ictal EEG normal in ~50%, yield rises with sleep-deprived/repeat recordings); tilt-table and Holter for suspected syncope; blood glucose, electrolytes, calcium, magnesium, renal/hepatic panel and toxicology guided by context; **lumbar puncture** if CNS infection suspected.

High-yield exam pointers

- ▶ Two commonest mimics: **syncope** (especially in elderly) and **PNES** (especially young women) — *video-EEG is the gold standard* for both.
- ▶ **Lateral** tongue bite, cyanosis, post-ictal confusion and **complete amnesia** favour seizure; **pallor**, erect posture, rapid recovery and recollection favour syncope.

- ▶ Convulsive syncope myoclonus is **multifocal, arrhythmic** and **<15 s** with **no EEG discharge**.
- ▶ **Post-ictal prolactin** (within 30 min) and **serum lactate >2.4 mmol/L** (up to 3 h) support epileptic over psychogenic events.
- ▶ PNES clues: forced eye closure, side-to-side head, pelvic thrusting, out-of-phase limb movements, waxing/waning long duration, **tip-of-tongue** biting; ~10–15% also have true epilepsy.
- ▶ TIA = *negative* symptoms, no march; **limb-shaking TIA = carotid stenosis**. Migraine aura = slow spread, **5–60 min** (vs epileptic aura <30 s).
- ▶ A single provoked seizure from a reversible metabolic/toxic cause is **NOT epilepsy** and usually needs no ASM.

SOURCE & COVERAGE

- ▶ **Harrison's Principles of Internal Medicine, 22e** — “Seizures and Epilepsy” (Differential Diagnosis of Seizures; Table 436-6 list of mimics; Table 436-7 seizure-vs-syncope; syncope, convulsive syncope and psychogenic seizures; post-ictal prolactin; diagnostic algorithm Fig. 436-2).
- ▶ **Bradley & Daroff's Neurology in Clinical Practice, 8e** — “The Epilepsies” (Differential Diagnosis: PNES semiology, syncope/convulsive syncope, migraine vs occipital seizure, parasomnias, narcolepsy-cataplexy, paroxysmal movement disorders, TIA/limb-shaking, transient global amnesia, age-specific imitators; evaluation of recent-onset seizures).
- ▶ **CMDT 2026** — “Nervous System Disorders” (Seizures & Epilepsy) (differential of focal vs generalized seizures: TIA, migraine aura, transient focal neurologic episodes/CAA, panic, rage, cardiac, brainstem ischaemia, PNES; serum lactate >2.4 mmol/L adjunct; management framing).
- ▶ *Coverage note:* Brazis (Localization) and DeJong (Neurologic Examination) carry no dedicated seizure-mimic chapter; depth was therefore drawn from Bradley's epilepsy chapter, which fully covers the subspecialty detail.

Paraneoplastic Neurological Syndromes: Presentation, Associated Tumours and Antibodies

Asked in: Paper IV May 2025 — RGUHS MD General Medicine

Definition / Introduction — Paraneoplastic neurological syndromes (PNS), also called paraneoplastic neurologic disorders (PNDs), are cancer-related, immune-mediated syndromes that can affect *any* level of the nervous system without direct tumour invasion, metastasis, or treatment toxicity. Most are triggered when a tumour ectopically expresses neuronal (“onconeuroal”) proteins, provoking an antineuronal antibody and T-cell response misdirected at the nervous system. They are clinically

important because in ~60–65% the neurological deficit precedes the cancer diagnosis, so recognition allows early tumour detection. Clinically disabling PNDs occur in 0.5–1% of all cancer patients, but in 2–3% of those with small-cell lung cancer (SCLC) or neuroblastoma and 30–50% of those with thymoma.

Pathogenesis — the two-arm rule (determines presentation, antibody and prognosis)

- ▶ **Antibodies against intracellular antigens** (e.g., Hu, Yo, Ri, Ma2, CRMP5/CV2, amphiphysin): the antibody is a *marker* but not directly pathogenic; injury is driven by **cytotoxic CD8⁺ T cells** producing irreversible neuronal loss → poorly responsive to immunotherapy. These strongly predict an underlying cancer.
- ▶ **Antibodies against cell-surface / synaptic antigens** (e.g., NMDAR, AMPAR, GABA-B/A R, LGI1, Caspr2, VGCC, glycine R): the antibody is **directly pathogenic** (receptor cross-linking, internalisation, functional blockade, or disruption of protein–protein interactions) and the effect is **reversible** → these respond to immunotherapy and tumour treatment, occur with or without cancer, and may affect children/young adults; some follow viral (herpes simplex, Japanese) encephalitis.
- ▶ **Antibody yield is limited**: only 60–70% of CNS PNDs and <20% of peripheral PNDs have a detectable antibody, so a negative panel does not exclude PNS.

Antibody-based risk classification (2021 framework, after Graus & Dalmau) with tumours

The probability of an underlying cancer is now graded by the antibody — high (>70%), intermediate (30–70%) or low (<30%) risk.

Antibody	Risk (cancer prob.)	Antigen site	Typical syndrome	Associated tumour
Anti-Hu (ANNA-1)	High	Intracellular	Encephalomyelitis, sensory neuronopathy	SCLC
Anti-Yo (PCA-1)	High	Intracellular	Rapidly progressive cerebellar degeneration	Ovary, breast
Anti-Ri (ANNA-2)	High	Intracellular	Cerebellar degeneration, opsoclonus, brainstem encephalitis	Breast, gynaecologic, SCLC
Anti-CRMP5 (CV2)	High	Intracellular	Encephalomyelitis, chorea, optic	SCLC, thymoma

Antibody	Risk (cancer prob.)	Antigen site	Typical syndrome	Associated tumour
			neuritis, uveitis, neuropathy	
Anti-Tr (DNER)	High	Cell surface	Rapidly progressive cerebellar syndrome	Hodgkin lymphoma
Anti-Ma2 / Ma proteins	High	Intracellular	Limbic, hypothalamic, brainstem encephalitis	Testicular germ-cell (Ma2); other solid (Ma)
Anti-PCA2 (MAP1B)	High	Intracellular	Sensorimotor neuropathy, cerebellar, encephalomyelitis	SCLC, breast
Anti-Kelch-like protein 11	High	Intracellular	Brainstem encephalitis, ataxia, sensorineural hearing loss	Seminoma / germ-cell, teratoma
Anti-amphiphysin	High	Intracellular*	Stiff-person syndrome, encephalomyelitis	Breast, SCLC
Anti-SOX1	High	Intracellular	LEMS, cerebellar syndrome	SCLC
Anti-NMDAR	Intermediate	Surface	Anti-NMDAR encephalitis	Ovarian teratoma (young women)
Anti-AMPA	Intermediate	Surface	Limbic encephalitis with relapses	SCLC, thymoma, breast
Anti-GABA-B R	Intermediate	Surface	Limbic encephalitis with early prominent seizures	SCLC
Anti-Caspr2	Intermediate	Surface	Morvan syndrome, neuromyotonia	Thymoma
Anti-mGluR5	Intermediate	Surface	Encephalitis (Ophelia syndrome)	Hodgkin lymphoma

Antibody	Risk (cancer prob.)	Antigen site	Typical syndrome	Associated tumour
Anti-VGCC (P/Q)	Intermediate	Surface	LEMS, cerebellar degeneration	SCLC
Anti-LGI1	Low	Surface	Limbic encephalitis, hyponatraemia, faciobrachial dystonic seizures	Rarely thymoma
Anti-GABA-A R	Low	Surface	Encephalitis, refractory seizures / status	Thymoma (~20%)
Anti-DPPX	Low	Surface	Agitation, myoclonus, hyperekplexia, diarrhoea/weight loss	B-cell neoplasms (rare)
Anti-glycine R	Low	Surface	PERM, stiff-person	Rarely thymoma, lung, Hodgkin
Anti-IgLON5	Low	Surface	NREM/REM parasomnia, stridor, bulbar/movement disorder	No tumour
Anti-GAD65	Low	Intracellular	Stiff-person, cerebellar ataxia, limbic encephalitis	Infrequent (thymoma, lung, breast)
Anti-AChR (muscle)	Low	Surface	Myasthenia gravis	Thymoma

*Amphiphysin is likely exposed at the cell surface during synaptic-vesicle endocytosis. Other low-risk antibodies (mGluR1–Hodgkin; AQP4; MOG; neuronal AChR–autonomic ganglionopathy/SCLC) carry little or no cancer association.

Clinical presentation by anatomical level (“classic” high-risk syndromes)

- ▶ **Limbic encephalitis** — subacute confusion, depression, agitation, anxiety, **prominent short-term memory loss**, temporal-lobe or generalised seizures; MRI shows uni-/bilateral mesial-temporal T2/FLAIR signal. Antigens: Hu, Ma2, AMPAR, GABA-B R, LGI1, Caspr2.
- ▶ **Paraneoplastic cerebellar degeneration (PCD)** — prodrome of dizziness/vertigo, then rapidly progressive dysarthria, truncal & appendicular ataxia, **downbeat nystagmus**; pathology =

extensive **Purkinje-cell loss**. Tumours: SCLC, breast, ovary, Hodgkin. Anti-Yo (breast/gynae), anti-Tr (Hodgkin), anti-VGCC/anti-Hu (SCLC).

- ▶ **Encephalomyelitis** — multifocal involvement of cortex, brainstem, cerebellum, spinal cord, dorsal root ganglia and autonomic nerves; Hu/CRMP5 with SCLC. Cardiac arrhythmia, postural hypotension and central hypoventilation may be fatal.
- ▶ **Brainstem encephalitis** — eye-movement disorder (nystagmus, opsoclonus, supranuclear/nuclear palsy), cranial-nerve palsies, dysarthria, dysphagia. Ma2 → *upper* brainstem with vertical gaze palsy (downward progression); Hu → *lower* brainstem (upward progression).
- ▶ **Opsoclonus-myoclonus** — involuntary chaotic multidirectional saccades + myoclonus + ataxia; **children** → **neuroblastoma** (≥50%), adults → SCLC, breast (anti-Ri). Thought to reflect disinhibition of the cerebellar fastigial nucleus.
- ▶ **Anti-NMDAR encephalitis** — young women/children; viral-like prodrome → severe psychiatric symptoms, insomnia, reduced verbal output, memory loss, seizures, fall in consciousness, **orofacial-limb-trunk dyskinesias**, autonomic instability and hypoventilation; **46% of females ≥12 yr have an ovarian teratoma**. ~85–90% recover with treatment.
- ▶ **Stiff-person spectrum** — progressive axial **rigidity and stimulus-sensitive painful spasms** with continuous motor-unit activity on EMG; GAD65 (mostly non-paraneoplastic), amphiphysin (paraneoplastic, breast/SCLC), glycine-R (PERM).
- ▶ **Sensory neuronopathy (dorsal root ganglionopathy)** — asymmetric, multimodal sensory loss, painful dysaesthesias, sensory **ataxia and pseudoathetosis**, absent/low SNAPs with **preserved motor conduction**; ~80% have SCLC with anti-Hu.
- ▶ **Neuromuscular junction / muscle / eye** — LEMS (proximal leg weakness, dry mouth/autonomic features, reflexes that *potentiate* after exercise; incremental CMAP at high-rate RNS; P/Q-VGCC; ~60% SCLC), **myasthenia gravis** (thymoma, AChR antibody), dermatomyositis (heliotrope rash, Gottron papules; TIF1-γ/NXP-2 predict malignancy), necrotizing autoimmune myopathy (anti-HMGCR/SRP), and **cancer-associated / melanoma-associated retinopathy** (anti-recoverin; night blindness, abnormal ERG).

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Two-arm pathogenesis schematic**. Labels: *Tumour cell expressing onconeural antigen* → *dendritic/antigen-presenting cell* → *regional lymph node* → *CD4⁺/CD8⁺ T cells + B cells*; left arm “Intracellular antigen (Hu/Yo/Ma2) → cytotoxic CD8⁺ T-cell attack → irreversible neuronal loss → poor immunotherapy response”; right arm “Cell-surface antigen (NMDAR/LGI1/VGCC) → plasma-cell antibody → receptor cross-linking/internalisation/blockade → reversible → immunotherapy-responsive”; mark the *blood-brain barrier*.

- ▶ **Neuraxis map of syndromes.** Label a midline CNS-to-muscle figure: *Cortex/limbic* = *limbic & cortical encephalitis*; *Brainstem* = *brainstem encephalitis*; *Cerebellum* = *PCD, opsoclonus-myoclonus*; *Spinal cord* = *myelitis, motor-neuron syndrome*; *Dorsal root ganglion* = *sensory neuronopathy*; *Autonomic nerves* = *dysautonomia/pseudo-obstruction*; *NMJ* = *LEMS / myasthenia gravis*; *Muscle* = *dermatomyositis, necrotizing myopathy*; *Retina* = *CAR / MAR*.

Clinical / Diagnostic significance

- ▶ **Diagnostic triad of certainty** (type of syndrome + a high/intermediate-risk antibody + a consistent cancer) lets the disorder be graded as definite vs possible PNS; an antibody whose tumour association is atypical (e.g., anti-Yo with lung cancer) should prompt a search for a *second* neoplasm.
- ▶ **CSF:** inflammatory profile — mild–moderate lymphocytic pleocytosis (<200 cells), raised protein, intrathecal IgG synthesis and oligoclonal bands.
- ▶ **MRI:** usually nonspecific except mesial-temporal FLAIR change in limbic encephalitis; later cerebellar atrophy in PCD. **Brain/body ¹⁸F-FDG-PET** can disclose tumours (and early inflammatory hypermetabolism) missed by other imaging.
- ▶ **Tumour hunt:** CT chest/abdomen + whole-body PET; **testicular/transvaginal ultrasound and pelvic MRI/CT** for germ-cell tumour/teratoma. If initial screen is negative, repeat periodically for ≥3 years (e.g., after a LEMS diagnosis). The **DELTA-P score** and **anti-SOX1** help predict SCLC in LEMS.
- ▶ **Management principles:** (1) **treat the tumour promptly** — the single most effective measure; (2) surface-antigen disorders → first-line glucocorticoids + IVIg + plasma exchange, second-line **rituximab/cyclophosphamide**; (3) intracellular-antigen disorders respond poorly — focus on tumour control and T-cell-directed therapy; (4) symptomatic agents — **3,4-diaminopyridine** for LEMS, GABA-enhancing drugs (diazepam, baclofen, valproate) for stiff-person syndrome.
- ▶ **Checkpoint inhibitors:** in <3% of treated patients cause neurologic immune-related adverse events that may carry classic neuronal antibodies and be clinically indistinguishable from spontaneous PNS.

High-yield exam pointers

- ▶ ~60–65% of PNS present **before** the cancer is known; suspect PNS with subacute, multifocal deficits and an inflammatory CSF.
- ▶ **Intracellular antigen = cytotoxic T-cell = irreversible = poor response; surface antigen = antibody-mediated = reversible = treatable.**

- ▶ Memorise the high-yield pairs: Hu–SCLC, Yo–ovary/breast, Tr(DNER)–Hodgkin, Ma2–testicular germ-cell, NMDAR–ovarian teratoma, VGCC–LEMS/SCLC, amphiphysin–breast/stiff-person, AChR–thymoma/MG.
- ▶ SCLC is the commonest single tumour across PNS; **neuroblastoma** drives childhood opsoclonus-myoclonus; **thymoma** has the highest PND frequency (30–50%).
- ▶ Faciobrachial dystonic seizures + hyponatraemia = **anti-LGI1**; Morvan syndrome/neuromyotonia = **anti-Caspr2**; PERM = **glycine-receptor**.
- ▶ LEMS = reflexes that **potentiate** after exercise + **incremental** RNS response; opposite of myasthenia gravis (decremental).
- ▶ For paraneoplastic **peripheral** neuropathy the only useful antibodies are **anti-Hu** and **anti-CRMP5/CV2**.
- ▶ Treat the tumour first; immunotherapy works best in surface-antibody syndromes and anti-NMDAR encephalitis (85–90% improve).

SOURCE & COVERAGE

- ▶ **Harrison's Principles of Internal Medicine, 22e** — “Paraneoplastic Neurologic Syndromes and Autoimmune Encephalitis” (Dalmau & Graus): antibody risk-classification tables (high/intermediate/low), pathogenesis, syndrome descriptions, NMDAR/LGI1/Caspr2 detail, management.
- ▶ **Bradley & Daroff's Neurology in Clinical Practice, 8e** — “Paraneoplastic Disorders of the Nervous System” (Rosenfeld & Dalmau): onconeural-antigen mechanism, antibody–syndrome–tumour table, PCD/encephalomyelitis/sensory-neuronopathy/LEMS detail, DELTA-P and SOX1, diagnostic certainty and FDG-PET.
- ▶ **CMDT 2026** — neurologic and cancer chapters for current tumour-screening and immunotherapy management context.

Coverage note: The corpus covers this topic in depth. The “high/intermediate/low-risk” labels follow the 2021 updated PNS diagnostic-criteria terminology used verbatim in Harrison 22e; the numeric PNS-Care score itself is not reproduced in the source and is therefore not stated.

Discuss the Causes and Management of Seizures

Asked in: Paper III Jun 2024 — RGUHS MD General Medicine

Definition / Introduction — A **seizure** (Latin *sacire*, “to take possession of”) is a *transient* occurrence of signs or symptoms due to **abnormal, excessive or synchronous neuronal activity** in the brain. **Epilepsy** is a chronic disorder of *recurrent unprovoked seizures*, operationally defined as **≥2 unprovoked seizures >24 h apart** (or one unprovoked seizure with a high recurrence risk, or an epilepsy syndrome).

About 5–10% of people have at least one seizure in life; epilepsy prevalence is 5–30 per 1000. A seizure is a *symptom*, not a disease — so management hinges on accurate classification, finding the cause, and rationally selecting an antiseizure medication (ASM).

Classification of Seizures (ILAE 2017)

Type determines aetiologic work-up, drug choice and prognosis. The 2017 ILAE scheme classifies by **onset, awareness and motor features**; the terms *simple/complex partial* and *secondary generalisation* are obsolete.

Onset	Subtypes	Key features
Focal onset (one hemispheric network)	<i>Aware vs impaired awareness; motor vs nonmotor; focal → bilateral tonic-clonic</i>	Aura, automatisms (lip-smacking, picking), Jacksonian march, Todd's paresis, <i>epilepsia partialis continua</i> ; often structural
Generalised onset (bilateral networks)	Motor: tonic-clonic, tonic, clonic, myoclonic, atonic (drop attacks), epileptic spasms; Nonmotor: typical / atypical absence	Ictal cry, tongue-bite, incontinence, post-ictal confusion; absence = abrupt, no post-ictal phase
Unknown onset	Motor / nonmotor / unclassified	Insufficient information

- ▶ **Typical absence** — onset 4–10 yr; brief lapses without postural loss; EEG 3-Hz **generalised spike-and-wave**, provoked by hyperventilation; 15–20% of childhood epilepsy.
- ▶ **Atypical absence** — slower onset/offset, EEG ≤ 2.5 -Hz spike-wave, with diffuse structural disease/developmental delay; drug-resistant.

Epilepsy syndromes (high-yield)

- ▶ **Juvenile myoclonic epilepsy (JME)** — early adolescence, morning myoclonic jerks, provoked by sleep deprivation; often GTCS $\pm$ absence; responds to valproate/levetiracetam.
- ▶ **Lennox-Gastaut syndrome** — *triad*: (1) multiple seizure types (tonic, atonic, atypical absence), (2) EEG slow (<3 Hz) spike-wave, (3) developmental delay; refractory.
- ▶ **Mesial temporal lobe epilepsy (MTLE)** — commonest focal-impaired-awareness syndrome; hippocampal sclerosis on T2 MRI; drug-refractory but **surgically curable**.

Causes / Aetiology of Seizures

Seizures result from a **shift in the excitation–inhibition balance**, produced by an interplay of *endogenous* (threshold/genetic), *epileptogenic* (lesional) and *precipitating* (provocative) factors. The ILAE recognises **six aetiologic categories (CMDT)**: **structural, genetic, infectious, metabolic, immune, unknown**.

Aetiology by age (clinically the most useful framework):

Age group	Common causes
Neonates (<1 month)	Perinatal hypoxia-ischaemia, intracranial haemorrhage/trauma, CNS infection, metabolic (hypoglycaemia, hypocalcaemia, hypomagnesaemia, pyridoxine [B6] deficiency), drug withdrawal, developmental/genetic disorders
Infants & children (1 mo–12 yr)	Febrile seizures, genetic/metabolic epilepsy syndromes, CNS infection, developmental disorders, trauma
Adolescents (12–18 yr)	Trauma, genetic disorders, infection, illicit drugs, brain tumour
Young adults (18–35 yr)	Trauma, alcohol withdrawal, illicit drugs, brain tumour, autoantibodies (e.g. anti-LGI1, anti-NMDA-R)
Older adults (>35 yr)	Cerebrovascular disease ($\approx$ 50% of new epilepsy >65 yr), brain tumour, alcohol withdrawal, metabolic (uraemia, hepatic failure, dysglycaemia, electrolytes), Alzheimer/degenerative, autoantibodies

Salient points on causes:

- ▶ **Febrile seizures** — 3 months–5 yr (peak 18–24 mo), prevalence 3–5%; *simple* (brief, generalised, single) carry no increased epilepsy risk, *complex* (>15 min, focal, or repeated) carry a 2–5% risk.
- ▶ **Head trauma** — penetrating wound, depressed skull fracture, intracranial haemorrhage or prolonged post-traumatic coma/amnesia → **30–50% risk** of epilepsy; severe penetrating injury up to 45%.
- ▶ **Provoked/acute symptomatic seizures** (metabolic, drug, alcohol withdrawal) are *not* epilepsy — treat the cause, not with chronic ASM.
- ▶ **Provoking drugs/toxins** — β -lactams, quinolones, **isoniazid**, tramadol/meperidine, bupropion, clozapine, lithium, theophylline, ciclosporin/tacrolimus, cocaine/amphetamine; and **withdrawal** of alcohol, benzodiazepines, barbiturates, baclofen.
- ▶ **Genetic channelopathies** — e.g. *SCN1A* (Dravet syndrome — **avoid Na-channel blockers**), *KCNQ2*, *CHRNA4*, *SLC2A1* (GLUT-1 deficiency → **ketogenic diet**).

Basic mechanism (pathophysiology — exam framer)

- ▶ Hallmark of a focal seizure is the **paroxysmal depolarisation shift (PDS)** — prolonged Ca^{2+} -mediated membrane depolarisation opening voltage-gated Na^+ channels, generating hyper-synchronous repetitive firing (the EEG “spike”).
- ▶ Spread is normally checked by GABAergic **surround inhibition**; recruitment occurs via rising extracellular K^+ , presynaptic Ca^{2+} accumulation and **NMDA-receptor** activation.

- ▶ Absence seizures arise from **thalamocortical oscillations** via **GABA-B receptors** and **T-type Ca^{2+} channels** (target of ethosuximide/valproate).
- ▶ **Epileptogenesis** = transformation of a normal network into a chronically hyperexcitable one (months–years after trauma/stroke/infection) — currently no proven *antiepileptogenic* drug.

Diagnostic evaluation

- ▶ **History** is paramount (diagnosis is largely clinical) — eyewitness account, aura, semiology, post-ictal state, precipitants, risk factors; *exclude mimics* (syncope, TIA, migraine, psychogenic non-epileptic seizures).
- ▶ **Blood work** — glucose, electrolytes, Ca^{2+} , Mg^{2+} , renal/hepatic function, CBC, toxicology screen; LP if meningitis/encephalitis suspected (mandatory in HIV); serum/CSF **autoantibodies** in fulminant epilepsy with psychiatric/cognitive change.
- ▶ **EEG** — supports diagnosis (interictal spikes/sharp waves), classifies seizures, guides prognosis; a normal interictal EEG **does not exclude** epilepsy (normal in 50–80% initially). Video-EEG telemetry is the gold standard for diagnostic uncertainty and presurgical localisation.
- ▶ **Neuroimaging** — MRI > CT for all new-onset seizures (detects tumour, vascular malformation, mesial temporal sclerosis, cortical dysplasia); emergent CT if mass/infection suspected and MRI unavailable.
- ▶ **Genetic testing** — for suspected genetic syndromes; guides therapy (e.g. *SLC2A1* → ketogenic diet; *ALDH7A1* → pyridoxine; avoid Na-blockers in *SCN1A*).
- ▶ **PNES vs epilepsy** — pelvic thrusting, side-to-side head movement, asynchronous limb shaking, ictal eye closure, waxing-waning, *no* post-ictal prolactin rise favour PNES; confirm with video-EEG.

Management — Antiseizure Drug (ASM) Therapy

ASMs act by **Na^{+} -channel block** (phenytoin, carbamazepine, lamotrigine, lacosamide, oxcarbazepine), **Ca^{2+} -channel block** (gabapentin, pregabalin; T-type — ethosuximide, valproate), **GABA potentiation** (benzodiazepines, barbiturates, valproate, tiagabine), **glutamate attenuation** (perampanel, topiramate, lamotrigine) and **SV2A modulation** (levetiracetam, brivaracetam).

General principles: treat reversible causes/avoid precipitants (esp. **sleep deprivation**) first; start ASM after a first seizure *only* with high recurrence risk (prior brain insult, epileptiform EEG, abnormal imaging, or nocturnal seizure); aim for **monotherapy at lowest effective dose**, titrate slowly; clinical seizure control, not serum level, is the endpoint.

Seizure type	First-line	Alternatives
Focal ($\pm$ bilateral TC)	Lamotrigine, Levetiracetam, Carbamazepine, Oxcarbazepine, Phenytoin	Zonisamide, Brivaracetam, Topiramate, Lacosamide,

Seizure type	First-line	Alternatives
		Valproate, Cenobamate, Perampanel
Generalised tonic-clonic	Valproate, Lamotrigine, Levetiracetam	Topiramate, Zonisamide, Perampanel (avoid CBZ/OXC/PHT — may worsen)
Typical absence	Ethosuximide, Valproate, Lamotrigine	Levetiracetam, Clonazepam
Myoclonic / atonic / atypical absence	Valproate, Lamotrigine, Topiramate	Clonazepam, Clobazam, Rufinamide, Fenfluramine

- ▶ **Key drug pearls:** Lamotrigine → rash/SJS (slow titration; even slower with valproate which doubles its half-life). Phenytoin → **non-linear kinetics**, gum hypertrophy, hirsutism, osteomalacia. Valproate → **teratogenic (neural tube defects), hepatotoxicity, thrombocytopenia** — *avoid in women of child-bearing age*. Carbamazepine → SIADH/hyponatraemia, marrow suppression; test *HLA-B1502 (Asians) for SJS risk before CBZ/PHT/OXC/LTG. Levetiracetam → **behavioural/mood effects but no significant interactions****.
- ▶ **Refractory epilepsy** (~30%, defined as failure of ≥2 appropriate ASMs): rational polytherapy with differing mechanisms → consider **surgery** (anteromedial temporal lobectomy/amygdalohippocampectomy makes ~70% of well-selected MTLE patients seizure-free; lesionectomy, corpus callosotomy, hemispherectomy), **laser thermal ablation**, **neurostimulation** (VNS, responsive neurostimulation, thalamic DBS), or **ketogenic diet**.

Status Epilepticus (SE) — the emergency

SE = continuous seizures or repetitive seizures without inter-ictal recovery of consciousness; operationally ≥5 min of generalised convulsive activity warrants treatment. Mortality up to 20%; commonest cause is ASM non-adherence/withdrawal. Stepwise protocol:

Stage	Therapy
0–5 min (stabilise)	ABC, O ₂ , IV access, check glucose → IV 50% dextrose 25–50 mL (+ thiamine), correct metabolic derangements
5–20 min (1st line — benzodiazepine)	IV lorazepam 0.1 mg/kg (4 mg, repeat once) or IM midazolam 10 mg or rectal diazepam 0.2 mg/kg
20–40 min (2nd line — IV ASM load)	Fosphenytoin 18–20 mg PE/kg @150 mg PE/min (or phenytoin 18–20 mg/kg @50 mg/min, ECG monitor) or Valproate 20–40 mg/kg or Levetiracetam 60 mg/kg (ESETT trial: all three equivalent)

Stage	Therapy
>40 min (refractory SE)	Add phenobarbital; continuous IV anaesthesia — midazolam infusion (0.2 mg/kg → 0.05–0.6 mg/kg/h), propofol (2 mg/kg → 2–10 mg/kg/h) or pentobarbital/thiopental , with intubation + continuous EEG

Non-convulsive SE is diagnosed on EEG and treated by the same ladder (IV anaesthesia often not required).

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **ILAE 2017 seizure classification tree** — top box “Seizure” branching to **Focal onset** (→ *aware / impaired awareness; motor / nonmotor; focal-to-bilateral tonic-clonic*), **Generalised onset** (→ *motor: tonic-clonic, myoclonic, atonic, spasms / nonmotor: typical & atypical absence*), and **Unknown onset**.
- ▶ **Stepwise status-epilepticus management ladder** — vertical timeline boxes: *0–5 min stabilise + IV glucose/thiamine → 5–20 min IV lorazepam / IM midazolam → 20–40 min fosphenytoin OR valproate OR levetiracetam → >40 min refractory: midazolam/propofol/pentobarbital infusion + continuous EEG.*

Clinical / Diagnostic significance

- ▶ **Classification drives therapy** — carbamazepine, oxcarbazepine and phenytoin can *aggravate* absence, myoclonic and atonic seizures; valproate/levetiracetam/lamotrigine are safe broad-spectrum choices.
- ▶ **First seizure ≠ epilepsy** — only ~30–50% recur; treat after one seizure only with defined high-risk features.
- ▶ **Time-critical SE** — outcome depends on the interval between onset and effective treatment; benzodiazepine + IV ASM load must not be delayed.
- ▶ **Women & epilepsy** — counsel on valproate teratogenicity, **folate 1–4 mg/d** pre-conception, enzyme-inducer effect on oral contraceptives, and vitamin K in the last weeks of pregnancy; prefer levetiracetam/lamotrigine.
- ▶ **SUDEP** — sudden unexpected death in epilepsy; risk rises with frequent nocturnal GTCS; mortality in epilepsy is 2–3× the general population.
- ▶ **Driving, occupation and lifestyle** counselling (avoid heights, unsupervised swimming/bathing) are integral to management.

High-yield exam pointers

- ▶ Epilepsy = ≥2 unprovoked seizures (or one + high recurrence risk).
- ▶ ILAE 2017: **Focal / Generalised / Unknown onset**; “partial” is obsolete.

- ▶ **Absence** = 3-Hz spike-wave, **ethosuximide** drug of choice (no benefit in GTCS).
- ▶ **Valproate** = broadest spectrum but **teratogenic** — avoid in women of child-bearing potential.
- ▶ **Lamotrigine** → SJS; **HLA-B1502* + carbamazepine → SJS in Asians**.
- ▶ **Lennox-Gastaut triad**: multiple seizure types + slow spike-wave + developmental delay.
- ▶ **Status epilepticus** treated at 5 min: lorazepam → fosphenytoin/valproate/levetiracetam (ESETT) → anaesthesia.
- ▶ **MTLE with hippocampal sclerosis** = drug-resistant but **surgically curable** (~70% seizure-free).
- ▶ Commonest cause of new-onset epilepsy in the **elderly** = **stroke**; in **young adults** = **trauma/alcohol withdrawal**.

SOURCE & COVERAGE

- ▶ **Harrison's Principles of Internal Medicine, 22e** — “Seizures and Epilepsy” (classification, aetiology by age, mechanisms, ASM selection & doses, status epilepticus, surgery, women/SUDEP).

Acute Ischemic Stroke Involving the Right Internal Capsule

Asked in: Paper III Jul 2021 — RGUHS MD General Medicine

Definition / Introduction — *Ischemic stroke* is the acute onset of a focal neurological deficit due to occlusion of a cerebral vessel producing infarction of brain tissue. The **internal capsule** is a compact band of ascending and descending white-matter fibres between the caudate/thalamus medially and the lentiform nucleus laterally; it carries the *corticospinal*, *corticobulbar* and *thalamocortical tracts*. Infarction here is most often a **small-vessel (lacunar) stroke** from occlusion of a single deep penetrator. A lesion of the **right** internal capsule produces a **contralateral (left-sided) deficit**, classically a *pure motor hemiparesis*, characteristically without cortical signs.

Functional anatomy & blood supply (basis of localization)

- ▶ The capsule has three parts: **anterior limb** (frontopontine, anterior thalamic radiation), **genu** (corticobulbar fibres) and **posterior limb** (corticospinal tract, superior thalamic/sensory radiations, and posteriorly the optic and auditory radiations).

- ▶ **Somatotopy of the corticospinal tract** in the posterior limb: face/arm fibres lie ventromedially (near the genu) and leg fibres dorsolaterally — so a small capsular lesion can affect *face, arm and leg together* (proportionate weakness), unlike cortical strokes which are patchy.
- ▶ **Arterial supply** (all are end-arteries with poor collaterals → infarcts are small but dense):
 - **Lenticulostriate branches** of the MCA (M1) → superior portions of anterior and posterior limbs, putamen, globus pallidus, caudate body, corona radiata.
 - **Anterior choroidal artery (AChA)** — arises from the internal carotid distal to the posterior communicating artery → **posterior limb of the internal capsule**, optic tract, lateral geniculate body, medial temporal lobe, midbrain.
 - **Recurrent artery of Heubner** (medial lenticulostriate from ACA A1/A2) → anterior limb and head of caudate.

Etiopathogenesis

- ▶ **Small-vessel / lacunar disease (commonest mechanism here; ~20–25% of all ischemic strokes):** chronic **hypertension** and **diabetes** cause *lipohyalinosis* (medial hypertrophy and fibrinoid deposition) or *microatheroma* at the origin of a 30–300 µm penetrating artery → in-situ thrombotic occlusion → a small infarct (lacune, 3 mm–2 cm; “lake” of fluid at autopsy). **Hypertension and age are the principal risk factors**; diabetes is also well recognised.
- ▶ **Tempo as a clue to mechanism:** slowly-paced (stuttering) deficits suggest haemodynamic failure of a tightly stenosed penetrator; rapid onset suggests in-situ thrombosis. A *crescendo* of stereotyped TIAs preceding a capsular lacune is the **capsular warning syndrome**.
- ▶ **Other mechanisms** producing capsular/striatocapsular infarction: artery-to-artery embolism from carotid plaque, cardioembolism (atrial fibrillation, valve disease, LV thrombus), large MCA-stem thrombosis with lenticulostriate involvement, and AChA-territory occlusion.
- ▶ **Ischemic cascade:** energy failure → loss of ionic gradients → glutamate excitotoxicity, Ca^{2+} influx, free-radical and arachidonic-acid generation, inflammation → infarct *core* surrounded by a salvageable, perfusion-dependent **penumbra** (the target of reperfusion therapy).

Mechanism	Typical source	Capsular relevance
Small-vessel (lacunar)	Lipohyalinosis / microatheroma of penetrator; HTN, DM	Most common — pure motor / sensorimotor lacune
Artery-to-artery embolism	Carotid bifurcation / arch plaque	Striatocapsular infarct
Cardioembolism	AF, valve disease, LV thrombus	Larger deep infarct
Large-vessel thrombosis	MCA-stem / ICA atherosclerosis	Lenticulostriate territory

Clinical features (lesion of the **RIGHT** internal capsule → **LEFT-sided deficit**)

- ▶ **Pure motor hemiparesis (the commonest lacunar syndrome):** a unilateral (left) motor deficit affecting face, arm and leg almost equally, often with mild dysarthria at onset, an extensor (Babinski) plantar response, and — crucially — **no aphasia, no apraxia, no agnosia, no sensory, visual or higher-cortical loss**. Because the lesion spares the cortex, *higher functions are intact*; and as the right hemisphere is non-dominant in most patients, language is preserved regardless.
- ▶ **Sensorimotor stroke:** lacune of the posterior limb plus adjacent posteroventral thalamus → combined left face–arm–leg motor and sensory deficit.
- ▶ **Ataxic hemiparesis:** posterior-limb lacune → left lower-limb-predominant weakness with disproportionate ipsilateral limb incoordination and an extensor plantar.
- ▶ **Dysarthria–clumsy hand syndrome:** lacune of the genu / anterior limb → dysarthria, dysphagia, supranuclear facial weakness, tongue deviation and loss of fine motor control of the left hand.
- ▶ **Anterior choroidal artery syndrome (Foix, 1925):** the classic triad of **contralateral hemiparesis (posterior-limb corticospinal fibres) + hemianesthesia (superior thalamic radiation) + homonymous hemianopia (optic tract/LGB/radiation)**. With a right AChA infarct expect additional non-dominant signs — *left visuospatial neglect, anosognosia, constructional apraxia* and a relative afferent pupillary defect.
- ▶ General features favouring ischemia over haemorrhage: deficit maximal at onset (or remitting), normal/only modestly raised BP, preserved consciousness. Recovery from small-vessel strokes is usually rapid and fairly complete (partial/complete resolution over 4–6 weeks), though early stuttering worsening can occur.

Lacunar syndrome	Usual capsular site	Left-sided manifestation (right capsule)
Pure motor hemiparesis	Posterior limb / corona radiata	Face + arm + leg weakness, ± dysarthria
Pure sensory stroke	VPL thalamus (± capsule)	Numbness/paraesthesia, cheiro-oral pattern
Ataxic hemiparesis	Posterior limb	Leg-predominant weakness + limb ataxia
Dysarthria–clumsy hand	Genu / anterior limb	Dysarthria + clumsy hand
Sensorimotor stroke	Posterolateral thalamus + posterior limb	Combined hemimotor + hemisensory loss

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Axial section of the internal capsule:** label *anterior limb, genu, posterior limb, head of caudate, thalamus, putamen, globus pallidus (lentiform nucleus)*; arrow the corticospinal somatotopy (**face/arm ventromedial, leg dorsolateral**) and the *optic/auditory radiations* in the retrolenticular part.

Lacunar syndrome	Usual capsular site	Left-sided manifestation (right capsule)
▶ Arterial supply schematic: show <i>MCA lenticulostriate branches, anterior choroidal artery (posterior limb), recurrent artery of Heubner (anterior limb)</i> feeding the capsule.		

Clinical / Diagnostic significance

- ▶ **Emergency non-contrast CT head first** — to *exclude haemorrhage*; it is insensitive to acute infarction (often normal in the first 6–24 h) but mandatory before thrombolysis.
- ▶ **Diffusion-weighted MRI is the gold standard** — confirms and localises the small capsular lacune.
- ▶ **Vascular & cardioembolic work-up:** CTA/MRA (great-vessel and intracranial stenosis), CT-perfusion to define core vs penumbra (selects late thrombectomy), carotid duplex, ECG and prolonged ambulatory monitoring for AF, transthoracic/transoesophageal echo, blood glucose, lipid profile, CBC; hypercoagulable screen in young/cryptogenic cases.
- ▶ **NIHSS** quantifies severity and guides reperfusion eligibility; “time last seen normal” defines the therapeutic window.

Management

A. Acute / hyperacute (penumbra rescue):

- ▶ **ABC**, finger-stick glucose (correct hypo-/hyperglycaemia), continuous monitoring; treat fever with antipyretics/cooling; keep glucose ~3.3–10.0 mmol/L (60–180 mg/dL).
- ▶ **Permissive hypertension:** lower BP only if **>220/120 mmHg**, or malignant hypertension / concurrent myocardial ischaemia, or **>185/110 mmHg if thrombolysis is planned** — collateral flow is pressure-dependent, so over-aggressive lowering worsens outcome.
- ▶ **IV thrombolysis (≤ 4.5 h of onset):** alteplase (rtPA) **0.9 mg/kg (max 90 mg)**, 10% as bolus then the remainder over 60 min; or **tenecteplase 0.25 mg/kg (max 25 mg) single IV bolus**. CT must show no haemorrhage and no oedema $> \frac{1}{3}$ MCA territory; observe contraindications (recent surgery/bleed, bleeding diathesis, uncontrolled BP). No other antithrombotic for 24 h.
- ▶ **Endovascular mechanical thrombectomy** for large-vessel occlusion (ICA, M1/M2, basilar): standard window **0–6 h**, and **6–24 h** in selected patients chosen by perfusion (core/penumbra mismatch) imaging — most relevant when the capsular infarct results from a proximal large-vessel clot rather than a pure lacune.
- ▶ **Supportive:** DVT prophylaxis with pneumatic compression stockings $\pm$ subcutaneous heparin; aspiration/pneumonia precautions. For large hemispheric infarcts with malignant oedema (peaks day 2–3): mannitol/hypertonic saline and **decompressive hemicraniectomy** (halves mortality); suboccipital decompression for space-occupying cerebellar infarction.

- ▶ Anticoagulation is NOT used routinely for acute atherothrombotic stroke (no benefit, more bleeding).

B. Secondary prevention (the mainstay for lacunar stroke):

- ▶ **Antiplatelets:** aspirin (after a 325 mg load, then 81 mg/d). For minor stroke / TIA (NIHSS <5) give **short-term dual antiplatelet therapy** — aspirin + clopidogrel (300–600 mg load then 75 mg/d) for ~21 days then single-agent — as in CHANCE/POINT; long-term DAPT (SPS3) is *avoided* in small-vessel stroke (more bleeding, no benefit).
- ▶ **Blood-pressure control is the single most effective measure** — target <130/80 mmHg long-term (thiazides and ACE inhibitors well supported); SPRINT supports lower targets.
- ▶ **High-intensity statin** (atorvastatin 80 mg / rosuvastatin 40 mg; SPARCL) to LDL <70 mg/dL; tight diabetic control; smoking cessation.
- ▶ **For cardioembolic source (AF):** oral anticoagulation — a DOAC (e.g., apixaban 5 mg BD) preferred over warfarin (INR 2–3); risk-stratify by CHA₂DS₂-VASc.
- ▶ **Carotid revascularisation** (endarterectomy) for significant ipsilateral symptomatic stenosis.

C. Rehabilitation: early multidisciplinary stroke-unit care with physiotherapy, occupational and speech therapy; constraint-induced movement therapy for hemiparesis; prevention of contractures, pressure sores and post-stroke depression — improves outcome and reduces mortality.

High-yield exam pointers

- ▶ Right internal-capsule lacune → **left pure motor hemiparesis of face, arm AND leg, with NO cortical signs and preserved language.**
- ▶ Posterior limb = corticospinal tract; **leg fibres dorsolateral, face/arm ventromedial.**
- ▶ **Anterior choroidal artery triad = hemiplegia + hemianaesthesia + hemianopia.**
- ▶ **Lipohyalinosis of penetrators from chronic hypertension** is the core pathology; HTN + age + diabetes are the key risk factors.
- ▶ **DWI-MRI** is the gold-standard investigation; **non-contrast CT** is done first only to exclude haemorrhage.
- ▶ **Alteplase 0.9 mg/kg ≤4.5 h** or **tenecteplase 0.25 mg/kg**; thrombectomy 0–6 h (up to 24 h by perfusion mismatch).
- ▶ Acute BP: treat only if >185/110 (if lysing) or >220/120 otherwise — *permissive hypertension*.
- ▶ Secondary prevention: antiplatelet + BP <130/80 + high-intensity statin; **DAPT for 21 days only** in minor stroke/TIA.
- ▶ **Capsular warning syndrome** = crescendo capsular TIAs that herald a completed lacune.

SOURCE & COVERAGE

Discuss the indications and options for reperfusion therapy in acute stroke

Asked in: Paper III May 2025 — RGUHS MD General Medicine

Definition / Introduction — *Reperfusion therapy* is the emergency restoration of blood flow to an acutely occluded cerebral artery, aiming to salvage the **ischaemic penumbra** (ischaemic but still viable tissue surrounding the infarct core) before it progresses to irreversible infarction. “**Time is brain**” — outcome is directly proportional to the speed of recanalisation. Two proven modalities exist: (1) **intravenous (IV) thrombolysis** with a plasminogen activator (alteplase or tenecteplase), and (2) **endovascular mechanical thrombectomy** for large-vessel occlusion (LVO). They are complementary, not mutually exclusive — eligible patients receive thrombolysis first (“bridging”) and then thrombectomy.

Rationale — the penumbra and the therapeutic window

- ▶ A cerebral blood flow of **0 mL/100 g/min** kills neurons within **4–10 min**; values **<16–18 mL/100 g/min** infarct within an hour; **<20 mL/100 g/min** causes reversible ischaemia (the penumbra) unless prolonged.
- ▶ Restoring flow re-supplies oxygen and glucose, reverses tissue acidosis, clears excitotoxic **glutamate** and reactive oxygen species, and halts cortical spreading depression — preventing the penumbra from infarcting.
- ▶ The penumbra (and thus the *individual* therapeutic window) is imaged as a **core–perfusion mismatch** on CT perfusion (CTP) or MR diffusion–perfusion (DWI/PWI) — this is what extends eligibility beyond the rigid clock-based windows.

Mandatory pre-reperfusion assessment (“Code Stroke”)

- ▶ Secure ABCs; finger-stick glucose (treat hypo-/hyperglycaemia — mimics).

- ▶ Establish **time last seen normal** (wake-up stroke = time patient went to bed) and quantify deficit with the NIHSS.
- ▶ **Emergency non-contrast CT (NCCT)** to exclude haemorrhage — the *only* mandatory imaging before IV thrombolysis (with glucose). No edema/hypodensity $> \frac{1}{3}$ of the MCA territory.
- ▶ For possible thrombectomy: **CT angiography (CTA)** (atria → vertex) to confirm LVO; add **CTP/MR perfusion** for late-window selection (6–24 h).
- ▶ Other labs (CBC, coagulation, ECG, electrolytes) must **not delay** thrombolysis in an otherwise-eligible patient.

Option 1 — Intravenous thrombolysis

Evidence: *NINDS rt-PA Study* established benefit of IV alteplase within 3 h (absolute 12% increase in minimal-disability outcome; symptomatic ICH 6.4% vs 0.6%). *ECASS III* extended efficacy to the 3–4.5 h window (good outcome 52.4% vs 45.2%, OR 1.34; sICH 2.4% vs 0.2%). Tenecteplase is **non-inferior** to alteplase and increasingly preferred as a single bolus.

Agent	Dose	Window	Notes
Alteplase (rt-PA)	0.9 mg/kg (max 90 mg); 10% as bolus, remainder over 60 min	0–4.5 h	US label 0–3 h; off-label/EU to 4.5 h. Asian dose often 0.6 mg/kg (less ICH)
Tenecteplase (TNK)	0.25 mg/kg IV push (max 25 mg) over ~5 s	0–4.5 h	Single bolus — no infusion; eases inter-hospital transfer for thrombectomy. Off-label

Indications (must satisfy ALL): clinical ischaemic stroke with disabling deficit; onset-to-needle ≤ 4.5 h; age ≥ 18 y; NCCT shows no haemorrhage and no large established infarct.

Key contraindications (Table 438-1 + NINDS exclusions):

Absolute	Relative / caution
Sustained BP $> 185/110$ mmHg despite treatment	Recent MI
Active bleeding / bleeding diathesis	GI or GU bleeding (within 21 days)
Recent head injury or intracerebral haemorrhage	Major surgery within preceding 14 days
Hypodensity $> \frac{1}{3}$ MCA territory / large infarct on CT	Rapidly improving or minor non-disabling deficit (NIHSS 0–5)
Platelets $< 100,000$; INR > 1.7 / PT > 15 s; heparin in 48 h	Seizure at onset (only if deficit is post-ictal)
Glucose < 50 mg/dL (2.8 mmol/L)	Arterial puncture at non-compressible site (7 days)

- ▶ **Extended/unknown-onset window:** MRI-based DWI–FLAIR mismatch (WAKE-UP) or perfusion mismatch (EXTEND) selects benefit up to ~9 h or on awakening — penumbra-guided, not clock-guided.
- ▶ **Peri-thrombolysis care:** lower BP to <185/110 (IV labetalol/nicardipine) before bolus; keep <180/105 for 24 h; **no antithrombotics for 24 h**; repeat CT for deterioration; for bleeding, stop infusion + give cryoprecipitate.

Option 2 — Endovascular mechanical thrombectomy (EVT)

LVO (MCA-M1, intracranial ICA, basilar) carries a large clot burden that often **fails to recanalise with IV thrombolysis alone** — these need EVT. Six 2015 RCTs (*MR CLEAN*, *ESCAPE*, *EXTEND-IA*, *SWIFT PRIME*, *REVASCAT*) proved benefit with **stent retrievers**: pooled OR 2.49; mRS 0–2 in 46% vs 26.5%, with a mortality benefit. Outcome is time-critical — odds of good outcome >3 if groin puncture <2 h, falling to ~2 by 8 h.

Indications — 2018 AHA/ASA Class I criteria:

- ▶ Pre-stroke mRS 0–1
- ▶ Causative occlusion of ICA or proximal MCA (M1)
- ▶ Age ≥18 y
- ▶ NIHSS ≥6
- ▶ ASPECTS ≥6 (limited established core on NCCT)
- ▶ Groin puncture within 6 h of onset
- ▶ Receipt of IV alteplase within 4.5 h **if eligible** (do not withhold/delay thrombolysis to do EVT)

Late window (6–24 h) — perfusion-selected (Class I/IIa):

- ▶ ****DAWN trial:** LVO, last-seen-well 6–24 h, clinical–core mismatch (RAPID software) → **good outcome** 47% vs 13%**.
- ▶ ****DEFUSE-3 trial:** perfusion mismatch, 6–16 h → **mRS 0–2 in 45% vs 17%****.
- ▶ Basilar occlusion: non-randomised data support thrombectomy up to **24 h**.
- ▶ **Stent retrievers are preferred** to older devices (e.g., MERCI coil retriever); aspiration catheters are an alternative. Bridging tenecteplase before transfer is increasingly favoured.

Integrated time-window algorithm

Time from onset	Reperfusion option
0–4.5 h	IV thrombolysis (alteplase/TNK) if eligible + EVT if anterior LVO
4.5–6 h	EVT for LVO (thrombolysis window closed)
6–24 h	EVT only if penumbra/mismatch on CTP/MR perfusion (DAWN/DEFUSE-3)

Time from onset	Reperfusion option
Wake-up / unknown, ≤ 9 h	IV thrombolysis if DWI-FLAIR or perfusion mismatch

Adjuncts and therapies that do NOT replace reperfusion

- ▶ **Antiplatelets:** Aspirin (160–325 mg) within 48 h gives a small net benefit (IST, CAST) — start after 24 h if thrombolysed. Short-term **dual antiplatelet** (aspirin + clopidogrel/ticagrelor) for 21 days in **minor stroke/TIA** (NIHSS $\leq 3-5$).
- ▶ **Anticoagulation:** No role in acute atherothrombotic stroke (no benefit, $\uparrow$ bleeding); reserved for dural sinus thrombosis.
- ▶ **Neuroprotection** (glutamate antagonists, hypothermia, magnesium, free-radical scavengers): **no agent proven** in humans despite >120 trials.
- ▶ **Decompressive hemicraniectomy** for malignant MCA infarction (within ~ 48 h) reduces mortality $\sim 50\%$ and improves survivor outcome; **suboccipital decompression** for space-occupying cerebellar infarct.
- ▶ **Supportive:** permissive hypertension (only treat if $>220/120$), euglycaemia, normothermia, stroke-unit care and early rehabilitation.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Penumbra schematic:** concentric zones — central black “core” (irreversible infarct) surrounded by a stippled “penumbra” (salvageable), with arrows labelled *Reperfusion* $\rightarrow$ *penumbra saved*; axis showing CBF thresholds (0 mL/100 g/min $\rightarrow$ death in 4–10 min, <20 $\rightarrow$ reversible ischaemia).
- ▶ **Acute-stroke reperfusion algorithm flowchart:** boxes — *Suspected stroke* $\rightarrow$ *Code Stroke / NCCT* $\rightarrow$ branch **No haemorrhage**; *Onset <4.5 h* $\rightarrow$ *IV thrombolysis (alteplase/TNK)* and *CTA* $\rightarrow$ *anterior LVO?* $\rightarrow$ *Thrombectomy (<6 h)*; *Onset 6–24 h* $\rightarrow$ *CTP/MR perfusion* $\rightarrow$ *favourable mismatch* $\rightarrow$ *Thrombectomy*. Label time windows on each arm.

Clinical / Diagnostic significance

- ▶ IV rt-PA raises the chance of recovery without significant disability from $\sim 26\%$ to $\sim 39\%$ when given <3 h; EVT makes functional independence $\geq 30\%$ more likely in LVO.
- ▶ **Door-to-needle ≤ 60 min** and **door-to-groin** times are key quality metrics; pre-hospital “stroke code” activation and tele-stroke speed delivery.
- ▶ **Systems of care:** primary stroke centres deliver thrombolysis and transfer (“drip-and-ship”) to **comprehensive/thrombectomy-capable centres**; the bolus-only tenecteplase simplifies transfer.

- ▶ After reperfusion: 24-h follow-up CT before starting antithrombotics; then establish aetiology (AF → anticoagulation; carotid stenosis >50% → endarterectomy; high-intensity statin, LDL <70 mg/dL) for secondary prevention.

High-yield exam pointers

- ▶ Two reperfusion options: **IV thrombolysis** (alteplase **0.9 mg/kg**, max 90 mg, 10% bolus + 60-min infusion; tenecteplase **0.25 mg/kg** bolus) and **mechanical thrombectomy** (stent retriever).
- ▶ IV thrombolysis window **≤4.5 h** (NINDS 0–3 h; ECASS III 3–4.5 h); thrombectomy **≤6 h**, extended to **24 h** with perfusion mismatch (**DAWN 6–24 h**, **DEFUSE-3 6–16 h**).
- ▶ **BP must be <185/110 mmHg** before thrombolysis; treat acute BP only if **>220/120 mmHg** otherwise.
- ▶ Only **NCCT + glucose** are mandatory before IV thrombolysis — don't wait for other labs.
- ▶ Thrombectomy Class I: **ICA/M1 occlusion**, **NIHSS ≥6**, **ASPECTS ≥6**, **pre-stroke mRS 0–1**, **age ≥18**, **groin <6 h**.
- ▶ Symptomatic ICH is the major thrombolysis complication (~6% NINDS) — reverse with **cryoprecipitate**.
- ▶ **No neuroprotective drug** is proven; aspirin only modest; anticoagulation not for acute atherothrombotic stroke.
- ▶ Bridging thrombolysis-then-thrombectomy is standard for eligible LVO; do **not** delay thrombolysis to perform EVT.

SOURCE & COVERAGE

- ▶ **Bradley & Daroff's Neurology in Clinical Practice, 8e** — “Ischemic Cerebrovascular Disease” (alteplase inclusion/exclusion criteria, 2018 AHA/ASA Box 65.8 thrombectomy criteria, MR CLEAN/ESCAPE/EXTEND-IA/SWIFT PRIME/REVASCAT, NNT/benefit data).
- ▶ **CMDT 2026** — “Nervous System Disorders / Stroke” (current dosing, tenecteplase non-inferiority, 0–4.5 h thrombolysis and 0–6/6–24 h embolectomy windows, extended-window perfusion selection, peri-thrombolysis BP control).

Endovascular revascularization for acute ischemic stroke

Asked in: Paper III Nov 2022 — RGUHS MD General Medicine

Definition / Introduction — *Endovascular revascularization* (endovascular mechanical **thrombectomy**) is the catheter-based removal of an occluding thrombus from a large intracranial artery to restore cerebral blood flow and salvage the ischemic **penumbra**. It is one of the six categories of acute ischemic stroke treatment in Harrison (medical support, IV thrombolysis, **endovascular revascularization**, antithrombotic treatment, neuroprotection, and stroke centers/rehabilitation). It is the definitive reperfusion therapy for **large-vessel occlusion (LVO)** strokes, which often fail to open with IV thrombolysis alone, and is used as an *alternative or adjunct* to IV thrombolysis.

Rationale and target lesions

- ▶ Ischemic stroke from **large-vessel intracranial occlusion** carries high rates of mortality and morbidity.
- ▶ These occlusions involve a **large clot burden** and often **fail to recanalize with IV thrombolysis alone**, providing the rationale for direct mechanical clot retrieval.
- ▶ **Eligible target vessels** (proven on CT angiography):
 - **Intracranial internal carotid artery (ICA)**
 - **Middle cerebral artery** — first division (M1) and second division (M2)
 - **Basilar artery (BA)** (posterior circulation)
- ▶ Thrombectomy is offered to patients who are **ineligible for or have contraindications to thrombolytics**, or who **failed to recanalize after IV thrombolysis**.
- ▶ Reperfusion aims to rescue the penumbra — clinical outcome is critically **time-dependent**.

Patient selection and time windows

- ▶ **Disabling deficit**: patients with NIHSS >5 (National Institutes of Health Stroke Scale) are candidates for thrombolytic and/or endovascular therapy.
- ▶ **Imaging gateway**: noncontrast head CT to exclude hemorrhage, then **CT angiography (CTA)** to confirm the LVO; for late windows, **CT perfusion / MR perfusion** to assess salvageable tissue.
- ▶ **Early window (<6 h from onset)**: thrombectomy for **ICA / M1–M2 / basilar** occlusion confirmed on CTA, **with or without** IV thrombolysis pretreatment.
- ▶ **Extended/late window (6–24 h, including wake-up and unwitnessed-onset strokes)**: effective **only if perfusion imaging shows good collaterals / a favorable mismatch** (small core, large penumbra). Selection rests on perfusion imaging rather than thrombolysis eligibility.
- ▶ **Posterior circulation**: for basilar artery occlusion, nonrandomized data show thrombectomy is **safe up to 24 h** from onset and is associated with lower 3-month Rankin scores.
- ▶ **Time is brain — procedural timing data**:
 - Odds of a good outcome **exceed 3** if **groin puncture occurs within 2 h** of symptom onset, but fall to ~2 if 8 h elapse.

- >80% of patients with vessel opening within 1 h of ED arrival had a good outcome, versus only one-third if 6 h elapsed.

Evidence base (key trials)

Trial group / window	Patients selected	Outcome (mRS 0–2 unless stated)
Six 2015 RCTs (combined meta-analysis); <6 h	ICA & MCA occlusion on CTA, ± IV tPA	Large benefit: OR 2.49 (95% CI 1.76–3.53, $p < .001$); 46% vs 26.5% (endovascular vs medical)
DAWN (Trevo stent retriever); up to 24 h	Wake-up / late-presenting, clinical–imaging mismatch	Good outcome 47% vs 13% ($p < .0001$)
DEFUSE-3; up to 16 h	Perfusion mismatch on CT/MR perfusion	Good outcome 45% vs 17% ($p < .001$)
Basilar occlusion (nonrandomized); up to 24 h	Posterior circulation LVO	Safe; lower 3-month Rankin scores

- ▶ mRS 0–2 = “normal or symptomatic but independent.”
- ▶ A more recent meta-analysis additionally demonstrated a **mortality benefit** with thrombectomy.
- ▶ One trial concluded patients were **home nearly 2 months earlier** when treated with endovascular therapy.

Procedure, adjuncts and bridging therapy

- ▶ **Technique:** catheter-based clot removal (stent retriever, e.g., *Trevo*, and/or aspiration) via femoral/groin access, with restoration of antegrade flow confirmed on catheter angiography.
- ▶ **Bridging with IV thrombolysis:** outcomes are **likely improved by giving IV rtPA before thrombectomy** when the patient is rtPA-eligible and it is safe to administer.
 - IV rtPA (alteplase): 0.9 mg/kg (max 90 mg), 10% as bolus then remainder over 60 min, within 4.5 h.
 - IV tenecteplase (TNK): 0.25 mg/kg IV bolus (max 25 mg) over 5 s. Recent data support **replacing rtPA with tenecteplase** before thrombectomy — its single-bolus administration (no 1-h infusion) **simplifies inter-hospital transfer** to an endovascular center and obviates critical-care transport. Several trials of TNK before endovascular therapy found it safe.
- ▶ **Adjunctive imaging workflow** (Fig. 438-3): noncontrast CT → CTA (confirm LVO; *hyperdense MCA sign* is highly specific but seen in only ~20%) → CT perfusion (core vs penumbra/mismatch) → catheter angiography with clot removal → follow-up diffusion-weighted MRI; advanced imaging can yield a **better-than-predicted** outcome.

Systems of care

- ▶ Now that thrombectomy is proven effective, **comprehensive stroke centers** that rapidly identify and treat LVO are an international priority.
- ▶ **Regional systems of care:** patients are first evaluated at **acute stroke-ready hospitals / primary stroke centers** (can give IV rtPA or tenecteplase), then **transferred to thrombectomy-capable or comprehensive stroke centers**, or **directly triaged** to such centers based on prehospital field assessment.
- ▶ **Telemedicine / telestroke** services extend evaluation for thrombolysis and endovascular treatment.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Acute stroke management pathway** (Fig. 438-2) — flowchart with labels: *Suspected acute stroke* → *Prehospital call ahead* → *Code stroke activation*; branch **Onset <6 h**: *CT no hemorrhage* → *IV PA if eligible (<4.5 h)* → *Perform CTA* → *ICA/M1-2 or BA occlusion?* → *Yes* → *Thrombectomy*; branch **Onset 6–24 h**: *CT no hemorrhage* → *CTA/CTP* → *Favorable perfusion?* → *Yes* → *Thrombectomy*; *No* → *Inpatient management*.
- ▶ **LVO imaging-to-reperfusion sequence** (Fig. 438-3) — panels labelled: *Noncontrast CT (hyperdense MCA sign, arrow)*; *CTA (MCA branch occlusion)*; *CT perfusion (core = no pink signal; penumbra = green, mismatch volume, mismatch ratio, Tmax >6.0 s, CBF <30%)*; *Catheter angiogram (occlusion → restored flow after clot removal)*; *Follow-up DWI (small residual infarct)*.

Clinical / Diagnostic significance

- ▶ Identifies the subgroup — **large-vessel occlusion** — that derives the greatest reperfusion benefit and that IV thrombolysis alone usually cannot recanalize.
- ▶ **CTA is the decision-maker** for early-window thrombectomy; **perfusion imaging** (CTP/MR perfusion) opens the 6–24 h window for wake-up and late-presenting strokes.
- ▶ Drives **prehospital triage and hospital networks**: “call ahead,” stroke-code activation, and direct routing to thrombectomy-capable centers shorten door-to-groin times.
- ▶ **Door/onset-to-reperfusion time is the strongest modifiable outcome determinant** — every minute of delay reduces the odds of independence.
- ▶ Reinforces post-reperfusion secondary prevention from the same chapter: high-intensity statin (atorvastatin 80 mg / rosuvastatin 40 mg, LDL <70 mg/dL), apixaban for atrial fibrillation, dual antiplatelet for minor stroke/intracranial atherosclerosis, and carotid endarterectomy for significant ICA stenosis.

High-yield exam pointers

- ▶ Endovascular thrombectomy = definitive therapy for **LVO** (intracranial ICA, MCA M1–M2, basilar artery).

- ▶ Use as **alternative or adjunct** to IV thrombolysis — for the ineligible, contraindicated, or failed-recanalization patient.
- ▶ **Early window <6 h** on CTA; **extended window up to 24 h** requires favorable perfusion mismatch/collaterals.
- ▶ Landmark numbers: **OR 2.49 (CI 1.76–3.53)**; mRS 0–2 **46% vs 26.5%**; **DAWN 47% vs 13%** (≤ 24 h); **DEFUSE-3 45% vs 17%** (≤ 16 h).
- ▶ **Time targets**: good-outcome odds >3 if **groin puncture <2 h**; **$>80\%$ good outcome if vessel opened within 1 h** of ED arrival.
- ▶ **Bridging**: give IV rtPA (**0.9 mg/kg**) or tenecteplase (**0.25 mg/kg bolus**) first if eligible; TNK simplifies transfer.
- ▶ **Hyperdense MCA sign** is highly specific but only $\sim 20\%$ sensitive for MCA occlusion.
- ▶ Requires **comprehensive/thrombectomy-capable stroke centers** and organized regional systems of care.

SOURCE & COVERAGE

Harrison 22e — Ch 438 “Ischemic Stroke” (TREATMENT: Endovascular Revascularization; Intravenous Thrombolysis; Stroke Centers; Figs. 438-2 and 438-3; Table 438-1).

Coverage note: Harrison names only the DAWN and DEFUSE-3 trials and the Trevo stent retriever; the six 2015 RCTs are described collectively (as a combined meta-analysis) and not individually named — the commonly examined names (MR CLEAN, ESCAPE, EXTEND-IA, SWIFT-PRIME, REVASCAT) are standard but are NOT in this chapter. Procedural grading/selection metrics frequently quoted in exams — **mTICI 2b–3 reperfusion grade**, **ASPECTS ≥ 6** , and aspiration-vs-stent-retriever device choice — are universally accepted standard practice but are also NOT explicitly stated in the provided Harrison text and should be cited as general knowledge, not from this chapter.

Reversible Causes of Dementia and Differentiation of Alzheimer’s Disease from Frontotemporal Dementia

Asked in: Paper III 15 Apr 2026 — RGUHS MD General Medicine

Definition / Introduction — **Dementia** is an *acquired*, usually progressive deterioration in two or more cognitive domains (episodic memory, language, visuospatial function, praxis, executive function, behaviour) of sufficient severity to impair the successful performance of activities of daily living, occurring in clear consciousness (distinguishing it from delirium). Although most cases are due to irreversible neurodegeneration (Alzheimer’s disease [AD] accounts for 60–70%), a clinically vital subset is **potentially reversible or treatable** — in a study of 1000 consecutive memory-clinic patients, $\sim 19\%$

had a potentially reversible *cause* and a further ~23% had a reversible *contributing condition*. Because no single treatable aetiology is common, a structured screen is mandatory in every patient so that a treatable cause is never missed.

Reversible / potentially treatable causes of dementia

The three commonest potentially reversible diagnoses are **depression (pseudodementia)**, **normal-pressure hydrocephalus (NPH)**, and **alcohol dependence**; *medication side-effects* should be sought in every patient. A useful working classification (Harrison Table 31-1, “potentially reversible” entries):

Category	Specific reversible causes
Drugs & toxins	Sedative–hypnotics, benzodiazepines, opioids/analgesics, anticholinergics, antiepileptics (chronic intoxication); alcohol dependence ; heavy-metal poisoning (lead, mercury, arsenic, manganese); organic toxins
Metabolic / endocrine / organ failure	Hypothyroidism ; adrenal insufficiency and Cushing’s syndrome; hypo- and hyperparathyroidism; chronic renal failure (uraemic encephalopathy); hepatic failure ; pulmonary failure (hypoxia / CO ₂ narcosis)
Nutritional deficiencies	Thiamine (B1) — Wernicke encephalopathy; vitamin B12 — subacute combined degeneration; niacin — pellagra; elevated homocysteine / folate deficiency
Infections	HIV (HIV-associated neurocognitive disorder); neurosyphilis ; progressive multifocal leukoencephalopathy (JC virus); tuberculous, fungal and protozoal CNS infection; Whipple’s disease
Structural / neurosurgical	Normal-pressure hydrocephalus ; chronic subdural haematoma ; primary or metastatic brain tumour
Autoimmune / inflammatory	Paraneoplastic and autoimmune limbic encephalitis (anti-LGI1, NMDA-R, Caspr2, AMPA-R); CNS vasculitis ; neurosarcoidosis ; corticosteroid-responsive (Hashimoto) encephalopathy
Psychiatric	Depression (pseudodementia) ; schizophrenia; conversion disorder
Miscellaneous	Recurrent non-convulsive seizures ; acute intermittent porphyria

- A simple bedside aide-mémoire is “**DEMENTIAS**”: **D**rugs, **E**motional/depression, **M**etabolic-endocrine, **E**yes & ears (sensory deprivation) / **N**utritional, **T**umour/trauma (SDH, NPH), **I**nfection, **A**utoimmune, **S**eizures/structural — all map onto the categories above.

Approach to detect a reversible cause (investigations)

- ▶ **Routine (AAN-recommended) screen** in all: complete blood count; electrolytes, glucose, renal and liver function; **thyroid function (TSH)**; serum vitamin B12; and **structural neuroimaging (MRI or non-contrast CT)** to exclude tumour, subdural haematoma, infarcts, white-matter disease and NPH.
- ▶ **Selective / focused tests** driven by clues: serum RPR/VDRL and **HIV serology**; lumbar puncture (cells, protein, oligoclonal bands, autoimmune-encephalitis antibodies, AD biomarkers) when infection/inflammation or rapidly progressive dementia is suspected; urine toxin / heavy-metal screen; ESR, CRP, ANA; anti-thyroperoxidase/thyroglobulin antibodies; 24-h urine copper (Wilson); EEG (non-convulsive seizures, CJD periodic complexes).
- ▶ NPH is suggested by the triad of **gait apraxia** (“magnetic” gait), **urinary incontinence** and **dementia** with ventriculomegaly disproportionate to sulcal atrophy; objective gait improvement after high-volume (30–50 mL) CSF removal (tap test) predicts response to ventriculoperitoneal shunting (gait improves most; cognition least).
- ▶ **Treatment of the reversible component**: thyroxine for hypothyroidism; thiamine/B12 replacement and folate for elevated homocysteine; antiretrovirals for HIV and antimicrobials for opportunistic infection; CSF shunting for NPH; surgery/radiotherapy/chemotherapy for neoplasm; immunotherapy (steroids/IVIG/plasma exchange) for autoimmune encephalitis; and **withdrawal of cognition-impairing drugs**.

Differentiating Alzheimer’s disease from frontotemporal dementia

Both are cortical neurodegenerative dementias and below age 65 FTD rivals AD as the commonest cause, so distinction is a frequent clinical problem. The two are separated on **age, presenting symptom, neuropsychological profile, behaviour, neurological signs, imaging, molecular pathology, genetics** and drug response:

Feature	Alzheimer’s disease (AD)	Frontotemporal dementia (FTD)
Typical onset age	Most common >65 yr; rises with each decade (insidious)	Younger — 5th–7th decade; ~30% present >65
First / presenting symptom	Episodic memory loss (recent memory) in ~75%	Personality / behaviour change (bvFTD) or progressive language failure (PPA); memory relatively spared
Cognitive (neuropsych) profile	Amnesic — impaired learning/delayed recall, then language, executive, visuospatial deficits	Executive dysfunction and/or language ; <i>relative sparing of episodic memory and visuospatial/drawing skills</i>

Feature	Alzheimer's disease (AD)	Frontotemporal dementia (FTD)
Behaviour / neuropsychiatry	Early irritability, anxiety, depression; social graces preserved until late	Early disinhibition, apathy, loss of empathy, compulsivity, hyperorality/overeating, loss of insight
Core clinical syndromes	Typical amnesic AD; atypical — posterior cortical atrophy, logopenic aphasia, frontal/dysexecutive, corticobasal	bvFTD (commonest), semantic-variant PPA, non-fluent/agrammatic PPA; ± FTD-MND, CBS, PSP-RS
Motor / neurological signs	Normal early; myoclonus, rigidity, parkinsonism only late	Early axial rigidity, vertical supranuclear gaze palsy, dystonia, alien limb, or motor-neuron disease
Structural MRI	Entorhinal + hippocampal (medial temporal) atrophy; posterior-predominant cortical atrophy	Frontal, insular and/or anterior temporal atrophy; <i>posterior parietal lobe spared</i>
FDG-PET	Temporo-parietal hypometabolism; posterior cingulate / precuneus involvement	Frontal and anterior temporal hypometabolism
Molecular pathology	A β neuritic plaques + neurofibrillary tangles of hyperphosphorylated tau; amyloid/tau PET positive	FTLD-tau (e.g. Pick bodies) or FTLD-TDP-43 (~90% combined); FTLD-FET ~10%; AD-tau PET ligands not reliably positive
Neurotransmitter deficit	Cholinergic loss (nucleus basalis of Meynert)	Cholinergic system relatively spared; serotonergic loss
Genetics	APP (chr 21), PSEN-1 (chr 14), PSEN-2 (chr 1) in <2%; ApoE ϵ 4 (chr 19) susceptibility (1 allele $\approx$ 2–3 $\times$, 2 alleles $\approx$ 10–15 $\times$ risk)	Autosomal dominant in 10–20%: C9orf72 (chr 9), GRN (chr 17), MAPT (chr 17)
Biofluid biomarkers	CSF/plasma: $\downarrow$ A β 42 (low A β 42/A β 40), $\uparrow$ p-Tau181/217	No specific positive AD biomarker; AD biomarkers <i>negative</i> support FTLD
Drug response	Cholinesterase inhibitors + memantine give modest symptomatic benefit; anti-A β antibodies (lecanemab, donanemab) in early AD	No disease-modifying or symptomatic cognitive drug; cholinesterase inhibitors may worsen behaviour, memantine ineffective; SSRIs for behavioural symptoms

Feature	Alzheimer's disease (AD)	Frontotemporal dementia (FTD)
Course / survival	Symptomatic duration typically 8–10 yr (range 1–25)	Median survival ~6 yr; FTD-MND ~3 yr

- **Practical discriminators for the exam:** an elderly patient who first *gets lost and forgets recent events*, with hippocampal atrophy and a positive amyloid scan → **AD**; a younger patient brought by family for *socially inappropriate behaviour, apathy, overeating and loss of empathy with preserved memory* and frontal atrophy → **FTD**. International consensus (Rascovsky) criteria for **bvFTD** require ≥3 of: early disinhibition, apathy/inertia, loss of sympathy/empathy, perseverative/compulsive behaviour, hyperorality/dietary change, and a dysexecutive neuropsychological profile that *sparing memory and visuospatial function*.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- **Two coronal-brain silhouettes side by side.** Label the *AD brain*: “Medial temporal / hippocampal + entorhinal atrophy”, “Posterior-predominant (temporo-parietal) cortical atrophy”, “Nucleus basalis of Meynert – cholinergic loss”. Label the *FTD brain*: “Frontal + anterior temporal + insular atrophy”, “Anterior cingulate / orbitofrontal involvement (salience network)”, “Posterior parietal lobe SPARED”.
- **A simple two-circle/branch chart of reversible causes** with the eight category headings as labels: Drugs/Toxins; Metabolic-Endocrine; Nutritional (B1/B12/Niacin); Infection (HIV, neurosyphilis, PML, Whipple); Structural (NPH, SDH, tumour); Autoimmune (limbic encephalitis, vasculitis, Hashimoto); Psychiatric (depression); Seizures/Porphyria — each annotated with its specific treatment.

Clinical / Diagnostic significance

- The whole point of enumerating reversible causes is **therapeutic**: even a screening test with a 1–2% yield is justified because the alternative is missing a curable dementia (e.g. B12 deficiency, hypothyroidism, NPH, neurosyphilis, autoimmune encephalitis).
- **Rapidly progressive dementia** (decline to dementia in <1 year) widens the differential to prion disease (CJD — cortical ribboning on DWI, periodic EEG complexes, RT-QuIC), autoimmune/paraneoplastic encephalitis and toxic-metabolic states — many of which are treatable, so it warrants aggressive CSF and antibody work-up.
- **Depression** must be actively screened for and treated (SSRI/SNRI) before labelling a patient as having irreversible dementia; conversely a true dementia may coexist with low mood.
- **Misclassifying FTD as AD matters**: cholinesterase inhibitors can aggravate FTD behaviour, anti-amyloid antibodies are inappropriate, the prognosis and genetic counselling (C9orf72, GRN, MAPT; possible MND) differ, and behavioural/psychosocial caregiver support is the mainstay.

High-yield exam pointers

- ▶ Dementia = acquired, progressive cognitive decline impairing ADLs in clear consciousness (vs delirium); AD = 60–70%, the commonest cause overall.
- ▶ ~19% of memory-clinic patients have a potentially reversible cause; commonest reversible trio = depression, NPH, alcohol + drug side-effects.
- ▶ Routine reversible-cause screen: TSH, B12, CBC, metabolic panel, MRI/CT ($\pm$ RPR/VDRL, HIV, LP).
- ▶ NPH triad = magnetic gait + urinary incontinence + dementia; CSF tap test predicts shunt response (gait improves most).
- ▶ AD = memory-first, hippocampal/posterior atrophy, amyloid + tau pathology, cholinergic loss, ApoE ϵ 4; FTD = behaviour/language-first, frontotemporal atrophy, tau or TDP-43 pathology, cholinergic sparing, C9orf72/GRN/MAPT.
- ▶ FTD spares episodic memory and visuospatial skills early; AD spares motor and behaviour/social graces early.
- ▶ Cholinesterase inhibitors + memantine help AD; they are ineffective or harmful in FTD (no cognition-modifying drug).
- ▶ FTD presents younger (5th–7th decade) and below 65 rivals AD in frequency.

SOURCE & COVERAGE

- ▶ CMDT 2026 — "Nervous System Disorders" (dementia evaluation, normal-pressure hydrocephalus, rapidly progressive dementia work-up, cholinesterase-inhibitor and memantine regimens, anti-amyloid therapy, FTD drug cautions).

Epilepsy syndromes

Asked in: Paper III 09/2025 — RGUHS MD General Medicine

Definition / Introduction — A *seizure* is a transient occurrence of signs or symptoms due to abnormal excessive or synchronous neuronal activity in the brain, while *epilepsy* is an enduring predisposition to recurrent unprovoked seizures. An **epilepsy syndrome** is a distinctive cluster of clinical and

electroencephalographic features — characteristic seizure type(s), age of onset, EEG signature, triggers, imaging, comorbidities and often a predictable prognosis — that occur together and suggest a common underlying mechanism. Recognising the syndrome (rather than just the seizure type) directs the choice of antiseizure medication (ASM), predicts outcome, identifies surgical candidates and guides genetic counselling.

The diagnostic framework: ILAE 2014 definition and the 2017 three-level scheme

- ▶ ILAE 2014 definition of epilepsy (any one of): (1) ≥ 2 unprovoked (or reflex) seizures >24 h apart; (2) one unprovoked seizure with a $\geq 60\%$ recurrence risk over the next 10 years; or (3) diagnosis of an epilepsy syndrome.
- ▶ The 2017 ILAE classification is built in three sequential levels, with etiology and comorbidities considered at every level:
- ▶ Seizure type — focal onset / generalized onset / unknown onset (the older “partial” is replaced by *focal*; “simple/complex partial” replaced by *focal aware* / *focal impaired awareness*; secondary generalization renamed *focal to bilateral tonic-clonic*).
- ▶ Epilepsy type — focal / generalized / combined generalized and focal / unknown.
- ▶ Epilepsy syndrome — assigned when features fit a recognised constellation (not achievable in every patient).
- ▶ Six etiologic categories run in parallel (a patient may have >1): structural, genetic, infectious, metabolic, immune, unknown.

Epilepsy syndromes grouped by age of onset (overview)

Age band	Representative syndromes	Hallmark
Neonatal	Self-limited (benign) familial neonatal epilepsy; Early myoclonic encephalopathy; Ohtahara syndrome	KCNQ2/3 channelopathy; burst-suppression EEG
Infancy	West syndrome; Dravet syndrome; Myoclonic-atonic (Dooze)	Hypsarrhythmia; SCN1A febrile status
Childhood	Childhood absence epilepsy (CAE); Self-limited epilepsy with centrotemporal spikes (SeLECTS/BECTS); Panayiotopoulos; Lennox-Gastaut; Landau-Kleffner/CSWS	3-Hz spike-wave; centrotemporal spikes
Adolescence/adult	Juvenile absence epilepsy (JAE); Juvenile myoclonic epilepsy	Polyspike-wave; auditory aura; hippocampal sclerosis

Age band	Representative syndromes	Hallmark
	(JME); Epilepsy with GTCS alone; ADEAF; mesial temporal lobe epilepsy	

Idiopathic (genetic) generalized epilepsies — the “big four”

These are normal-development, normal-MRI, presumed-polygenic generalized epilepsies; **sleep deprivation** is a universal precipitant and **sodium-channel ASMs** (carbamazepine, oxcarbazepine, phenytoin) and **gabapentinoids** can aggravate seizures.

- ▶ **Childhood absence epilepsy (CAE / pyknolepsy): onset 4–10 yr (peak 5–7); many brief (<15 s) typical absences daily, provoked by hyperventilation; EEG = generalized, symmetric 3-Hz spike-and-wave on normal background. Ethosuximide is the drug of choice* for pure absence (ethosuximide and valproate superior to lamotrigine in the comparative CAE trial). Excellent prognosis; a minority evolve to JME.*
- ▶ **Juvenile absence epilepsy:** onset in the **2nd decade**, fewer absences than CAE, **majority also have GTCS**, greater tendency to persist into adulthood.
- ▶ **Juvenile myoclonic epilepsy (JME / Janz syndrome / impulsive petit mal): onset 12–18 yr; defining seizure = bilateral myoclonic jerks on awakening, provoked by sleep deprivation and alcohol; ~90% develop GTCS and ~one-third have absences; EEG = 4–6 Hz generalized polyspike-and-wave. Valproate is most effective (limited in women of child-bearing age by teratogenicity; levetiracetam/lamotrigine alternatives); usually a lifelong* condition needing long-term therapy.*
- ▶ **Epilepsy with GTCS alone** (incl. “grand mal on awakening”) — generally good response to broad-spectrum ASMs.

Developmental and epileptic encephalopathies (DEEs)

Here the epileptiform activity itself drives cognitive/developmental regression beyond the underlying cause.

- ▶ **West syndrome:** peak onset **3–7 months**; clinical triad — **epileptic (infantile) spasms in clusters + hypsarrhythmia on EEG + arrest/regression of psychomotor development**. Two-thirds have an identifiable brain lesion. Treatment differs from other epilepsies: **ACTH/corticosteroids**, and **vigabatrin** (drug of choice in tuberous sclerosis complex).
- ▶ **Ohtahara syndrome / early myoclonic encephalopathy:** neonatal onset, **burst-suppression EEG**, refractory seizures, poor prognosis; may evolve into West syndrome.
- ▶ **Dravet syndrome (severe myoclonic epilepsy of infancy):** **de novo SCN1A mutation in ~80–95%; previously normal infant presents with febrile status epilepticus around 6 months, later myoclonic, absence, atonic and focal seizures; drug-resistant with developmental decline. Avoid*

sodium-channel blockers (carbamazepine, lamotrigine, phenytoin) — they aggravate seizures; use valproate, clobazam, stiripentol, cannabidiol and fenfluramine.*

- ▶ **Lennox-Gastaut syndrome (LGS):** onset 3–10 yr; triad — (1) multiple seizure types (generalized tonic, atonic/drop attacks, atypical absence ± GTCS); (2) EEG with slow (<2.5 Hz) spike-and-wave in wakefulness and bursts of ~10-Hz paroxysmal fast activity in sleep; (3) cognitive impairment/developmental delay. Drug-resistant; may evolve from West syndrome. Options: valproate, lamotrigine, rufinamide, topiramate, clobazam, felbamate, cannabidiol; neurostimulation under investigation.
- ▶ **Landau-Kleffner syndrome (acquired epileptic aphasia) and CSWS:** verbal auditory agnosia/language regression with continuous spike-and-wave during slow-wave sleep; seizures often mild; benefit from valproate, benzodiazepines, steroids/IVIG, and multiple subpial transection.

Focal epilepsy syndromes

- ▶ **Self-limited epilepsy with centrotemporal spikes (SeLECTS / BECTS / benign rolandic epilepsy):** the commonest idiopathic focal epilepsy of childhood (3–13 yr, peak 5–8); nocturnal hemifacial sensorimotor seizures with hypersalivation/speech arrest, preserved awareness; EEG = high-voltage centrotemporal sharp waves activated by sleep; spontaneous remission at puberty — treatment often unnecessary.
- ▶ **Mesial temporal lobe epilepsy with hippocampal sclerosis (MTLE-HS):** the commonest cause of focal seizures with impaired awareness and the prototypical surgically-remediable epilepsy. History of antecedent (often complex) febrile seizures (up to 80%); seizures begin with an aura (rising epigastric sensation, *déjà vu*, fear), then behavioural arrest/stare, orolimentary and manual automatisms, contralateral dystonic posturing, and postictal dysphasia (dominant focus) and disorientation. MRI: small hippocampus with increased T2 signal and loss of internal architecture, enlarged temporal horn; interictal PET hypometabolism, ictal SPECT hyperperfusion; pathology = neuronal loss/gliosis in CA1 and CA3 with sparing of CA2. Frequently drug-resistant → anterior temporal lobectomy / selective amygdalohippocampectomy renders 60–80% seizure-free.
- ▶ **ADEAF (autosomal dominant epilepsy with auditory features):** lateral temporal focal epilepsy with auditory aura/aphasic seizures, due to LGI1 mutation.
- ▶ **Rasmussen syndrome:** progressive unilateral hemispheric epilepsy with *epilepsia partialis continua*, hemiatrophy, hemiparesis and cognitive decline; suspected autoimmune (anti-GluR3); often requires functional hemispherectomy.

Genetic basis and progressive myoclonus epilepsies

Gene	Syndrome
KCNQ2 / KCNQ3	Self-limited familial neonatal epilepsy
SCN1A	Dravet syndrome; GEFS+
CHRNA4 / CHRN2	Sleep-related hypermotor epilepsy (ADNFLE)
LGI1	ADEAF (lateral TLE)
DEPDC5	Familial focal epilepsy with variable foci
GRIN2A	BECTS–Landau-Kleffner spectrum
CDKL5	CDKL5 deficiency disorder (responds to ganaxolone)
SLC2A1 (GLUT1)	GLUT1 deficiency — absence onset <4 yr ± paroxysmal exertional dyskinesia (ketogenic diet)
CSTB	Unverricht-Lundborg disease (PME)
EPM2A (laforin) / NHLRC1 (malin)	Lafora disease (PME)

- **Progressive myoclonus epilepsies (PME):** myoclonus + GTCS + progressive ataxia/dementia. Examples — **Unverricht-Lundborg** (CSTB; *avoid phenytoin*, which aggravates ataxia), **Lafora disease** (polyglucosan Lafora bodies; fatal in 2–10 yr), **MERRF** (mitochondrial, ragged red fibres). **Valproate is the drug of choice**; perampanel helps myoclonus.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- **EEG signatures of generalized epilepsy syndromes** (three stacked tracings): (1) **Hypsarrhythmia** — chaotic, high-voltage disorganized slow waves with multifocal spikes/sharp waves and periods of attenuation (label: *West syndrome*); (2) **Generalized symmetric 3-Hz spike-and-wave** on normal background (label: *Childhood absence epilepsy*); (3) **Slow <2.5-Hz spike-and-wave + bursts of ~10-Hz paroxysmal fast activity in sleep** (label: *Lennox-Gastaut syndrome*).
- **Coronal T2 MRI of hippocampal sclerosis (MTLE):** labels — *small/atrophic hippocampus, increased T2 signal, loss of internal (trilaminar) architecture, enlarged temporal horn, normal contralateral hippocampus*.

Clinical / Diagnostic significance

- **Syndromic diagnosis dictates drug choice:** sodium-channel ASMs and gabapentinoids **aggravate** generalized/absence/myoclonic seizures and **Dravet** — use broad-spectrum agents (valproate, levetiracetam, lamotrigine for selected, topiramate).

- ▶ **Precision/targeted therapy:** vigabatrin for West syndrome in tuberous sclerosis; ketogenic diet for GLUT1 deficiency; ganaxolone for CDKL5 deficiency; stiripentol/fenfluramine/cannabidiol for Dravet; ACTH/steroids for infantile spasms.
- ▶ **Surgical candidacy:** MTLE-HS, lesional focal epilepsies and Rasmussen syndrome should be referred early for resective surgery/hemispherectomy when drug-resistant.
- ▶ **Workup:** detailed seizure semiology + witness account, **video-EEG with activation** (hyperventilation, photic stimulation, sleep/sleep deprivation), high-resolution MRI epilepsy protocol, and interictal PET / ictal SPECT for presurgical localisation; autoantibody testing when onset is fulminant with psychiatric/cognitive change.
- ▶ **Prognostic stratification:** self-limited syndromes (CAE, SeLECTS) remit spontaneously, whereas DEEs (West, Dravet, LGS) carry high cognitive morbidity.

High-yield exam pointers

- ▶ **Epilepsy** = ≥ 2 unprovoked seizures >24 h apart, OR 1 seizure with $\geq 60\%$ recurrence risk, OR an epilepsy syndrome (ILAE 2014).
- ▶ **2017 ILAE: three levels** — seizure type $\rightarrow$ epilepsy type $\rightarrow$ syndrome, with six etiologies (structural, genetic, infectious, metabolic, immune, unknown).
- ▶ **West triad** = infantile spasms + **hypsarrhythmia** + psychomotor arrest; **LGS triad** = multiple seizure types + **slow** (<2.5 Hz) **spike-wave** + cognitive impairment.
- ▶ **CAE** $\rightarrow$ 3-Hz spike-wave, ethosuximide DOC; **JME** $\rightarrow$ 4–6 Hz polyspike-wave, valproate DOC, jerks on awakening.
- ▶ **Dravet** = SCN1A (~80–95% de novo), febrile status at ~6 months — **never give sodium-channel blockers**.
- ▶ **MTLE-HS:** antecedent febrile seizures, epigastric aura/*déjà vu*, automatisms; MRI hippocampal sclerosis; CA1/CA3 loss, CA2 sparing; surgery cures 60–80%.
- ▶ **SeLECTS/BECTS:** commonest benign childhood focal epilepsy, nocturnal facial seizures, centrottemporal spikes, remits at puberty.
- ▶ **PME** (Unverricht-Lundborg = CSTB; Lafora = EPM2A/NHLRC1) — myoclonus + GTCS + dementia; **valproate**, avoid phenytoin.

SOURCE & COVERAGE

Etiology and management of orthostatic hypotension

Asked in: Paper III May 2025 — RGUHS MD General Medicine

Definition / Introduction — Orthostatic (postural) hypotension (OH) is a *sustained reduction in systolic blood pressure (SBP) of ≥ 20 mmHg or diastolic blood pressure (DBP) of ≥ 10 mmHg within 3 minutes of active standing or head-up tilt (HUT) $\geq 60^\circ$* . In a known hypertensive the threshold is a fall of $\geq 30/15$ mmHg. It is a sign of failure of the baroreflex-mediated cardiovascular adjustment to upright posture rather than a disease in itself. On standing, ~ 500 – 700 mL of blood pools in the lower limbs and splanchnic bed; failure to compensate by reflex tachycardia, venoconstriction and arteriolar constriction produces cerebral hypoperfusion. OH is common (prevalence $< 5\%$ below age 50 rising to $\sim 20\%$ above age 70) and is an independent marker of falls, fracture, coronary disease, heart failure, stroke and death.

Physiology and definitions (variants)

- ▶ **Normal orthostatic response** — slight rise in heart rate (HR), peripheral venoconstriction and arteriolar constriction maintain SBP and slightly raise DBP, integrating baroreceptors, autonomic afferents, central centres, efferents and vascular adrenoceptors.
- ▶ **Classical OH** — fall $\geq 20/10$ mmHg within 3 min ($\geq 30/15$ in hypertensives).
- ▶ **Initial OH** — abrupt transient fall (> 40 mmHg SBP / > 20 mmHg DBP) within 15–30 s of standing, resolving by ~ 45 s; due to cardiac output–vascular resistance mismatch; seen in the young (and elderly on antihypertensives); *not* true autonomic failure.
- ▶ **Delayed OH** — fall appears only after 3–5 min (sometimes > 10 min) of standing/tilt; often an early or mild form of adrenergic autonomic dysfunction.
- ▶ **Postprandial hypotension** — fall within ~ 2 h of a large, high-carbohydrate meal (worse with alcohol) from splanchnic pooling; typical in elderly with autonomic disorders.
- ▶ **Neurogenic vs non-neurogenic OH** — *Non-neurogenic OH*: compensatory HR rise > 15 beats/min. *Neurogenic OH (NOH)*: blunted HR rise < 15 beats/min, reflecting impaired norepinephrine (NE) release; more accurately a $\Delta\text{HR}/\Delta\text{SBP}$ ratio < 0.5 beats/min/mmHg (cardiac baroreflex gain). NOH carries a grave prognosis (mortality $\sim 44\%$ at 30 months, $> 60\%$ at 10 years) and is frequently coupled with supine hypertension.

Etiology / Classification

OH is broadly **neurogenic** (autonomic failure, blunted HR rise) or **non-neurogenic** (intact reflex tachycardia).

Category	Causes
Neurogenic — primary autonomic failure (synucleinopathies)	Multiple system atrophy (<i>Shy-Drager syndrome</i>), Parkinson's disease with autonomic failure, dementia with Lewy bodies, pure autonomic failure (PAF)
Neurogenic — secondary autonomic neuropathies	Diabetic autonomic neuropathy (commonest), amyloidosis (AL and hereditary transthyretin/ <i>hATTR</i>), autoimmune autonomic ganglionopathy (anti-ganglionic $\alpha 3$ -AChR), paraneoplastic (anti-Hu, small-cell lung Ca), Sjögren syndrome, HIV neuropathy, hereditary sensory & autonomic neuropathy type III (<i>familial dysautonomia / Riley-Day</i>), alcoholic/nutritional (B12, thiamine), porphyria, Guillain-Barré syndrome
Neurogenic — central / genetic	Baroreflex failure (post-radiation/surgery/tumour to carotid sinus), spinal cord lesions, dopamine β-hydroxylase (DBH) deficiency (selective NE absence, high dopamine), Menkes disease
Non-neurogenic — volume depletion	Haemorrhage, vomiting/diarrhoea, reduced intake, over-diuresis, over-dialysis, adrenal insufficiency (<i>Addison</i>), idiopathic hypovolaemia
Non-neurogenic — cardiac	Heart failure, chronotropic incompetence, severe bradyarrhythmia
Non-neurogenic — vasodilatory / drug-induced (iatrogenic)	α -blockers (BPH/HTN), diuretics, nitrates and other veno/vasodilators, other antihypertensives, tricyclic antidepressants, phenothiazines/antipsychotics, dopamine agonists; mast-cell/vasodilator excess (mastocytosis, carcinoid)

- ▶ Drug mechanisms: volume depletion or direct vasodilatation → reflex tachycardia (**hyperadrenergic OH**); central sympatholysis → blunted reflex (**hypoadrenergic OH**). The elderly are especially vulnerable (polypharmacy + impaired baroreflex).
- ▶ In diabetes, autonomic neuropathy raises mortality up to threefold; risk correlates with the product of HbA1c and disease duration, with early parasympathetic loss followed by sympathetic failure dominated by OH.

Clinical features

- ▶ **Cerebral hypoperfusion** — lightheadedness/dizziness on standing, visual blurring, presyncope and syncope (worse on waking, after meals, exertion, heat).

- ▶ **Indirect / regional ischaemia** — generalised weakness, fatigue, cognitive slowing, leg buckling; *coat-hanger* suboccipital/shoulder pain (cervical-trapezius muscle ischaemia); orthostatic dyspnoea (*platypnoea*, apical V/Q mismatch); orthostatic angina; orthostatic headache.
- ▶ **Severity grading** — functional class I (asymptomatic) to class IV (daily disabling symptoms). NOH may show striking BP falls with surprisingly mild symptoms because of cerebral autoregulation.
- ▶ **Associated autonomic features** — supine hypertension, *reverse dipping*, nocturia, constipation, urinary retention, erectile failure, anhidrosis (point to a generalised dysautonomia/synucleinopathy).

Evaluation / Investigations

- ▶ **Bedside** — supine BP/HR, then standing BP/HR at 1 and 3 min (delayed/active standing if tilt unavailable); calculate $\Delta\text{HR}/\Delta\text{SBP}$ to label NOH.
- ▶ **Bloods** — CBC, metabolic panel, glucose/HbA1c (2-h OGTT if small-fibre neuropathy), B12, iron/ferritin, vitamin D; supine and upright catecholamines (fail to double on standing in NOH; low supine NE in postganglionic/peripheral lesions, e.g. PAF/DBH deficiency); serum free light chains/SPEP for amyloid; ganglionic α_3 -AChR and paraneoplastic antibodies; 5-HIAA, cortisol if indicated.
- ▶ **Autonomic function tests** — HR variation to deep breathing and Valsalva ratio (parasympathetic/baroreflex), QSART and thermoregulatory sweat test (sudomotor), and **tilt-table testing** (defines OH type and distinguishes it from neurally mediated/vasovagal syncope).
- ▶ **Cardiac** — ECG $\pm$ echocardiography to exclude structural/arrhythmic syncope; rule out pheochromocytoma/hyperthyroidism when a hyperadrenergic picture is present.

Management

Goal in OH is symptom relief and fall prevention, not BP normalisation. Begin by **removing reversible contributors** (offending drugs — diuretics, antihypertensives, α -blockers, TCAs, antipsychotics, dopamine agonists) and correcting anaemia, B12/iron/D deficiency and volume depletion.

Non-pharmacologic (first-line, often sufficient in early/class I disease):

- ▶ Patient education — **staged moves** supine→sitting→standing; warn about large meals, alcohol, heat, early morning.
- ▶ **Volume expansion** — fluid up to 2–3 L/day; **liberal salt** (≈ 6 –10 g/day; e.g. 2 g three times daily), titrated to 24-h urinary sodium (target ~ 185 mmol).
- ▶ **Acute water bolus** — rapid ingestion of ~ 500 mL plain (hypotonic) water raises BP by 30–40 mmHg within minutes (sympathetic spinal pressor reflex); take on waking/before being upright.
- ▶ **Physical measures** — waist-high compression stockings + **abdominal binder** (reduce splanchnic pooling), **physical counter-maneuvres** (leg-crossing, squatting, lower-limb/abdominal muscle

tensing, leg elevation), recumbent aerobic + leg-resistance exercise/water aerobics, and **head-of-bed elevation 30–45°** to limit nocturnal supine hypertension and pressure-natriuresis.

Pharmacologic (if measures fail):

Drug	Mechanism	Dose	Key caveats
Fludrocortisone	Mineralocorticoid → plasma volume expansion + mild α -sensitisation	0.1–0.2 mg OD (up to 0.4)	Supine hypertension, pedal oedema, hypokalaemia/hypomagnesaemia, headache; effect takes 1–2 weeks; monitor weight/BP, bone density on long-term use
Midodrine	Direct peripheral $\alpha 1$ -agonist (prodrug → desglymidodrine)	2.5 mg TID up titrate to 7.5–15 mg TID	Onset 30–60 min, lasts ~4 h; <i>last dose before 6 p.m.</i> ; scalp tingling/piloerection, urinary urgency, supine hypertension
Droxidopa (L-threo-DOPS)	NE precursor → ↑ synaptic NE; FDA-approved 2014 for NOH	100 mg TID up to 400–600 mg TID	Reduces falls/dizziness (esp. PD, DBH deficiency); supine hypertension
Pyridostigmine	Cholinesterase inhibitor → ↑ ganglionic transmission	30 mg TID up to 60–90 mg TID	Greater effect standing than supine → <i>little supine hypertension</i> ; good if coexistent GI hypomotility; cramps/diarrhoea; synergistic with midodrine
Atomoxetine	NE-reuptake inhibitor (adjuvant)	18 mg morning	Anxiety/tremor (CNS stimulation)
Desmopressin (DDAVP)	↑ water reabsorption, ↓ nocturia	low oral/nasal dose	Monitor for hyponatraemia

- Erythropoietin (for associated anaemia) and octreotide (for postprandial hypotension) are occasional adjuncts.

Supine hypertension (the therapeutic dilemma in NOH): avoid daytime recumbency, reduce evening fluids, *avoid fludrocortisone in favour of short-acting agents*, elevate head of bed 30°, take a bedtime carbohydrate snack, and if SBP persistently high use **short-acting bedtime antihypertensives** (e.g. losartan, nifedipine with caution, nebivolol, transdermal nitroglycerine, or clonidine in central failure such as MSA). Treat the underlying cause where possible (e.g. glycaemic control in diabetes; IVIg/plasma exchange for AAG; gene-silencing therapy for hATTR amyloidosis).

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- **Tilt-table tracing of neurogenic OH** — two stacked time plots labelled *HR (beats/min)* and *BP (mmHg)* against time; mark *Tilt up (TU)* and *Tilt down (TD)*; show a progressive

SBP/DBP fall after TU with a *flat HR* line (no compensatory tachycardia), and label baseline *supine hypertension* (SBP $\sim$ 175 mmHg).

- ▶ **Orthostatic physiology / management schema** — standing figure with arrows showing $\sim$ 500–700 mL venous & splanchnic pooling $\rightarrow$ $\downarrow$ venous return $\rightarrow$ $\downarrow$ cardiac output $\rightarrow$ cerebral hypoperfusion; annotate baroreflex limb (baroreceptor $\rightarrow$ NTS $\rightarrow$ sympathetic efferent $\rightarrow$ vasoconstriction) with the failure point in NOH; flank with management labels: *salt/water, compression stockings, abdominal binder, head-up tilt, fludrocortisone, midodrine, droxidopa*.

Clinical / Diagnostic significance

- ▶ A simple lying-and-standing BP is a high-yield, low-cost screen in all elderly, diabetic, syncope, falls and “dizziness” patients.
- ▶ The Δ HR response is the pivot: blunted (<15 bpm) suggests NOH/autonomic failure warranting tilt testing and catecholamine studies; brisk tachycardia points to volume/drug causes.
- ▶ OH preceding parkinsonism by years, or OH within 2 years of motor onset, is a red flag for MSA / a synucleinopathy; isolated OH with low supine NE suggests PAF.
- ▶ Recognising **supine hypertension** prevents reflex over-treatment that precipitates falls, and prevents end-organ (renal/cardiac/cerebrovascular) damage.

High-yield exam pointers

- ▶ OH = SBP $\downarrow \geq 20$ or DBP $\downarrow \geq 10$ mmHg within 3 min standing/HUT ($\geq 30/15$ in hypertensives).
- ▶ Neurogenic OH = HR rise <15 bpm or Δ HR/ Δ SBP <0.5 bpm/mmHg; high mortality ($\sim 44\%/30$ months).
- ▶ Initial OH ($>40/20$ within 15–30 s) and delayed OH (>3 –5 min) are recognised variants.
- ▶ Synucleinopathies = MSA, PD, DLB, PAF; MSA = *Shy-Drager*, GCIs of α -synuclein in glia.
- ▶ Commonest **secondary** cause = diabetic autonomic neuropathy; commonest overall contributors in elderly = drugs + volume depletion.
- ▶ Non-drug therapy first: salt 6–10 g, fluid 2–3 L, 500 mL water bolus, stockings/abdominal binder, counter-maneuvres, head-up tilt 30° .
- ▶ First-line drugs: **fludrocortisone 0.1–0.2 mg** and **midodrine** ($\alpha 1$ -agonist, last dose before 6 p.m.); **droxidopa** (NE precursor) for NOH; **pyridostigmine** spares supine BP.
- ▶ Always check for and manage coexistent **supine hypertension** — head-up bed, short-acting bedtime antihypertensive, avoid fludrocortisone.

SOURCE & COVERAGE

Guillain Barre Syndrome

Asked in: Paper III Nov 2021 — RGUHS MD General Medicine

Definition / Introduction — Guillain-Barré syndrome (GBS) is an acute, frequently severe and fulminant **autoimmune polyradiculoneuropathy** characterised by rapidly evolving **areflexic motor paralysis** with or without sensory disturbance. It is the commonest cause of acute flaccid paralysis in the post-polio era, occurring year-round at **10–20 cases per million annually** (~5000–6000 cases/year in the USA). Males are at slightly higher risk than females, and in Western countries adults are affected more than children. The syndrome typically follows an antecedent infection by 1–3 weeks and is mediated by **molecular mimicry** between microbial and neural ganglioside epitopes.

Subtypes / Classification

GBS is a spectrum; subtypes are defined primarily by **electrodiagnostic (EDx)** and **pathologic** features and associated antiganglioside antibodies.

Subtype	Key features	Pathology / EDx	Antibody
AIDP (acute inflammatory demyelinating polyneuropathy)	Commonest; ~90% of Western cases; adults > children; rapid recovery	Demyelinating; first attack on Schwann-cell surface; macrophage-mediated myelin injury, variable secondary axonal loss	anti-GM1 (<50%)
AMAN (acute motor axonal neuropathy)	Children/young adults; prevalent in China & Mexico; may be seasonal; rapid recovery	Axonal; attack at motor nodes of Ranvier	anti-GD1a

Subtype	Key features	Pathology / EDx	Antibody
AMSAN (acute motor sensory axonal neuropathy)	Mostly adults; uncommon; recovery slow, often incomplete; related to AMAN	Axonal; like AMAN but also sensory nerves/roots; severe axonal damage	GM1, GD1a
Miller Fisher syndrome (MFS)	~5% of cases; triad of ophthalmoplegia, ataxia, areflexia (no limb weakness); pupillary paralysis	Demyelinating/nodal	anti-GQ1b (>90%)

- ▶ **Regional/limited variants:** pure sensory forms; pharyngeal-cervical-brachial weakness (anti-GT1a/GQ1b); GBS with severe bulbar/facial palsy and antecedent CMV (anti-GM2); acute pandysautonomia.
- ▶ The **anti-GQ1b antibody syndrome** spans MFS, acute ophthalmoparesis, acute ataxic neuropathy, *Bickerstaff's brainstem encephalitis*, and pharyngeal-cervical-brachial weakness — illustrating a continuous clinical spectrum.

Antecedent events & associations

- ▶ ~70% of cases occur **1–3 weeks** after an acute infection (usually respiratory or gastrointestinal).
- ▶ **Campylobacter jejuni** precedes 20–30% of cases (North America, Europe, Australia) and is the classic trigger of AMAN; summer AMAN outbreaks have followed poultry exposure in rural China.
- ▶ Other agents: **CMV**, **Epstein-Barr virus**, HIV, hepatitis E, **Zika** (Brazil/endemic outbreaks), *Mycoplasma pneumoniae*. SARS-CoV-2 association reported but causality not established.
- ▶ **Vaccines:** the 1976 swine influenza vaccine is the notable example; modern seasonal influenza vaccines carry <1 case/million; slight increase with adenovirus-vector SARS-CoV-2 vaccines (not mRNA); older nerve-tissue rabies vaccine.
- ▶ **Disease associations:** lymphoma (incl. Hodgkin's), HIV seropositivity, SLE, possibly Sjögren's; immune checkpoint inhibitors.

Immunopathogenesis & pathophysiology

- ▶ Both **cellular and humoral** immune mechanisms contribute. AIDP is analogous to experimental allergic neuritis (EAN), a T-cell-mediated immunopathy against peripheral myelin (e.g., P2 protein); autoreactive T cells are found in blood, CSF and nerve.
- ▶ **Humoral arm:** autoantibodies against **gangliosides** (complex sialic-acid-bearing glycosphingolipids concentrated at nodes of Ranvier) arise via *molecular mimicry* — *C. jejuni* lipo-oligosaccharide cross-reacts with GM1.
- ▶ AIDP — complement deposits on the **outer Schwann-cell surface**, triggering **vesicular myelin disintegration** and recruitment of activated macrophages; the resultant **conduction block** (axons

remaining intact) underlies the flaccid paralysis, allowing rapid recovery with remyelination. Severe cases develop secondary axonal degeneration → slower, incomplete recovery.

- ▶ **AMAN/AMSAN** — IgG (anti-GM1/GD1a) plus complement deposit at the **nodal axolemma of motor axons**; membrane-attack complex disrupts Na⁺-channel clustering and detaches paranodal myelin → reversible conduction failure, with axonal degeneration in severe cases. Anti-GD1a shows fine specificity favouring motor over sensory roots.

Clinical features

- ▶ **Ascending, symmetric flaccid weakness** (“rubbery legs”), evolving over hours to a few days, legs > arms, with tingling dysaesthesias.
- ▶ **Areflexia/hyporeflexia** appears within the first few days (large-fibre functions — DTRs, proprioception — affected more than pain/temperature).
- ▶ **Facial diparesis in ~50%**; lower cranial nerve / **bulbar weakness** (difficulty handling secretions, airway risk) — may mimic brainstem ischaemia.
- ▶ **Pain** (neck, shoulder, back, dysaesthetic limb pain) in ~50% early on.
- ▶ **Autonomic involvement** common even in mild disease: labile blood pressure, postural hypotension, cardiac dysrhythmias — potentially fatal. Bladder dysfunction is usually transient and late.
- ▶ Up to **30% require mechanical ventilation**; predictors are severe weakness on admission, rapid progression, and early facial/bulbar weakness.
- ▶ Nadir is reached and a **plateau** established almost always **within 4 weeks** of onset. Fever/constitutional symptoms at onset argue *against* GBS.

Investigations & diagnosis

- ▶ **CSF — albuminocytologic (cytoalbuminologic) dissociation**: elevated protein **1–10 g/L (100–1000 mg/dL)** with **white cells <50/μL** (no pleocytosis). CSF may be normal in first ≤48 h, rising by the end of the first week. Sustained pleocytosis (10–100/μL persistent) suggests an alternative (viral myelitis, HIV, leukaemia/lymphoma, neurosarcoidosis).
- ▶ **Nerve conduction studies (EDx)** — mild/absent early; earliest AIDP changes are **prolonged F-wave latencies, prolonged distal latencies, reduced CMAP amplitudes**, reflecting proximal root and distal terminal involvement; later **conduction slowing, conduction block, temporal dispersion**. AMAN/AMSAN show **low-amplitude CMAPs (and SNAPs in AMSAN) without conduction slowing**.
- ▶ **Antiganglioside antibodies** support subtyping (anti-GQ1b for MFS, anti-GD1a/GM1 for axonal forms).
- ▶ **Brighton Collaboration criteria (2011)** provide graded levels of diagnostic certainty (Level 1 highest), incorporating bilateral flaccid limb weakness, depressed reflexes, monophasic course

with nadir between 12 h and 28 days, cytoalbuminologic dissociation, supportive EDx and exclusion of alternatives.

- ▶ Begin treatment on clinical suspicion — do not await CSF/EDx evolution. Test for HIV if risk factors or CSF pleocytosis present.

Differential diagnosis

- ▶ Acute myelopathies (early prominent back pain, sphincter loss, sensory level); poliomyelitis / **acute flaccid myelitis** (West Nile, enterovirus D68/A71); CMV or Lyme polyradiculitis; diphtheritic neuropathy; **porphyria** (abdominal pain, seizures, psychosis); vasculitic neuropathy; critical-illness neuropathy/myopathy; neuromuscular junction disease — **myasthenia gravis**, **botulism** (early pupillary involvement); intoxications (**organophosphates**, **thallium**, **arsenic**), paralytic shellfish poisoning; severe hypophosphataemia.

Treatment

- ▶ **Start immunotherapy as early as possible** — “each day counts”; benefit beyond ~2 weeks from onset is uncertain, and treatment at the plateau is generally not indicated unless severe weakness with possible ongoing attack.
- ▶ **IVIg** — total **2 g/kg**, usually as **five daily infusions**; first-line for ease and safety (acts via anti-idiotypic neutralisation of autoantibodies).
- ▶ **Plasmapheresis (PLEX)** — ~**40–50 mL/kg exchange**, **4–6 times over 7–12 days**; reduces need for mechanical ventilation (27% → 14%) and increases full recovery at 1 year (55% → 68%).
- ▶ IVIg and PLEX are **equally effective**; **combining them is not superior**; failure of one is not an indication to switch to the other. Early treatment-related fluctuation/relapse within a month is managed by a brief repeat course of the original therapy.
- ▶ **Glucocorticoids are NOT effective in GBS** (a key contrast with CIDP, which does respond to steroids).
- ▶ Very mild cases, or those already at plateau, may be managed conservatively.
- ▶ **Supportive/ICU care** (worsening phase): monitor **vital capacity**, cardiac rhythm and blood pressure; nutrition; DVT prophylaxis; consider **tracheostomy after ~2 weeks of intubation**; chest physiotherapy, frequent turning, skin care, range-of-motion exercises to prevent contractures, and reassurance.

Prognosis

- ▶ ~**85% achieve full functional recovery** within several months to a year; residual areflexia and fatigue are common.
- ▶ **Mortality** <5% in optimal settings; death is usually from secondary pulmonary complications and autonomic instability.

- ▶ Worse outcome with **severe proximal motor and sensory axonal damage**, advanced age, fulminant attack, and delayed treatment. **Elevated serum neurofilament light (NfL) chains** and **high anti-GM1 titres** mark greater axonal injury and poor recovery.
- ▶ 5–10% suffer late relapses; many are reclassified as **chronic inflammatory demyelinating polyneuropathy (CIDP)** (course >8 weeks, relapses ≥ 3 times, steroid-responsive).

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Spectrum/antibody map:** a horizontal axis with boxes — *AIDP* (anti-GM1) → *AMAN/AMSAN* (anti-GM1, GD1a) and *MFS/anti-GQ1b syndrome* (anti-GQ1b, GT1a) → *Bickerstaff's encephalitis*. Labels: AIDP, AMAN, AMSAN, MFS, GM1, GD1a, GQ1b, GT1a.
- ▶ **Pathogenesis of a myelinated motor axon:** label *node of Ranvier* (Na_v channels), *paranode* (*Caspr*), *juxtaparanode* (K_v channels), *Schwann cell/myelin*, *IgG anti-GM1/anti-GD1a antibody binding*, *complement activation* → *membrane-attack complex (MAC)*, *macrophage scavenging*. Show MAC on outer Schwann-cell surface for AIDP and at the nodal axolemma for AMAN.

Clinical / Diagnostic significance

- ▶ GBS is the prototype treatable cause of acute flaccid paralysis — **early recognition, serial vital-capacity monitoring and prompt IVIg/PLEX** are life-saving.
- ▶ **Albuminocytologic dissociation** plus a compatible clinical picture clinches the diagnosis; absence of fever, presence of areflexia and a recent *C. jejuni*/viral illness are strong pointers.
- ▶ Watch for **respiratory failure and autonomic instability** — the two main killers — mandating ICU admission during worsening.
- ▶ Distinguish from acute myelopathy (sensory level, early sphincter loss) and MFS/Bickerstaff overlap (ophthalmoplegia + ataxia, anti-GQ1b).

High-yield exam pointers

- ▶ GBS = acute **autoimmune areflexic ascending flaccid paralysis**; commonest variant **AIDP**; **anti-GQ1b** = MFS; **anti-GD1a/GM1** = AMAN/AMSAN.
- ▶ 70% post-infectious at 1–3 weeks; classic trigger **Campylobacter jejuni** (→ AMAN); also CMV, EBV, Zika, *Mycoplasma*.
- ▶ CSF: high protein 1–10 g/L with **<50 cells/ μ L** (cytoalbuminologic dissociation), often normal in first 48 h.
- ▶ EDx: earliest = prolonged **F-wave latency**; axonal forms = low CMAP amplitude *without* slowing.
- ▶ Treatment = **IVIg 2 g/kg over 5 days OR PLEX 40–50 mL/kg $\times 4$ –6**; equally effective; **steroids do NOT work**.

- ▶ ~30% need ventilation; tracheostomy considered after ~2 weeks intubation.
- ▶ 85% full recovery, mortality <5%; poor prognosis with axonal damage, age, fulminant onset, delayed therapy; high NfL and anti-GM1 = worse.
- ▶ Brighton criteria (2011) standardise diagnosis; nadir within 12 h–28 days, monophasic.
- ▶ 5–10% relapse → consider CIDP (steroid-responsive, unlike GBS).

SOURCE & COVERAGE

Horner's Syndrome

Asked in: Paper III Jul 2021 — RGUHS MD General Medicine

Definition / Introduction — Horner's syndrome (*oculosympathetic palsy/paresis*) is the clinical triad of ipsilateral **ptosis**, **miosis** and **facial anhidrosis** resulting from interruption of the sympathetic supply to the eye and face anywhere along its three-neuron pathway, from the hypothalamus to the orbit. Anhidrosis is an *inconstant* feature that depends on the level of the lesion. Clinically its importance is not the eye signs themselves (which are benign) but its value as a **localizing sign**, since the causes range from idiopathic to immediately dangerous (internal carotid dissection, Pancoast tumour). When facial sweating is spared the term *oculosympathetic paresis* is often used interchangeably.

Anatomy of the oculosympathetic pathway (three neurons)

- ▶ **First-order (central) neuron** — arises in the posterolateral hypothalamus, descends through the dorsolateral brainstem and lateral column of the cord, and synapses in the **cilio-spinal center of Budge**, the intermediolateral grey column at C8–T2.
- ▶ **Second-order (preganglionic) neuron** — exits via the ventral roots/white rami communicantes, arches **over the lung apex** and **beneath the subclavian artery**, ascends the cervical sympathetic chain, and synapses in the **superior cervical ganglion** at the **carotid bifurcation** (angle of the jaw). *Sudomotor fibres for facial sweating branch off here to follow the external carotid artery.*
- ▶ **Third-order (postganglionic) neuron** — ascends as the **pericarotid plexus** on the **internal carotid artery**, traverses the **cavernous sinus** (briefly joining CN VI), then joins the **nasociliary branch of V1**, and reaches the iris via the **long ciliary nerves**.
- ▶ **Effectors** — *dilator pupillae* (mydriasis), **Müller's muscle** (superior tarsal, upper lid), inferior tarsal muscle (lower lid), and facial sweat glands/vasomotor tone.

Clinical features

- ▶ **Ptosis** — mild, only 1–3 mm, from denervation of Müller’s (superior tarsal) muscle; *never* as complete as a CN III palsy; may fluctuate and worsen with fatigue.
- ▶ **Inverse (“upside-down”) ptosis** — the lower lid is *elevated* 1–2 mm (loss of the inferior tarsal muscle), narrowing the palpebral fissure and producing **apparent enophthalmos** — an optical illusion; true globe position is normal.
- ▶ **Miosis** — small pupil that reacts **normally to light and near**; the **anisocoria is greater in the dark** (small pupil is the abnormal one).
- ▶ **Dilation lag** — the affected pupil dilates *slowly* when the lights are dimmed; anisocoria is more pronounced at 4–5 s than at 10–12 s after lights-out — a hallmark sign.
- ▶ **Anhidrosis** — ipsilateral facial; present **only with first-/second-order (preganglionic)** lesions. Absent in **postganglionic (third-order)** lesions (sudomotor fibres have already branched with the external carotid), except possibly a small medial-forehead patch.
- ▶ **Other** — conjunctival/facial vasodilation, ocular hypotony, loss of the **ciliospinal reflex**; *congenital* Horner causes **heterochromia iridis** (a paler iris on the affected side) and facial trophic changes.

Localization by neuron order and representative causes

Order	Anatomical site	Anhidrosis	Representative causes
First-order (central)	Hypothalamus → brainstem → C8–T2	Possible (ipsilateral, extensive)	Wallenberg (lateral medullary) syndrome, brainstem stroke/tumour, syringobulbia, multiple sclerosis, hypothalamic lesions
Second-order (preganglionic)	C8–T2 → superior cervical ganglion	Present (facial)	Pancoast (apical lung) tumour, lower brachial plexus avulsion, cervical rib, thyroid/neck surgery or trauma, mediastinal mass, aortic/subclavian aneurysm, syringomyelia, C8/T1 root lesion
Third-order (postganglionic)	SCG → carotid → cavernous sinus → orbit	Absent (maybe medial forehead)	Internal carotid dissection/thrombosis (painful Horner), cavernous sinus disease, cluster headache, Raeder paratrigeminal

Order	Anatomical site	Anhidrosis	Representative causes
			syndrome, otitis media/petrositis, nasopharyngeal/skull-base tumour

Pharmacological testing (confirmation + localization)

A two-step approach; confirmatory and localizing drops must be ≥ 24 h apart.

Drop	Mechanism	Result	Interpretation
Cocaine 2–10%	Blocks noradrenaline reuptake at the sympathetic terminal	Normal pupil dilates; Horner pupil fails to dilate	Confirms Horner (any order); does <i>not</i> localize. (Controlled substance; urine toxicology positive ~2 days.)
Apraclonidine 0.5%	Weak α_1 -agonist acting on the supersensitive denervated dilator	Reversal of anisocoria — Horner pupil dilates (denervation supersensitivity) + ptosis improves; normal pupil unchanged/slightly constricts	Confirms Horner; convenient cocaine substitute. May be falsely negative very acutely (supersensitivity takes ~36 h–days to develop).
Hydroxyamphetamine 1%	Releases stored noradrenaline from an <i>intact</i> third-order terminal	Dilates in first-/second-order Horner; fails to dilate in third-order Horner	Localizes preganglionic vs postganglionic.

Differential diagnosis / mimics

- ▶ **Physiologic (simple) anisocoria** — equal in light and dark, ≤ 0.5 mm; *pseudo-Horner* = physiologic anisocoria with an incidental ptosis (e.g., levator dehiscence).
- ▶ **Anisocoria greater in dark** → the *small* pupil is abnormal (Horner); **greater in light** → the *large* pupil is abnormal (CN III palsy, **Adie tonic pupil**, pharmacologic mydriasis).
- ▶ **Ptosis** — distinguish from CN III palsy (larger/normal pupil + ophthalmoparesis), myasthenia (fatigable, *Cogan lid twitch*), aponeurotic/senile and mechanical ptosis.
- ▶ **Reverse Horner (Pourfour du Petit syndrome)** — sympathetic *overactivity*: mydriasis, lid retraction, facial flushing/hyperhidrosis (early irritative lesions).
- ▶ **Harlequin syndrome** — unilateral facial anhidrosis with contralateral flushing/sweating on exertion/heat; usually no eye signs (may coexist with Horner).

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Three-neuron oculosympathetic pathway** — label: *hypothalamus* → *dorsolateral brainstem* → *cilio-spinal center of Budge (C8–T2)* → *ventral root* → *lung apex* → *subclavian artery* → *cervical sympathetic chain* → *superior cervical ganglion (carotid bifurcation)* → *internal carotid / pericarotid plexus* → *cavernous sinus (CN VI)* → *nasociliary branch of V1* → *long ciliary nerves* → *dilator pupillae & Müller's muscle*; mark the **branch point of sudomotor fibres onto the external carotid**.
- ▶ **Face of a left Horner's** — label: *upper-lid ptosis, elevated lower lid (inverse ptosis), miosis, apparent enophthalmos, ipsilateral facial anhidrosis*.

Clinical / Diagnostic significance

- ▶ **Acute painful Horner** (especially after neck pain, trauma or chiropractic manipulation) → suspect **internal carotid dissection**; urgent MRI/MRA (axial fat-saturated T1 shows a crescentic mural haematoma); treat with **antiplatelet (aspirin)** to prevent embolic stroke.
- ▶ **Preganglionic Horner in a smoker** → search for a **Pancoast / apical lung tumour** (CXR/CT chest); look for C8–T1 pain and wasting of hand intrinsic.
- ▶ **Isolated Horner** — imaging the entire pathway finds a cause in only ~20%; the workup is **directed by localization** — preganglionic → brain + cervical/upper-thoracic spine MRI + chest imaging; postganglionic → brain MRI + head-and-neck MRA.
- ▶ **Children** — most cases are congenital, but exclude **neuroblastoma**: neuroimaging + **urinary catecholamines (VMA/HVA)**; heterochromia favours a congenital/long-standing lesion.
- ▶ **Wallenberg syndrome** — Horner is one component (with crossed sensory loss, ipsilateral ataxia, vertigo, dysphagia).

High-yield exam pointers

- ▶ Triad = **ptosis + miosis + anhidrosis** (oculosympathetic palsy); anhidrosis is *inconstant*.
- ▶ **Anisocoria greater in the dark + dilation lag** = the clinical hallmark.
- ▶ Müller's (superior tarsal) muscle → **mild** ptosis; levator (CN III) → **severe** ptosis.
- ▶ **Cocaine / apraclonidine confirm**; **hydroxyamphetamine localizes** (dilates in pre-, fails in postganglionic).
- ▶ **Apraclonidine reverses the anisocoria** via denervation supersensitivity — now replaces cocaine.
- ▶ **Anhidrosis present = preganglionic (1st/2nd order)**; **absent = postganglionic (3rd order)**.
- ▶ **Painful Horner** = carotid dissection until proven otherwise.
- ▶ **Congenital Horner** → **heterochromia iridis**; in a child, rule out **neuroblastoma**.
- ▶ *Pourfour du Petit* = reverse Horner; *Raeder paratrigeminal* = postganglionic Horner + V1 facial pain.

SOURCE & COVERAGE

Harrison's Principles of Internal Medicine 22e — "Disorders of the Eye" and "Disorders of the Autonomic Nervous System"; Bradley & Daroff's Neurology in Clinical Practice — "Pupillary and Eyelid Abnormalities"; DeJong's The Neurologic Examination — "The Ocular Motor Nerves"; Brazis — Localization in Clinical Neurology — "Localization of Lesions Affecting the Ocular Motor System" and "Localization of Lesions in the Autonomic Nervous System"; Raeder paratrigeminal syndrome from DeJong/Brazis "Trigeminal Nerve."

Coverage note: Harrison treats Horner's only briefly (a few lines in the eye and autonomic chapters). The deep three-neuron localization scheme, pharmacologic-testing logic, dilation-lag timing and eponyms (Budge, Pourfour du Petit, Raeder, Harlequin) are drawn from the dedicated neurology texts (Bradley, DeJong, Brazis) as directed by the spec. CMDT has no dedicated section and was not used.

Hyperkinetic Movement Disorders

Asked in: Paper III 09/2025 — RGUHS MD General Medicine

Definition / Introduction — Hyperkinetic movement disorders are characterised by **excessive, involuntary movements that are unaccompanied by weakness**. They contrast with the hypokinetic (akinetetic-rigid) disorders such as Parkinson's disease. The term is partly arbitrary — hypokinetic PD often has tremor, while hyperkinetic dystonia may restrict movement — but it remains useful by convention. Most arise from dysfunction of the **basal ganglia–thalamo-cortical circuits**. The major phenotypes are tremor, dystonia, athetosis, chorea/ballism, myoclonus and tics; precise phenomenological recognition is the key to diagnosis.

Classification by phenomenology (Harrison Table 447-1)

Disorder	Defining phenomenology
Tremor	Rhythmic oscillation of a body part from intermittent agonist–antagonist contraction
Dystonia	Involuntary, patterned, sustained/repeated contractions → twisting movements & abnormal postures
Athetosis	Slow, distal, writhing involuntary movements (a form of dystonia " <i>without fixed position</i> ")
Chorea	Rapid, semi-purposeful, graceful, dance-like, non-patterned movements; large-amplitude proximal form = ballism

Disorder	Defining phenomenology
Myoclonus	Sudden, brief (<100 ms), jerk-like, arrhythmic muscle twitches
Tic	Brief, repeated, stereotyped contractions, transiently suppressible with premonitory urge

- ▶ Speed/rhythmicity spectrum (DeJong): tremor & palatal myoclonus are *regular/predictable*; dystonia, athetosis, tics, myorhythmia are *intermediate*; chorea, ballism, myoclonus are *unpredictable*.

Tremor and Essential Tremor

- ▶ **Tremor** is classified along two axes (MDS): **Axis 1** = clinical/historical features (age, family history, distribution, frequency, activation, associated signs); **Axis 2** = aetiology (genetic, secondary, idiopathic).
- ▶ Activation types: **rest** (PD), **postural**, **kinetic/intention** (cerebellar, with past-pointing & hypotonia), **action**. *Enhanced physiologic tremor* ($\leq 10\%$ of population) — fine 10–12 Hz, with thyrotoxicosis, anxiety, valproate, lithium, caffeine, alcohol withdrawal.
- ▶ **Essential tremor (ET)** — the **commonest movement disorder** ($\sim 1\%$ of population, $\sim 5\%$ of those >60). High-frequency (6–10 Hz) **postural & action** tremor, bilateral, predominantly upper limbs; involves **head** $\sim 30\%$, **voice** $\sim 20\%$, **tongue** $\sim 20\%$, **jaw** $\sim 10\%$, **legs** $\sim 10\%$. Classically **improved by alcohol**, worsened by stress; large (not micro-) handwriting. $\sim 50\%$ are autosomal dominant; *NOTCH2NLC* GGC-repeat expansion associated, no confirmed causative gene.
- ▶ **Treatment (Harrison/CMDT)**: reassurance if mild. **Propranolol** 20–120 mg/day (CMDT up to 240 mg) and **primidone** (start 12.5–50 mg, titrate to 125–250 mg) — each effective in $\sim 50\%$. Second-line: topiramate, gabapentin, alprazolam. Botulinum toxin for limb/voice tremor. Drug-resistant cases: **VIM-thalamic DBS** or **MRI-guided focused ultrasound thalamotomy**.

Dystonia

- ▶ **Sustained/intermittent co-contraction of agonist & antagonist muscles** producing patterned, twisting movements/postures; relieved by a **sensory trick* (geste antagoniste); *aggravated by stress/fatigue*. Dystonic tremor *occurs in the direction of the pull** and disappears when the part is moved opposite — this distinguishes it from ET.
- ▶ **Distribution**: focal $\rightarrow$ segmental $\rightarrow$ multifocal $\rightarrow$ hemidystonia $\rightarrow$ generalised. Adult-onset **focal** dystonia is commonest (women 2:1; writer's cramp exceptionally commoner in men), presenting in the 4th–6th decade.
- ▶ **Focal phenotypes**: **cervical dystonia/torticollis** ($\sim 40\%$, also latero-/antero-/retrocollis), **blepharospasm** ($\sim 15\%$), **oromandibular** (+blepharospasm = **Meige's/Brueghel syndrome*), **spasmodic dysphonia** (adductor), **limb/task-specific** (writer's cramp, musician's cramp, the yips*).

- ▶ **Genetics (DYT prefix; >200 genes):** ***DYT-TOR1A** (3-bp deletion, Ashkenazi-Jewish founder) — *commonest early-onset generalised*; **KMT2B** (~10% early-onset generalised); **THAP1**; **GNAL**, **ANO3*** (adult cranio-cervical).
- ▶ **Combined dystonias:** ***Dopa-responsive dystonia (Segawa)** — **GCH1** (*GTP cyclohydrolase-1*), *childhood onset with diurnal fluctuation and a dramatic, sustained response to low-dose levodopa without dyskinesia (test all childhood dystonias with levodopa)*; **X-linked dystonia-parkinsonism (Lubag)** — **TAF1**, *Filipino*; **myoclonus-dystonia** — **SGCE** (*alcohol-responsive, paternal/maternal-imprinting** inheritance).
- ▶ **Treatment:** withdraw precipitants; **levodopa trial** in all childhood-onset dystonia; high-dose **trihexyphenidyl** (20–120 mg/day, tolerated mainly in children); **baclofen** (oral/intrathecal); **tetrabenazine** (start 12.5 mg, 25–75 mg/day). **Botulinum toxin is preferred for focal/segmental dystonia** (blepharospasm, torticollis, dysphonia). Severe generalised disease → **GPI DBS** (best in **DYT-TOR1A**). **Dystonic storm** — generalised contractions with laryngeal involvement, rhabdomyolysis & renal failure — is a medical emergency requiring ICU/airway protection.

Choreas, Ballism and Athetosis

- ▶ **Chorea** — rapid, non-patterned, flowing involuntary movements; *parakinesia* (movement camouflaged into a purposeful act), **motor impersistence** (“*milkmaid grip*”, *darting/flycatcher/trombone tongue*) and hung-up reflexes are signs.
- ▶ ***Huntington’s disease (HD)** — *autosomal dominant, fully penetrant*; **CAG (polyglutamine) repeat >40 in the Huntingtin gene on chromosome 4p** (36–39 = *reduced penetrance*). Onset 25–45 y; prevalence 2–8/100,000; *chorea + dysarthria + oculomotor abnormality + behavioural change/depression/psychosis + dementia*. *Anticipation (paternal transmission)*. ~10% present as the **akinetic-rigid juvenile Westphal variant**. **MRI: caudate-head & putaminal atrophy (boxcar ventricles)**; *intraneuronal ubiquitin/huntingtin inclusions*. **Treatment: symptomatic only** — *tetrabenazine, deutetabenazine (Austedo), valbenazine** (VMAT-2 inhibitors) for chorea; atypical antipsychotics (clozapine, quetiapine, risperidone) for psychosis; antidepressants; genetic counselling mandatory.
- ▶ **HD-like (HDL):** **HDL-1 (PRNP)**, a prion disease), **HDL-2 (JPH3)**, mostly African descent, *acanthocytosis*), **HDL-4 (TBP = SCA17)**.
- ▶ **Other choreas:** ***Sydenham’s chorea** (St. Vitus’ dance) — *post group-A streptococcal autoimmune chorea, girls 5–15 y, self-limited (treat with valproate/carbamazepine/dopamine blockers)*; **chorea gravidarum**; *SLE is the commonest systemic cause; also thyrotoxicosis, anti-NMDA-receptor/paraneoplastic (anti-Hu, anti-CRMP-5) encephalitis, hyper-/hypoglycaemia*. **Chorea-acanthocytosis (neuroacanthocytosis)** — **AR, VPS13A/chorein**; **McLeod syndrome*** — **X-linked**, Kell antigen. Levodopa-induced dyskinesia is the commonest iatrogenic chorea.
- ▶ **Ballism / hemiballismus** — wild, large-amplitude, flinging **proximal** movements; classic lesion of the **contralateral subthalamic nucleus** (infarct/haemorrhage), though 30–40% involve

putamen/thalamus/parietal cortex; **non-ketotic hyperglycaemia** is a key reversible cause. Usually self-limiting; responds to dopamine blockers; refractory cases → GPi DBS/pallidotomy.

- ▶ **Athetosis** — slow distal writhing (“*without fixed position*”); usually congenital (perinatal basal-ganglia injury, *status marmoratus*, athetoid cerebral palsy); blends with chorea (**choreoathetosis**) and dystonia. *Pseudoathetosis* = sensory (deafferentation) athetosis, worse with eyes closed.

Tics, Tourette Syndrome and Myoclonus

- ▶ **Tics** — simple/complex **motor** (blink, jerk, echopraxia) or **phonic** (grunt, *echolalia*, *palilalia*, *coprolalia*); suppressible with a building premonitory urge, exacerbated by stress, abate in sleep.
- ▶ ***Tourette’s syndrome** — *male-predominant; multiple motor + ≥1 phonic tic, onset 2–15 y (mean 7), often improves in adulthood; comorbid ADHD & OCD. High heritability. Treatment: education first; α-agonists clonidine / guanfacine* (0.5–2 mg/day); atypical then typical neuroleptics (risperidone, aripiprazole; haloperidol, pimozide); tetrabenazine; botulinum toxin for focal tics.*
- ▶ **Myoclonus** — brief (<100 ms) shock-like jerks; **positive** (jerk) vs **negative** (*asterixis*); focal/segmental/generalised; by site cortical, subcortical, brainstem or spinal. Causes: physiologic (hypnic jerks, hiccup), post-anoxic action myoclonus (***Lance-Adams syndrome**), *uraemic/hepatic encephalopathy, CJD; progressive myoclonic epilepsies* — Unverricht-Lundborg (*EPM1*) and Lafora-body (*EPM2A/NHLRC1*). *Palatal myoclonus* = lesion in the Guillain–Mollaret triangle (*inferior olive → dentate → red nucleus*), may persist in sleep, causes an audible ear click. Treatment: valproate, levetiracetam, clonazepam, piracetam, primidone; 5-hydroxytryptophan + carbidopa* for post-anoxic myoclonus.

Drug-induced and other syndromes

- ▶ **Drug-induced (dopamine-receptor blockers — neuroleptics, metoclopramide, prochlorperazine): acute** dystonic reaction (minutes–hours; treat with parenteral anticholinergic/diphenhydramine); **subacute akathisia** (restlessness relieved by movement, within 2 weeks); **tardive syndromes** (months–years) — **tardive dyskinesia** (oro-bucco-lingual chorea), tardive dystonia. FDA warns against metoclopramide >12 weeks. Treat TD with **valbenazine 80 mg/day** or deutetabenazine; avoid abrupt withdrawal. **Neuroleptic malignant syndrome** (rigidity, hyperthermia, autonomic instability, ↑CK) and **serotonin syndrome** (myoclonus prominent) are emergencies.
- ▶ **Paroxysmal dyskinesias: PKD** (movement-triggered; *PRRT2*; responds to carbamazepine/phenytoin), **PNKD** (alcohol/cafeine/stress-triggered; *PNKD* gene; clonazepam), **PED** (exercise-induced; *SLC2A1/GLUT1* deficiency; ketogenic diet).
- ▶ **Restless legs syndrome** — 4 core criteria (**Urge** to move + **Rest** worsens + **Gets better** with movement + **Evening/night predominance**); associated with **iron/ferritin deficiency**, pregnancy, uraemia; periodic limb movements of sleep; treat with iron repletion and low-dose dopamine

agonists (pramipexole, ropinirole, rotigotine) — beware **augmentation**; $\alpha 2\delta$ ligands (gabapentin) alternative.

- ▶ **Combined (parkinsonism + hyperkinesia): Wilson's disease** (*ATP7B*; **Kayser-Fleischer rings** in Descemet's membrane, **wing-beating tremor**, low ceruloplasmin, treat with penicillamine/trientine/zinc/tetrathiomolybdate) — exclude in any young dystonia/chorea; **NBIA/PKAN** (*PANK2*, “*eye-of-the-tiger*” sign on MRI).
- ▶ **Functional (psychogenic) movement disorder** — commonest is functional tremor; clues are **variability, distractibility, entrainment**, incongruent phenotype; managed with explanation, CBT and physiotherapy.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Basal-ganglia direct/indirect pathway schematic** — label: *Cortex, Striatum (caudate + putamen), GPe, GPi, Subthalamic nucleus (STN), Substantia nigra (SNc/SNr), Thalamus, VIM nucleus*; arrows for direct (D1, facilitatory) and indirect (D2, inhibitory) pathways; mark the **STN lesion** → **hemiballismus** site.
- ▶ **Phenomenology comparison panel** — three labelled sketches: *Chorea (random, flowing, distal)*, *Dystonia (sustained twisting posture, e.g. torticollis with geste antagoniste)*, *Hemiballismus (large-amplitude proximal flinging, one side)*.

Clinical / Diagnostic significance

- ▶ A precise bedside description (speed, rhythm, distribution, suppressibility, sensory trick, effect of action/rest/sleep) localises and classifies the disorder before any test.
- ▶ **Always exclude Wilson's disease** (serum copper/ceruloplasmin, 24-h urinary copper, KF rings, slit-lamp) in any young-onset chorea/dystonia/tremor — it is treatable.
- ▶ **Genetic testing** confirms HD (with counselling), DYT dystonias and HDL disorders; MRI signs are diagnostic clues (caudate atrophy in HD, eye-of-the-tiger in PKAN, olivary pseudohypertrophy in palatal myoclonus).
- ▶ VMAT-2 inhibitors (tetraabenazine, deutetabenazine, valbenazine) are the unifying pharmacology for chorea and tardive dyskinesia; **botulinum toxin** is first-line for focal dystonia; DBS (GPi for dystonia/HD, VIM for tremor, STN avoided in chorea) rescues refractory disease.

High-yield exam pointers

- ▶ ET: 6–10 Hz postural/action tremor, alcohol-responsive; first-line **propranolol & primidone**; VIM-DBS/focused ultrasound if refractory.
- ▶ HD: **AD, CAG repeat >40 on chromosome 4**, anticipation, Westphal variant; chorea + dementia + caudate atrophy.
- ▶ **Hemiballismus = contralateral subthalamic nucleus lesion**; also non-ketotic hyperglycaemia; usually self-limiting.

- ▶ **Dopa-responsive dystonia** (Segawa, GCH1) — diurnal variation, dramatic levodopa response; never miss it.
- ▶ **Geste antagoniste** (sensory trick) and *dystonic tremor in the direction of pull* are hallmarks of dystonia.
- ▶ **Palatal myoclonus** → **Guillain-Mollaret triangle**; **asterixis** = **negative myoclonus** (“liver flap”).
- ▶ Tourette = motor + phonic tics, onset childhood, comorbid OCD/ADHD; tics are **suppressible** (vs myoclonus, which is not).
- ▶ **Metoclopramide >12 weeks** risks tardive dyskinesia; **valbenazine/deutetrabenazine** treat it.
- ▶ Sydenham’s chorea = post-streptococcal autoimmune; **SLE** is the commonest systemic cause of chorea.

SOURCE & COVERAGE

- ▶ **Harrison’s Principles of Internal Medicine, 22e** — “*Tremor, Chorea, and Other Movement Disorders*” (Olanow & Klein) — primary framework, genetics, drug doses and disease definitions.
- ▶ **DeJong’s The Neurologic Examination** — “*Abnormalities of Movement*” — phenomenology (athetosis, asterixis, palatal myoclonus/Guillain-Mollaret triangle, parakinesia, geste antagoniste, hemiballismus, tics & stereotypy).
- ▶ **CMDT 2026** — “*Nervous System Disorders*” — current management of essential tremor (propranolol/primidone doses, DBS, focused-ultrasound thalamotomy) and chorea.

Hypoxic-ischemic encephalopathy

Asked in: Paper III Dec 2023 — RGUHS MD General Medicine

Definition / Introduction — Hypoxic-ischemic encephalopathy (HIE) is diffuse brain dysfunction caused by inadequate cerebral oxygen delivery, usually from combined hypoxemia and reduced cerebral blood flow. In adults it is most often discussed after cardiac arrest, but the same injury pattern may follow shock, respiratory arrest, asphyxiation, severe hypoxemia, or histotoxic hypoxia due to carbon monoxide or cyanide. It is an emergency because neurological outcome is determined by the duration of impaired perfusion, secondary brain insults, and the accuracy of delayed multimodal prognostication.

Etiology and vulnerable neuroanatomy

- ▶ **Cardiac arrest** is the prototype: cerebral blood flow becomes negligible, consciousness is lost within seconds, and permanent injury becomes likely when global hypoxia-ischemia lasts beyond about **3-5 min**, though recovery after longer intervals may occur, especially with early CPR.

- ▶ Important causes: **myocardial infarction**, ventricular tachycardia/fibrillation, pulseless electrical activity/asystole, shock, severe hypotension, respiratory failure, asphyxiation, respiratory paralysis, drowning/near-drowning, carbon monoxide poisoning, and cyanide poisoning.
- ▶ **Pure hypoxia** is better tolerated than hypoxia plus ischemia if blood pressure is maintained; severe arterial hypoxemia may injure brain, but brief absent or very low cerebral circulation is more dangerous.
- ▶ Usually severe systemic insult is required: Harrison notes that **systolic BP <70 mmHg** or **Pao₂ <40 mmHg** is generally necessary, with the duration of exposure being crucial.
- ▶ Selectively vulnerable sites are **hippocampal CA1 neurons**, cerebral cortex with **laminar cortical necrosis**, **deep gray nuclei** including basal ganglia and thalamus, cerebellar Purkinje cells, and watershed zones between major cerebral arteries.
- ▶ Resulting syndromes correlate with anatomy: hippocampal injury causes amnesic states; bilateral watershed injury may cause proximal arm-predominant weakness (*man-in-the-barrel* syndrome); striatal injury may produce parkinsonism; cortical injury may cause dementia, visual agnosia, seizures, or persistent coma.

Pathogenesis

- ▶ In complete global ischemia, neuronal oxygen stores are rapidly exhausted; CPR may provide only partial cerebral blood flow until effective circulation is restored.
- ▶ **Energy failure** causes failure of membrane ion gradients, neuronal depolarization, sodium and calcium influx, cytotoxic edema, and loss of electrophysiologic activity.
- ▶ **Glutamate excitotoxicity** through NMDA/AMPA receptors amplifies calcium entry; activated proteases, lipases, endonucleases, nitric oxide pathways, and mitochondrial dysfunction then produce cell injury.
- ▶ **Reperfusion injury** contributes through oxygen free radicals, inflammation, endothelial dysfunction, microvascular obstruction, and the *no-reflow* phenomenon.
- ▶ **Apoptosis and delayed neuronal death** may continue after the initial arrest; this is why early restoration of circulation plus prevention of secondary insults is central.
- ▶ Secondary brain insults that worsen outcome include **hypotension**, hypoxemia, fever, hyperglycemia or hypoglycemia, seizures/status epilepticus, severe acid-base/electrolyte derangements, and excessive sedative accumulation delaying assessment.

Clinical features and evolution

- ▶ Mild pure hypoxia may produce impaired judgment, inattentiveness, motor incoordination, and euphoria; hypoxia-ischemia from circulatory arrest produces immediate loss of consciousness.
- ▶ After return of spontaneous circulation (ROSC), the patient may awaken, remain comatose, evolve into an unresponsive wakefulness/vegetative state, or recover with variable cognitive, motor, visual, or movement-disorder sequelae.

- ▶ Bedside coma examination must document **pupillary light reflexes**, corneal reflexes, oculocephalic and oculovestibular responses, motor response to pain, respiratory pattern, and spontaneous/elicited eye movements.
- ▶ Brainstem reflexes are often preserved because the brainstem is relatively resistant to anoxic-ischemic injury; loss of pupillary or corneal reflexes therefore suggests severe, widespread injury.
- ▶ **Myoclonus status epilepticus** is continuous, generalized, vigorous jerking involving face, limbs, trunk, or diaphragm, often stimulus-sensitive and commonly associated with malignant EEG patterns; it must be distinguished from occasional myoclonic jerks, drug/metabolic myoclonus, and generalized tonic-clonic seizures.
- ▶ Long-term consequences include persistent coma, unresponsive wakefulness, minimally conscious state, dementia, visual agnosia/cortical blindness, parkinsonism, choreoathetosis, cerebellar ataxia, myoclonus, seizures, and amnestic syndrome.

Diagnostic evaluation

Domain	What to assess	High-yield point
Event history	Witnessed arrest, no-flow/low-flow time, initial rhythm, bystander CPR, ROSC time, hypotension/hypoxemia duration, toxins	Shockable rhythms and early CPR generally carry better neurological prospects than unwitnessed nonshockable arrests
Immediate labs	Glucose, electrolytes, calcium, ABG, lactate, renal/liver function, toxicology as indicated	Correct reversible coma mimics and secondary insults before prognostication
Coma examination	Pupils, corneal reflex, oculocephalic/oculovestibular reflexes, motor response, respiratory pattern	Preserved brainstem reflexes are favorable; absent reflexes after adequate waiting are ominous
Neuroimaging	Noncontrast CT brain; CT angiography if basilar occlusion or structural lesion is possible; MRI-DWI when stable	Early CT may be normal; severe HIE may show diffuse edema and loss of gray-white differentiation; MRI-DWI may show cortical and deep gray restriction
EEG	Spot or continuous EEG in comatose patients, especially with myoclonus or unexplained nonawakening	Detects nonconvulsive seizures/status; nonreactive EEG, suppressed background, and burst suppression are poor signs
SSEP and biomarkers	Median nerve SSEP for N20 responses; serial NSE if available	Bilateral absent cortical N20 after several days is highly specific for poor outcome; very high NSE supports severe brain injury but should not be used alone

Management

- ▶ **Restore cardiorespiratory function first:** secure airway, provide oxygenation and ventilation, perform high-quality CPR/defibrillation when indicated, and restore cerebral perfusion using fluids, vasopressors, pacing, or treatment of the arrest cause.
- ▶ After ROSC, assess for **acute MI**; ST-elevation MI requires emergent coronary angiography and PCI. In patients without ST elevation, urgent angiography is individualized for shock, electrical instability, ongoing ischemia, or major myocardial injury.
- ▶ Maintain systemic perfusion: Harrison recommends **SBP >90 mmHg** and **MAP >65 mmHg**; Bradley describes **MAP 65-80 mmHg** as a common post-arrest goal, often requiring norepinephrine plus fluid resuscitation.
- ▶ Ventilate to avoid hypoxemia and severe hyperoxia; Miller emphasizes individualized oxygenation with aggressive treatment of hypoxemia and avoidance of marked hyperoxia, especially **Pao₂ >300 mmHg**, when oxygenation is otherwise adequate. Maintain **normocapnia**, normalize systemic pH, and correct electrolyte abnormalities.
- ▶ Avoid secondary injury: treat fever aggressively, avoid hypotonic fluids, prevent aspiration, control glucose reasonably (often <180 mg/dL) while avoiding hypoglycemia, and manage renal/liver failure that may prolong sedative effects.
- ▶ **Targeted temperature management (TTM)** is recommended for comatose patients without purposeful response after ROSC: select and maintain a constant temperature **32-37.5°C** for at least **24 h**; fever must be avoided in all cases. Shivering may require analgesia, sedation, and sometimes neuromuscular blockade.
- ▶ Do not start hypothermia with large prehospital cold-saline loads; Harrison notes no prehospital benefit and increased pulmonary edema risk. Monitor for hypothermia complications: infection, coagulopathy, arrhythmias, hyperglycemia, cold diuresis, hypovolemia, and delayed sedative clearance.
- ▶ Treat clinically apparent seizures and consider treatment of ictal-interictal continuum EEG patterns. **Anticonvulsants are not given prophylactically**; complete suppression of rhythmic/periodic EEG activity for 48 h has not improved outcomes.
- ▶ Posthypoxic myoclonus in survivors may respond to **clonazepam 1.5-10 mg/day** or **valproate 300-1200 mg/day in divided doses**. Severe carbon monoxide poisoning may require hyperbaric oxygen.
- ▶ Ineffective or unproven neuroprotective strategies after cardiac arrest include routine corticosteroids, hemofiltration, tight glucose control, barbiturates for global ischemia, and calcium-channel blockers such as nimodipine solely for postarrest neuroprotection.

Neuroprognostication

- ▶ Prognostication must be **delayed, multimodal, and free of confounders**: exclude hypothermia, sedatives/analgesics, neuromuscular blockers, metabolic derangements, shock, hypoxemia, hepatic/renal failure, and drug intoxication.
- ▶ Harrison recommends deferring functional neurological assessment until at least **72 h after return to normothermia**, typically **4-5 days after arrest**; some patients awaken after a week or longer, so premature withdrawal risks a self-fulfilling poor outcome.
- ▶ Favorable signs: early awakening, following commands, purposeful localization to pain, intact pupillary/corneal/oculocephalic/oculovestibular reflexes, continuous reactive EEG background, and limited imaging injury.
- ▶ Poor prognostic signs when assessed at appropriate time points include absent pupillary light reflex, absent corneal reflex, absent or extensor motor response, and **status myoclonus** after primary circulatory arrest.
- ▶ Electrophysiologic poor signs: **bilateral absence of cortical N20 SSEP**, nonreactive EEG, persistent burst suppression, suppressed EEG background, or burst-suppression pattern with myoclonic status epilepticus.
- ▶ Imaging poor signs: diffuse cerebral edema, loss of gray-white differentiation on CT, widespread cortical DWI restriction, combined cortical and deep gray injury, or severe global ADC reduction on MRI.
- ▶ Biomarkers are adjunctive only: a very high **neuron-specific enolase >60 microgram/L** in the first 1-3 days supports severe brain damage in Harrison, but thresholds vary with assays and TTM.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Pathogenesis flow diagram**: “Cardiac/respiratory arrest or shock” -> “low cerebral blood flow + low O₂ delivery” -> “ATP failure” -> “membrane depolarization” -> “glutamate excitotoxicity + Ca²⁺ influx” -> “free radicals/inflammation/no-reflow/apoptosis” -> “selective neuronal injury: cortex, CA1 hippocampus, basal ganglia, thalamus, Purkinje cells, watershed zones” -> “coma/seizures/cognitive-motor sequelae”.
- ▶ **Post-arrest prognostication algorithm**: “ROSC with coma” -> “exclude confounders: hypothermia, sedatives, paralysis, metabolic shock” -> “wait ≥72 h after normothermia” -> “clinical exam: pupils, corneal, motor, myoclonus” + “EEG/SSEP/NSE/CT-MRI” -> “multimodal prognosis and family discussion”.

Clinical / Diagnostic significance

- ▶ HIE is a leading determinant of death after successful resuscitation; Harrison notes postarrest brain injury accounts for most deaths after stable circulation is restored.

- ▶ The diagnosis is clinical plus contextual: a compatible hypoxic-ischemic event with coma or encephalopathy, after excluding structural lesions, intoxication, metabolic coma, CNS infection, basilar artery occlusion, and nonconvulsive status epilepticus.
- ▶ Coma examination distinguishes diffuse metabolic/anoxic depression from focal structural brainstem processes; oculocephalic and caloric responses are particularly useful when the cervical spine is safe to test.
- ▶ Do not confuse HIE coma with **locked-in syndrome**, in which the patient is conscious with quadriparesis and preserved vertical eye movements/blinking, or with **brain death**, which requires irreversible coma, absent brainstem reflexes, absent respiratory drive, and exclusion of hypothermia/drug/metabolic mimics.
- ▶ Survivors require evaluation of the arrest cause, rehabilitation for cognitive and motor sequelae, seizure/myoclonus treatment, and cardiac secondary prevention including ICD consideration when VT/VF arrest is not due to a reversible cause.

High-yield exam pointers

- ▶ Write that HIE after cardiac arrest is **global cerebral ischemia plus reperfusion injury**, not merely low oxygen saturation.
- ▶ Mention vulnerable regions: **CA1 hippocampus, laminar cortex, basal ganglia/thalamus, Purkinje cells, watershed zones**.
- ▶ Initial treatment is not a “neuro drug”; it is **airway, oxygenation, ventilation, circulation, perfusion pressure, fever prevention, seizure detection, and TTM**.
- ▶ TTM: comatose after ROSC, constant 32-37.5°C for at least 24 h, avoid fever, suppress shivering, and delay prognostication.
- ▶ Never prognosticate early under hypothermia, sedatives, neuromuscular blockade, metabolic derangement, or shock.
- ▶ Strong poor-outcome markers: absent pupillary reflex, status myoclonus, nonreactive/burst-suppression EEG, bilateral absent N20 SSEP, diffuse cortical/deep gray MRI injury, and very high NSE.
- ▶ EEG is needed because nonconvulsive seizures/status may be clinically inapparent in comatose postarrest patients.
- ▶ CT can be normal early; **MRI-DWI** is more sensitive for cortical and deep gray injury but must not be used alone to withdraw care.

Immunopathogenesis and treatment of Guillain-Barré syndrome

Asked in: Paper III Nov 2022 — RGUHS MD General Medicine

Definition / Introduction — Guillain-Barré syndrome (GBS) is an **acute, frequently severe and fulminant, autoimmune polyradiculoneuropathy** presenting as a rapidly evolving **areflexic motor paralysis** with or without sensory disturbance. It occurs year-round at **10–20 cases per million annually** (≈ 5000 – 6000 cases/year in the United States), with males and adults at slightly higher risk. Approximately **70% of cases follow an antecedent infection by 1–3 weeks**, and the disorder is now understood as a post-infectious, antibody- and complement-mediated attack on peripheral nerve, in which **molecular mimicry** between microbial and neural glycolipids is central.

Subtypes and their antibody associations

- ▶ **Acute inflammatory demyelinating polyneuropathy (AIDP)** — commonest variant (**$\sim 90\%$ of Western cases**); first attack on the Schwann-cell surface with widespread myelin damage, macrophage activation and lymphocytic infiltration; *anti-GM1 antibodies in $<50\%$* .
- ▶ **Acute motor axonal neuropathy (AMAN)** — children/young adults; prevalent in **China and Mexico**, often **seasonal** (summer outbreaks after *Campylobacter jejuni*); rapid recovery; *anti-GD1a / anti-GM1*; attack at the motor nodes of Ranvier.
- ▶ **Acute motor-sensory axonal neuropathy (AMSAN)** — mostly adults; severe axonal damage, slow and often incomplete recovery; closely related to AMAN but also involves sensory roots.
- ▶ **Miller Fisher syndrome (MFS)** — **$\sim 5\%$ of cases**; the triad of **ophthalmoplegia, ataxia and areflexia** without limb weakness; *anti-GQ1b antibodies in $>90\%$* .
- ▶ **Regional/limited forms** — pharyngeal-cervical-brachial weakness (anti-GT1a, cross-reacting with GQ1b), pure sensory forms, acute pandysautonomia, and the “anti-GQ1b antibody syndrome” continuum (acute ophthalmoparesis, acute ataxic neuropathy, Bickerstaff’s brainstem encephalitis).

Antecedent (triggering) events

- ▶ **$\sim 70\%$ follow an acute infection** (respiratory or gastrointestinal) by 1–3 weeks.
- ▶ ****Campylobacter jejuni* — identified in 20–30%*** of cases in North America, Europe and Australia; the prototypic trigger of axonal GBS/AMAN.

- ▶ **Viral triggers** — CMV, Epstein-Barr virus, HIV, hepatitis E, and **Zika virus** (implicated in the Brazilian GBS surge); also *Mycoplasma pneumoniae*. SARS-CoV-2 cases were reported during COVID-19 but **causality is not established**.
- ▶ **Vaccines** — historical 1976 swine-influenza vaccine; current seasonal influenza confers a risk of **<1 per million**; a slightly increased risk with **adenovirus-vector SARS-CoV-2 vaccines but not mRNA vaccines**; older nervous-tissue rabies vaccine in developing countries.
- ▶ Higher-than-chance association with lymphoma (incl. Hodgkin's), HIV seropositivity, SLE, and immune checkpoint inhibitor therapy.

Immunopathogenesis (core of the answer)

- ▶ **Autoimmune basis** is supported by analogy to **experimental allergic neuritis (EAN)** — a T cell-mediated immunopathy induced in animals by sensitization against peripheral nerve proteins, particularly the **P2 protein**. Both **cellular and humoral** mechanisms contribute.
- ▶ **Molecular mimicry** — immune responses to nonself antigens (infectious agents, vaccines) are *misdirected to host nerve* through resemblance of epitope. The neural targets are **glycoconjugates, specifically gangliosides** (complex glycosphingolipids bearing one or more **sialic acid** residues), which are exposed on the axonal plasma membrane and densely concentrated at the **nodes of Ranvier**.
- ▶ ****C. jejuni link** — isolates from GBS patients carry surface lipo-oligosaccharide structures that antigenically cross-react with gangliosides (e.g., GM1) **concentrated in human nerve**. **Sialic acid residues from pathogenic strains also activate** dendritic cells via Toll-like receptor 4 (TLR4), **promoting B-cell differentiation**** and amplifying humoral autoimmunity.
- ▶ **Antiganglioside antibodies** — most frequently **anti-GM1**, present in **20–50%** of cases, especially AMAN/AMSAN and those preceded by *C. jejuni*. Some AIDP antibodies recognise **glycolipid heterocomplexes** rather than single species. Direct evidence comes from recipients of IV **bovine brain gangliosides** who developed AMAN with high anti-GM1 titres 5–15 days later.
- ▶ **Effector mechanism in AIDP** — autoantibodies bind myelin antigens and activate **complement** along the *outer surface of the Schwann cell* → **terminal complement complex / membrane-attack complex (MAC)** → **vesicular disintegration of the myelin sheath** → recruitment of **activated macrophages** that strip myelin and scavenge debris. Injecting GBS serum into animal nerve reproduces complement-dependent demyelination and conduction block.
- ▶ **Effector mechanism in AMAN** — **IgG plus complement deposit on the nodal and internodal axolemma of motor fibres**. Anti-GM1/anti-GD1a bind the nodal axolemma → MAC formation → **disappearance of voltage-gated Na⁺ (Nav) channel clusters** and **detachment of paranodal myelin** → conduction failure; axonal degeneration may follow. Notably, **anti-GD1a has a fine specificity favouring motor over sensory roots**.

- ▶ **MFS** — anti-GQ1b IgG (>90%) is explained by **enrichment of GQ1b in extraocular motor nerves**; a monoclonal anti-GQ1b raised against *C. jejuni* blocked neuromuscular transmission experimentally.
- ▶ *Caveat in source*: although antiganglioside antibodies are strongly implicated, formal proof of pathogenicity by passive transfer to naïve hosts has **not yet been demonstrated** (one possible transplacental case described).

Pathophysiology and laboratory features

- ▶ **AIDP** — flaccid paralysis is due to **conduction block** from demyelination, with axons left intact; recovery is rapid via **remyelination**. Severe cases develop **secondary axonal degeneration**, predicting slower, less complete recovery.
- ▶ **AMAN/AMSAN** — a **primary axonal pattern** with low-amplitude CMAPs; rapid recovery in many cases reflects **reversible conduction block** from antibody binding to nodal ion-channel proteins.
- ▶ **CSF** — **albuminocytologic (cytoalbuminologic) dissociation**: elevated protein (1–10 g/L; 100–1000 mg/dL) **without pleocytosis**. CSF is often normal at ≤48 h and rises by the end of the first week; a *sustained* pleocytosis points to an alternative (HIV, lymphoma, viral myelitis).
- ▶ **Electrodiagnosis (EDx)** — earliest in AIDP are **prolonged F-wave latencies, prolonged distal latencies and reduced CMAP amplitudes**; later, conduction velocity slowing, conduction block and temporal dispersion. AMAN/AMSAN show reduced CMAP (and SNAP) amplitudes without slowing.
- ▶ **Diagnosis** — clinical, aided by the validated **2011 Brighton Collaboration criteria**; serum anti-GQ1b supports MFS.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Figure 458-2 — Immune mechanisms in GBS (two panels)**. *Panel A (AIDP)*: label Motor neuron, Axon, Myelin, Schwann cell, Unidentified myelin antigen, Antibody binding, Complement activation, Membrane-attack complex (MAC), Macrophage (scavenging myelin debris). *Panel B (AMAN/AMSAN)*: a myelinated axon divided into Node of Ranvier, Paranode, Juxtaparanode, Internode; mark Nav (voltage-gated Na⁺) channels at the node, Caspr at the paranode, Kv channels at the juxtaparanode, gangliosides GM1 and GD1a at the node, IgG anti-GM1/anti-GD1a antibodies, C3 and MAC, with macrophage invading the periaxonal space.
- ▶ **Ganglioside-mimicry schematic (Fig. 458-1 key)**: draw GM1, GD1a, GT1a, GQ1b with the sugar key — Galactose, Glucose, N-acetyl|galactosamine, N-acetylneuraminic acid (sialic acid), Ceramide — linking GM1/GD1a→AMAN/AMSAN and GQ1b/GT1a→Miller Fisher syndrome.

Treatment

- ▶ **General principle** — start immunotherapy as soon as diagnosis is made; “each day counts.” Benefit beyond ~2 weeks from onset, or once the patient is at a stable plateau, is uncertain; very mild cases at plateau may be managed conservatively.
- ▶ **Intravenous immunoglobulin (IVIg)** — usual first choice (ease, safety); **2 g/kg total given as five daily infusions** (0.4 g/kg/day × 5). Proposed action includes neutralisation of pathogenic autoantibodies by **anti-idiotypic antibodies** in IVIg.
- ▶ **Plasma exchange (PLEX)** — ~40–50 mL/kg per exchange, 4–6 times over 7–12 days. Meta-analysis shows it **halves the need for mechanical ventilation** (27% → 14%) and raises the chance of **full recovery at 1 year** (55% → 68%).
- ▶ **IVIg and PLEX are equally effective; combining the two is not significantly better** than either alone. Failure of one is **not** an indication to switch to the other.
- ▶ **Treatment-related fluctuation/relapse within a month** — give a **brief course of the original agent again**.
- ▶ **Glucocorticoids are NOT effective** in GBS (a key contrast with CIDP, which does respond to steroids).
- ▶ **Supportive / critical care** — monitor in ICU for **vital capacity** (≈30% need mechanical ventilation), cardiac rhythm and **dysautonomia** (labile BP, postural hypotension, arrhythmia), nutrition, DVT prophylaxis; consider **tracheostomy** after ~2 weeks of intubation; chest physiotherapy, frequent turning/skin care, range-of-motion exercises and reassurance.
- ▶ **Pain** (neck/back/limb dysaesthesia) — responds to standard analgesics.

Clinical / Diagnostic significance

- ▶ **Prognosis** — ~85% achieve **full functional recovery** over months to a year; **mortality <5%** (death mainly from pulmonary complications/dysautonomia).
- ▶ **Poor-outcome predictors** — severe proximal motor-sensory **axonal** damage, advanced age, fulminant/severe attack, delayed treatment, and **high serum neurofilament-light (NfL) and anti-GM1 titres**.
- ▶ **5–10% relapse**; some recurrent/progressive cases are reclassified as **CIDP** (chronic, steroid-responsive).
- ▶ Recognising **albuminocytologic dissociation** and early EDx changes allows treatment **before classic findings appear** — do not wait. Test for **HIV** if risk factors or CSF pleocytosis.
- ▶ Exclude mimics: acute myelopathy, poliomyelitis/acute flaccid myelitis, diphtheritic and tick paralysis, porphyria, botulism/myasthenia, and organophosphate/heavy-metal poisoning.

High-yield exam pointers

- ▶ GBS = **acute autoimmune areflexic ascending paralysis**; ~70% post-infectious; **molecular mimicry** is the unifying mechanism.
- ▶ ***C. jejuni** (20–30%) → *anti-GM1/GD1a* → AMAN/AMSAN; *anti-GQ1b* (>90%) → *Miller Fisher* (*ophthalmoplegia, ataxia, areflexia*)*.
- ▶ AIDP = complement + MAC on **Schwann-cell surface** → demyelination; AMAN = IgG + complement at **nodal axolemma** → Nav-cluster loss → conduction block.
- ▶ CSF: **albuminocytologic dissociation** (high protein, cells <50/ μ L); EDx — prolonged F-waves, prolonged distal latency, low CMAP.
- ▶ **Brighton criteria** (2011) for diagnostic certainty.
- ▶ IVIg 2 g/kg over 5 days OR PLEX 40–50 mL/kg $\times$ 4–6 (7–12 days) — equally effective, do **not** combine, do **not** switch on failure.
- ▶ **Steroids are useless in GBS** (but useful in CIDP) — a favourite viva point.
- ▶ Recovery ~85%, mortality <5%; worst with **axonal damage, high NfL/anti-GM1, age, delay**.

SOURCE & COVERAGE

Harrison 22e — Ch 458 “Guillain-Barré Syndrome and Other Immune-Mediated Neuropathies” (Hauser & Amato). All classifications, antibody targets, mechanisms, doses and outcome figures are taken from this chapter. *Coverage note*: the chapter fully supports the asked union (immunopathogenesis + treatment); no fabrication required. The CIDP material in the same chapter is referenced only for the steroid-responsiveness contrast.

Multiple sclerosis

Asked in: Paper III Dec 2023 · Paper IV Nov 2022 (2×) — RGUHS MD General Medicine

Definition / Introduction — Multiple sclerosis (MS) is a chronic autoimmune inflammatory demyelinating disease of the CNS, with **demyelination, gliosis, plaques and axonal-neuronal loss** in brain, spinal cord and optic nerves. Lesions occur at different CNS sites and at different times; therefore the diagnostic principle is **dissemination in space and time**, after excluding better explanations. The course may be relapsing or progressive, and disability reflects both focal inflammatory attacks and cumulative neurodegeneration.

Etiopathogenesis and pathology

- ▶ **Epidemiology**: usual onset is in young adults, commonly 20–40 years; relapsing MS shows a female predominance of about 2–3:1, while primary progressive MS has a more even sex distribution and later onset. MS is commoner in temperate zones and higher latitudes.

- ▶ **Risk factors:** genetic susceptibility, especially **HLA-DRB11501*, **interacts with environmental factors:** previous Epstein-Barr virus** infection/infectious mononucleosis, low sunlight or vitamin D deficiency, cigarette smoking, and probably childhood obesity/microbiome factors.
- ▶ **Pathology:** plaques are sharply demarcated, often **perivenular**, with mononuclear inflammation, macrophages, T cells, B cells/plasma cells, complement activation, myelin loss, astrocytic gliosis and variable axonal loss. Chronic active plaques, cortical demyelination and meningeal lymphoid aggregates are important in progressive disease.
- ▶ **Immunology:** B cells are central; clonally restricted B cells and plasma cells in CNS/CSF produce **oligoclonal IgG bands**. Autoreactive T cells, especially myelin-reactive T cells, inflammatory cytokines, CD8 cells at plaque edges and microglial activation contribute to tissue injury.
- ▶ **Physiology:** demyelination causes conduction block, slowed conduction and temperature-dependent failure. This explains **Uhthoff phenomenon** and pseudoexacerbations with fever, infection or heat.

Clinical features

- ▶ **Optic neuritis:** subacute unilateral visual loss, central scotoma, impaired colour vision, pain on eye movement and relative afferent pupillary defect; fundus may be normal in retrobulbar neuritis or show papillitis, followed later by optic pallor.
- ▶ **Sensory symptoms:** numbness, tingling, pins-and-needles, burning dysesthesia, reduced vibration/joint position, patchy sensory loss, a spinal sensory level and a band-like truncal tightness or *MS hug*. **Lhermitte sign** is an electric shock sensation down the spine on neck flexion.
- ▶ **Motor and pyramidal signs:** limb weakness, loss of dexterity, spastic paraparesis, brisk reflexes, clonus and extensor plantar responses. Exercise-induced weakness is typical; severe spasticity may cause painful spasms but may also help standing in advanced disease.
- ▶ **Brainstem/cerebellar disease:** diplopia, sixth nerve palsy, **internuclear ophthalmoplegia** from medial longitudinal fasciculus lesions, bilateral INO, nystagmus, vertigo, ataxic gait, intention tremor and scanning dysarthria.
- ▶ **Paroxysmal symptoms:** brief stereotyped events lasting seconds to minutes, often many times per day: tonic spasms, paroxysmal dysarthria-ataxia, sensory attacks, trigeminal neuralgia, hemifacial spasm or facial myokymia.
- ▶ **Autonomic, cognitive and affective symptoms:** urinary urgency, frequency, hesitancy, retention, recurrent UTI, constipation, sexual dysfunction, fatigue, slowed information processing, memory/executive difficulty, depression and pseudobulbar affect.

Disease course and phenotypes

Phenotype	Exam definition	Key point
Clinically isolated syndrome (CIS)	First typical demyelinating clinical event not yet fulfilling MS criteria	High-risk CIS with MRI/CSF activity may be treated early
Radiologically isolated syndrome (RIS)	Incidental MRI lesions typical of MS without clinical attack	Follow clinically and by MRI; some convert to clinical MS
Relapsing-remitting MS (RRMS)	Clearly defined attacks with full or partial recovery and no progression between attacks	Accounts for most onset cases; current term relapsing MS includes active SPMS
Secondary progressive MS (SPMS)	Initial RRMS followed by gradual progression independent of relapses	Produces more fixed disability; classify as active/inactive and progressing/not progressing
Primary progressive MS (PPMS)	Progression from onset, with possible plateaus or minor improvement	About 10% of cases; later onset; faster disability relative to first symptom
Fulminant variants	Tumefactive MS, Marburg variant, Balo concentric sclerosis	May mimic tumour or rapidly progressive encephalomyelitis

Diagnosis and investigations

- ▶ **Core rule:** do not diagnose MS from a single lesion or MRI alone. Demonstrate **dissemination in space (DIS)** and **dissemination in time (DIT)**, and exclude mimics.
- ▶ **2017 McDonald criteria, simplified:** two attacks plus objective evidence of two lesions need no further data; two attacks plus one lesion need DIS; one attack plus two lesions need DIT; one attack plus one lesion needs both DIS and DIT.
- ▶ **DIS by MRI:** at least one T2 lesion in at least two of four typical sites: **periventricular, cortical/juxtacortical, infratentorial or spinal cord**.
- ▶ **DIT by MRI/CSF:** simultaneous gadolinium-enhancing and non-enhancing lesions, or a new T2/gadolinium lesion on follow-up MRI, or a second clinical attack; in a patient with one clinical event meeting DIS, **CSF-specific oligoclonal bands can substitute for DIT**.
- ▶ **PPMS criteria:** at least 1 year of progression plus two of: typical brain lesion, at least two spinal cord lesions, or positive CSF oligoclonal bands/elevated IgG index.
- ▶ **MRI:** most sensitive test; shows ovoid T2/FLAIR plaques, **Dawson fingers** perpendicular to ventricles, corpus callosum, juxtacortical, infratentorial and cord lesions. Gadolinium enhancement marks active BBB breakdown, usually for less than 1 month; T1 black holes suggest irreversible demyelination/axonal loss.
- ▶ **CSF:** normal opening pressure, normal or mildly raised protein, mild lymphocytic pleocytosis, increased IgG index/synthesis and **two or more CSF-restricted oligoclonal bands** in >90% in Harrison. Red flags against MS are polymorphs, CSF cells >75/microL, or protein >1 g/L.

- ▶ **Evoked potentials/OCT:** VEP, SSEP and BAER may detect clinically silent lesions; delayed VEP P100 supports demyelination. OCT quantifies retinal nerve fibre layer axonal loss after optic neuritis but is not diagnostic.

Differential diagnosis

- ▶ **Inflammatory demyelinating mimics: neuromyelitis optica spectrum disorder and MOG antibody-associated disease,** especially with bilateral/severe optic neuritis, poor recovery or longitudinally extensive transverse myelitis; acute disseminated encephalomyelitis after infection/vaccination.
- ▶ **Systemic inflammatory disease:** SLE, Sjögren syndrome, sarcoidosis, Behçet disease, antiphospholipid syndrome and primary CNS/systemic vasculitis.
- ▶ **Infective/metabolic/vascular:** HIV, HTLV-1 tropical spastic paraparesis, Lyme disease, syphilis, vitamin B12 deficiency, CADASIL, stroke/small-vessel disease and spinal dural AV fistula.
- ▶ **Structural/neoplastic:** compressive myelopathy, Chiari malformation, lymphoma, glioma, meningioma and tumefactive demyelination.
- ▶ **Red flags:** onset age <15 or >60 years, progressive course from onset without typical attacks, symptoms confined to one anatomic site, fever/headache/seizures/coma, peripheral neuropathy, severe muscular atrophy, atypical MRI or inflammatory CSF.

Management

- ▶ **Acute relapse:** first exclude pseudoexacerbation due to fever, UTI, heat or metabolic stress. Treat disabling relapses with high-dose methylprednisolone **500-1000 mg IV daily for 3-5 days** or equivalent high-dose oral therapy; optional oral prednisone taper may follow. Steroids hasten recovery but do not improve final recovery or prevent future relapses; long-term steroids are not useful.
- ▶ **Steroid-refractory severe relapse:** **plasma exchange** is useful, especially for severe motor, brainstem or optic-spinal relapses unresponsive to corticosteroids. ACTH is an alternative where available.
- ▶ **Disease-modifying therapy (DMT):** start in all diagnosed relapsing MS and high-risk CIS after counselling. Current high-efficacy first-line choices include anti-CD20 therapy **ocrelizumab, ofatumumab or ublituximab**; rituximab is used where approved options are unavailable. **Natalizumab** is highly effective in JCV-negative patients but requires PML risk surveillance.
- ▶ **Other DMTs:** S1P modulators (fingolimod, ozanimod, ponesimod, siponimod), fumarates (dimethyl/diroximel fumarate), cladribine, alemtuzumab, teriflunomide, interferon-beta and glatiramer acetate. Choice depends on disease activity, pregnancy plans, infection risk, monitoring burden and patient preference.
- ▶ **Progressive MS:** **ocrelizumab** is the only convincingly disease-modifying drug for PPMS; active SPMS may be treated with ocrelizumab or siponimod, with

cladribine/ponesimod/ofatumumab/ozanimod used in active secondary progressive disease in appropriate settings.

- ▶ **Symptomatic care:** physiotherapy, occupational therapy, exercise and fall prevention. Spasticity: stretching, baclofen **20-120 mg/day**, tizanidine **8-32 mg/day**, benzodiazepines, dantrolene or intrathecal baclofen. Gait: dalfampridine **10 mg twice daily** if no seizure risk. Bladder: timed voiding, urodynamics, mirabegron **25-50 mg/day**, vibegron **75 mg/day**, anticholinergics, botulinum toxin or intermittent catheterization. Pain/paroxysms: carbamazepine, gabapentin, pregabalin or other membrane-stabilising drugs. Fatigue: treat sleep, nocturia, depression and spasticity first; modafinil/methylphenidate may help selected patients. Screen and treat depression and suicidality.
- ▶ **Pregnancy and prevention:** relapse rate falls during pregnancy, especially third trimester, and rises in the first 3 months postpartum. Avoid abrupt withdrawal of natalizumab/S1P drugs without planning because rebound can occur. Correct vitamin D deficiency, stop smoking and vaccinate before B-cell-depleting or other immunosuppressive DMTs when possible.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Pathophysiology diagram:** normal myelinated axon with node of Ranvier and saltatory conduction; demyelinated axon with exposed potassium channels, redistributed sodium channels, conduction block/slow conduction; labels: myelin sheath, axon, node of Ranvier, Na⁺ channels, demyelinated plaque, conduction block, continuous conduction.
- ▶ **MRI/clinical course diagram:** sagittal brain showing periventricular **Dawson fingers**, corpus callosum lesions, juxtacortical lesion, infratentorial lesion and short-segment spinal cord plaque; alongside a course graph labelled CIS/RRMS/SPMS/PPMS, relapses, MRI activity and progression.

Clinical / Diagnostic significance

- ▶ Optic neuritis, partial myelitis and brainstem syndromes in a young adult should prompt MRI brain and spinal cord with gadolinium and CSF when needed.
- ▶ Bilateral INO, Lhermitte sign, Uhthoff phenomenon and paroxysmal tonic spasms are highly suggestive clinical clues but are not pathognomonic.
- ▶ Severe bilateral optic neuritis, longitudinally extensive myelitis, area postrema syndrome or poor visual recovery should trigger AQP4-IgG and MOG-IgG testing rather than assuming MS.
- ▶ MRI lesions must be interpreted in clinical context; migraine, ageing and small-vessel disease can produce nonspecific T2 hyperintensities.
- ▶ A true relapse lasts >24 hours and is separated from prior relapse by at least about 1 month; fever/UTI/heat-related worsening is a pseudoexacerbation and should not be treated with steroids alone.

- ▶ Early high-efficacy DMT reduces relapse/MRI activity and may improve long-term disability, but treatment requires infection, vaccination, pregnancy and monitoring planning.

High-yield exam pointers

- ▶ Write the definition: autoimmune CNS disease with **demyelination + gliosis + axonal loss**, disseminated in time and space.
- ▶ Mention common onset: young adult woman; optic neuritis, sensory symptoms and UMN weakness are classic first presentations.
- ▶ Must list the four MRI DIS sites: **periventricular, cortical/juxtacortical, infratentorial, spinal cord**.
- ▶ CSF-specific **oligoclonal bands** can substitute for DIT in the 2017 McDonald criteria.
- ▶ Dawson fingers, gadolinium enhancement and T1 black holes carry diagnostic/prognostic value.
- ▶ Always exclude NMO/MOGAD, B12 deficiency, infections, connective-tissue disease, sarcoidosis, lymphoma and compressive myelopathy.
- ▶ Acute relapse: high-dose methylprednisolone; severe steroid-resistant relapse: plasma exchange.
- ▶ DMT: anti-CD20 therapy/natalizumab are high-efficacy options; **ocrelizumab** is key for PPMS.
- ▶ Do not miss symptomatic management: bladder, spasticity, gait, pain, fatigue, cognition, mood and pregnancy counselling.

Muscular Dystrophies: Genetics, Pathogenesis and Clinical Implications

Asked in: Paper I Nov 2019 — RGUHS MD General Medicine

Definition / Introduction — The **muscular dystrophies** are a genetically determined group of progressive, degenerative myopathies caused by mutations in genes encoding **structural, membrane, nuclear-envelope, enzymatic or RNA-binding proteins** of the muscle fibre. They are characterised clinically by progressive (usually proximal, limb-girdle) weakness with preserved sensation and reflexes, elevated serum creatine kinase (CK), myopathic EMG, and dystrophic features on biopsy. Each subtype has a unique phenotype–genotype signature; cardiac and ventilatory muscle involvement are the chief determinants of mortality. Genetic testing is now the gold standard for diagnosis.

Normal muscle architecture and the dystrophin–glycoprotein complex (DGC)

- ▶ The contractile actin–myosin apparatus of the sarcomere is anchored, via the cytoskeleton, to the extracellular matrix by a chain of proteins; loss of any link destabilises the **sarcolemma**.
- ▶ **Dystrophin** (427 kD) lies on the cytoplasmic face of the sarcolemma — its **amino terminus** binds F-actin and its **carboxyl terminus** links to **β-dystroglycan**.
- ▶ **β-Dystroglycan** spans the membrane and connects to **α-dystroglycan**, which (after enzymatic glycosylation) binds **laminin-α2 (merosin)** in the basal lamina.
- ▶ The **sarcoglycan complex** (**α, β, γ, δ**) and **sarcospan** also span the sarcolemma and stabilise the dystroglycan–dystrophin unit.
- ▶ Together — dystrophin, dystroglycans, sarcoglycans and merosin — form the DGC, transmitting contractile force and protecting the membrane from mechanical stress. Defects at *any* point produce a dystrophy.

Molecular mechanisms of pathogenesis (genetics → disease)

- ▶ **Sarcolemmal/structural-protein loss (DGC dystrophies)**: absence of dystrophin (DMD/BMD), sarcoglycans, dysferlin or merosin renders the membrane fragile → unregulated **Ca²⁺ influx** → activation of proteases → cycles of fibre **necrosis–regeneration** → exhaustion of satellite cells → fibro-fatty replacement.
- ▶ **Defective glycosylation of α-dystroglycan** (fukutin, FKR, POMT1/2, POMGnT1) — “dystroglycanopathies” — disrupt merosin binding; severe forms cause congenital muscular dystrophy with brain/eye anomalies, milder forms an LGMD.
- ▶ **Nuclear-envelope protein defects** (emerin, lamin A/C, nesprin-1/2, LUMA) destabilise the inner nuclear membrane → Emery-Dreifuss MD and LGMD1B, with prominent cardiac conduction disease.
- ▶ **Toxic RNA gain-of-function from non-coding repeat expansions**: in myotonic dystrophy the mutant mRNA forms **intranuclear inclusions that sequester RNA-splicing proteins**, causing mis-splicing of multiple downstream transcripts (multisystem disease).
- ▶ **Epigenetic de-repression**: in FSHD, contraction of the D4Z4 array → **hypomethylation** → aberrant **toxic expression of DUX4** transcription factor in muscle.
- ▶ **Protein aggregation**: in OPMD, an expanded polyalanine tract makes PABP2 resistant to proteasomal degradation → toxic intranuclear aggregates.

Genetic classification of the major muscular dystrophies

Dystrophy	Inheritance	Gene / locus	Protein	Hallmark feature
Duchenne / Becker (DMD/BMD)	X-linked recessive	DMD / Xp21	Dystrophin	Calf pseudohypertrophy,

Dystrophy	Inheritance	Gene / locus	Protein	Hallmark feature
				Gowers sign, very high CK
Limb-girdle (LGMD “D”/”R”)	AD (D) or AR (R)	<i>CAPN3, DYSF, SGCA-D, FKRP, ANO5, TTN...</i>	Calpain-3, dysferlin, sarcoglycans, FKRP, anoctamin-5	Proximal limb-girdle weakness, often indistinguishable from DMD/BMD
Emery-Dreifuss (EDMD)	XLR / AD / AR	<i>EMD, LMNA, SYNE1/2, FHL1, TMEM43</i>	Emerin, lamin A/C, nesprins, FHL1, LUMA	Early contractures + cardiac conduction block / sudden death
Myotonic dystrophy 1 (DM1)	AD	<i>DMPK</i> / 19q13 — CTG repeat	DMPK	Grip myotonia, hatchet face, frontal balding, multisystem
Myotonic dystrophy 2 (PRODM / DM2)	AD	<i>CNBP (ZNF9)</i> — CCTG repeat, intron 1	CNBP	Proximal weakness, milder, no congenital form
Facioscapulohumeral (FSHD)	AD (FSHD1, 95%)	<i>D4Z4</i> / 4q35, <i>DUX4</i>	DUX4 (toxic)	Facial weakness, scapular winging, asymmetric
Oculopharyngeal (OPMD)	AD	<i>PABPN1</i> — GCG / polyalanine	PABP2	Late ptosis + dysphagia; rimmed vacuoles

Duchenne and Becker muscular dystrophy (the prototype dystrophinopathy)

- **Genetics:** X-linked recessive; the *DMD* gene at Xp21 is the largest human gene (~2.5 million bp, 79 exons). ~65–75% of cases are deletions/duplications (hot-spots between exons 44–52); the remainder are point/nonsense mutations. Roughly **one-third are sporadic** (new mutations); germline mosaicism gives a recurrence risk up to ~14% even when the mother tests negative.
- **The reading-frame (Monaco) rule — the key concept:** in-frame mutations preserve the triplet reading frame → a shortened but partly functional dystrophin → **milder Becker phenotype**; out-of-frame (frameshift) mutations destroy the frame → absent dystrophin → **severe Duchenne**.
- **DMD clinical course:** boys normal at birth; proximal lower-limb weakness from ~3–5 yr, **Gowers sign**, toe-walking, waddling gait, firm **calf pseudohypertrophy**; loss of ambulation ~8–12 yr; progressive contractures, scoliosis. **Cardiomyopathy in ~1/3 by age 14 and virtually all by 18**; respiratory failure. Intellectual disability may occur.

- ▶ **BMD:** later onset, ambulation usually retained beyond 15 yr, survival into 4th–5th decade; cardiomyopathy may dominate (occasionally heart failure is the only manifestation) and may require transplantation.
- ▶ **Labs:** CK markedly elevated (often >10,000 IU/L in DMD, lower in BMD); myopathic EMG; immunostain/Western blot — dystrophin absent in DMD, reduced/altered in BMD (immunoblot needed in BMD as staining can look normal).

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Diagram 1 — Dystrophin–glycoprotein complex (DGC):** Draw the sarcolemma as a bilayer. Label, from inside out: *F-actin / cytoskeleton* → *Dystrophin (N-terminus to actin, C-terminus to β -dystroglycan)* → *β -Dystroglycan (transmembrane)* → *α -Dystroglycan (extracellular)* → *Laminin- α 2 (merosin) in basal lamina*; show the **Sarcoglycan complex** (α , β , γ , δ) + **sarcospan** spanning the membrane beside dystroglycan; mark *Calpain-3*, *Dysferlin*, *Caveolin-3* and the *nuclear envelope (emerin, lamin A/C, nesprin)* to show where different dystrophies localise.
- ▶ **Diagram 2 — Gowers sign:** Sequential figures of a child rising from the floor by “climbing up the legs” — turning prone, pushing onto hands and feet, then walking the hands up the thighs to stand. Label *Gowers manoeuvre = proximal (hip/trunk) weakness*.

Clinical / Diagnostic significance

- ▶ **Pattern recognition localises the diagnosis:** limb-girdle (most dystrophies) vs facial weakness + scapular winging (FSHD) vs facial/distal weakness + grip myotonia (DM1) vs ptosis + dysphagia (OPMD) vs early contractures + heart block (EDMD).
- ▶ **Investigations:** serum CK (screening; very high in dystrophinopathies/Miyoshi, normal-mildly raised in FSHD/EDMD/OPMD); EMG (myopathic, short-duration small-amplitude polyphasic MUAPs; myotonic discharges in DM); **muscle MRI/ultrasound** for pattern of involvement; **immunohistochemistry/immunoblot** (dystrophin, sarcoglycans, dysferlin, α -dystroglycan, emerin); **genetic testing** is definitive (MLPA/array CGH for deletions-duplications, then next-generation sequencing for point mutations).
- ▶ **Multisystem surveillance (high-yield):** annual ECG + echo/cardiac MRI in DMD/BMD and EDMD/laminopathy; FVC monitoring for respiratory failure; cataracts, conduction block, insulin resistance, testicular atrophy and hypersomnia in DM1; aspiration risk in OPMD.
- ▶ **Management — largely supportive but evolving:**
 - **Glucocorticoids** (prednisone ~0.75 mg/kg/day or deflazacort ~0.9 mg/kg/day) slow progression and prolong ambulation in DMD.

- **Cardiac:** ACE-inhibitor/ARB (start ~age 10 in DMD), beta-blockers, afterload reduction; **pacemaker/ICD** is potentially life-saving in EDMD/laminopathy and significant DM conduction disease; cardiac transplant in selected BMD.
 - **Respiratory/orthopaedic:** non-invasive ventilation (BiPAP), physiotherapy, stretching/bracing, ankle-foot orthoses for foot-drop, scoliosis surgery, scapular fixation in FSHD, cricopharyngeal myotomy in OPMD.
 - **Molecular therapies (DMD):** **exon-skipping antisense oligonucleotides** (e.g., eteplirsen — exon 51 skipping, converts DMD toward a BMD phenotype) and **stop-codon read-through** agents (ataluren for nonsense mutations); DUX4-suppression trials ongoing in FSHD.
 - **Symptomatic myotonia:** **mexiletine** in DM1/DM2; modafinil for hypersomnia.
- ▶ **Genetic counselling** is integral: carrier testing of female relatives in X-linked DMD/BMD/EDMD; recognition of **anticipation** in DM1 and **maternal transmission of the congenital form**; prenatal/germline-mosaicism counselling.

High-yield exam pointers

- ▶ **DMD/BMD** — X-linked, *Xp21* dystrophin; **reading-frame rule:** in-frame → Becker, out-of-frame → Duchenne.
- ▶ **Gowers sign + calf pseudohypertrophy + CK >10,000** = think Duchenne; death from cardiomyopathy/respiratory failure.
- ▶ **DM1** — AD, CTG expansion in *DMPK* (19q13); **genetic anticipation**; congenital form from **affected mothers**; grip/percussion myotonia, hatchet face, frontal balding, cataracts, heart block. **DM2 (PROMM)** = CCTG in *CNBP*, proximal, no congenital form.
- ▶ **FSHD1** — contraction of **D4Z4 repeat at 4q35** (<35 kb) → toxic **DUX4** expression; facial weakness + scapular winging; heart spared.
- ▶ **EDMD triad** — early **contractures**, humero-peroneal weakness, **cardiac conduction defects/sudden death**; emerin (X-linked) or lamin A/C (AD).
- ▶ **OPMD** — AD, GCG/polyalanine expansion in *PABPN1*; late ptosis + dysphagia; **rimmed vacuoles**, 8.5-nm intranuclear tubular filaments.
- ▶ **LGMD** — new ENMC nomenclature: AD = **LGMD-D**, AR = **LGMD-R**; commonest adult types — calpainopathy (R1), FKRP (R9), anoctaminopathy (R12).
- ▶ **Always exclude treatable mimics** — immune-mediated necrotising myopathy (anti-HMGCR/anti-SRP) can mimic LGMD.

SOURCE & COVERAGE

- ▶ **Harrison's Principles of Internal Medicine, 22e** — “Muscular Dystrophies and Other Muscle Diseases” (Amato & Brown).

- **Bradley & Daroff's Neurology in Clinical Practice, 8e** — “Disorders of Skeletal Muscle” (dystrophin–glycoprotein complex, *DMD* gene structure/hot-spots, reading-frame rule, *DMD/BMD* clinical course and therapy including exon-skipping/ataluren, *LGMD* classification).

Myasthenia gravis

Asked in: Paper III Nov 2019 — RGUHS MD General Medicine

Definition / Introduction — Myasthenia gravis (MG) is the commonest primary disorder of the neuromuscular junction (NMJ), an **antibody-mediated autoimmune disease** characterised by **fatigable weakness of skeletal muscle**. The fundamental defect is a **reduction in the number of functioning acetylcholine receptors (AChRs)** at the post-synaptic muscle membrane, most often caused by anti-AChR antibodies, producing weakness that worsens with repeated activity and improves with rest. It is eminently treatable, with contemporary mortality falling from ~70% a century ago to the present 1–5%.

Pathophysiology and immunopathology

- **Normal transmission:** acetylcholine (ACh) is synthesised in the motor nerve terminal and stored in vesicles (quanta); a nerve action potential releases ACh from **150–200 vesicles**, which binds AChRs packed on the crests of post-synaptic folds. The **AChR is a pentamer (2 α , 1 β , 1 δ , and 1 γ or ϵ)** around a central cation pore; ACh binding opens the channel, Na⁺ entry depolarises the end-plate, and if large enough triggers a muscle action potential. Transmission is terminated by **acetylcholinesterase (AChE)**.
- **Clustering machinery:** presynaptic **agrin** binds **LRP4**; the agrin–LRP4 complex activates **MuSK** (muscle-specific tyrosine kinase), which recruits **DOK7** and **rapsyn** to cluster AChRs. These molecules underlie both autoimmune MG and the congenital myasthenic syndromes.
- **Core defect in MG:** fewer available AChRs **plus flattened, “simplified” post-synaptic folds** and a widened synaptic cleft → small end-plate potentials that fail to reach threshold → transmission failure. Normal **presynaptic “rundown”** (declining ACh release on repetitive activity) superimposed on this margin recruits fewer fibres with each impulse → clinical **fatigue** and the **decremental response** on repetitive nerve stimulation (RNS).
- **Anti-AChR antibodies (IgG, T-cell dependent)** reduce receptors by three mechanisms: (1) **cross-linking and accelerated endocytosis/turnover** of AChRs; (2) **complement-mediated lysis** of the post-synaptic membrane; (3) **direct blockade** of the ACh-binding site.
- **MuSK antibodies** are **IgG4** — they **do not fix complement** (hence anti-MuSK MG does not respond to complement inhibitors); they block MuSK–LRP4 binding. **LRP4 antibodies** are **IgG1**, complement-activating, like AChR antibodies.

- ▶ **Thymus:** abnormal in ~75% of AChR-antibody-positive patients — ~65% **hyperplastic** (germinal centres), ~10–15% **thymoma**. Thymic **myoid cells** express surface AChR and may initiate autosensitisation; **Treg deficiency/dysfunction** permits escape of autoreactive lymphocytes.

Clinical features and subtypes

- ▶ **Cardinal feature:** painless, **fatigable weakness** — worse with use and late in the day, better after rest/sleep; **fluctuating** course with exacerbations and remissions, especially in the first 1–3 years.
- ▶ **Ocular (initial in ~two-thirds):** **ptosis and diplopia**; if weakness stays confined to ocular muscles for ≥ 2 –3 years, generalisation is unlikely (**ocular MG**, ~10–15%; up to ~50–58% in Asians).
- ▶ **Bulbar/facial:** “snarling”/**myasthenic sneer** on smiling, **nasal regurgitation**, dysphagia, nasal or “mushy” dysarthria, hoarseness, fatigable chewing.
- ▶ **Axial/limb:** neck-extensor weakness $\rightarrow$ “**dropped-head**”; limb weakness typically **proximal and** may be asymmetric; **deep-tendon reflexes preserved**; **sensation normal**.
- ▶ **Generalisation** occurs in ~85% within ~3 years. **MuSK-MG:** prominent **bulbar, neck and respiratory** weakness with **muscle atrophy**, female predominance, often poor/worsening response to anticholinesterases.

Subtype	Onset / sex	Antibody	Thymus
Ocular	Any; childhood in Asia	AChR (~50%)	Usually normal
Early-onset (EOMG)	<50 y; F>M	AChR	Hyperplasia
Late-onset (LOMG)	>50 y; M>F	AChR $\pm$ titin, ryanodine	Normal/atrophic
Thymomatous	Peak ~50 y; M=F	AChR + striational (titin, ryanodine)	Thymoma
MuSK	30–50 y; marked F	MuSK (IgG4)	Normal/minimal
LRP4 / seronegative	Often younger	LRP4 (IgG1) / none detectable	Hyperplasia in some

MGFA clinical classification

- ▶ **Class I** — ocular weakness only ($\pm$ eyelid-closure weakness), all other muscles normal.
- ▶ **Class II** — mild generalised weakness; **III** — moderate; **IV** — severe generalised (each subdivided **a** = limb/axial predominant, **b** = bulbar/respiratory predominant).
- ▶ **Class V** — intubation (with or without ventilation) = **myasthenic crisis**. (*Harrison/landmark trials enrol “class II–IV” gMG and grade severity with MGADL and QMG scores.*)

Diagnosis and evaluation

- ▶ **Bedside provocation / clinical signs:** sustained upgaze provokes **ptosis**; Cogan’s “**lid twitch**” (lid overshoot on saccade from down- to up-gaze); **enhanced ptosis** / “**curtain sign**” (lifting one lid

worsens the other); “peek sign” and inability to “bury the eyelashes” on forced closure; **pseudo-internuclear ophthalmoplegia**; the **ice-pack test** — 2 min of cooling a ptotic lid producing ≥ 2 mm lid rise (high sensitivity).

- **Serology: anti-AChR antibody** (radioimmunoassay) — **~85% positive in generalised**, **~50% in ocular MG**; virtually diagnostic but a negative test does **not** exclude MG. **Anti-MuSK** in **~40% of AChR-negative generalised MG**; **anti-LRP4** in a small proportion of double-seronegatives. **Striational antibodies (titin, ryanodine)** are non-pathogenic but flag **thymoma/older or severe disease**.
- **Electrodiagnosis: RNS at 2–3 Hz shows a decrement >10%** (test weak/proximal muscles); **single-fibre EMG — increased jitter and blocking with normal fibre density** — is the most sensitive test (confirmatory but not specific).
- **Anticholinesterase test: edrophonium** historically (rapid onset/short action); now largely abandoned for serology/EMG.
- **Search for associated disease: chest CT/MRI** (thymoma — present in ~10–15%); **thyroid function** (hyper-/hypothyroidism in ~3–8%); screen for SLE/RA, and pre-immunosuppression work-up — TB, hepatitis, glucose/HbA1c, blood pressure, bone densitometry; baseline spirometry (FVC, MIP/MEP).

Differential diagnosis

Disorder	Distinguishing features
Lambert–Eaton myasthenic syndrome (LEMS)	Proximal lower-limb weakness, areflexia, autonomic symptoms (dry mouth, orthostasis); P/Q-type VGCC antibody; RNS shows decrement at low rate but $\geq 100\%$ increment at high rate (20–50 Hz)/post-exercise; ~paraneoplastic with SCLC. Treat with 3,4-DAP (amifampridine) + pyridostigmine
Congenital myasthenic syndromes	Non-autoimmune; onset infancy/childhood; seronegative ; >30 genes (commonest <i>CHRNε</i> , also <i>RAPSN</i> , <i>COLQ</i> , <i>DOK7</i>)
Botulism	Descending paralysis, dilated/poorly reactive pupils , autonomic features; incremental CMAP at high-rate RNS
Drug-induced / ICI-related MG	Penicillamine; checkpoint inhibitors (overlap myositis/myocarditis , high mortality)
Others	Graves’/thyroid ophthalmopathy, intracranial compressive lesion, oculopharyngeal dystrophy, mitochondrial PEO/Kearns–Sayre

Treatment

- ▶ **Symptomatic — anticholinesterase:** pyridostigmine 30–60 mg every 4–8 h (max ~360–480 mg/day); onset 15–30 min, lasts 3–4 h; muscarinic side effects (cramps, diarrhoea, salivation) countered by glycopyrrolate/loperamide. **Anti-MuSK patients respond poorly and may worsen.**
- ▶ **Thymectomy:** mandatory for **thymoma**; the MGTX trial showed extended trans-sternal thymectomy in **non-thymomatous, AChR-positive generalised MG** improves strength, lowers prednisone/second-line needs and hospitalisations — offer to patients <65 y unless purely ocular. Not established for MuSK/seronegative MG. Optimise strength (IVIg/PLEX) before surgery; **never an emergency procedure.**
- ▶ **Chronic immunosuppression: corticosteroids** — start low and up-titrate (or pre-treat with IVIg/PLEX before high dose to avoid early steroid worsening). **Steroid-sparing:** azathioprine (2–3 mg/kg; *avoid allopurinol*), mycophenolate mofetil (1–1.5 g bid), calcineurin inhibitors (cyclosporine/tacrolimus). **Rituximab** (anti-CD20) is **highly effective in MuSK-MG** and beneficial in new-onset disease (RINOMAX/RITUXIMAB data).
- ▶ **Newer targeted agents** — work within weeks, used as bridge or in refractory disease:
 - **Complement (C5) inhibitors:** eculizumab, ravulizumab (IV mAbs), zilucoplan (SC peptide) — only for **AChR-positive generalised MG**; **meningococcal vaccination required** (B + ACWY).
 - **FcRn antagonists:** efgartigimod (IV/SC), rozanolixizumab (SC; the **only one approved for both AChR- and MuSK-positive MG**) — increase IgG catabolism, lowering pathogenic antibody.
- ▶ **Rapid rescue:** plasmapheresis (5–6 exchanges) and IVIg 2 g/kg over 2–5 days — equally effective for crisis or peri-operative optimisation.

Myasthenic crisis and drugs to avoid

- ▶ **Myasthenic crisis** = exacerbation severe enough to threaten life, usually **ventilatory failure** needing intubation/NIV (= MGFA class V). Commonest trigger is **intercurrent infection**; manage in ICU with airway support, treat infection, and **PLEX or IVIg**. Distinguish from **cholinergic crisis** (anticholinesterase excess — now rare).
- ▶ **Drugs that worsen MG (avoid):** aminoglycosides, fluoroquinolones, macrolides; non-depolarising neuromuscular blockers; β -blockers; procainamide, quinine/quinidine, chloroquine/mefloquine; IV magnesium; penicillamine (can cause MG); botulinum toxin; immune-checkpoint inhibitors.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Diagram 1 — Normal vs myasthenic NMJ (side-by-side):** label *motor axon terminal*, *ACh vesicles (quanta)*, *active zone*, *voltage-gated Ca^{2+} channel*, *synaptic cleft*, *AChR on crests of post-synaptic folds*, *AChE*, *voltage-gated Na^{+} channels*, *agrin-LRP4-MuSK-DOK7-rapsyn*

clustering complex. On the MG side label: **reduced AChR number, flattened/simplified post-synaptic folds, widened synaptic cleft, AChR autoantibody + complement (membrane attack complex)**.

- ▶ **Diagram 2 — Myasthenic facies:** label **bilateral ptosis, compensatory frontalis contraction/raised eyebrow, myasthenic “snarl/sneer” on smiling, head drop**.

Clinical / Diagnostic significance

- ▶ **Pattern recognition:** fatigable, fluctuating weakness with **ocular onset, preserved reflexes and normal sensation** is the clinical signature; confirm with serology + RNS/SFEMG before committing to long-term immunotherapy and surgery.
- ▶ **Antibody status guides therapy:** MuSK-MG (IgG4) ignores complement inhibitors but responds to rituximab/rozanolixizumab; AChR-MG suits **complement inhibitors**.
- ▶ **Always image the chest** — thymoma changes management (mandatory thymectomy, striational-antibody association).
- ▶ **Monitor FVC/MIP/MEP serially;** falling vital capacity heralds crisis. **Vaccinate against meningococcus** before C5 inhibitors.
- ▶ **~20% achieve sustained remission;** thymectomy improves the odds in AChR-positive disease.

High-yield exam pointers

- ▶ Pentameric AChR ($2\alpha\beta\delta\gamma\epsilon$); ACh from 150–200 vesicles per impulse.
- ▶ Anti-AChR: 85% generalised / 50% ocular; anti-MuSK = ~40% of AChR-negative generalised MG (IgG4, no complement).
- ▶ RNS decrement >10% at 2–3 Hz; SFEMG jitter = most sensitive. MG decrements; LEMS increments.
- ▶ **Ice-pack test:** ≥ 2 mm lid rise after 2 min cooling. **Cogan lid-twitch, curtain sign, peek sign** are clinical clues.
- ▶ **Thymoma** in ~10–15%; **thymic hyperplasia** in ~65% of AChR-positive MG; F:M $\approx$ 3:2.
- ▶ **MGTX trial:** thymectomy benefits non-thymomatous AChR-positive generalised MG.
- ▶ **Crisis** = ventilatory failure $\rightarrow$ ICU + PLEX/IVIg; commonest trigger = infection.
- ▶ **Avoid:** aminoglycosides, quinolones, macrolides, β -blockers, magnesium, penicillamine, neuromuscular blockers, checkpoint inhibitors.
- ▶ MuSK-MG often worsens with anticholinesterases; treat with rituximab.

SOURCE & COVERAGE

- ▶ **Harrison's Principles of Internal Medicine, 22e** — “Myasthenia Gravis and Other Diseases of the Neuromuscular Junction” (pathophysiology, antibody mechanisms, diagnostic table, MGTX, complement/FcRn agents, crisis, drugs to avoid).
- ▶ **Bradley & Daroff's Neurology in Clinical Practice, 8e** — “Disorders of Neuromuscular Transmission” (clinical subtypes, ocular signs — lid twitch, curtain/peek sign, pseudo-INO; immunopathology, electrodiagnosis, HLA associations).
- ▶ **CMDT 2026** — “Nervous System Disorders: Myasthenia Gravis” (current drug doses, thymectomy and FcRn/complement-inhibitor management).

Coverage note: The full MGFA clinical classification (classes I–V with a/b subdivisions) is standard internal medicine; the corpus references MGFA “class II–IV” and the MGADL/QMG severity scores but does not tabulate every subclass. The older **Osserman classification** is not in the corpus and is omitted.

Narcolepsy

Asked in: Paper I May 2019 — RGUHS MD General Medicine

Definition / Introduction — Narcolepsy is a chronic, lifelong **central disorder of hypersomnolence** characterised by difficulty sustaining wakefulness, dysregulation of REM sleep (intrusion of REM phenomena into wakefulness) and disturbed nocturnal sleep. The cardinal feature is **excessive daytime sleepiness (EDS)** present in 100% of patients, classically accompanied by the *narcoleptic tetrad* of cataplexy, sleep paralysis and hypnagogic hallucinations. It results from selective loss of the hypothalamic **orexin (hypocretin)** neurons and affects about **1 in 2000** people, with onset typically between 10–30 years of age.

Pathophysiology — the orexin (hypocretin) deficiency

- ▶ Caused by **loss of the lateral/posterior hypothalamic neurons that produce orexin-A and orexin-B (hypocretin-1 and -2)** neuropeptides. Orexins normally promote long episodes of wakefulness and suppress REM sleep by exciting the wake-promoting monoaminergic nuclei (noradrenergic locus coeruleus, serotonergic raphe, histaminergic tuberomammillary nucleus).
- ▶ Loss of orexin signalling **destabilises the sleep–wake “flip-flop” switch** → frequent intrusions of sleep into wakefulness and **untimed REM sleep** (causing cataplexy, sleep paralysis, hallucinations).
- ▶ **Type 1 narcolepsy** (with cataplexy): near-complete (~90%) loss of orexin neurons → **very low/undetectable CSF orexin (hypocretin-1)**. **Type 2** (without cataplexy): orexin levels usually normal; partial neuronal loss or other uncharacterised mechanisms.

- ▶ **Autoimmune mechanism** (strongly supported): narcolepsy has the **strongest known HLA association** of any disease — ***HLA DQB1\06:02 is present in >90% of type 1 patients (CMDT: 85–95%) versus only 12–25% of the general population.** Hypothesised molecular mimicry*: *immune response to influenza, Streptococcus or other infections cross-reacts with orexin neurons in genetically susceptible (DQB1\06:02+) individuals*; patients show heightened T-cell responses (CD4⁺/CD8⁺) against orexin peptides.
- ▶ A documented **8- to 12-fold rise in childhood narcolepsy** followed the *Pandemrix* H1N1 influenza vaccine (AS03-adjuvanted) in Europe — supporting the infection/vaccine-triggered autoimmune model.
- ▶ **Secondary (“symptomatic”) narcolepsy**: damage to the hypothalamic orexin neurons or their projections by anti-Ma2 **paraneoplastic antibodies**, severe traumatic brain injury, diencephalic/midbrain tumours, strokes, multiple sclerosis, encephalitis or **Niemann-Pick disease type C**.

Clinical features — the narcoleptic tetrad and beyond

Feature	Frequency	Key clinical points
Excessive daytime sleepiness / sleep attacks	100%	Irresistible sleep at inappropriate times (talking, driving, eating); naps last minutes–20–30 min; patient wakes refreshed (unlike OSA)
Cataplexy	~60–70%	Sudden bilateral loss of muscle tone, consciousness retained ; triggered by strong emotion (laughter, excitement, anger >95%); spares respiratory and ocular muscles
Sleep paralysis	25–50%	Inability to move/speak at sleep onset (hypnagogic) or on waking (hypnopompic); lasts up to 15–20 min; frightening
Hypnagogic/hypnopompic hallucinations	20–40%	Vivid, often frightening visual (also auditory/vestibular) imagery at sleep–wake transition
Disturbed nocturnal sleep	70–80%	Fragmented sleep with frequent awakenings
Automatic behaviour	20–40%	Semi-purposeful acts (e.g., writing nonsense, driving to wrong place) with amnesia, from microsleeps

- ▶ **Cataplexy in detail:** muscle weakness from **decreased noradrenergic excitation + increased GABA/glycinergic inhibition of spinal motor neurons** — essentially REM atonia intruding into wakefulness. During the attack, muscle stretch reflexes, **H-reflex and F-responses are reduced/absent**; EEG shows wakefulness (if >1–2 min, REM appears). Usually appears months–years after sleep attacks; **status cataplecticus** may follow abrupt withdrawal of anticataplectic drugs.
- ▶ The full tetrad (all four) occurs in only ~10%; three of four in ~30%. **Cataplexy is the most specific symptom** — it occurs in almost no other disorder, hence it defines type 1.
- ▶ **Children** may present atypically with hyperactivity, prolonged nocturnal sleep, *cataplectic facies* (facial hypotonia, ptosis, tongue protrusion) or perioral dystonic movements unrelated to emotion.
- ▶ **Comorbidities:** obesity/raised BMI, type 2 diabetes, REM sleep behaviour disorder (up to 36%, often drug-induced), periodic limb movements (10–60%), sleep apnoea (~30%, often central), depression and anxiety.

Classification (ICSD-3) and diagnostic criteria

Narcolepsy is part of the **Central Disorders of Hypersomnolence** (ICSD-3, AASM 2014), which also include idiopathic hypersomnia, Kleine-Levin syndrome, hypersomnia due to a medical/medication/psychiatric disorder, and insufficient sleep syndrome.

Parameter	Narcolepsy type 1 (NT1)	Narcolepsy type 2 (NT2)
Older name	Narcolepsy with cataplexy / hypocretin-deficiency syndrome	Narcolepsy without cataplexy
Cataplexy	Present	Absent
CSF hypocretin-1	≤110 pg/mL (or ≤⅓ of normal mean)	>110 pg/mL (normal)
MSLT	Mean sleep latency ≤8 min + ≥2 SOREMPs (1 may be a sleep-onset REM on prior PSG)	Same MSLT criterion
HLA DQB1*06:02	~100% positive	~25% positive

- ▶ **Reclassification rule:** an NT2 patient later found to have CSF hypocretin-1 ≤110 pg/mL is reclassified as NT1.
- ▶ **Diagnostic workup:** clinical history (chronic EDS + cataplexy is often sufficient); quantify sleepiness with the **Epworth Sleepiness Scale**; confirm objectively with **overnight polysomnography (PSG)** followed next day by the **Multiple Sleep Latency Test (MSLT)**.
- ▶ **MSLT protocol:** five 20-minute nap opportunities every 2 hours; positive when **mean sleep latency <8 min and REM (SOREMP) in ≥2 naps**. A sleep-onset REM period within 15 min at

night is also supportive. **Stop stimulants 1 week and antidepressants 3 weeks** before the test (they suppress REM); ensure adequate prior sleep.

Differential diagnosis

- ▶ **Of sleep attacks / EDS:** obstructive sleep apnoea (most common cause; un-refreshing naps, snoring, obesity), insufficient sleep syndrome, **idiopathic hypersomnia** (prolonged un-refreshing sleep, “sleep drunkenness”, **no SOREMPs**, no cataplexy), Kleine-Levin syndrome (recurrent hypersomnia + hyperphagia + hypersexuality in young males), circadian rhythm disorders, drug/alcohol-related hypersomnolence.
- ▶ **Of cataplexy:** partial complex seizure (altered consciousness, postictal confusion, epileptiform EEG), absence and atonic seizures, drop attacks, syncope, vertebrobasilar insufficiency, basilar migraine, and **pseudocataplexy** (functional, triggered by negative thoughts, lasting minutes–hours).

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Hypnogram comparison (healthy vs narcolepsy)** — two stacked sleep-stage tracings against clock time. Labels: *Awake, REM, N1, N2, N3*; *clock time 20:00 → 16:00*; “**sleep-onset REM period (SOREMP) <15 min**”, “fragmented nocturnal sleep”, “frequent daytime naps containing REM” on the narcolepsy trace; “normal long NREM-before-REM latency” on the healthy trace.
- ▶ **Orexin pathophysiology schematic** — *lateral/posterior hypothalamus* with **orexin (hypocretin) neurons** projecting to wake-promoting nuclei (*locus coeruleus – NE; raphe – 5-HT; tuberomammillary nucleus – histamine*) and inhibiting **VLPO**. Show **autoimmune destruction** (label: *HLA DQB1*06:02, CD4⁺/CD8⁺ T cells, molecular mimicry, H1N1/Streptococcus**) → loss of orexin → unstable sleep–wake switch → “**EDS + REM intrusion (cataplexy, sleep paralysis, hallucinations)**”.

Clinical / Diagnostic significance

- ▶ **Investigations:** PSG + MSLT are the diagnostic standard; **CSF hypocretin-1 ≤ 110 pg/mL** is highly specific for NT1 and useful when MSLT is equivocal or REM-suppressing drugs cannot be stopped; ***HLA DQB1*06:02*** typing supports (but does not confirm — common in healthy people) the diagnosis. Screen for secondary causes (anti-Ma2, neuroimaging) if onset is atypical or focal signs are present.
- ▶ **Treatment is symptomatic** — there is no cure. Non-pharmacological: regular adequate nocturnal sleep, **scheduled 15–20 min afternoon naps**, sleep hygiene, support groups, and **driving counselling** (legal/safety responsibility — advise against driving until effectively treated).

Target	Drug (dose)	Class / mechanism
EDS	Modafinil 200–400 mg every morning	Wake-promoting agent (first line)
	Armodafinil 150–250 mg morning	R-isomer of modafinil, longer-acting
	Methylphenidate 10–20 mg bid; dextroamphetamine 10 mg bid	Stimulants (abuse/sympathomimetic risk)
	Solriamfetol 75–150 mg/day	Norepinephrine–dopamine reuptake inhibitor
	Pitolisant 8.9–35.6 mg/day	Selective histamine H3 receptor antagonist/inverse agonist
Cataplexy	Venlafaxine 37.5–150 mg; fluoxetine 10–40 mg	SNRI / SSRI (suppress REM)
	Protriptyline 10–40 mg/d; clomipramine 25–50 mg/d (imipramine)	TCAs (anticholinergic limits use)
Both EDS + cataplexy + fragmented sleep	Sodium oxybate (gamma-hydroxybutyrate) 3–9 g in 2 nightly divided doses (bedtime + 2.5–4 h later); low-sodium (calcium/magnesium/potassium/sodium oxybate) versions	Consolidates slow-wave sleep

- ▶ No antidepressant is FDA-approved specifically for narcolepsy, though they are standard for cataplexy. **Pitolisant and oxybates** uniquely improve both sleepiness and cataplexy.

High-yield exam pointers

- ▶ **Narcoleptic tetrad** = EDS + cataplexy + sleep paralysis + hypnagogic hallucinations; only ~10% have all four, EDS is universal.
- ▶ **NT1** = cataplexy + CSF hypocretin-1 ≤ 110 pg/mL; **NT2** = no cataplexy, normal hypocretin.
- ▶ ***HLA DQB1*06:02**** — strongest HLA disease association; >90% of NT1 but present in 12–25% of normals (not diagnostic alone).
- ▶ **MSLT diagnostic**: mean sleep latency <8 min + ≥ 2 SOREMPs; SOREMP <15 min at night supportive.
- ▶ **Cataplexy** = sudden emotion-triggered atonia with **preserved consciousness**, spares respiratory/ocular muscles; abolished reflexes; most specific feature.
- ▶ **Pandemrix H1N1 vaccine** and influenza/*Streptococcus* → autoimmune trigger via molecular mimicry.
- ▶ **First-line for EDS** = modafinil; newer agents **pitolisant** (H3 inverse agonist) and **solriamfetol** (NDRI).

- ▶ Sodium oxybate (GHB) treats EDS, cataplexy and disrupted night sleep together.
- ▶ Stop stimulants 1 week and antidepressants 3 weeks before MSLT to avoid REM suppression.

Orthostatic hypotension

Asked in: Paper II Sep 2025 — RGUHS MD General Medicine

Definition / Introduction — Orthostatic (postural) hypotension (OH) is defined (Freeman *et al.*, 2011 consensus) as a sustained fall in systolic blood pressure (SBP) ≥ 20 mmHg or in diastolic blood pressure (DBP) ≥ 10 mmHg within 3 minutes of active standing or of head-up tilt (HUT) $\geq 60^\circ$. In patients with supine hypertension a drop of $\geq 30/15$ mmHg is used. It is a cardinal sign of sympathetic vasoconstrictor (autonomic) failure and a major cause of orthostatic intolerance, falls, syncope and increased mortality, especially in the elderly and in neurodegenerative disease. Prevalence rises from $<5\%$ below age 50 to $\sim 20\%$ above age 70.

Normal orthostatic homeostasis and pathophysiology

- ▶ On standing, ~ 500 – 700 mL of blood (Bradley: 300 – 800 mL) pools in the lower limbs and splanchnic venous bed, reducing venous return, cardiac filling and stroke volume.
- ▶ The fall in BP unloads aortic/carotid baroreceptors $\rightarrow$ reduced afferent traffic to the *nucleus tractus solitarius* $\rightarrow$ reflex sympathetic activation (arteriolar + venoconstriction, $\uparrow$ heart rate, $\uparrow$ contractility) and vagal withdrawal.
- ▶ Net normal response: SBP changes little (falls ~ 10 mmHg), DBP rises ~ 5 mmHg, heart rate rises 5 – 20 beats/min; the leg and abdominal muscle pump aids venous return.
- ▶ OH results when this reflex arc fails at any level — afferent (baroreceptors), central integration, efferent sympathetic outflow, or peripheral release of norepinephrine — or when cardiac output/intravascular volume is inadequate.
- ▶ The hallmark of neurogenic OH (NOH) is inadequate peripheral norepinephrine release $\rightarrow$ failure of vasoconstriction, with a blunted compensatory tachycardia.

Diagnostic criteria and variants

Variant	Defining features
Classical OH	Sustained $\downarrow$ SBP ≥ 20 or $\downarrow$ DBP ≥ 10 mmHg within 3 min of standing/HUT
OH with supine hypertension	Orthostatic drop $\geq 30/15$ mmHg
Initial OH	Transient $\downarrow$ SBP > 40 / $\downarrow$ DBP > 20 mmHg within 15–30 s, recovering by 45 s; young subjects; cardiac output–vascular resistance mismatch (not autonomic failure)
Delayed (late) OH	SBP steady for first 3–5 min then falls (sometimes only after 10 min tilt); early/mild adrenergic failure
Postprandial OH	BP fall within ~ 2 h of a large, high-carbohydrate meal $\pm$ alcohol (splanchnic pooling); elderly/autonomic patients

- **Neurogenic vs non-neurogenic OH** — a compensatory HR rise > 15 beats/min indicates *non-neurogenic* OH (volume depletion, drugs, cardiac); HR rise < 15 beats/min suggests **neurogenic OH**.
- A more accurate marker is the $\Delta\text{HR}/\Delta\text{SBP}$ ratio (cardiac baroreflex gain): < 0.5 beats/min/mmHg after 3 min strongly indicates NOH.

Etiology

Neurogenic OH (autonomic failure)	Non-neurogenic OH
Primary (synucleinopathies): Multiple system atrophy (MSA / Shy-Drager), Parkinson's disease with autonomic failure, Dementia with Lewy bodies, Pure autonomic failure (Bradbury-Eggleston)	Volume depletion: haemorrhage, vomiting/diarrhoea, dehydration, over-diuresis, dialysis
Secondary peripheral autonomic neuropathies: Diabetic autonomic neuropathy, amyloidosis (AL & hereditary ATTR), autoimmune autonomic ganglionopathy (anti-g-AChR $\alpha 3$), paraneoplastic, Sjögren, GBS, HIV, porphyria, alcoholic, B12 deficiency	Cardiac: heart failure, chronotropic incompetence, bradyarrhythmias
Hereditary: Familial dysautonomia (Riley-Day / HSAN III), dopamine β -hydroxylase (DBH) deficiency	Drug-induced (very common): α -blockers, diuretics, nitrates/vasodilators, tricyclics, phenothiazines/antipsychotics, dopamine agonists, antihypertensives
Spinal cord: traumatic quadriplegia, syringomyelia, MS	Endocrine: Addison disease, hypoadosteronism, pheochromocytoma; vasodilator excess (mastocytosis, carcinoid)

Clinical features

- ▶ **Cerebral hypoperfusion:** lightheadedness/dizziness on standing (commonest), presyncope, blurred or tunnel vision, cognitive slowing/"brain fog", **syncope and falls**.
- ▶ **Regional ischaemia:** "coat-hanger" neck/shoulder/sub-occipital pain (cervical-trapezius muscle ischaemia); **platypnea** (orthostatic dyspnoea from apical lung hypoperfusion); orthostatic angina; orthostatic headache.
- ▶ **Triggers:** rising in the morning (worst after bed rest), large meals/alcohol, heat, fever, exercise, hyperventilation, sepsis, surgery, intensified antihypertensives.
- ▶ Many patients — especially with chronic NOH — are **asymptomatic or present only with falls**, because cerebral autoregulation compensates; symptom reports alone are unreliable in the elderly.
- ▶ **Supine hypertension** coexists in >50% of autonomic-failure OH (baroreflex impairment), giving "reverse dipping" (higher nocturnal than morning BP) and end-organ damage.
- ▶ **Functional classes I–IV** grade severity from asymptomatic (class I) to severe daily disabling symptoms (class IV).

Investigations / autonomic testing

- ▶ **Bedside orthostatic vitals** — supine BP/HR, then BP/HR at **1 and 3 min** of standing (gold-standard bedside test); repeat as a single reading may mislead.
- ▶ **Tilt-table testing (60–70°)** with beat-to-beat finger arterial pressure — detects OH/NOH and distinguishes vasovagal, vasodepressor and cardioinhibitory syncope; pharmacologic provocation (nitroglycerin/isoproterenol) increases sensitivity.
- ▶ **Cardiovascular autonomic reflexes:** heart-rate variation to deep breathing and the **Valsalva manoeuvre/ratio** (parasympathetic/baroreflex), BP response to Valsalva (sympathetic adrenergic).
- ▶ **Sudomotor tests:** **QSART** (postganglionic sudomotor), **thermoregulatory sweat test** (pre- + postganglionic); **skin punch biopsy** for epidermal nerve fibre density and **phosphorylated α -synuclein** deposits (synucleinopathy).
- ▶ **Plasma catecholamines (supine + upright):** central/preganglionic NOH — normal supine NE that fails to rise on standing; peripheral/postganglionic — **low supine NE** (PAF often <200, even <100 pg/mL) failing to rise.
- ▶ **Bloods to find a cause:** CBC, metabolic panel, HbA1c/2-h GTT, B12, ferritin, vitamin D; serum free light chains/SPEP (amyloid); ganglionic AChR & paraneoplastic antibodies; TTR gene testing; fat-pad aspirate if amyloid suspected.

Management

Non-pharmacologic (first-line, often sufficient in mild/early OH):

- ▶ **Withdraw/reduce offending drugs** (diuretics, α -blockers, nitrates, tricyclics, antipsychotics, dopamine agonists) and correct iron/B12/D deficiency, anaemia, volume depletion.
- ▶ **↑Fluid to ~2–3 L/day and salt to 2 g, 2–3×/day**; a rapid **500 mL water bolus** gives a useful short-term pressor response.
- ▶ **Staged posture changes, physical counter-manoevres** (leg-crossing, leg/abdominal muscle tensing, squatting), **waist-high compression stockings** and an **abdominal binder** (reduces splanchnic pooling).
- ▶ **Head-of-bed elevation 30° at night** — reduces supine hypertension, nocturnal natriuresis and nocturia.

Drug	Class / action	Dose	Caution
Fludrocortisone	Mineralocorticoid — volume expansion + mild α -effect	0.1–0.2 (up to 0.4) mg morning	Supine HTN, hypokalaemia, oedema; check bone density long-term
Midodrine	Direct α_1 -agonist	2.5 mg TID → 15 mg TID (usual 7.5–10)	Onset 30–60 min, lasts ~4 h; last dose before 6 pm ; scalp tingling, piloerection, urinary urgency, supine HTN
Droxidopa	Norepinephrine precursor (newest agent, approved for NOH)	100 → 400–600 mg TID	Supine HTN; reduces falls in PD
Pyridostigmine	Cholinesterase inhibitor (↑ganglionic transmission)	30 → 60 mg TID	No supine HTN ; helps GI hypomotility; cramps/diarrhoea
Atomoxetine	NE-reuptake inhibitor (adjuvant)	18 mg morning	CNS stimulation, tremor, anxiety
Desmopressin (DDAVP)	↑water reabsorption	low oral/nasal at night	Reduces nocturia; monitor for hyponatraemia

- ▶ **Supine hypertension** complicating treatment: keep head of bed up, short-acting bedtime antihypertensive, monitor end-organ function; avoid long-acting pressors late in the day.
- ▶ **DBH deficiency** is uniquely treated by **droxidopa** (replaces absent norepinephrine).

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Baroreflex arc on standing**: label — *gravitational blood pooling (lower limbs + splanchnic bed), ↓venous return / ↓stroke volume, aortic & carotid sinus baroreceptors, nucleus tractus solitarius (medulla), sympathetic efferent (norepinephrine → vasoconstriction, ↑HR,*

↑*contractility*), *vagal withdrawal*; mark the **site of failure in neurogenic OH** (reduced peripheral NE release).

- ▶ **Tilt-table tracing (BP & HR vs time):** label — *supine baseline (with supine hypertension ~175 mmHg), tilt-up, progressive sustained fall in SBP ≥ 20 mmHg, blunted/absent compensatory HR rise (< 15 bpm) = neurogenic OH* (contrast with POTS: HR rise ≥ 30 bpm without sustained OH).

Clinical / Diagnostic significance

- ▶ OH is an **independent predictor of falls, fractures, coronary heart disease, heart failure, stroke and death**; NOH carries a grim prognosis — mortality ~44% at 30 months and >60% at 10 years (Bradley: 64% 10-year mortality), mostly from synucleinopathies and diabetes.
- ▶ It is a **key early clue to MSA** (symptomatic OH within 2 years, poor levodopa response, “hot cross bun” pons sign, glial cytoplasmic α -synuclein inclusions; cardiac MIBG uptake preserved in MSA but reduced in PD/DLB/PAF).
- ▶ Distinguish from **POTS** (chronic orthostatic intolerance + HR rise ≥ 30 bpm [≥ 40 if < 19 yr] without sustained OH) and from **reflex/vasovagal syncope**.
- ▶ Always **measure both supine and standing BP at 1 and 3 min** in any patient with falls, syncope, dizziness, frailty or polypharmacy — the diagnosis is easily missed.

High-yield exam pointers

- ▶ OH = $\downarrow$ SBP ≥ 20 or $\downarrow$ DBP ≥ 10 mmHg within 3 min of standing/tilt ($\geq 30/15$ if supine HTN) — Freeman 2011 consensus.
- ▶ **Neurogenic vs non-neurogenic:** HR rise < 15 bpm or $\Delta\text{HR}/\Delta\text{SBP} < 0.5$ bpm/mmHg = neurogenic.
- ▶ **Initial OH** ($> 40/20$ mmHg, < 30 s, young, recovers by 45 s) is **not** autonomic failure; **delayed OH** is beyond 3 min.
- ▶ **Coat-hanger headache** (neck/shoulder muscle ischaemia) and **platypnea** are characteristic clues.
- ▶ Commonest **primary** cause = **synucleinopathies** (MSA/Shy-Drager, PD, DLB, PAF); commonest **secondary** = diabetic autonomic neuropathy; commonest **reversible** cause = **drugs**.
- ▶ **>50% of autonomic-failure OH have supine hypertension** (“reverse dipping”).
- ▶ First-line drugs: **fludrocortisone** and **midodrine**; **droxidopa** for NOH; **pyridostigmine** avoids supine HTN.
- ▶ **Midodrine last dose before 6 pm**; salt 2 g TID, fluids 2–3 L/day, **500 mL water bolus** = rapid pressor; **head-up tilt 30°** at night.

Posterior circulation stroke

Asked in: Paper III May 2022 · Paper II May 2019 (2×) — RGUHS MD General Medicine

Definition / Introduction — *Posterior (vertebrobasilar) circulation stroke* is ischemic infarction within the territory supplied by the paired **vertebral arteries**, the **basilar artery** and the paired **posterior cerebral arteries (PCAs)**, which together perfuse the brainstem, cerebellum, thalamus, occipital lobes and medial temporal lobes. Because the brainstem packs long tracts, cranial-nerve nuclei and reticular structures in close apposition, occlusion of each vessel produces its own distinctive, often eponymous syndrome. The hallmark of brainstem ischemia is “**crossed**” **findings** — ipsilateral cranial-nerve signs with contralateral long-tract (motor/sensory) signs. Basilar occlusion in particular is a treatable but potentially devastating emergency carrying high mortality.

Vascular anatomy (basis of localization)

- ▶ **Vertebral artery** — arises from the innominate artery on the right and the subclavian artery on the left; four segments: **V1** (origin to C6 transverse foramen), **V2** (C6→C2), **V3** (around the atlas to pierce dura at the foramen magnum), **V4** (intracranial). The two vertebrals join to form the basilar at the **pontomedullary junction**; only **V4** gives branches to brainstem/cerebellum.
- ▶ **Posterior inferior cerebellar artery (PICA)** — proximal segment supplies the **lateral medulla**; distal branches supply the inferior cerebellar surface.
- ▶ **Basilar artery** — supplies the base of the pons and superior cerebellum via **three branch groups**: (1) **paramedian** (7–10) → medial pontine wedge; (2) **short circumferential** (5–7) → lateral two-thirds of pons + middle/superior cerebellar peduncles; (3) **bilateral long circumferential** = **superior cerebellar (SCA)** and **anterior inferior cerebellar (AICA)** arteries → cerebellar hemispheres. The basilar divides into two PCAs in the **interpeduncular fossa**.
- ▶ **PCA origin variants** — both PCAs arise from the basilar bifurcation in **75%**; in **20%**, one arises from the ipsilateral ICA via the posterior communicating artery (“**fetal**” PCA); in **5%**, both arise

from the ICAs. PCA divides at the posterior communicating artery into a proximal **P1** (precommunal) and distal **P2** segment.

Aetiology and mechanisms

- ▶ **Atherothrombosis** — predilection for **V1 and V4** segments of the vertebral artery; basilar atheroma is most frequent in the **proximal basilar and distal vertebral** segments. In-situ thrombosis of small penetrating (perforator) branches causes lacunar brainstem strokes.
- ▶ **Embolism** — cardiac or artery-to-artery emboli from proximal vertebral/basilar lodge at the **top of the basilar** (“top-of-the-basilar” syndrome) or at the PCA.
- ▶ **Arterial dissection** — vertebral artery dissection (V2/V3 mobile segments; spontaneous, traumatic, or after **spinal manipulative therapy**); a vertebral dissection may extend into the basilar.
- ▶ **Fibromuscular dysplasia** and, rarely, **osteophytic** encroachment in the vertebral foramina.
- ▶ **Subclavian steal** — subclavian occlusion proximal to the vertebral origin reverses ipsilateral vertebral flow; ipsilateral arm exercise “steals” flow and provokes posterior-circulation TIAs.

Clinical syndromes by arterial territory

Artery / territory	Eponym	Key clinical features (source-grounded)
PCA – P1 (midbrain/thalamus)	Weber	Ipsilateral CN III palsy + contralateral hemiplegia (cerebral peduncle)
PCA – P1	Claude	Ipsilateral CN III palsy + contralateral cerebellar ataxia (red nucleus/dentatothalamic tract)
PCA – thalamogeniculate perforators	Déjérine-Roussy	Contralateral hemisensory loss → later searing/burning thalamic pain
PCA – artery of Percheron	—	Bilateral paramedian thalamic infarct: upgaze paresis, drowsiness, abulia
PCA – P2 (occipitotemporal)	—	Contralateral homonymous hemianopia (without macular sparing) ; alexia without agraphia; amnesia; peduncular hallucinosis
Bilateral distal PCA	Anton / Balint	Cortical blindness with denial (Anton); disordered visual scanning (Balint)

Artery / territory	Eponym	Key clinical features (source-grounded)
Vertebral/PICA – lateral medulla	Wallenberg	(see focused box)
Vertebral – medial medulla	Dejerine medial medullary	Contralateral hemiparesis sparing face + position-sense loss + ipsilateral tongue weakness (CN XII)
Basilar – complete	Locked-in	Quadriplegia + bilateral cranial-nerve signs, preserved consciousness
SCA	—	Severe ipsilateral cerebellar ataxia, N/V, dysarthria; contralateral pain/temp loss (limbs, body, face)
AICA	—	Ipsilateral deafness, facial weakness, vertigo, tinnitus, ataxia, Horner; contralateral pain/temp loss

Lateral medullary (Wallenberg) syndrome — high-yield focus

- **Cause** — embolic occlusion/thrombosis of the **V4 vertebral segment** in most cases; **PICA** occlusion in the remainder.
- **Ipsilateral** — facial pain/numbness (descending trigeminal tract), **Horner's syndrome** (descending sympathetic tract), cerebellar ataxia/falling to side of lesion, **dysphagia, hoarseness, palatal/vocal-cord palsy, diminished gag** (CN IX–X, nucleus ambiguus), vertigo/nystagmus (vestibular nuclei).
- **Contralateral** — impaired pain and temperature over the body (spinothalamic tract).
- **Key pearl** — **hemiparesis is NOT typical**; its presence points elsewhere. Dysphagia and aspiration risk dominate management.

Top-of-the-basilar and basilar occlusion

- **Top-of-the-basilar (embolic)** — sudden **bilateral** signs: ptosis, pupillary asymmetry/unreactive pupils, somnolence; vertical-gaze palsy; posturing and **myoclonic jerks simulating seizure**; visual and behavioural disturbances.
- **Complete basilar occlusion** — constellation of **bilateral long-tract signs (motor + sensory) with cranial-nerve and cerebellar dysfunction**; a “**locked-in**” state (preserved awareness, quadriplegia, anarthria, vertical eye/blink-only communication) indicates complete pontine + lower midbrain infarction. Carries **high mortality**.

- ▶ **Warning prodrome** — repetitive short-lived TIAs (5–30 min, several/day) with vertigo, diplopia, dysarthria, circumoral numbness; a “**herald hemiparesis**” may precede basilar occlusion. Recognising impending basilar occlusion *before* infarction is the therapeutic goal.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Diagram 1 — Posterior circulation arterial tree (Harrison Fig. 437-6):** Draw the two vertebral arteries uniting into the **basilar artery**, then the basilar bifurcating into both **posterior cerebral arteries**. Label: *Vertebral artery, Basilar artery, Posterior inferior cerebellar artery (PICA), Anterior inferior cerebellar artery (AICA), Superior cerebellar artery (SCA), Posterior cerebral artery (PCA), Posterior communicating artery, Deep penetrating (paramedian) branches of the basilar artery.*
- ▶ **Diagram 2 — Axial medulla for Wallenberg syndrome (Fig. 437-7):** Cross-section of medulla labelling the shaded **lateral medullary zone**: *Spinothalamic tract, Descending sympathetic tract (Horner), Nucleus ambiguus (CN IX–X), Vestibular nucleus, Spinal tract/nucleus of CN V, Inferior cerebellar peduncle (restiform body), Inferior olive, Pyramid (medial — spared).*

Clinical / Diagnostic significance

- ▶ **Imaging** — Non-contrast CT excludes haemorrhage but **frequently misses posterior-fossa infarcts** owing to bone (beam-hardening) artefact; look for the **hyperdense basilar artery sign** (intraluminal thrombus). CTA (aortic arch to vertex) confirms vertebral/basilar occlusion and selects thrombectomy targets. **MRI with DWI** is markedly superior to CT for brainstem/cerebellar ischemia.
- ▶ **Acute reperfusion** — **IV thrombolysis** with alteplase (rtPA 0.9 mg/kg, max 90 mg; 10% bolus) or tenecteplase 0.25 mg/kg IV bolus within 4.5 h of last-known-well, after excluding haemorrhage. **Endovascular mechanical thrombectomy** for large-vessel occlusion (ICA/M1–M2 or **basilar artery**) up to 24 h with perfusion-imaging selection in the 6–24 h window; **basilar thrombectomy can be life-saving**.
- ▶ **Cerebellar infarction is a neurosurgical emergency** — may mimic labyrinthitis (vertigo, vomiting); even small oedema obstructs the 4th ventricle/aqueduct causing **hydrocephalus** and **brainstem compression** → **coma and respiratory arrest**. **Suboccipital (posterior-fossa) decompression** is recommended for deteriorating patients and should precede significant brainstem compression. Head/neck pain should prompt suspicion of **vertebral dissection**.
- ▶ **Secondary prevention** — antiplatelet therapy / risk-factor control for atherothrombotic disease; anticoagulation for cardioembolism; dissection managed with antithrombotics. **Déjérine-Roussy thalamic pain** responds poorly to analgesics — use **carbamazepine, gabapentin, or tricyclic antidepressants**.

High-yield exam pointers

- ▶ Posterior circulation = **vertebrals + basilar + PCAs**; vertebrals fuse at the **pontomedullary junction**, basilar splits at the **interpeduncular fossa**.
- ▶ **Crossed signs** (ipsilateral CN + contralateral long tract) localize to the brainstem.
- ▶ **Wallenberg** = V4/PICA; vertigo, ipsilateral Horner + bulbar palsy + facial sensory loss, contralateral body pain/temp loss, **no hemiparesis**.
- ▶ **Weber** = CN III + contralateral hemiplegia; **Claude** = CN III + contralateral ataxia; **Benedikt-type** features (red nucleus tremor) overlap.
- ▶ **PCA P2** → homonymous hemianopia **without macular sparing**; bilateral → **Anton's syndrome** (cortical blindness with denial).
- ▶ **Locked-in syndrome** = ventral pontine infarct; conscious, quadriplegic, communicates by **vertical eye movements/blinking**.
- ▶ **Hyperdense basilar artery sign**; CT misses posterior-fossa strokes — get MRI-DWI.
- ▶ **Cerebellar infarct** → watch for hydrocephalus/herniation → **suboccipital decompression**.
- ▶ Reperfusion: **thrombolysis ≤4.5 h**, **thrombectomy ≤24 h** (basilar occlusion can be salvaged).

SOURCE & COVERAGE

Harrison 22e — Ch 437 “Introduction to Cerebrovascular Diseases” (posterior-circulation anatomy and clinical syndromes, Figs. 437-5 to 437-11) + Ch 438 “Ischemic Stroke” (thrombolysis, thrombectomy, cerebellar-infarct decompression). Coverage note: All territory syndromes, eponyms, anatomy, imaging and acute-management points above are sourced from these two chapters. *Benedikt's syndrome* is named as a standard textbook overlap of the P1 midbrain syndrome (red-nucleus involvement) but is not given that eponym verbatim in the provided text; the underlying lesion (dentatorubrothalamic/red nucleus with rubral tremor) is described. Vertebral-artery segmental anatomy detail and Brazis-style localization tables corroborate the same content.

Posterior Reversible Encephalopathy Syndrome

Asked in: Paper III Nov 2021 — RGUHS MD General Medicine

Definition / Introduction — Posterior Reversible Encephalopathy Syndrome (PRES) is a clinico-radiological syndrome of acute neurological dysfunction (headache, seizures, altered consciousness, visual loss) accompanied by characteristic **vasogenic oedema** that predominantly affects the **posterior (parieto-occipital) white matter**. Harrison groups it among the **hyperperfusion disorders**, in which seemingly diverse conditions — hypertensive encephalopathy, eclampsia, post-carotid endarterectomy syndrome and calcineurin-inhibitor/drug toxicity — share a final common pathway of **hyperperfusion**.

due to endothelial dysfunction. The term is partly a misnomer: the syndrome is *not always reversible* and is *not always limited to the posterior brain*.

Pathophysiology

- ▶ The brain maintains nearly **constant cerebral blood flow (CBF)** across a wide range of systemic pressures by **autoregulation** — arteriolar vasodilation when systemic BP falls and arteriolar vasoconstriction when it rises. **Cerebral perfusion pressure (CPP) = MAP – ICP**.
- ▶ Beyond the upper limit of autoregulation, flow becomes **pressure-dependent**, producing hyperperfusion. **Vasogenic oedema** is the primary process causing neurological dysfunction.
- ▶ Two mechanisms are proposed (both probably contribute in every case):
 - **Exceeding the cerebral autoregulatory threshold** → increased CBF with **capillary leakage of fluid into the interstitium** (the “increased-pressure / breakthrough” model).
 - **Direct impairment of the blood–brain barrier (BBB)** itself by toxic or autoimmune endothelial injury (the “endothelial-dysfunction” model).
- ▶ **Why posterior predilection?** The posterior (vertebrobasilar) circulation is postulated to have a **lower threshold for autoregulatory breakthrough** and/or a **vasculopathy that is more common in these vessels**, owing to relatively sparse sympathetic innervation.
- ▶ A **noninflammatory vasculopathy** (vascular narrowing, especially in the posterior circulation) may be seen on vessel imaging; whether it is a primary cause of the oedema or a secondary phenomenon remains unclear.

Etiology / Classification

Harrison (Table 318-3) divides the causes mechanistically into those dominated by **raised capillary pressure** and those dominated by **endothelial dysfunction**.

Mechanism	Representative etiologies
Increased capillary pressure dominates	Hypertensive encephalopathy, including secondary causes — renovascular hypertension, pheochromocytoma, cocaine use
	Post-carotid endarterectomy syndrome
	Pre-eclampsia / eclampsia
Endothelial dysfunction dominates	Calcineurin-inhibitor toxicity — cyclosporine, tacrolimus
	Chemotherapeutic agent toxicity — cytarabine, azathioprine, 5-fluorouracil, cisplatin, methotrexate, TNF- α antagonists
	HELLP syndrome (hemolysis, elevated liver enzymes, low platelets)

Mechanism	Representative etiologies
	Hemolytic-uremic syndrome (HUS)

- ▶ **Drug culprits behave atypically:** cyclosporine (and other agents) can precipitate PRES even at low doses or after years of treatment, and a normal serum drug level does not exclude the drug as the trigger.
- ▶ **Rapidity of BP rise, rather than the absolute value of pressure, appears to be the most important risk factor** — explaining why PRES can occur at modest BP in previously normotensive patients (e.g., eclampsia, post-transplant).

Clinical features

- ▶ **Headache** — non-specific, ranging from mild to severe; no characteristic quality.
- ▶ **Seizures** — frequent and often the presenting event; of multiple types depending on the severity and location of oedema. **Nonconvulsive seizures occur**, so a **low threshold for EEG** must be maintained.
- ▶ **Altered consciousness** — a spectrum from confusion to coma.
- ▶ **Focal neurological deficits** — the typical deficit is **cortical visual loss** (cortical blindness), reflecting the **occipital-lobe** involvement; visual hallucinations and field defects may occur.
- ▶ **Any focal deficit can occur** depending on the territory affected — e.g., after carotid endarterectomy, deficits referable to the **ipsilateral, newly reperfused hemisphere**.

Investigations / Neuroimaging

- ▶ **MRI is the investigation of choice.** Classically shows **high T2 / FLAIR signal of oedema, predominantly in the posterior occipital lobes, not respecting any single vascular territory** (Harrison Fig. 318-7 — a patient on cyclosporine after liver transplant presenting with seizures, headache and cortical blindness, with bilateral occipital white-matter signal change).
- ▶ **CT is less sensitive** but may show **patchy hypodensity** in the involved territory.
- ▶ **Vessel imaging** (MRA/CTA/angiography) may demonstrate **vascular narrowing, especially in the posterior circulation** (the noninflammatory vasculopathy).
- ▶ **CSF analysis** is often performed to exclude mimics but **yields nonspecific results**.
- ▶ **EEG** — used liberally because nonconvulsive status epilepticus is common; **continuous EEG monitoring** is often required.
- ▶ Serum studies to identify the precipitant (BP trend, renal/hepatic function, platelets and LDH for HELLP/HUS, pregnancy status); remember that **normal calcineurin-inhibitor levels do not exclude drug-induced PRES**.

Management

- ▶ **Treat the precipitant and lower the blood pressure judiciously** — the two pillars of therapy.

- ▶ **Antihypertensive therapy (when BP is elevated):** use titratable IV agents — **labetalol** or **nicardipine** (per Ch 318). In the broader setting of a **hypertensive emergency** (SBP/DBP $\geq 180/100$ with end-organ damage), Harrison (Ch 288) lists **IV nicardipine** (most commonly used; avoid in severe aortic stenosis), **IV labetalol** (avoid in obstructive airways disease/COPD, bradycardia, second-/third-degree block) and **IV sodium nitroprusside**.
- ▶ **Controlled, not abrupt, BP reduction:** if BP is very high, **lower the MAP by ~20% initially**. Over-aggressive lowering may drop perfusion **below the patient's autoregulatory range and precipitate secondary ischaemia/infarction**. Aim for reduction rather than immediate normalisation, then transition to oral agents.
- ▶ **Remove / reduce the offending drug:** lower the dose of or discontinue the **calcineurin inhibitor** (cyclosporine, tacrolimus); **sirolimus** (few recorded neurotoxic cases) may be a reasonable alternative in transplant patients.
- ▶ **Seizure control:** identify and treat seizures; **anticonvulsants are effective** when seizure activity is documented. In the **special case of eclampsia**, **magnesium sulfate** is the agent of choice for seizure control (and definitive treatment is delivery of the fetus).
- ▶ **Treat the underlying medical condition** — e.g., delivery in eclampsia, management of HELLP/HUS, withdrawal of cocaine/sympathomimetics, resection of pheochromocytoma.
- ▶ **Supportive neurocritical care** — control of cerebral oedema and seizures, with serial imaging to confirm radiological resolution.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Axial brain MRI (FLAIR) in PRES** — draw both cerebral hemispheres at the occipital level; shade **bilateral, symmetric high-signal (white) areas in the parieto-occipital white matter**. Labels: *Occipital lobe (parieto-occipital white matter oedema), Bilateral / symmetric, Vasogenic oedema — high T2/FLAIR signal, Does not respect a single vascular territory, Relative cortical sparing, Posterior > anterior distribution.*
- ▶ **Cerebral autoregulation curve** — plot CBF (y-axis) against MAP/CPP (x-axis). Labels: *Autoregulatory plateau (constant CBF), Lower limit (below which CBF falls — ischaemia), Upper limit / breakthrough (above which CBF rises — hyperperfusion → vasogenic oedema → PRES), Arteriolar vasodilation (low BP), Arteriolar vasoconstriction (high BP).*

Clinical / Diagnostic significance

- ▶ PRES is a **treatable, frequently reversible cause of acute encephalopathy/seizures/cortical blindness** — prompt recognition and BP/drug control usually reverse the clinical and radiological abnormalities; delayed or excessive BP lowering risks **infarction and irreversible deficits**.

- ▶ **High-yield clinical contexts:** eclampsia/HELLP in obstetrics, post-transplant patients on calcineurin inhibitors, chemotherapy recipients, hypertensive emergency, renovascular hypertension and pheochromocytoma, and cocaine/sympathomimetic use.
- ▶ Always **review the full medication list** in any transplant or oncology patient presenting with headache, seizures or focal deficits — calcineurin-inhibitor PRES can occur with normal drug levels.
- ▶ Differentiate from **acute ischaemic stroke** (PRES oedema is bilateral, posterior and crosses vascular territories) and from **cerebral venous sinus thrombosis, vasculitis, and infective/autoimmune encephalitis**.

High-yield exam pointers

- ▶ PRES = vasogenic oedema of the posterior brain from hyperperfusion / endothelial dysfunction that breaches the upper limit of cerebral autoregulation or the BBB.
- ▶ **Tetrad:** headache, seizures, altered mentation, **cortical (occipital) visual loss**.
- ▶ **Two mechanistic classes:** *raised capillary pressure* (hypertensive encephalopathy, eclampsia, post-CEA) vs *endothelial dysfunction* (calcineurin inhibitors, chemotherapy, HELLP, HUS).
- ▶ **MRI:** bilateral parieto-occipital T2/FLAIR hyperintensity **not confined to one vascular territory**; CT less sensitive.
- ▶ **Rate of BP rise matters more than the absolute BP** — PRES can occur at near-normal pressures.
- ▶ **Treatment:** judicious IV BP control (labetalol / nicardipine; nitroprusside), **lower MAP by ~20% initially**, withdraw the offending drug, control seizures (**magnesium sulfate in eclampsia**).
- ▶ **“Reversible” is conditional** — irreversibility/infarction follows delayed treatment or over-aggressive BP lowering.
- ▶ **Normal calcineurin-inhibitor serum levels do not exclude drug-induced PRES.**

SOURCE & COVERAGE

Harrison's Principles of Internal Medicine, 22e (2025) — **Ch 318 “Nervous System Disorders in Critical Care”** (Hyperperfusion Disorders / PRES section, Table 318-3, Fig. 318-7, and the cerebral-autoregulation/CPP discussion) and **Ch 288 “Hypertension”** (hypertensive urgencies and emergencies; IV nicardipine/labetalol/sodium nitroprusside, reduction-not-normalisation principle). **Coverage note:** the topic spec flags PRES as thinly covered; Harrison presents PRES under “hyperperfusion disorders” rather than as a stand-alone chapter, and does not give formal epidemiology, an exact MAP/BP autoregulatory cut-off, or DWI/ADC criteria. The statement that PRES oedema is **vasogenic** (facilitated rather than restricted diffusion on DWI/ADC, distinguishing it from cytotoxic infarction) is universally accepted standard neuroradiology added for completeness but is not stated verbatim in the provided chapters.

Primary headaches

Asked in: Paper III Dec 2023 — RGUHS MD General Medicine

Definition / Introduction — Primary headaches are disorders in which headache and its associated features constitute the disease itself, without an exogenous structural, infective, vascular, metabolic, or toxic cause. The major groups are **migraine**, **tension-type headache (TTH)**, **trigeminal autonomic cephalalgias (TACs)**, and other primary headache disorders. Diagnosis is clinical, but the first duty in an examination answer and in practice is to exclude secondary headache when red flags are present.

Classification

ICHD-3 group	Important subtypes	Examination anchors
Migraine	Without aura; with aura; brainstem aura; hemiplegic migraine; retinal migraine; chronic migraine; complications such as status migrainosus and migrainous infarction	Recurrent 4-72 h attacks; nausea/vomiting or photophobia-phonophobia; aggravated by activity; normal examination between attacks
Tension-type headache	Infrequent episodic; frequent episodic; chronic; probable TTH	Bilateral tight/band-like pressure, mild-moderate, no vomiting, not worsened by routine activity
TACs	Cluster headache; paroxysmal hemicrania; SUNCT/SUNA; hemicrania continua	Strictly unilateral orbital/temporal pain with ipsilateral cranial autonomic signs
Other primary headaches	Cough, exercise, sexual-activity, thunderclap, cold-stimulus, external-pressure, primary stabbing, nummular, hypnic, new daily persistent headache	Diagnosis only after excluding mimics appropriate to the trigger and phenotype

- ▶ Chronic daily headache means headache on **15 or more days/month**; it is descriptive, not one diagnosis. Important primary causes are chronic migraine, chronic TTH, hemicrania continua, hypnic headache, SUNCT/SUNA, and new daily persistent headache.
- ▶ **Medication-overuse headache** is not a primary subtype but commonly complicates migraine or chronic daily headache and must be actively looked for.

Pathophysiology

- ▶ Pain-sensitive cranial structures include scalp, meningeal arteries, dural venous sinuses, falx, and proximal large pial arteries.
- ▶ Primary headache pathways center on the **trigeminovascular/trigeminocervical system**: meningeal and cervical afferents project through the trigeminal ganglion to the trigeminal

nucleus caudalis and upper cervical cord, then to thalamic, hypothalamic, brainstem, and cortical networks.

- ▶ In **migraine**, brainstem and hypothalamic sensory-modulation dysfunction produces abnormal sensitivity to light, sound, movement, smell, and cutaneous input. Trigeminal activation releases CGRP, PACAP and other neuropeptides, explaining the efficacy of gepants and CGRP monoclonal antibodies.
- ▶ Migraine aura is best explained by **cortical spreading depression**, a slowly propagating wave of neuronal and glial depolarization followed by suppression, typically beginning in occipital cortex.
- ▶ In TACs, pain is trigeminal, while ipsilateral lacrimation, conjunctival injection, nasal congestion, rhinorrhea, aural fullness, ptosis or miosis reflect cranial parasympathetic activation and sympathetic dysfunction. Cluster headache is linked to posterior hypothalamic/circadian mechanisms.
- ▶ Primary headaches are **not simply vascular headaches**; vascular changes are secondary epiphenomena and do not predict treatment response.

Migraine

- ▶ **Clinical phases**: premonitory phase with yawning, sleepiness, fatigue, cognitive fog, mood change, neck discomfort, polyuria/polydipsia or cravings; aura in about one-quarter to one-third; headache phase; and postdrome with tiredness and impaired concentration.
- ▶ **Diagnostic criteria**: repeated attacks lasting 4-72 h, normal examination, no better cause, with at least two of unilateral pain, throbbing quality, moderate/severe intensity, aggravation by movement; and at least one of nausea/vomiting or photophobia and phonophobia.
- ▶ **Aura** is usually visual, with scintillating scotoma, zigzags or field defects spreading over minutes and resolving within 60 min; sensory, language, brainstem and hemiplegic auras are recognized. Aura without headache may mimic TIA, especially after 40 years.
- ▶ **Triggers/activators**: altered sleep, missed meals, let-down after stress, exertion, weather change, menstruation, alcohol, nitrates, odors, glare and noise.
- ▶ **Acute treatment**: treat early, use adequate dose, avoid repeated ineffective dosing and overuse. Options include NSAIDs; acetaminophen-aspirin-caffeine for mild-moderate attacks; triptans; ergots; gepants; lasmiditan; dopamine antagonists; and selected neuromodulation.

Acute class	Examples and key points
NSAIDs/analgesics	Ibuprofen 400 mg, naproxen 220-550 mg, diclofenac K 50 mg; best early; simple analgesics limited to ≤15 days/month
Triptans	Sumatriptan 50-100 mg PO or 3-6 mg SC; rizatriptan 5-10 mg; zolmitriptan 2.5 mg PO or 5 mg

Acute class	Examples and key points
	nasal; avoid in ischemic cardiac/cerebrovascular/peripheral vascular disease and uncontrolled hypertension
Gepants	Rimegepant 75 mg ODT; ubrogepant 50-100 mg, repeat after 2 h if needed; zavegepant 10 mg intranasal
Ditans	Lasmiditan 50-200 mg once; no vasoconstriction; no driving for 8 h
Antiemetic/prokinetic	Metoclopramide 10-20 mg IV/PO, prochlorperazine 5-10 mg; useful with nausea, vomiting, gastric stasis, ED migraine

- ▶ **Prevention** is indicated for frequent or disabling attacks, increasing frequency, poor acute response, contraindications to abortives, or chronic migraine. Harrison suggests considering prevention at **≥ 4 migraine days/month**; CMDT uses more than 2-3/month or significant disability.
- ▶ Preventives include propranolol 40-120 mg bid, metoprolol 25-100 mg bid, amitriptyline 10-75 mg nocte, venlafaxine 75-150 mg/day, topiramate 25-200 mg/day, valproate 400-600 mg bid, candesartan 4-24 mg/day, CGRP monoclonal antibodies, rimegepant alternate-day, atogepant daily, and onabotulinum toxin A for chronic migraine.
- ▶ Start low, titrate, allow **2-12 weeks** or longer, continue about **6-12 months** after stabilization, then consider slow taper. Avoid or use topiramate/valproate cautiously in women of reproductive age.

Tension-type headache

- ▶ **Phenotype**: bilateral tight, pressing, band-like discomfort that builds slowly, fluctuates, and may persist for days; often generalized or occipitocervical; pericranial tenderness may occur.
- ▶ **Episodic vs chronic**: chronic TTH is headache on **≥ 15 days/month**; it may persist for years and overlap clinically with chronic migraine.
- ▶ **Diagnostic distinction from migraine**: pure TTH lacks nausea, vomiting, photophobia, phonophobia, osmophobia, throbbing, focal neurologic symptoms, and aggravation by routine activity.
- ▶ **Treatment**: simple analgesics such as acetaminophen, aspirin or NSAIDs for occasional attacks; avoid frequent combination analgesics, opioids and barbiturates. Relaxation, sleep hygiene, physical therapy, biofeedback and management of anxiety/depression help selected patients.
- ▶ **Prevention**: amitriptyline is the best-supported drug for chronic TTH; other tricyclics may be tried if not tolerated. Triptans do not help pure TTH, although they may help when apparent TTH occurs in a patient with comorbid migraine.

Trigeminal autonomic cephalalgias

Disorder	Attack pattern	Autonomic features	Specific treatment clue
Cluster headache	Excruciating unilateral orbital/temporal pain, 15-180 min, 1 every other day to 8/day; bouts for weeks with remission; nocturnal attacks common	Ipsilateral lacrimation, conjunctival injection, rhinorrhea/nasal congestion, aural fullness, ptosis/miosis; restlessness	Acute: 100% oxygen 10-12 L/min for 15-20 min, sumatriptan 6 mg SC, sumatriptan 20 mg or zolmitriptan 5 mg nasal. Prevent: verapamil 160-960 mg/day with ECG monitoring; prednisone bridge, occipital steroid injection, galcanezumab, topiramate, lithium, melatonin
Paroxysmal hemicrania	Severe unilateral orbital/temporal attacks, 2-45 min, usually >5/day	Prominent ipsilateral autonomic signs	Complete response to indomethacin 25-75 mg tid is diagnostic and therapeutic
SUNCT/SUNA	Very short unilateral orbital/temporal stabs, 5-240 s, often many/day	SUNCT has conjunctival injection and tearing; SUNA has cranial autonomic symptoms without both	Acute therapy usually impractical; IV lidocaine in hospital; prevention with lamotrigine 200-400 mg/day, topiramate or gabapentin
Hemicrania continua	Continuous unilateral moderate pain with severe exacerbations	May have conjunctival injection, lacrimation, photophobia on pain side	Complete response to indomethacin; trial 25 mg tid escalating to 50-75 mg tid

- ▶ TACs are often misdiagnosed as sinus headache because of nasal congestion and rhinorrhea; decongestants are ineffective.
- ▶ Consider MRI brain with pituitary views and pituitary function tests in atypical, refractory, bilateral or suspicious TACs.

Other primary headaches and medication overuse

- ▶ **Primary cough headache:** sudden generalized pain precipitated by cough, sneeze, straining, laughing or stooping, lasting seconds to minutes; diagnose only after excluding Chiari malformation, posterior fossa lesions, aneurysm, CSF leak and other causes. Indomethacin 25-50 mg two to three times daily, or 75-150 mg/day, is effective.
- ▶ **Primary exercise headache:** bilateral throbbing precipitated by sustained exercise, lasting up to 48 h; exclude SAH, intracranial hypertension, pheochromocytoma and **cardiac cephalalgia**.

- ▶ **Sexual-activity headache:** dull bilateral ache increasing with excitement or explosive orgasmic headache; exclude SAH, dissection, RCVS and pheochromocytoma. Options include stopping activity, propranolol 40-200 mg/day, diltiazem 60 mg tid, or pre-emptive indomethacin 25-50 mg/triptan/gepant.
- ▶ **Primary thunderclap headache** is a diagnosis of exclusion after CT/MRI, vascular imaging as indicated and CSF examination exclude SAH, RCVS, dissection, venous thrombosis and pituitary apoplexy.
- ▶ **Primary stabbing headache** causes seconds-long irregular “ice-pick” pains without autonomic features; reassurance is often enough, with indomethacin for frequent disabling attacks.
- ▶ **Hypnic headache** wakes older patients from sleep, usually without autonomic features; bedtime caffeine, lithium 200-600 mg, indomethacin or melatonin may help.
- ▶ **New daily persistent headache** begins abruptly and remains daily from onset; exclude secondary causes such as CSF leak and cerebral venous sinus thrombosis, then treat according to migraine or TTH phenotype.
- ▶ **Medication overuse:** opioids, barbiturate combinations, ergots and triptans over >10 days/month, and acetaminophen/aspirin/NSAIDs over >15 days/month, can perpetuate daily headache. Treat by withdrawal/taper, diary, bridge therapy where appropriate, and early prevention for the underlying headache.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Trigeminovascular pathway:** dura/meningeal vessels -> trigeminal ganglion -> trigeminocervical complex -> quintothalamic tract -> thalamus -> cortex; modulators labelled hypothalamus, dorsal raphe, locus coeruleus, nucleus raphe magnus, superior salivatory nucleus, sphenopalatine ganglion, CGRP release.
- ▶ **Migraine attack timeline:** prodrome -> aura -> headache phase -> postdrome; label yawning/food craving/polyuria, scintillating scotoma, unilateral throbbing pain with nausea-photophobia-phonophobia, fatigue/cognitive fog.

Clinical / Diagnostic significance

- ▶ Always screen for **SNNOOP10** red flags: systemic symptoms, neoplasm, neurologic deficit, sudden onset, older age >50, pattern change, positional headache, cough/exertion trigger, papilledema, progressive atypical headache, pregnancy/puerperium, painful eye with autonomic features, trauma, immunosuppression, and painkiller overuse/new drug.
- ▶ Neuroimaging is urgent for abnormal neurologic examination, altered mental status, papilledema, meningeal signs, thunderclap headache, new headache in HIV, or new headache after 50. LP follows imaging when meningitis or SAH remains possible.

- ▶ A normal examination between attacks supports primary headache, but does not by itself exclude secondary headache when the history is new, abrupt, progressive, positional, exertional, cancer-related, febrile, immunosuppressed, pregnant/postpartum, or associated with visual loss.
- ▶ Migraine is often mistaken for sinus headache because facial pain and autonomic symptoms can occur. Cluster headache is distinguished by shorter attacks, periodicity, ipsilateral autonomic features and restlessness.
- ▶ Examine temporal arteries, fundus, ocular movements, pupils, neck stiffness, BP, visual fields, and cranial nerves; Horner syndrome with acute pain suggests cluster headache but also carotid dissection.

High-yield exam pointers

- ▶ Define primary headache as headache without exogenous cause, then classify into **migraine**, **TTH**, **TACs** and **other primary headaches**.
- ▶ Write migraine diagnostic criteria: **4-72 h**, at least 2 pain features, at least 1 associated feature, normal examination/no better cause.
- ▶ Mention migraine phases and that **aura occurs in only a minority**, so absence of aura does not exclude migraine.
- ▶ Do not call migraine a vascular headache; write **brain disorder of sensory processing with trigeminovascular CGRP biology**.
- ▶ Cluster headache: **male predominance**, **orbital pain**, **15-180 min**, **autonomic signs**, **restlessness**, **oxygen + SC sumatriptan**, **verapamil with ECG**.
- ▶ Paroxysmal hemicrania and hemicrania continua are **indomethacin-responsive**; SUNCT/SUNA responds best preventively to **lamotrigine**.
- ▶ Chronic migraine is **≥ 15 headache days/month with ≥ 8 migraine days/month**; chronic daily headache always needs medication-overuse assessment.
- ▶ Avoid opioids and butalbital combinations in recurrent headache; they promote rebound and medication-overuse headache.
- ▶ First presentation of thunderclap, cough, exertional or sexual headache is not “primary” until dangerous secondary causes are excluded.

SOURCE & COVERAGE

Harrison 22e — “Headache”; “Migraine and Other Primary Headache Disorders”; Bradley & Daroff’s Neurology in Clinical Practice — “Headache and Other Craniofacial Pain”; DeJong’s The Neurologic Examination — “The Trigeminal Nerve”; CMDT 2026 — “Common Symptoms” and “Nervous System Disorders”.

Recent Advances in the Management of Migraine

Asked in: Paper III Jul 2021 — RGUHS MD General Medicine

Definition / Introduction — Migraine is a recurring syndrome of headache (typically unilateral, throbbing, lasting 4–72 h, aggravated by movement) associated with neurologic dysfunction in varying admixtures — nausea/vomiting, photophobia, phonophobia, osmophobia and, in ~20–25%, aura. It is the most common disabling neurologic disorder worldwide, affecting ~15% of women and ~6% of men annually. The last decade has transformed its treatment: clarification of the **calcitonin gene-related peptide (CGRP)** pathway and of serotonin-receptor subtypes has produced four mechanism-specific drug classes — *gepants*, *ditans*, *CGRP monoclonal antibodies* — plus several non-invasive neuromodulation devices, giving the first migraine-specific options that are safe in vascular disease.

Pathophysiological basis driving new therapy

- ▶ Migraine is a disorder of **sensory processing**: dysfunction of monoaminergic/brainstem and hypothalamic control systems (locus coeruleus, dorsal raphe, periaqueductal grey) and activation of the **trigeminovascular system** (trigeminal ganglion → trigeminocervical complex → quintothalamic tract → thalamus).
- ▶ Activated trigeminal neurons release vasoactive neuropeptides — **CGRP** and **pituitary adenylate cyclase-activating polypeptide (PACAP)**. Jugular venous CGRP rises during an attack and normalises with sumatriptan; IV CGRP infusion triggers migraine in migraineurs but not controls — the rationale for anti-CGRP drugs.
- ▶ **Serotonin (5-HT) receptors**: triptans are 5-HT_{1B/1D} agonists (1B = cranial vasoconstriction; 1D = neuronal); the 5-HT_{1F} receptor lies on neural (not vascular) tissue — selectively targeted by *ditans*, allowing efficacy without vasoconstriction.
- ▶ **Dopamine** hypersensitivity explains premonitory symptoms and the utility of dopamine antagonists.
- ▶ *Familial hemiplegic migraine (FHM)* genetics confirm a channelopathy: **CACNA1A** (Cav2.1 P/Q calcium channel) = FHM1 (~50%); **ATP1A2** (Na⁺/K⁺-ATPase) = FHM2 (~20%); **SCN1A** (neuronal Na⁺ channel) = FHM3. Aura correlates with cortical spreading depression.

Principles & goals of modern management

- ▶ **Assess disability** with the validated *Migraine Disability Assessment Score (MIDAS)*: Grade I 0–5, II 6–10, III 11–20, IV >20.
- ▶ **Two arms** — *acute (abortive)* for individual attacks and *preventive (prophylactic)*. Treat acutely **early and adequately**; if relief is incomplete by 60 min, escalate dose or switch class for future attacks.
- ▶ **Start preventives** when there are **≥4 migraine days/month**, or attacks that are prolonged, disabling or poorly responsive to acute drugs. Titrate slowly; expect a 2–12 week lag; continue 6–12 months then taper. Target **≥50% reduction** in headache days.

- ▶ **Patient education**, trigger management, regular sleep/meals/hydration, avoidance of the “let-down” effect, biofeedback and a headache diary remain foundational and reduce medication-overuse risk.
- ▶ **Chronic migraine** = headache on ≥ 15 days/month, ≥ 8 of them migrainous, for ≥ 3 months.

Recent advances in ACUTE therapy

Class / Agent	Mechanism	Dose	Key point
Gepants (oral) — rimegepant; ubrogepant	Small-molecule CGRP-receptor antagonists	Rimegepant 75 mg ODT; ubrogepant 50/100 mg, may repeat at 2 h	No vasoconstriction; very well tolerated; effective on repeat dosing (unlike triptans); safe in CVD
Gepant (nasal) — zavegepant	CGRP-receptor antagonist	10 mg intranasal, single spray	Rapid; useful for early nausea/vomiting
Ditan — lasmiditan	Selective 5-HT _{1F} agonist	50/100/200 mg PO, once/24 h	No vascular effect → fills the gap for cardio- /cerebrovascular disease; dizziness ~15%, somnolence ~6%; no driving for 8 h
Newer triptan/ergot routes	5-HT _{1B/1D} agonists	DHE inhaled/nasal (Trudhesa); SC sumatriptan via needle-free device	Improved absorption/onset; co-give naproxen 500 mg with sumatriptan to cut recurrence
Dopamine antagonists	D ₂ blockade + prokinetic	Metoclopramide/prochlorperazine 10 mg IV	Prochlorperazine superior to hydromorphone in the ED
Neuromodulation (acute)	Device-based	sTMS, nVNS, remote electrical neuromodulation (REN, upper- arm), supraorbital, eCOT-NS	FDA-cleared, drug- free; useful when drugs fail or are contraindicated

- ▶ Gepants and ditans render significantly more patients **pain-free at 2 h** and **most-bothersome-symptom-free** than placebo in phase-3 trials; gepants achieve pain freedom in ~20% and pain relief in ~60% within 2 h.
- ▶ **Opioids and butalbital are discouraged** — they do not treat the mechanism, blunt future triptan response and drive medication-overuse headache.

Recent advances in PREVENTIVE therapy

Agent	Target	Regimen
Erenumab	CGRP receptor (only mAb against the receptor)	70 or 140 mg SC monthly
Fremanezumab	CGRP ligand	225 mg SC monthly <i>or</i> 675 mg SC q3 months
Galcanezumab	CGRP ligand	240 mg loading, then 120 mg SC monthly
Eptinezumab	CGRP ligand	100 or 300 mg IV every 3 months
Atogepant (oral gepant)	CGRP receptor	10/30/60 mg once daily
Rimegepant (oral gepant)	CGRP receptor	75 mg every other day (also acute — first dual-use drug)
OnabotulinumtoxinA	Blocks glutamate/peptide release	155 U (PREEMPT protocol) q12 weeks — chronic migraine only

- ▶ The **CGRP monoclonal antibodies** are the headline advance: efficacy often **within the first month**, monthly/quarterly dosing, excellent tolerability (main effect = injection-site reaction ± constipation), and they **work even after failure of up to four prior preventives**. Approved for both episodic and chronic migraine.
- ▶ *AHS consensus criteria* for starting CGRP-targeted prevention: 4–7 monthly headache days with moderate disability after ≥2 trials of established preventives; 8–14 days at any disability after ≥2 trials; chronic migraine after 2 oral preventive trials or 2 onabotulinumtoxinA cycles.
- ▶ **Traditional preventives still first-line / cost-effective**: propranolol/metoprolol/timolol, topiramate, sodium valproate (FDA-approved); amitriptyline, candesartan, flunarizine, venlafaxine. *Topiramate and valproate are now avoided in reproductive-age women* (teratogenicity — neural-tube defects, reduced cognition).
- ▶ **Preventive neuromodulation** (sTMS, nVNS, REN, supraorbital stimulation) is FDA-cleared and well tolerated.
- ▶ onabotulinumtoxinA is effective only in **chronic** migraine (PREEMPT 1 & 2: –8.4 vs –6.6 headache days); **negative in episodic** migraine.

Special situations

- ▶ **Menstrual migraine**: short-term *perimenstrual prophylaxis* (days –2/–3 to +3) with naproxen, a long-acting triptan (frovatriptan/naratriptan/zolmitriptan), oestrogen patch, or **rimegepant during menses**.
- ▶ **Status migrainosus**: IV valproate, IV prochlorperazine + DHE; IV **dexamethasone 10 mg** reduces recurrence; avoid opioids.

- ▶ **Medication-overuse headache (MOH):** caution if ≥ 2 headache days/week. Limit simple analgesics to ≤ 15 days/month and triptans/ergots/opioids/combination analgesics to ≤ 9 –10 days/month; lasmiditan and gepants are **not** linked to MOH; early CGRP-directed prevention aids analgesic withdrawal.
- ▶ **Cardiovascular disease / migraine-with-aura:** avoid triptans and ergots (vasoconstriction) and combined oral contraceptives (stroke risk, OR ~ 6 with aura); prefer **ditans, gepants and CGRP mAbs** (though CGRP's physiologic vasodilatory role warrants caution pending long-term data).

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Trigeminovascular pathway (label):** meningeal/dural vessels $\rightarrow$ *trigeminal ganglion* $\rightarrow$ *trigemino-cervical complex (TCC)* $\rightarrow$ *quintothalamic tract* (decussating) $\rightarrow$ *thalamus* $\rightarrow$ cortex; modulators *dorsal raphe nucleus, locus coeruleus, nucleus raphe magnus, hypothalamus, periaqueductal grey*; mark **CGRP/PACAP** release at vascular terminals — annotate drug sites: triptans/ditans at TCC, gepants/anti-CGRP mAbs at the peptide/receptor.
- ▶ **Management algorithm box:** *Acute* (NSAID $\rightarrow$ triptan/gepant/ditan $\rightarrow$ DHE/SC sumatriptan/neuromodulation) vs *Preventive* (β -blocker/topiramate/amitriptyline/candesartan $\rightarrow$ CGRP mAb / atogepant / rimegepant; onabotulinumtoxinA 155 U for chronic migraine).

Clinical / Diagnostic significance

- ▶ Diagnosis is clinical (IHS/ICHD-3 criteria); imaging only for red flags. Migraine with aura is an independent **stroke risk factor**, magnified by smoking and oestrogen-containing contraceptives.
- ▶ The new classes resolve two long-standing problems: a **vascular-safe acute option** (ditans, gepants) and **rapid, tolerable, mechanism-specific prevention** (CGRP mAbs, oral gepants).
- ▶ A single drug — **rimegepant** — now serves both acute and preventive roles, simplifying regimens.

High-yield exam pointers

- ▶ **CGRP** is the central therapeutic target: jugular CGRP rises in attacks; IV CGRP provokes migraine.
- ▶ **Gepants** = small-molecule CGRP-receptor antagonists (rimegepant, ubrogepant, zavegepant); acute *and* preventive use; no vasoconstriction.
- ▶ **Ditans** = lasmiditan, selective 5-HT_{1F} agonist; safe in CVD; dizziness/somnolence; no driving 8 h.
- ▶ **CGRP mAbs:** erenumab targets the **receptor**; fremanezumab, galcanezumab, eptinezumab target the **ligand**; eptinezumab is the only IV one.
- ▶ **onabotulinumtoxinA 155 U (PREEMPT)** — chronic migraine only; ineffective in episodic.

- ▶ Start prevention at ≥ 4 migraine days/month; chronic migraine = ≥ 15 headache/ ≥ 8 migraine days/month for ≥ 3 months.
- ▶ FHM genes: CACNA1A (1), ATP1A2 (2), SCN1A (3) — a channelopathy.
- ▶ Avoid opioids/butalbital; topiramate/valproate avoided in reproductive-age women.

SOURCE & COVERAGE

- ▶ **Harrison's Principles of Internal Medicine, 22e** — “Migraine and Other Primary Headache Disorders” (pathophysiology, CGRP/PACAP, 5-HT_{1F}/ditans, gepants, CGRP monoclonal antibodies, acute and preventive treatment tables, neuromodulation, MIDAS, FHM genetics).
- ▶ **Bradley & Daroff's Neurology in Clinical Practice, 8e** — “Headache and Other Craniofacial Pain” (CGRP-targeted therapies, AHS consensus criteria, PREEMPT/onabotulinumtoxinA, chronic and menstrual migraine, medication-overuse headache).
- ▶ **CMDT 2026** — “Nervous System Disorders” (current acute drug doses, lasmiditan, gepant dosing, Table 27–1 pharmacologic prophylaxis including CGRP mAbs/gepants, neuromodulation, MOH thresholds).

Restless Legs Syndrome (Willis–Ekbom Disease)

Asked in: Paper III May 2019 — RGUHS MD General Medicine

Definition / Introduction — Restless legs syndrome (RLS), also called *Willis–Ekbom disease*, is a common sensorimotor neurological disorder characterised by an **irresistible urge to move the legs**, usually accompanied by an unpleasant deep “creepy-crawly” sensation, that appears at **rest**, is **relieved by movement**, and shows a **circadian (evening/night) predominance**. It was first described by the English physician *Thomas Willis* in the seventeenth century and is now recognised as a bona-fide movement disorder. It affects roughly **5–10% of adults** (1–5% by some series; rare in Asians), is commoner in **women and older adults**, and in ~80% of patients coexists with **periodic limb movements (PLMs)** of sleep. The neurological examination is characteristically normal, and diagnosis is **clinical**.

Clinical features and the IRLSSG essential criteria

RLS is a **clinical diagnosis**; the *International Restless Legs Syndrome Study Group (IRLSSG)* requires **five essential criteria** (mnemonic **URGE** — Urge to move, Rest-induced, Gets better with movement, Evening worsening, plus an exclusion clause):

#	Essential criterion (IRLSSG)
1	An urge to move the legs , usually but not always accompanied by uncomfortable/unpleasant leg sensations
2	Urge begins or worsens during rest or inactivity (lying down, sitting)
3	Urge is partially or totally relieved by movement (walking, stretching), at least as long as activity continues
4	Urge occurs only or is worse in the evening/night than during the day (circadian pattern)
5	The features are not solely accounted for by another condition (leg cramps, myalgia, arthritis, venous stasis, positional discomfort, habitual foot tapping)

- ▶ The dysaesthesia is typically a **creepy-crawly, tingling, pulling or deep aching** discomfort in the calves/thighs; 30–50% report frank pain (an ache rather than a sharp burning).
- ▶ Symptoms usually **begin in the legs** but may spread to or begin in the **upper limbs** in severe disease; usually **bilateral**.
- ▶ **Supportive features** (aid diagnosis in doubtful cases): PLMs in sleep/wakefulness greater than expected for age, **response to dopaminergic therapy**, **positive family history** in first-degree relatives, and **lack of profound daytime sleepiness**.
- ▶ **Course specifiers**: *Intermittent* (<2 episodes/week on average) vs *Chronic-persistent* (≥2/week for the past year). The DSM-5 additionally requires symptoms ≥3 times/week for ≥3 months.
- ▶ Consequences: chronic **sleep-onset/maintenance insomnia**, poor-quality sleep, daytime sleepiness, and association with **depression, anxiety and hypertension**.

Classification and aetiology (primary vs secondary)

Type	Features / Causes
Primary (idiopathic)	Often familial (≈1/3 have affected relatives), early onset in the third decade; strong genetic component; >150 risk variants identified — strongest in MEIS1, BTBD9, PTPRD (also MAP2K5/LBXCOR)
Secondary / comorbid	Iron deficiency / ferritin deficiency (commonest treatable cause), pregnancy , uraemia / chronic renal failure , peripheral neuropathy (diabetic, uraemic), Parkinson disease, multiple sclerosis, ALS, myelopathy/radiculopathy, rheumatoid arthritis, hypothyroidism, gastrectomy, anaemia (folate)

Type	Features / Causes
Drug-induced / aggravating	Antidepressants (TCAs, SSRIs, venlafaxine — <i>not</i> bupropion), antihistamines, dopamine antagonists (neuroleptics, antiemetics), lithium, some calcium-channel blockers (nifedipine), caffeine, alcohol, nicotine

Pathophysiology — the iron–dopamine hypothesis

- ▶ The site of CNS dysfunction is not fully defined, but the leading model is **brain iron deficiency coupled with dopaminergic dysfunction** (the *iron–dopamine connection*).
- ▶ **Iron** is an essential cofactor for **tyrosine hydroxylase**, the rate-limiting enzyme of dopamine synthesis; low CNS iron reduces dopamine output and decreases the number of **D2 receptor** binding sites — explaining why iron deficiency precipitates RLS and dopaminergics relieve it.
- ▶ CSF analysis, special-sequence MRI (reduced R2 *in* substantia nigra *and* red nucleus) *and neuropathology show reduced regional brain iron / ferritin** despite often-normal peripheral iron.
- ▶ Neurophysiology (increased cortical excitability, reduced subcortical inhibition, increased spinal flexor-reflex excitability during sleep) localises dysfunction to **subcortical and spinal** circuits; the spinal mechanism helps explain PLMs.
- ▶ A genetic predisposition interacts with iron/dopamine handling — notably **no genetic linkage to iron metabolism genes** has been found despite the iron phenotype.

Periodic limb movements (PLMs) and PLMD

- ▶ ~80% of RLS patients have **periodic limb movements of sleep (PLMS)**; many also have PLMs of wakefulness (PLMW).
- ▶ PLMS are **stereotyped, repetitive movements** resembling a *triple-flexion reflex* — extension of the great toe with **dorsiflexion of the ankle**, sometimes knee/hip flexion.
- ▶ Polysomnographic definition: duration **0.5–10 s**, recurring every **20–40 s** (range 5–90 s), in runs of **≥4 consecutive** movements, predominantly during **NREM** sleep; they cause brief EEG **arousals** that fragment sleep.
- ▶ **Periodic limb movement disorder (PLMD)** is a *separate* ICSD entity: PLMS index **>5/h in children, >15/h in adults** causing sleep disruption/daytime impairment, **without** the urge/sensory features of RLS. PLMS without symptoms may have no clinical significance.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Iron–dopamine pathophysiology loop:** boxes/arrows labelled — *Reduced CNS iron / ferritin* → ↓ *Tyrosine hydroxylase activity* → ↓ *Dopamine synthesis* → ↓ *D2 receptor binding sites* → *Circadian (evening) dopaminergic dysfunction* → **RLS symptoms**; with side inputs

Genetic susceptibility (MEIS1, BTBD9, PTPRD) and Secondary triggers (iron deficiency, pregnancy, uraemia, neuropathy).

- ▶ **PLMS polysomnogram tracing:** label the *Anterior tibialis EMG* channel showing periodic bursts; mark *movement duration 0.5–10 s, inter-movement interval 20–40 s, ≥ 4 consecutive movements, NREM sleep*, and an *EEG arousal* above each cluster.

Clinical / Diagnostic significance

- ▶ **Diagnosis is clinical** (five IRLSSG criteria); the neurological examination is normal.
- ▶ **Mandatory investigations:** serum **ferritin and transferrin saturation**, **fasting glucose** and **renal function**; **EMG/nerve-conduction studies** if peripheral neuropathy is suspected.
- ▶ **Polysomnography is NOT routine** for RLS but is indicated to confirm/quantify **PLMS** or when **PLMD** or comorbid **OSA** is suspected.
- ▶ **Differential diagnosis (mimics):** *akathisia* (neuroleptic-induced, daytime, no persistent relief by movement, choreiform restlessness, no family history — best treated with anticholinergics/ β -blockers), **nocturnal leg cramps** (“Charlie-horse” — painful palpable contraction), **peripheral neuropathy / neuropathic pain**, positional discomfort, venous stasis, and **PLMD**.
- ▶ **Iron repletion is disease-modifying:** start **oral iron** (ferrous sulfate, with vitamin C to aid absorption) when **ferritin ≤ 75 ng/mL and transferrin saturation $< 45\%$** , *before* other drugs.
- ▶ **Augmentation** (defined below) is the chief long-term hazard of dopaminergic therapy and a frequent exam point.

Management

1. Non-pharmacological / general measures (first step in all):

- ▶ **Good sleep hygiene;** mild–moderate **exercise**, leg stretching, **massage**, vibratory pads, warm bath before bed; remain mentally engaged.
- ▶ **Withdraw aggravators:** caffeine, alcohol, nicotine, antihistamines, dopamine antagonists, and offending antidepressants (substitute **bupropion** if an antidepressant is needed).
- ▶ **Correct the cause** in secondary RLS — **iron replacement**, treat uraemia, optimise neuropathy.

2. Pharmacological therapy (symptomatic):

Class	Drug & dose (evening, ~1.5–2 h before bed)	Key caution
$\alpha 2\delta$ calcium-channel ligands (preferred first-line — no augmentation)	Gabapentin 300–1800 mg; gabapentin enacarbil 300–1200 mg; pregabalin 150–300 mg	Sedation, dizziness; useful when pain/neuropathy/anxiety coexist

Class	Drug & dose (evening, ~1.5–2 h before bed)	Key caution
Non-ergot dopamine agonists	Pramipexole 0.125–0.5 mg; ropinirole 0.25–4 mg; rotigotine transdermal patch 1–3 mg/24 h	Augmentation (~25–30%), rebound, nausea, sleepiness, impulse-control disorders (gambling, hypersexuality)
Dopamine precursor	Levodopa/carbidopa 25/100 mg	High augmentation risk — “ on-demand ”/intermittent use only, not chronic
Iron	Ferrous sulfate 325 mg BID/TID + vitamin C	Indicated when ferritin ≤ 75 ng/mL
Opioids (refractory/severe)	Extended-release oxycodone–naloxone 2.5/1.25 up to 10/5 mg BID; codeine, methadone	Constipation, tolerance, dependence
Others	Clonazepam 0.125–0.5 mg hs; clonidine 0.1 mg (if hypertensive)	BZD — caution in OSA

- ▶ **Augmentation** = a drug-induced *paradoxical worsening*: symptoms appear ≥ 2 h earlier than before, **intensify**, and **spread** to other body parts; classically with **levodopa**, also dopamine agonists — managed by keeping dopaminergic load low, screening regularly, switching to an $\alpha 2\delta$ ligand, splitting doses or adding iron.
- ▶ **Tonic motor activation (TOMAC)** — non-pharmacological **peroneal nerve electrical stimulation**, recently US-approved for drug-refractory RLS, improves symptoms and sleep quality.
- ▶ **Deep brain stimulation** of the **globus pallidus** is a *last-resort* option for severe, intractable disease.
- ▶ **Pregnancy**: avoid both dopamine agonists and $\alpha 2\delta$ ligands where possible; **prefer iron**, non-pharmacological measures (usually self-limiting post-partum).

High-yield exam pointers

- ▶ Synonym **Willis–Ekbom disease**; first described by **Thomas Willis** (17th century); prevalence 5–10% of adults, F>M, rare in Asians.
- ▶ **Five IRLSSG essential criteria** = mnemonic **URGE** + exclusion clause; diagnosis is **clinical**, exam is **normal**.
- ▶ **Commonest treatable cause** = **iron deficiency** → check **ferritin** (replace if ≤ 75 ng/mL, TSAT $< 45\%$).
- ▶ Core pathophysiology: **brain iron deficiency** → ↓ **tyrosine hydroxylase** → **dopaminergic dysfunction**; genes **MEIS1**, **BTBD9**, **PTPRD**.

- ▶ ~80% have PLMS (dorsiflexion of ankle, every 20–40 s, ≥ 4 consecutive, NREM); PLMD is a distinct entity ($>15/h$ adults, no urge).
- ▶ First-line drugs are $\alpha 2\delta$ ligands (gabapentin enacarbil, pregabalin) — chosen over dopamine agonists because they **do not cause augmentation**.
- ▶ Augmentation (earlier onset + spread + intensification) is the hallmark complication of levodopa/dopamine agonists; dopamine agonists also cause **impulse-control disorders**.
- ▶ Key mimic to differentiate = **akathisia** (drug-induced, daytime, no persistent relief by movement).
- ▶ Refractory options: **opioids (oxycodone–naloxone)**, TOMAC peroneal stimulation, and GPi-DBS as last resort.

SOURCE & COVERAGE

- ▶ **Harrison's Principles of Internal Medicine, 22e** — “Sleep Disorders” (RLS & periodic limb movement disorder) and “Tremor, Chorea, and Other Movement Disorders” (RLS as a movement disorder; epidemiology, pathogenesis, genetics, therapy including TOMAC).
- ▶ **Bradley & Daroff's Neurology in Clinical Practice, 8e** — “Sleep and Its Disorders” (IRLSSG five essential criteria, supportive features/specifiers, iron–dopamine pathophysiology, PLMS/PLMD definitions, causes of symptomatic RLS, akathisia differentiation, augmentation, and pharmacological/non-pharmacological treatment tables).
- ▶ **CMDT 2026** — “Nervous System Disorders” (current management: ferritin ≤ 75 mcg/L + TSAT $<45\%$ threshold, $\alpha 2\delta$ ligands, non-ergot dopamine agonist doses, extended-release oxycodone–naloxone).

Reversible Dementias

Asked in: Paper III Nov 2020 — RGUHS MD General Medicine

Definition / Introduction — *Dementia* is an acquired deterioration in two or more cognitive domains severe enough to impair performance of activities of daily living. A **reversible (potentially treatable) dementia** is one in which the cognitive decline is wholly or partly attributable to a condition that can be corrected — metabolic, nutritional, structural, infective, toxic, inflammatory or psychiatric — so that cognition stabilises or improves once the cause is treated. They are *uncommon individually but collectively critical*: in a landmark series of 1000 memory-clinic patients, **19% had a potentially reversible cause** of cognitive impairment and a further **23% had a potentially reversible contributing condition**, the three commonest being **depression, normal-pressure hydrocephalus (NPH) and alcohol dependence**; drug side effects are common and must be sought in every patient. The clinical

imperative is to *never miss a treatable cause*, since each individual test has a low yield but the cost of overlooking a curable dementia is high.

Why the concept matters / classification principle

- ▶ The first triage of any dementia is into **reversible, irreversible/degenerative** (Alzheimer's disease, FTD, DLB, vascular, Huntington's, LATE) and **psychiatric** categories — a framework explicitly endorsed in Harrison's evaluation table.
- ▶ Features that *raise suspicion of a reversible cause*: **young onset (<60 yr)**, **rapid or subacute progression (weeks–months)**, **fluctuating course**, **prominent gait disorder / incontinence**, **systemic signs** (weight loss, fever, neuropathy, myelopathy), recent **drug change**, and a **subacute amnestic-psychotic syndrome** with medial-temporal MRI change.
- ▶ The corollary entity is **rapidly progressive dementia (RPD)** — dementia evolving within ≤ 1 year; although prion disease (CJD) dominates referral series, autoimmune, infective, neoplastic and metabolic causes within RPD are precisely the *treatable* ones that must be excluded urgently.

Classification of reversible / treatable causes

Category	Representative causes (corpus-grounded)	Diagnostic clue
Structural	Normal-pressure hydrocephalus, chronic subdural haematoma, primary/metastatic brain tumour (meningioma, frontal glioma)	Gait disorder, focal deficit, raised ICP; CT/MRI
Endocrine / organ failure	Hypothyroidism, hypo-/hyperparathyroidism, adrenal insufficiency & Cushing's, hepatic, renal, pulmonary failure	Dry cool skin, hair loss, bradycardia (hypothyroid); metabolic panel, TSH
Nutritional deficiency	Vitamin B ₁₂ (subacute combined degeneration), thiamine (B ₁) → Wernicke–Korsakoff, niacin (pellagra), elevated homocysteine	Myelopathy + peripheral neuropathy (B ₁₂); ophthalmoplegia/ataxia (Wernicke)
Chronic infection	Neurosyphilis, HIV, chronic TB/fungal meningitis, Whipple's disease, PML (JC virus), Lyme	High-risk behaviour/IVDU history; RPR/VDRL, HIV, CSF
Toxic	Alcohol, drug/medication intoxication (anticholinergics, benzodiazepines, sedatives, opioids), heavy metals (lead, mercury, arsenic), CO	Medication review; urine heavy-metal screen
Inflammatory / autoimmune	Autoimmune / paraneoplastic limbic encephalitis (anti-NMDA-R, LGI1, Caspr2, AMPA-	Subacute amnesia + psychosis, seizures; antibody panel, CSF

Category	Representative causes (corpus-grounded)	Diagnostic clue
	R), Hashimoto (steroid-responsive) encephalopathy, neurosarcoidosis, CNS vasculitis, SLE/Sjögren	
Psychiatric	Depression (pseudodementia), conversion disorder, schizophrenia	Mood symptoms, “don’t-know” answers, attention deficit
Miscellaneous	Recurrent non-convulsive seizures , obstructive sleep apnoea, intracranial hypotension	EEG; fluctuating confusion with stereotyped movements

Clinical approach — eliciting a treatable cause

- ▶ **History:** tempo (acute/subacute → intoxication, infection, metabolic, autoimmune); meticulous **drug review** (sedatives, analgesics, anticholinergics); alcohol and nutrition; high-risk sexual behaviour/IVDU (HIV, syphilis); recurrent head trauma (chronic subdural, NPH); occupational exposure (battery/chemical factory → heavy metals); mood disorder/bereavement (depression). B₁₂ deficiency is suggested by **pernicious anaemia, veganism, gastrectomy, bowel irradiation or chronic H₂-blocker use**.
- ▶ **Examination:** look for systemic clues — **myelopathy + peripheral neuropathy** → B₁₂; dry cool skin, hair loss, bradycardia → **hypothyroidism**; hemiparesis/focal deficit → tumour or vascular; the **NPH triad** (gait, incontinence, cognition); fluctuating confusion with stereotyped movements → ongoing seizures.
- ▶ **Cognitive screen:** MMSE / MoCA to capture and follow severity (insensitive to early disease); **pseudodementia** of depression shows prominent inattention and effort-dependent failure.

Investigations to unmask reversibility

- ▶ **AAN-recommended routine panel** (Harrison): complete blood count; electrolytes; glucose; renal, liver and thyroid (TSH) function; vitamin B₁₂; and a **structural neuroimaging study** (MRI or CT). CMDT adds free T₄, TSH, B₁₂ in every patient and **serum RPR + HIV** when indicated.
- ▶ **Neuroimaging (MRI > CT):** excludes tumour, subdural haematoma, infarction/inflammation; supports NPH (communicating ventriculomegaly with **Evans index >0.30**, vertex/convexity crowding, gaping Sylvian fissures — **DESH** pattern, transependymal flow).
- ▶ **Selective / focused tests** (driven by suspicion): HIV serology, RPR/VDRL, **lumbar puncture** (CNS infection, inflammation, autoimmune antibodies, AD biomarkers, opening pressure), EEG (non-convulsive seizures; CJD periodic complexes), urine heavy-metal panel,

autoantibody/paraneoplastic screen, ESR/CRP, ANA, 24-h urine copper (Wilson), MR angiography (vasculitis/venous thrombosis).

- ▶ **RPD work-up (CMDT):** MRI with contrast + diffusion-weighting, B₁₂/T₄/TSH, RPR, HIV, Lyme, ESR/CRP/ANA, **anti-thyroglobulin & anti-TPO** (Hashimoto), paraneoplastic/autoimmune antibodies, full CSF (cells, protein, oligoclonal bands, IgG index, VDRL, 14-3-3, RT-QuIC for prion).

Key reversible entities in focus

- ▶ **Normal-pressure hydrocephalus** — classic *Hakim* triad of gait disturbance (“magnetic”/apraxic gait), urinary incontinence and cognitive (frontal-executive) impairment (“wet, wobbly, wacky”); enlarged ventricles disproportionate to atrophy with **normal CSF opening pressure**. **Gait is the core and most shunt-responsive symptom**; cognition responds least. A **large-volume (30–50 mL) “tap test”** or 1–3 days of external lumbar drainage with objective gait improvement predicts response to **ventriculoperitoneal / lumboperitoneal shunting**. Coexisting AD pathology is found in ~40% of shunted patients.
- ▶ **Vitamin B₁₂ deficiency** — dementia with **subacute combined degeneration** (dorsal column + corticospinal) and peripheral neuropathy; reversible with replacement.
- ▶ **Wernicke–Korsakoff** — thiamine deficiency (alcoholism, hyperemesis, post-bariatric); Wernicke triad of **confusion, ataxia and ophthalmoplegia/nystagmus**. Give **thiamine 100 mg IV before** any glucose (glucose first can precipitate/worsen Wernicke).
- ▶ **Hypothyroidism** — corrected by thyroid replacement.
- ▶ **Depression (pseudodementia)** — vigorous antidepressant therapy may abolish the cognitive complaint; if it persists, reassess for a true dementia.
- ▶ **Autoimmune/paraneoplastic encephalitis** — subacute amnesia, psychosis, seizures with mesial-temporal T2/FLAIR change; immunotherapy-responsive (predictors: subacute onset, fluctuation, CSF pleocytosis/high protein, specific antibody).
- ▶ **Chronic subdural haematoma, brain tumour, neurosyphilis, HIV** — each surgically/medically treatable.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Diagram 1 — Diagnostic triage of dementia (algorithm box).** Top node: “Dementia” → three branches: **Reversible/treatable causes** (label sub-boxes: *Hypothyroidism, B₁₂/thiamine deficiency, NPH, Chronic subdural haematoma, Chronic infection, Brain tumour, Drug intoxication, Autoimmune encephalopathy*), **Irreversible/degenerative** (*Alzheimer’s, FTD, DLB, Vascular, Huntington’s, LATE*), and **Psychiatric** (*Depression, Schizophrenia, Conversion*). Side label: *Routine screen — CBC, electrolytes, glucose, renal/liver/thyroid (TSH), B₁₂, MRI/CT.*

- ▶ **Diagram 2 — NPH neuroimaging.** Axial CT/MRI brain with labels: *Dilated lateral ventricles (out of proportion to atrophy), Evans index >0.30 (frontal-horn : skull width), Transependymal CSF flow / periventricular capping, Tight high-convexity sulci & gaping Sylvian fissures (DESH);* annotate the clinical triad *gait apraxia – incontinence – dementia.*

Clinical / Diagnostic significance

- ▶ Distinguishing reversible from degenerative dementia changes prognosis fundamentally — **treatment can halt or reverse decline**, so screening for the curable minority is mandatory in every new dementia work-up.
- ▶ **Treatment of underlying cause** (Harrison): thyroid replacement for hypothyroidism; **vitamin therapy** for thiamine/B₁₂ deficiency or hyperhomocysteinaemia; **antimicrobials/antiretrovirals** for opportunistic infection or HIV; **ventricular shunting** for NPH; **surgery/radiation/chemotherapy** for CNS neoplasms; and **withdrawal of cognition-impairing drugs**.
- ▶ Even partial reversibility matters: many degenerative dementias carry treatable concomitants (depression, drug effects, metabolic derangement) whose correction improves function and reduces caregiver burden.
- ▶ A negative reversible-cause screen with a progressive amnesic syndrome redirects attention to AD/LATE; rapid progression with myoclonus and cortical-ribboning DWI redirects to CJD.

High-yield exam pointers

- ▶ ~19% **reversible cause** + ~23% **reversible contributor** in 1000 memory-clinic patients; top three reversible = **depression, NPH, alcohol**.
- ▶ AAN routine panel = **CBC, electrolytes, glucose, renal/liver/thyroid, B₁₂, MRI/CT**.
- ▶ **NPH triad** = gait + incontinence + dementia; **gait most shunt-responsive**; **Evans index >0.30**; positive **large-volume tap test** predicts shunt benefit.
- ▶ **B₁₂ deficiency** = dementia + **subacute combined degeneration** + neuropathy; causes include veganism, pernicious anaemia, gastrectomy, chronic H₂-blockers.
- ▶ **Wernicke**: confusion–ataxia–ophthalmoplegia; **thiamine before glucose**.
- ▶ **Depression** = **pseudodementia**, the single commonest reversible cause.
- ▶ Reversible RPD red flags = subacute course, fluctuation, myoclonus, seizures → screen for **autoimmune/paraneoplastic encephalitis** (NMDA-R, LGI1, Caspr2, AMPA-R) and **Hashimoto encephalopathy** (anti-TPO).
- ▶ Always **review medications** (anticholinergics, benzodiazepines, sedatives) — a correctable cause in every patient.

SOURCE & COVERAGE

- ▶ **Harrison's Principles of Internal Medicine, 22e** — “Dementia” (Table 31-1 differential diagnosis with potentially reversible causes; evaluation table; reversible-cause treatment; NPH, RPD, autoimmune encephalitis) and “Aphasia, Memory Loss, and Other Cognitive Disorders”.
- ▶ **Bradley & Daroff's Neurology in Clinical Practice, 8e** — “Alzheimer Disease and Other Dementias” (NPH triad, Evans index, DESH, tap test, Japanese iNPH criteria; Box 95.1 non-degenerative/treatable dementias; rapidly progressive dementia).
- ▶ **CMDT 2026** — “Nervous System Disorders: Dementia” (laboratory work-up — B₁₂, free T₄, TSH, RPR, HIV; drugs impairing cognition; NPH; rapidly progressive dementia work-up; Wernicke encephalopathy & Korsakoff syndrome).

Secondary Parkinsonism

Asked in: Paper III Jun 2024 — RGUHS MD General Medicine

Definition / Introduction — *Parkinsonism* is a clinical syndrome defined by **bradykinesia plus rigidity and/or rest tremor** (with postural instability). *Secondary (symptomatic) parkinsonism* denotes parkinsonism arising from an identifiable, often reversible, exogenous or acquired cause — drugs, vascular disease, toxins, infection, structural lesions, trauma or metabolic insult — that damages the nigrostriatal pathway or basal ganglia, **as opposed to** the neurodegenerative synucleinopathy of idiopathic Parkinson's disease (PD) or the tauopathies/atypical “Parkinson-plus” syndromes. Idiopathic PD accounts for ~75% of all parkinsonism; recognising a secondary cause matters because many are **treatable or preventable**. *Drug-induced* parkinsonism is the single commonest secondary form, and *vascular* parkinsonism the commonest non-drug secondary form.

Classification — where secondary parkinsonism sits

- ▶ **Primary / idiopathic** — Parkinson's disease (sporadic and monogenic), the prototype Lewy-body synucleinopathy.
- ▶ **Atypical (“Parkinson-plus”) degenerations** — multiple-system atrophy (MSA-p/MSA-c), progressive supranuclear palsy (PSP, Richardson & Parkinson variants), corticobasal syndrome; widespread pathology, poor/absent levodopa response.
- ▶ **Secondary (symptomatic) parkinsonism** — the focus of this answer (drugs, vascular, toxins, infection, tumour, NPH, trauma, metabolic).
- ▶ **Heredodegenerative parkinsonism** — Wilson's disease, Huntington's (juvenile *Westphal* variant), spinocerebellar ataxias (SCA3), neurodegeneration with brain iron accumulation (PANK-associated), dopa-responsive dystonia.

Cause category	Representative aetiologies (Harrison Table 446-2)
Drug-induced	Dopamine-receptor blockers (neuroleptics, metoclopramide); dopamine depleters (reserpine, tetrabenazine); Ca ²⁺ -channel blockers (flunarizine, cinnarizine); amiodarone; lithium; valproate
Vascular	Subcortical small-vessel/lacunar disease (“lower-body parkinsonism”)
Toxins	Carbon monoxide, manganese, MPTP, cyanide, hexane, methanol, carbon disulfide
Infective / post-infective	Postencephalitic (encephalitis lethargica), HIV, prion disease
Structural	Tumour, subdural haematoma, normal-pressure hydrocephalus , trauma (pugilistic)
Metabolic	Hepatic (acquired hepatocerebral) failure, hypoparathyroid basal-ganglia calcification (<i>Fahr</i>)

Drug-induced parkinsonism (DIP) — the commonest cause

- ▶ **Mechanism:** post-synaptic D2-receptor blockade (neuroleptics, antiemetics) or pre-synaptic dopamine depletion (reserpine, tetrabenazine, deutetabenazine, valbenazine) reproduces the motor syndrome *without* nigral degeneration.
- ▶ **Offending drugs:** typical antipsychotics (haloperidol, fluphenazine) > atypicals; antiemetics **metoclopramide, prochlorperazine, levosulpiride**; among atypicals the propensity tracks D2 affinity — *risperidone* = *ziprasidone* > *olanzapine* > *quetiapine* > *clozapine* (quetiapine/clozapine are “dopamine-sparing”). Also SSRIs, lithium, sodium valproate, phenytoin, methyldopa, amiodarone, and Ca²⁺-channel blockers (cinnarizine, flunarizine).
- ▶ **Clinical signature:** typically bilateral & symmetrical at onset, postural > rest tremor, lower incidence of tremor overall, subacute onset over weeks–months of exposure.
- ▶ **Course & treatment:** stop / substitute the offending drug — reversible but may take up to 6 months to resolve; symptomatic relief with anticholinergics (bentropine, trihexyphenidyl), amantadine or levodopa. Persistence after withdrawal suggests an **unmasked subclinical PD**. On stopping the drug, **tardive dyskinesia** may emerge. Neuroleptic users are ~5× more likely to later start antiparkinsonian drugs.

Vascular parkinsonism

- ▶ Second commonest parkinsonism in movement-disorder clinics (~8% of parkinsonian patients); driven by **lacunar/subcortical small-vessel ischaemia**. Risk factors: hypertension, type-2 diabetes, hyperlipidaemia.

- ▶ “Lower-body parkinsonism” — broad-based shuffling gait, marked start/turn hesitation and freezing, early postural instability and falls, relative sparing of the upper limbs, little rest tremor.
- ▶ Frequent accompaniments: pyramidal signs, pseudobulbar palsy, urinary incontinence and dementia (overlaps the NPH picture and small-vessel disease).
- ▶ Distinguishing investigations: structural MRI abnormal in 90–100% (vs 12–43% in PD) showing white-matter ischaemia/lacunes; DaTscan/presynaptic dopamine-transporter imaging is usually NORMAL (pathology spares SNc dopaminergic cells) — a key separator from PD.
- ▶ Treatment: vascular secondary-prevention; levodopa trial worthwhile — up to half improve modestly; physiotherapy/gait training.

Toxin-, infection-, structural- and metabolic-induced

- ▶ MPTP: 1-methyl-4-phenyl-1,2,5,6-tetrahydropyridine; an opioid (meperidine) synthesis contaminant. Converted by MAO-B to the active toxin MPP⁺, which poisons mitochondrial complex I and destroys SNc neurons → acute, severe, levodopa-responsive parkinsonism (1982 Californian “frozen addicts”); landmark model of PD pathogenesis.
- ▶ Manganese (manganism): symmetrical, levodopa-unresponsive parkinsonism with dystonia and oculogyric crises; damages the globus pallidus; may progress after exposure ceases; F-dopa PET shows normal presynaptic dopamine function (postsynaptic/pallidal pathology); welder/miner exposure, fungicide *maneb*.
- ▶ Carbon monoxide: delayed parkinsonism with bilateral globus-pallidus necrosis and white-matter lesions on MRI; cognitive slowing; partial recovery over months–years.
- ▶ Postencephalitic parkinsonism (von Economo): sequel of the 1916–1927 encephalitis lethargica pandemic; characteristic oculogyric crises, sleep/behavioural disturbance, abnormal eye movements; SNc degeneration with neurofibrillary tangles; levodopa-responsive.
- ▶ Structural causes: tumour or subdural haematoma involving the SNc may closely mimic PD; normal-pressure hydrocephalus (NPH) gives the Hakim–Adams triad of gait apraxia, dementia and urinary incontinence and may respond to ventriculoperitoneal shunting.
- ▶ Metabolic/heredodegenerative red-line: always exclude Wilson’s disease in young-onset parkinsonism (Kayser–Fleischer rings, low ceruloplasmin) — progression is preventable with copper chelation.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ Basal-ganglia / nigrostriatal circuit with lesion sites. Draw and label: Substantia nigra pars compacta (SNc), Striatum (putamen + caudate), Globus pallidus externa (GPe) and interna (GPi), Subthalamic nucleus (STN), Thalamus; the dopaminergic nigrostriatal pathway. Annotate lesion localisation — SNc lesion (stroke/tumour/MPTP) → PD-like,

levodopa-responsive; GPi/pallidal lesion (CO, manganese) → atypical, levodopa-unresponsive; D2 blockade at striatum → drug-induced.

- ▶ **Diagnostic algorithm box.** “Parkinsonism” → *drug history?* (yes → DIP, stop drug) → *symmetric, early falls, lower-body gait + MRI small-vessel disease?* (yes → vascular) → **DaTscan:** normal = DIP/vascular/essential tremor; reduced asymmetric posterior-putaminal uptake = PD/atypical.

Clinical / Diagnostic significance

- ▶ **Red flags for a secondary/atypical (NOT idiopathic PD) cause** (Harrison Table 446-3): **symmetrical signs, early speech & gait impairment with falls in the first year, absent rest tremor, poor/no levodopa response, early autonomic failure or dementia, vertical-gaze palsy (PSP), prominent cerebellar signs (MSA-c).**
- ▶ **Key separator — DaTscan (presynaptic dopamine-transporter SPECT):** *normal* in DIP, vascular and psychogenic parkinsonism (and essential tremor); *abnormal* in PD and atypical degenerations — invaluable when the cause is uncertain.
- ▶ **MRI** screens for vascular disease, NPH, tumour, basal-ganglia signal change (manganese T2 pallidal hyperintensity, CO pallidal necrosis).
- ▶ **Reversibility is the management theme:** withdraw culprit drugs/toxins; control vascular risk; shunt NPH; chelate Wilson’s. Where dopaminergic agents are tried (vascular, MPTP, postencephalitic, structural SNc), response guides prognosis.
- ▶ If an antipsychotic remains essential, switch to a **dopamine-sparing agent** (quetiapine/clozapine) or, for PD-psychosis, the 5-HT_{2A} inverse agonist **pimavanserin**.

High-yield exam pointers

- ▶ Parkinsonism = **bradykinesia + rigidity ± rest tremor**; PD ≈ 75% of cases; ~24% clinical misdiagnosis rate without strict (UK Brain Bank / MDS) criteria.
- ▶ **Commonest secondary cause = drug-induced** (neuroleptics, **metoclopramide**, cinnarizine/flunarizine, reserpine/tetrabenazine, lithium, valproate).
- ▶ DIP is **symmetrical, postural-tremor predominant, reversible** (may take up to 6 months); treat by stopping the drug ± anticholinergics/amantadine.
- ▶ **Vascular parkinsonism = “lower-body parkinsonism”**, falls, pyramidal/pseudobulbar signs, MRI small-vessel disease, **normal DaTscan**, poor but worth-trying levodopa response.
- ▶ MPTP → MPP⁺ via MAO-B → **complex-I inhibition**; manganese & CO damage the **globus pallidus** → levodopa-unresponsive parkinsonism.
- ▶ **Oculogyric crises** = postencephalitic and acute drug-induced dystonic reactions; **Hakim triad** (gait + dementia + incontinence) = NPH.

- ▶ Always exclude **Wilson's disease** in patients < 40 years — treatable with copper chelators.
- ▶ **DaTscan normal** in drug-induced/vascular/psychogenic/essential tremor; **abnormal** in PD and atypical parkinsonism.

Temporal Lobe Epilepsy

Asked in: Paper III Nov 2021 — RGUHS MD General Medicine

Definition / Introduction — Temporal lobe epilepsy (TLE) is a **focal (localization-related) epilepsy** in which seizures arise from neuronal networks within one temporal lobe, classically producing **focal seizures with impaired awareness** preceded by a stereotyped aura. Its commonest form, the **mesial temporal lobe epilepsy (MTLE) syndrome**, is *the most common syndrome associated with focal seizures with impairment of consciousness* and is defined by distinctive clinical, EEG, and pathologic features, the hallmark substrate being **hippocampal sclerosis** demonstrable on high-resolution MRI. It is clinically important because MTLE *tends to be refractory to anticonvulsants but responds well to surgical intervention*.

Classification and seizure semiology

- ▶ **Terminology (ILAE 2017)**: the term *partial* is obsolete — seizures are **focal** or **generalized**. The old categories “simple/complex partial” are eliminated; focal seizures are now described by **awareness (intact vs impaired)**, **onset (motor vs nonmotor)**, and whether they **evolve to bilateral tonic-clonic seizures** (formerly “secondary generalization”).
- ▶ **Two anatomical subtypes**:
 - **Mesial TLE** — arises from hippocampus/amygdala/parahippocampal gyrus; usually due to **hippocampal sclerosis**; the prototypic surgically remediable syndrome.

- **Lateral (neocortical) TLE** — arises from the lateral temporal neocortex; includes the genetic form ADEAF (autosomal dominant epilepsy with auditory features) due to **LGI1 (10q24)** mutations, presenting with **ictal auditory symptoms or aphasia**, onset usually **10–25 years**.
- ▶ **Aura (focal seizure with intact awareness)** — a focal seizure without cognitive disturbance, stereotypic for the patient; temporal-lobe auras include:
 - **Olfactory** hallucinations of acrid odors (e.g., burning rubber, bleach) and **gustatory** sensations (bitter, metallic).
 - **Epigastric “rising” sensation** ascending to the head; auditory phenomena (simple or complex sounds).
 - **Experiential/psychic symptoms** — intense **fear**, a dreamlike state, **depersonalization**, *déjà vu*, and **micropsia/macropsia** (objects appearing smaller or larger).
- ▶ **Focal seizure with impaired awareness** — aura → **motionless stare / behavioral arrest** (onset of impaired awareness) → **automatisms** (chewing, lip-smacking, swallowing, “picking” hand movements, or elaborate behaviors). **Unilateral dystonic posturing** of a limb may occur.
- ▶ **Postictal state** — **disorientation, anterograde amnesia**, and transient deficits from postictal inhibition (e.g., **dysphasia** when the focus is in the dominant hemisphere). Recovery takes seconds to hours. A focal seizure may **evolve to a bilateral tonic-clonic seizure**.

Characteristics of the mesial temporal lobe epilepsy syndrome (Table 436-3)

Domain	Features
History	History of febrile seizures; family history of epilepsy; early onset; rare generalized seizures; seizures may remit and reappear ; seizures often intractable
Clinical	Aura common; behavioral arrest/stare; complex automatisms ; unilateral posturing ; postictal disorientation; memory loss ; dysphasia (dominant-hemisphere focus)
EEG	Unilateral or bilateral anterior temporal spikes
Functional imaging	Hypometabolism on interictal PET; hyperperfusion on ictal SPECT; material-specific memory deficits on intracarotid amobarbital (Wada) test
MRI	Small hippocampus with increased T2 signal and loss of trilaminar (internal laminar) architecture ; small temporal lobe; enlarged temporal horn

Domain	Features
Pathology	Highly selective loss of specific hippocampal cell populations in most cases; granule cell layer dispersion ; gliosis

Pathophysiology — hippocampal sclerosis and epileptogenesis

- ▶ Seizures reflect a **shift in the normal balance of excitation and inhibition** in the CNS; in MTLE this is anchored in **hippocampal sclerosis**, which appears *essential to the pathophysiology for many patients*.
- ▶ **Selective neuronal loss**: many patients show highly selective loss of neurons that normally **inhibit the main excitatory neurons of the dentate gyrus**, with **reorganization (sprouting)** of **surviving neurons** that increases network excitability.
- ▶ **Epileptogenesis** — the transformation of a normal network into a chronically hyperexcitable one. A precipitating injury (e.g., prolonged/complex febrile seizure, head trauma, infection) creates a focal region of structural change → **local hyperexcitability** → further structural change → spontaneous seizures, typically after a **latent interval of months to years**.
- ▶ Additional mechanisms: chronic alterations in **glutamate and GABA receptor function** and induction of **inflammatory cascades**.
- ▶ **Risk factors / associations**: an antecedent history of **febrile seizures** (complex febrile seizures carry a 2–5% epilepsy risk) and a **family history of epilepsy**; TLE usually presents in **childhood**, related either to mesial temporal sclerosis (MTLE) or to other focal abnormalities such as **cortical dysgenesis**.

Investigations

- ▶ **Routine interictal EEG** — may be normal or show **anterior temporal spikes/sharp waves**; because the medial temporal focus is deep, the scalp EEG can be **nonlocalizing**.
- ▶ **Inpatient video-EEG monitoring** — captures habitual seizures to **localize and lateralize** the focus and correlate semiology with EEG/imaging; the cornerstone of presurgical evaluation.
- ▶ **High-resolution MRI (3 T)** — demonstrates the **hippocampal sclerosis triad**: high T2 signal, blurred internal laminar architecture, and reduced hippocampal volume (Fig. 436-1).
- ▶ **Functional/adjunctive imaging** — interictal PET (hypometabolism), ictal SPECT (hyperperfusion), and MEG to verify the epileptogenic zone.
- ▶ **Neuropsychological testing, intracarotid amobarbital (Wada) test, and functional MRI** — lateralize **language and memory** before resection.
- ▶ **Invasive monitoring** when noninvasive data are insufficient: **robot-assisted stereo-EEG (depth electrodes)** or subdural electrodes; intraoperative **electrocorticography and functional mapping** delineate **eloquent cortex**.

- Differentiate from psychogenic nonepileptic seizures and syncope; bizarre stereotyped paroxysmal behaviour should not be dismissed as non-epileptic without EEG.

Management — medical and surgical

- Medical (first line for focal seizures): drugs of choice are carbamazepine (or oxcarbazepine / eslicarbazepine), lamotrigine, phenytoin, and levetiracetam — broadly similar efficacy; choice is driven by pharmacokinetics, toxicity, and comorbidity. Aim for monotherapy at the maximally tolerated dose.

Drug	Typical adult dose	Key caution
Carbamazepine	600–1800 mg/d	Leukopenia, aplastic anemia, hepatotoxicity; <i>HLA-B linked</i> SJS in Asian/European ancestry
Oxcarbazepine	900–2400 mg/d	Avoids “toxic epoxide”; hyponatremia
Lamotrigine	150–500 mg/d	Rash / Stevens-Johnson — slow titration (lower with valproate)
Levetiracetam	1000–3000 mg/d	No major interactions; irritability/psychiatric effects
Phenytoin	300–400 mg/d (3–6 mg/kg)	Nonlinear kinetics; gum hypertrophy, hirsutism, osteoporosis
Valproic acid	—	Useful when seizures generalize; teratogenic, hepatotoxic
Topiramate / Zonisamide	200–400 mg/d	Renal stones; cognitive slowing
Lacosamide / Brivaracetam / Perampanel / Gabapentin	adjunctive	Add-on options for focal seizures
Cenobamate	100–400 mg/d	For focal epilepsy uncontrolled by up to 3 drugs

- Refractory MTLE → surgery: because MTLE often fails subsequent drug trials, give an **efficient but relatively brief medical trial**, then refer for surgical evaluation rather than years of uncontrolled seizures.
 - Anteromedial temporal lobectomy or the more limited amygdalohippocampectomy is the commonest procedure.
 - Outcome: ~70% of well-selected patients become seizure-free and a further 15–25% achieve ≥90% seizure reduction; clinically significant surgical complications are <5%. Patients generally continue antiseizure drugs postoperatively.
 - Stereotactic laser thermal (interstitial) ablation — a less invasive means of destroying the focus.

- ▶ **Palliative neurostimulation** (for non-resectable / multifocal / eloquent-cortex foci): **vagus nerve stimulation (VNS)** (open-loop, left vagus; limited efficacy), **responsive neurostimulation (RNS)** (closed-loop intracranial; ~15% seizure-free), and **anterior thalamic deep brain stimulation (DBS)**.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Coronal MRI of hippocampal sclerosis (Fig. 436-1):** outline both temporal lobes at the level of the hippocampal bodies. Labels — *Left hippocampus (small, high T2 signal, loss of internal architecture), Normal right hippocampus, Enlarged left temporal horn, T2-weighted MRI, 3 Tesla.*
- ▶ **Hippocampal circuit schematic:** Labels — *Dentate gyrus (granule cell loss + dispersion), CA1, CA3, Loss of inhibitory interneurons, Mossy-fibre sprouting / aberrant excitatory reorganization, Amygdala, Entorhinal cortex.*

Clinical / Diagnostic significance

- ▶ A stereotyped aura (*déjà vu*, rising epigastric sensation, olfactory hallucination) followed by stare and automatisms is the bedside signature of TLE and should prompt MRI of the temporal lobes.
- ▶ **Dysphasia/anterograde amnesia** postictally helps **lateralize** the focus to the dominant hemisphere — relevant to surgical risk to memory and language.
- ▶ The **concordance** of video-EEG, MRI hippocampal sclerosis, interictal PET hypometabolism and ictal SPECT defines a **surgically remediable** syndrome — one of the few epilepsies where surgery can be curative.
- ▶ Recognizing drug-resistance early avoids prolonged morbidity (injury, psychosocial harm, increased mortality including SUDEP) and the chance of seizure freedom with timely surgery.
- ▶ Identifying **lateral TLE / ADEAF (LGI1)** matters for genetic counselling and prognosis distinct from MTLE.

High-yield exam pointers

- ▶ **MTLE = commonest cause of focal seizures with impaired awareness; substrate = hippocampal sclerosis.**
- ▶ **Hippocampal sclerosis triad on MRI:** small hippocampus + increased T2 signal + loss of internal (trilaminar) architecture.
- ▶ **EEG:** unilateral/bilateral **anterior temporal spikes**; scalp EEG may be nonlocalizing (deep focus).
- ▶ Classic history: **antecedent febrile seizures + family history of epilepsy + early onset + drug-refractory course.**

- ▶ Semiology: aura → **behavioral arrest/stare** → **oroalimentary & manual automatisms** → **postictal confusion ± dysphasia**.
- ▶ Pathology: selective hippocampal neuronal loss, **granule cell dispersion**, **gliosis**; epileptogenesis after a **latent period**.
- ▶ Drugs of choice (focal): carbamazepine, oxcarbazepine, lamotrigine, phenytoin, levetiracetam.
- ▶ **Surgery (anteromedial temporal lobectomy/amygdalohippocampectomy)**: ~70% seizure-free, complications <5%.
- ▶ Non-resectable foci → VNS / RNS / thalamic DBS; **Wada test** assesses language & memory before resection.

SOURCE & COVERAGE

Harrison's Principles of Internal Medicine, 22e — Ch 436 "Seizures and Epilepsy" (MTLE syndrome, Table 436-3, Fig. 436-1 hippocampal sclerosis, focal seizure semiology, epileptogenesis, Table 436-9 antiseizure drugs, surgical/neurostimulation treatment). Coverage note: Harrison addresses TLE within the broader seizures/epilepsy chapter and does not give a separate "Engel" surgical outcome classification or detailed dual-pathology discussion; carbamazepine/phenytoin dose ranges and the SJS/HLA association quoted are from Table 436-9 and the drug-selection text. No fabricated specifics added.

Tic Douloureux (Trigeminal Neuralgia)

Asked in: Paper III Nov 2020 — RGUHS MD General Medicine

Definition / Introduction — *Tic douloureux* (trigeminal neuralgia, TN) is a chronic, episodic facial pain syndrome characterised by **paroxysms of excruciating, electric shock-like or lancinating pain** confined to one or more divisions of the **fifth cranial (trigeminal) nerve**, classically the maxillary (V2) and mandibular (V3) divisions on one side. The pain is brief (seconds to ≤2 minutes), stereotyped, triggered by innocuous cutaneous or intraoral stimuli, and — in the *classical* form — occurs **without any demonstrable objective sensory or motor deficit**. The term "tic" reflects the involuntary wince the patient gives at the height of each spasm. It is the prototype of a hyperexcitable cranial neuralgia and one of the most painful conditions in clinical medicine.

Epidemiology & Aetiopathogenesis

- ▶ **Incidence** ~4–8 per 100,000 per year; ~60% occur in **women**; onset is after age 40 in ~90% of cases, with incidence rising progressively with age (middle-aged and elderly predominate).
- ▶ **Pathophysiology** — Symptoms arise from **ectopic generation of action potentials** in pain-sensitive afferents of the trigeminal root, just before it enters the lateral surface of the pons (the *root entry zone*).

- A compressing vessel or lesion causes **focal demyelination of large myelinated (non-nociceptive) fibres**, rendering them hyperexcitable; these become **electrically (ephaptically) coupled** to adjacent small unmyelinated/poorly myelinated pain fibres.
- This *cross-talk* explains why innocuous tactile stimuli carried by large fibres can ignite paroxysms of pain — the basis of **trigger zones**.
- ▶ **Neurovascular compression** is the commonest cause: an aberrant or ectatic vessel — most often the **superior cerebellar artery**, occasionally AICA/PICA or the **superior petrosal vein** — loops onto the nerve root. Age-related **brain sagging and vascular tortuosity/thickening** explain the prevalence in later life.
- ▶ The trigeminal root is uniquely **ensheathed by oligodendrocyte (CNS-type) myelin for up to ~7 mm** after leaving the pons; this is why a **demyelinating MS plaque** at the root entry zone produces TN, and why TN in a young or bilateral patient should prompt a search for multiple sclerosis.

Clinical Features

- ▶ **Character:** superficial, stabbing, “electric-shock”, shooting or lancinating; each jab lasts seconds, recurring as single jabs or clusters, day and night, for weeks–months before remitting.
- ▶ **Distribution:** unilateral, in V2 and/or V3 (lips, gums, cheek, chin); **isolated V1 (ophthalmic) involvement is extremely rare**.
- ▶ **Trigger zones:** typically near the **nasolabial fold**, lips, or tongue; the trigger may be remote from the felt pain. Provoking acts include **washing the face, shaving, brushing teeth, chewing, talking, smiling, or a cold draught of air**.
- ▶ Patients hold the face still while talking and may avoid eating, leading to **weight loss, dehydration, and depression**.
- ▶ **Course:** exacerbating–remitting over years; remissions may last months but the disorder usually recurs, with attacks becoming more frequent and remissions shorter over time. A residual dull ache may linger between jabs in advanced disease.
- ▶ *Pretrigeminal neuralgia:* some patients have prodromal toothache/sinusitis-like pain for hours before classical TN develops in the same distribution.
- ▶ **Cardinal negative sign:** in *classical* TN, **examination is normal** — no sensory loss, no masticatory weakness. Objective sensory loss or jaw weakness redefines the problem as **trigeminal neuropathy** (a secondary/structural cause).

ICHD-3 Classification (etiological subtypes)

Subtype	Defining feature	Examination	Implication
Classical TN	Neurovascular compression with nerve-root atrophy or displacement (on MRI/at surgery)	Normal	Microvascular decompression candidate
Secondary TN	Underlying disease — MS plaque, cerebellopontine-angle tumour, brainstem/pontine infarct, mass	Often abnormal; may show concomitant continuous pain	Treat the cause; surgery inappropriate in MS
Idiopathic TN	No cause and no morphological nerve change despite vessel contact	Normal	Medical therapy

- *Secondary causes (Brazis): MS plaque, cerebellopontine-angle tumour (meningioma, schwannoma), aberrant superior cerebellar artery, cavernous malformation, lipoma, brainstem/pontine infarction, Chiari malformation, basilar invagination.*

Differential Diagnosis

Condition	Discriminating points
Dental/sinus/jaw disease	Local pathology; pain not lancinating/triggered
Migraine / cluster headache	Deep-seated, steady pain, longer duration; <i>cluster-tic</i> = rare coexistence
Paroxysmal hemicrania, SUNCT/SUNA	Prominent cranial autonomic features (lacrimation, conjunctival injection); distinct frequency/duration
Giant-cell (temporal) arteritis	Superficial facial pain but not shock-like ; myalgia, systemic symptoms, elevated ESR/CRP
Glossopharyngeal neuralgia	Identical-quality pain but in throat/tonsillar fossa , radiating to ear; triggered by swallowing; may cause bradycardia/syncope
Trigeminal neuropathy	Objective sensory loss / jaw weakness → mass, zoster, connective-tissue disease, <i>numb-chin (mental neuropathy)</i> may signal malignancy
Atypical/persistent idiopathic facial pain	Constant burning , ill-defined, often in middle-aged women with depression

Investigations

- ▶ **High-resolution, contrast-enhanced brain MRI ($\pm$ MR angiography)** in essentially all patients — to exclude secondary causes (demyelinating plaque, pontine lacunar infarct, CPA tumour, skull-base infiltration) and to demonstrate the offending vessel/neurovascular conflict before planning decompression.
- ▶ **Secondary cause is more likely** if age <40 years, bilateral symptoms, or any objective neurological sign.
- ▶ **ESR / CRP** if temporal arteritis is suspected.
- ▶ **Blink-reflex / trigeminal-evoked studies and EMG are normal** in idiopathic TN (abnormal results suggest a structural lesion).

Management

A. Medical therapy (first line for classical/idiopathic TN) — sodium-channel-blocking anticonvulsants are the drugs of choice.

Drug	Dose	Notes / toxicity
Carbamazepine (<i>drug of choice</i>)	Start 100 mg with food; $\uparrow$ 100 mg/day q1–2 days; maintenance ~200 mg QID; >1200 mg/day gives no extra benefit	Effective in 50–75%; dizziness, imbalance, sedation, agranulocytosis (monitor CBC), hyponatraemia, deranged LFTs
Oxcarbazepine	300–1200 mg BID	Probably equi-efficacious, less marrow toxicity but watch hyponatraemia
Phenytoin	300–400 mg/day	Useful if above fail/not tolerated; IV fosphenytoin 15–20 mg PE/kg aborts a severe acute attack
Lamotrigine	up to 400 mg/day	Add-on / alternative
Baclofen	10–20 mg TID	Alone or in combination
Topiramate	50 mg BID	Alternative
Gabapentin / pregabalin	gabapentin up to 3600 mg/day	Benign profile; <i>especially useful in MS-related TN</i>

- ▶ Monitor **CBC, LFTs and serum sodium** for the first months and yearly. If effective, continue ~1 month then taper to test for remission.
- ▶ *Proparacaine* anaesthetisation of the ipsilateral conjunctival sac can give temporary relief in an acute crisis.

B. Surgical / interventional therapy (drug failure or intolerance) — initial relief in $\geq 80\%$ of patients.

Procedure	Mechanism	Efficacy / drawbacks
Microvascular decompression (MVD) — <i>Jannetta</i> , via suboccipital craniotomy	Separates offending vessel from nerve root (non-destructive)	>70% relief , low recurrence; best for classic lancinating pain ; major-surgery risks; preop MRA essential
Gamma-knife stereotactic radiosurgery	Focused radiation to nerve root	Complete relief in ~½ (often delayed onset); low risk of numbness; recurrence in ~½ over 2–3 yr ; less effective than MVD but few serious complications; no GA needed
Radiofrequency thermal rhizotomy	Heat lesion of ganglion/nerve (destructive)	>95% short-term relief ; recurrence up to ½; facial numbness, masseter weakness, corneal denervation/ neurokeratitis with V1 lesions
Percutaneous balloon compression	Mechanical injury to ganglion (under GA)	Similar short/long-term relief; commonly causes ipsilateral facial numbness
Peripheral alcohol/glycerol block	Absolute alcohol 0.5–0.75 mL to mental/infraorbital/supraorbital nerve	Low morbidity, temporary numbness, corneal sensation preserved ; relapse in 6–18 months

- ▶ In MS-related TN, open surgical exploration/MVD is inappropriate; ablative (less invasive) techniques may help.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Trigeminal nerve and its three sensory divisions on the face** — label: *Ophthalmic (V1), Maxillary (V2), Mandibular (V3) dermatomes; Gasserian (semilunar/trigeminal) ganglion in Meckel's cave; superior orbital fissure (V1), foramen rotundum (V2), foramen ovale (V3)*; mark the typical **trigger zone at the nasolabial fold**.
- ▶ **Neurovascular conflict at the root entry zone** — label: *pons, trigeminal root entry zone, superior cerebellar artery looping onto nerve, zone of focal demyelination, and adjacent site of microvascular decompression (Teflon pledget)*.

Clinical / Diagnostic significance

- ▶ TN is a **clinical diagnosis**; the triad of *paroxysmal, triggerable, unilateral V2/V3 shock-like pain with a normal examination* is highly specific.

- ▶ A **normal neurological examination** is reassuring, but any objective deficit (sensory loss, jaw deviation, corneal hypoaesthesia) mandates MRI to exclude a structural lesion — *re-labelled trigeminal neuropathy*.
- ▶ **Young or bilateral TN** → think **multiple sclerosis** (demyelinating plaque at the root entry zone).
- ▶ An **isolated numb chin (mental neuropathy)** can be the sole herald of systemic malignancy — never dismiss it.
- ▶ Carbamazepine response is so characteristic that a good response supports the diagnosis; failure should prompt re-evaluation for a secondary cause.

High-yield exam pointers

- ▶ **Tic douloureux = trigeminal neuralgia**; paroxysmal lancinating pain, V2/V3 > V1, unilateral, seconds-long, with **trigger zones** (nasolabial fold).
- ▶ Incidence 4–8/100,000/yr; ~60% **women**; onset >40 yr in 90%.
- ▶ Cause = **neurovascular compression, most often the superior cerebellar artery**, at the **root entry zone**, causing focal demyelination and ephaptic cross-talk.
- ▶ **No objective sensory/motor loss in classical TN** — its presence ⇒ *trigeminal neuropathy / secondary cause*.
- ▶ **ICHD-3**: classical (vascular compression + atrophy), secondary (MS, tumour — may have *continuous* background pain), idiopathic.
- ▶ **Carbamazepine is the drug of choice** (effective 50–75%); alternatives — oxcarbazepine, phenytoin, lamotrigine, baclofen, gabapentin, topiramate.
- ▶ Severe acute attack — **IV fosphenytoin 15–20 mg PE/kg**.
- ▶ Surgery of choice in drug failure = **microvascular decompression (Jannetta, >70% durable relief)**; ablative options — RF rhizotomy, balloon compression, gamma-knife.
- ▶ **Young/bilateral TN** ⇒ **exclude MS**; obtain **high-resolution contrast MRI + MRA**.

SOURCE & COVERAGE

Treatment and Prevention of Cluster Headache

Asked in: Paper III Nov 2022 — RGUHS MD General Medicine

Definition / Introduction — Cluster headache is a relatively rare (population frequency ~0.1%) but highly stereotyped *trigeminal autonomic cephalalgia* (TAC) characterised by attacks of deep, retro-orbital, excruciating, explosive, strictly **unilateral** pain lasting 15–180 minutes, accompanied by **ipsilateral cranial autonomic features** and a striking **circadian/circannual periodicity**. Attacks occur from once every other day to eight times a day, are often nocturnal (~50%), and men are affected about three times more often than women. Because attacks peak rapidly and are agonising, management has two arms that must run together: **fast-acting abortive (acute) therapy** for individual attacks and **transitional + maintenance preventive therapy** to suppress attacks until the bout naturally remits.

Goals and general principles of management

- Two parallel objectives: (1) **abort the acute attack** rapidly, and (2) **prevent attacks** until the bout is over — *the most satisfactory strategy is preventive suppression of attacks for the duration of the cluster bout, while every patient also needs an acute treatment at some time.*
- Tailor preventive choice to **bout length and pattern**: short-bout episodic patients suit a brief “transitional” course; patients with long bouts or **chronic cluster headache** (remission <3 months without treatment) need agents that are **safe for prolonged use**.
- Avoid known **triggers during a bout**, notably **alcohol**.
- Oral sumatriptan and simple analgesics/decongestants are **ineffective** — patients mislabelled with “sinus headache” are commonly mistreated.

Acute (abortive) attack treatment

Attacks peak within minutes, so only **rapid-onset, parenteral/inhaled/intranasal** routes work; oral drugs are too slow.

Modality	Regimen (Harrison 22e)	Notes
High-flow oxygen	100% O ₂ at 10–12 L/min for 15–20 min via non-rebreather	High flow + high O ₂ content essential; <i>ultra-high flow with a demand valve</i> may help some patients; first-line, very safe
Sumatriptan SC	6 mg SC (3–4 mg SC also effective where available)	Aborts attack in 10–15 min; no tachyphylaxis with repeated use

Modality	Regimen (Harrison 22e)	Notes
Sumatriptan nasal	20 mg intranasal	Useful when patient prefers not to self-inject
Zolmitriptan nasal	5 mg intranasal	Effective alternative nasal triptan
Non-invasive vagus nerve stimulation (nVNS)	Three 2-min cycles consecutively at onset on the side of pain; may repeat after 9 min	FDA-cleared for acute treatment of episodic cluster headache

- Oral sumatriptan is NOT effective for acute attacks or for prevention.
- Triptan cautions: avoid in established/uncontrolled coronary or cerebrovascular disease and uncontrolled hypertension; respect total daily triptan limits.

Preventive treatment (Table 441-8)

Preventives are split into **short-term (transitional)** therapy — to gain rapid control while a slow maintenance drug is titrated — and **long-term (maintenance)** therapy. Choice depends on bout length.

Setting	Agent and dose (Harrison 22e)
Short-term / transitional (episodic CH)	Prednisone 1 mg/kg up to 60 mg/day, tapering over ~21 days (e.g. 60 mg/day ×7 days then rapid taper)
	Verapamil 160–960 mg/day (started during bout)
	Galcanezumab 300 mg SC
	Greater occipital nerve (GON) injection — local anaesthetic + corticosteroid
Long-term / maintenance (episodic CH and prolonged/chronic CH)	Verapamil 160–960 mg/day
	nVNS 6–24 stimulations/day
	Melatonin 9–12 mg/day
	Topiramate 100–400 mg/day
	Lithium 400–800 mg/day

- Glucocorticoids are the most reliable *transitional* drug for short bouts: a 10-day course of prednisone (60 mg/day for 7 days, then rapid taper) often interrupts the bout while verapamil takes effect.
- Greater occipital nerve injection (lidocaine + corticosteroid, ipsilateral) is proven in randomised controlled trials, giving benefit lasting up to 6–8 weeks — an excellent transitional option.

- ▶ Galcanezumab is a calcitonin gene-related peptide (CGRP) monoclonal antibody, FDA-approved for episodic cluster headache; 300 mg SC reduces attack frequency, is well tolerated, and is often an effective option.

Verapamil — the first-line maintenance preventive

- ▶ Most experts favour verapamil as first-line prevention for chronic cluster headache and prolonged bouts; it compares favourably with lithium in practice.
- ▶ Dosing: start 40–80 mg twice daily; titrate in 80-mg increments; effective doses may be as high as 960 mg/day — often far exceeding cardiac doses.
- ▶ Common side effects: constipation, leg/ankle swelling, gingival hyperplasia.
- ▶ Key safety concern — cardiac conduction: verapamil slows AV-nodal conduction and can cause heart block; monitor the PR interval on ECG.
 - ~20% develop ECG abnormalities, possible at doses as low as 240 mg/day, and these can worsen over time even on a stable dose.
- ▶ ECG monitoring schedule: baseline ECG in all patients; repeat ECG 10 days after each dose increase above 240 mg/day; on long-term verapamil, ECG every 6 months.

Neuromodulation and refractory / chronic disease

When medical therapy fails in chronic cluster headache, neuromodulation is considered:

- ▶ Sphenopalatine ganglion (SPG) stimulation with an implanted battery-free stimulator — effective in RCTs for both aborting attacks and reducing attack frequency over time.
- ▶ nVNS — compares favourably with standard of care in open-label experience (and is FDA-cleared for acute episodic attacks).
- ▶ Occipital nerve stimulation (ONS) — beneficial in open-label use.
- ▶ Deep-brain stimulation (DBS) of the posterior hypothalamic grey matter — successful in about 50% of treated patients, but its risk–benefit ratio makes it inappropriate until all less invasive options are exhausted.
- ▶ Destructive trigeminal procedures are *not* part of cluster-headache management (they are seldom useful even in the related TACs and cause long-term complications).

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ Stepwise management algorithm of cluster headache — three columns/boxes:
- ▶ Acute attack → labels: 100% O₂ 10–12 L/min × 15–20 min, Sumatriptan 6 mg SC, Sumatriptan 20 mg / Zolmitriptan 5 mg nasal, nVNS (3 × 2-min cycles).
- ▶ Transitional prevention → labels: Prednisone 60 mg taper over 21 days, GON injection (LA + steroid), Galcanezumab 300 mg SC.

- ▶ *Maintenance prevention* → labels: **Verapamil 160–960 mg/day (first-line)**, **Lithium 400–800 mg/day**, **Topiramate 100–400 mg/day**, **Melatonin 9–12 mg/day**, **nVNS** → arrow to **Refractory chronic CH** → **SPG stimulation / ONS / DBS posterior hypothalamus**.
- ▶ **Side-of-pain autonomic features sketch** — a face with right-sided labels: **conjunctival injection / lacrimation**, **rhinorrhoea / nasal congestion**, **ptosis + miosis (partial Horner)**, **aural fullness**, with the central label **posterior hypothalamic “pacemaker” activation**.

Clinical / Diagnostic significance

- ▶ **Restless behaviour** (pacing, rocking, head-rubbing) during an attack is a useful bedside clue distinguishing cluster headache from migraine (where patients lie still) and supports starting abortive therapy promptly.
- ▶ **Baseline ECG before verapamil** and serial monitoring are mandatory because of dose-dependent AV block — a frequently tested safety pearl.
- ▶ Because TACs over-represent **pituitary tumour-related headache**, pituitary imaging (MRI) and pituitary function tests (prolactin, growth hormone) should be obtained when clinically indicated before committing to lifelong therapy.
- ▶ High-flow oxygen is the safest abortive and is preferred in patients with vascular contraindications to triptans.
- ▶ Distinguish from indomethacin-responsive TACs: **paroxysmal hemicrania and hemicrania continua respond completely to indomethacin** — verapamil/oxygen do not abort them — so an indomethacin trial is diagnostically and therapeutically decisive in the differential.

High-yield exam pointers

- ▶ **Two arms:** rapid abortive therapy **plus** preventive suppression for the whole bout.
- ▶ **Acute first-line:** **100% O₂ 10–12 L/min for 15–20 min** and **sumatriptan 6 mg SC** (no tachyphylaxis).
- ▶ **Oral sumatriptan is useless** in cluster headache (too slow).
- ▶ **Verapamil = first-line maintenance preventive**, 160–960 mg/day; titrate in 80-mg steps with **ECG monitoring** (PR interval, AV block).
- ▶ **Transitional bridge:** prednisone 60 mg taper over ~21 days and/or **greater occipital nerve injection** (benefit 6–8 weeks).
- ▶ **Galcanezumab (anti-CGRP mAb) 300 mg SC** — FDA-approved for **episodic cluster headache**.
- ▶ Other maintenance options: **lithium, topiramate, melatonin, nVNS**.
- ▶ **Refractory chronic CH:** SPG stimulation, occipital nerve stimulation, DBS of posterior hypothalamus (~50% success).
- ▶ Counsel **alcohol avoidance** during the cluster bout.

SOURCE & COVERAGE

Harrison's Principles of Internal Medicine, 22e — Ch 441 "Migraine and Other Primary Headache Disorders" (Trigeminal Autonomic Cephalalgias / Cluster Headache section; Tables 441-7 and 441-8). All drugs, doses, monitoring rules and neuromodulation data are taken from this chapter. Coverage note: triptan cardiovascular cautions are standard, universally-accepted internal medicine added for completeness and are not elaborated in this specific chapter section.

Trigeminal Neuralgia

Asked in: Paper III Jul 2020 — RGUHS MD General Medicine

Definition / Introduction — *Trigeminal neuralgia* (TN; *tic douloureux*) is a chronic disorder characterised by recurrent, brief paroxysms of excruciating, electric shock-like or lancinating unilateral facial pain confined to one or more divisions of the fifth (trigeminal) cranial nerve. The pain is stereotyped, often triggered by innocuous cutaneous stimulation of a "trigger zone," and—in its classic form—occurs with **no demonstrable objective sensory loss** on examination. It is among the most severe pains known to medicine and the commonest cranial neuralgia, with an annual incidence of **4–8 per 100,000**.

Epidemiology & aetiopathogenesis

- ▶ **Demographics:** affects middle-aged and elderly persons; onset is after age 40 years in ~90% of patients, with incidence rising progressively with age. ~60% of cases occur in **women**. Rare familial clustering is described.
- ▶ **Neurovascular compression (classic TN):** the dominant mechanism. Compression of the trigeminal nerve root at or near its **root entry zone (REZ)** into the lateral pons by an aberrant vessel—most often the **superior cerebellar artery**, occasionally the anterior/posterior inferior cerebellar arteries or a tortuous **superior petrosal vein**—produces focal demyelination.
- ▶ **Anatomical vulnerability:** for up to ~7 mm after leaving the pons, the trigeminal root is ensheathed by central **oligodendrocyte-derived myelin** rather than Schwann-cell myelin; this transitional zone is uniquely susceptible to demyelination and explains the predilection of *multiple sclerosis* (MS) plaques to cause TN.
- ▶ **Electrophysiology of pain:** demyelination renders large myelinated (touch) fibres hyperexcitable and **ephaptically (electrically) coupled** with adjacent small unmyelinated/poorly-myelinated pain fibres. Ectopic generation of action potentials and ephaptic cross-talk explain why a light tactile stimulus, carried by large fibres, can ignite a paroxysm of pain.
- ▶ **Age relationship:** age-related brain sagging and increasing vascular tortuosity/thickening account for the rising prevalence in later life.

- ▶ **Secondary causes:** MS, pontine lacunar infarct, and structural lesions of the cerebellopontine angle/Meckel's cave (acoustic schwannoma, meningioma, trigeminal neuroma, aneurysm, metastasis) — these typically produce *trigeminal neuropathy* with objective signs.

Clinical features

- ▶ **Quality:** sudden, excruciating, superficial **stabbing/electric shock-like/lancinating** pain; the patient may wince visibly—hence “tic.”
- ▶ **Duration & pattern:** each jab lasts seconds to a minute or two; experienced as single jabs or clusters that blur together; recurs frequently day and night for weeks–months, with a tendency to **spontaneous remission** (months–years) and eventual relapse.
- ▶ **Distribution:** strictly **unilateral**; most often the **maxillary (V2) and mandibular (V3)** divisions (lips, gums, cheek, chin); isolated **ophthalmic (V1)** involvement is *rare*.
- ▶ **Trigger zones:** characteristic—small areas on the face, lips, nasolabial fold, or tongue where light touch provokes attacks. Common triggers: **washing/touching the face, brushing teeth, shaving, chewing, talking, smiling, a cold draught of air**. Patients hold the face still and avoid eating to prevent attacks (may lead to weight loss, dehydration, depression).
- ▶ **Cardinal negative sign:** in classic TN, **objective sensory loss CANNOT be demonstrated** and the motor (masticatory) division is intact. Sensory loss or jaw weakness signals a *secondary* cause (trigeminal neuropathy).

Classification (ICHD-3)

Type	Defining feature
Classical TN	Demonstrable neurovascular compression (MRI/surgery) with associated nerve-root atrophy or displacement
Secondary TN	Due to an identifiable underlying disease — multiple sclerosis or a space-occupying lesion ; may have continuous/near-continuous background pain ± sensory signs
Idiopathic TN	No underlying cause and no morphological nerve-root change despite vessel contact

Differential diagnosis

- ▶ **Dental/sinus/jaw disease** — must be excluded first.
- ▶ **Migraine / cluster headache** — pain is deep, steady, throbbing (not superficial stabbing); rarely *cluster-tic* syndrome combines both.
- ▶ **Paroxysmal hemicrania, SUNCT/SUNA** — distinguished by attack frequency/duration and prominent cranial **autonomic** features (conjunctival injection, tearing).

- ▶ **Giant-cell (temporal) arteritis** — superficial facial pain but not shock-like; jaw claudication, myalgia, raised ESR/CRP.
- ▶ **Glossopharyngeal neuralgia** — identical-quality lancinating pain in the **throat/tonsillar fossa radiating to ear**, triggered by swallowing/coughing; may cause bradycardia/syncope.
- ▶ **Persistent idiopathic facial pain** (atypical facial pain) — constant, poorly localised, deep aching pain without trigger zones; not relieved by nerve blocks.
- ▶ **Trigeminal neuropathy** — sensory loss ± masticatory weakness; from Sjögren's, connective-tissue disease, herpes zoster, leprosy, tumour, or isolated *mental neuropathy* (numb-chin sign) warning of systemic malignancy.
- ▶ **Bilateral or young-onset TN** ⇒ **think MS** (demyelinating plaque at the pontine REZ).

Investigations

- ▶ TN is a **clinical diagnosis**; idiopathic TN has normal laboratory studies, and blink-reflex/EMG are normal.
- ▶ **MRI brain (high-resolution, contrast-enhanced)**: mandatory to exclude secondary causes (MS plaque, pontine infarct, posterior-fossa/CP-angle tumour, skull-base infiltration). Secondary causes are more likely when onset is <40 years or symptoms are **bilateral**.
- ▶ **High-resolution MR angiography (MRA)**: demonstrates the neurovascular relationship at the REZ and is used **pre-operatively** to plan microvascular decompression.
- ▶ ESR/CRP if temporal arteritis is suspected.

Management

A. Medical (first-line): Sodium-channel-blocking anticonvulsants are the drugs of choice.

Drug	Typical regimen	Notes
Carbamazepine (DOC)	Start 100 mg once daily with food; ↑ by 100 mg every 1–2 days; maintenance ~200 mg QID; doses >1200 mg/day give no extra benefit	Effective in 50–75%; watch dizziness, ataxia, sedation, rare agranulocytosis — monitor CBC, LFT
Oxcarbazepine	300–1200 mg BID	Equally efficacious, less marrow toxicity; risk of hyponatraemia — monitor serum Na ⁺
Phenytoin	300–400 mg/day	Alternative if above fail/not tolerated
Lamotrigine	up to 400 mg/day	Add-on / second line
Baclofen	10–20 mg TID	Add-on, useful adjunct
Topiramate	50 mg BID	Option

Drug	Typical regimen	Notes
Gabapentin / Pregabalin	gabapentin up to 3600 mg/day	Benign profile; especially useful in MS-related TN

- ▶ If a drug is effective, continue ~1 month then taper to test for remission; use the lowest dose that controls pain.
- ▶ **Acute severe crisis:** IV fosphenytoin 15–20 mg PE/kg; topical ophthalmic **proparacaine** to the ipsilateral conjunctival sac can give hours–days of relief.

B. Surgical / interventional (drug-refractory): provide initial pain relief in ≥80%.

- ▶ **Microvascular decompression (MVD)** — *most definitive*; suboccipital/retromastoid craniotomy with posterior-fossa exploration, mobilisation of the offending vessel and interposition of a synthetic pad. >70% efficacy with durable relief (Jannetta's series of 1155 patients: ~70% excellent relief at 10 years). Preserves facial sensation; mortality ~1%; risk to CN IV/VII/VIII. Preferred in younger, medically fit patients; best for classic lancinating pain.
- ▶ **Percutaneous radiofrequency thermal rhizotomy** of the gasserian ganglion — short-term relief in >90–95%; long-term recurrence up to one-third; produces facial numbness, possible masseter weakness, and—after V1 lesions—corneal anaesthesia/neurokeratitis. Favoured in elderly/comorbid patients (no general anaesthesia).
- ▶ **Percutaneous balloon compression** of the trigeminal ganglion — similar relief; performed under general anaesthesia; recurrence ~2–3 years; commonly causes ipsilateral facial numbness.
- ▶ **Stereotactic Gamma Knife radiosurgery** — least invasive; complete (sometimes delayed) relief in ~half; recurrence in one-third over 2–3 years; low risk of facial numbness.
- ▶ **Peripheral alcohol/nerve block** (mental, infraorbital, supraorbital) — simple, temporary (relapse in 6–18 months).
- ▶ **Ablative procedures risk anaesthesia dolorosa** (painful posttraumatic trigeminal neuropathy) in ~0–3%, which can be worse than the original pain — informs careful patient selection.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Trigeminal nerve & its three divisions:** label *Gasserian (semilunar/trigeminal) ganglion in Meckel's cave*, *Ophthalmic V1 → superior orbital fissure*, *Maxillary V2 → foramen rotundum*, *Mandibular V3 → foramen ovale*, motor root to muscles of mastication, and the cutaneous sensory territories of V1/V2/V3 on the face.
- ▶ **Neurovascular conflict at the root entry zone:** label *pons*, *trigeminal nerve root*, *root entry zone (REZ)*, *superior cerebellar artery looping onto the nerve*, *zone of focal demyelination*, and the *transitional central (oligodendrocyte) myelin segment (~7 mm)*.

Clinical / Diagnostic significance

- ▶ A **negative neurological examination with a typical history** clinches classic TN; *any* sensory deficit, jaw weakness, deafness, or bilateral pain mandates a search for a structural/secondary cause.
- ▶ **Young patient / bilateral TN** → screen for **multiple sclerosis**; **numb chin** → exclude systemic malignancy.
- ▶ MRA-defined neurovascular conflict identifies patients most likely to benefit from MVD.
- ▶ Carbamazepine response is itself supportive of the diagnosis; failure should prompt re-evaluation for secondary causes.

High-yield exam pointers

- ▶ TN = paroxysmal, unilateral, lancinating pain in V2/V3 > V1, with **trigger zones** and **no sensory loss** (classic) — *tic douloureux*.
- ▶ Commonest cause = **neurovascular compression by the superior cerebellar artery** at the pontine REZ → focal demyelination + ephaptic transmission.
- ▶ **Carbamazepine is the drug of choice** (effective 50–75%); **oxcarbazepine** = better tolerated alternative (beware hyponatraemia).
- ▶ **Bilateral / age <40 / sensory signs** ⇒ **secondary TN** — think MS or posterior-fossa tumour; do MRI.
- ▶ MVD is the most durable surgery (>70% at 10 years, preserves sensation); ablative procedures risk facial numbness and **anaesthesia dolorosa**.
- ▶ Doses of carbamazepine >1200 mg/day **add no benefit**; monitor CBC (agranulocytosis), LFTs, Na⁺.
- ▶ **Glossopharyngeal neuralgia** is the throat/ear analogue — same drugs (carbamazepine first), may cause bradycardia/syncope.
- ▶ ICHD-3 trichotomy: **classical** (vascular, with root atrophy), **secondary** (MS/SOL), **idiopathic**.

SOURCE & COVERAGE

- ▶ **Harrison's Principles of Internal Medicine, 22e** — “Trigeminal Neuralgia, Bell's Palsy, and Other Cranial Nerve Disorders” (anatomy, pathophysiology, drug doses, surgical options).
- ▶ **Bradley & Daroff's Neurology in Clinical Practice, 8e** — “Headache and Other Craniofacial Pain” (ICHD-3 classification, neurovascular conflict, Jannetta MVD series, anesthesia dolorosa, acute-attack fosphenytoin, alcohol blocks).

Wernicke Encephalopathy

Asked in: Paper III Dec 2023 — RGUHS MD General Medicine

Definition / Introduction — Wernicke encephalopathy is an acute, potentially fatal neuropsychiatric emergency due to **thiamine (vitamin B1) deficiency**. It classically presents with **confusion, ophthalmoplegia/nystagmus, and gait ataxia**, but the complete triad is absent in many patients. It is the acute stage of the Wernicke-Korsakoff spectrum; delayed or inadequate treatment may leave irreversible amnesia and confabulation.

Etiology and risk settings

- ▶ **Thiamine physiology:** thiamine is a water-soluble vitamin with small body stores; continuous dietary supply is needed. It acts as thiamine pyrophosphate in carbohydrate, amino-acid, and lipid metabolism, including alpha-ketoacid decarboxylation and transketolase reactions.
- ▶ **Alcohol use disorder** is the commonest setting in adult medicine: alcohol reduces intake, impairs intestinal absorption and metabolism/storage of thiamine, and increases urinary losses.
- ▶ **Non-alcoholic high-risk states:** hyperemesis gravidarum, anorexia/eating disorders, systemic malignancy, AIDS, chronic protein-calorie undernutrition, prolonged fasting or starvation, dieting, prolonged IV feeding, refeeding after starvation, hemodialysis/peritoneal dialysis, and gastrointestinal or **bariatric/metabolic surgery**.
- ▶ **Precipitating event:** IV glucose, carbohydrate loading, enteral/parenteral nutrition, or refeeding in a thiamine-depleted patient may acutely precipitate Wernicke encephalopathy and lactic acidosis.
- ▶ **Associated deficiency syndromes:** wet beriberi causes high-output heart failure with tachycardia, cardiomegaly, edema and warm extremities; dry beriberi causes symmetric sensorimotor polyneuropathy with pain, paresthesia and loss of reflexes, legs more than arms.

Pathogenesis and vulnerable neuroanatomy

- ▶ Thiamine deficiency impairs cerebral energy metabolism, especially in metabolically active periventricular and diencephalic structures; pyruvate may accumulate and transketolase activity falls.
- ▶ Characteristic sites are **periaqueductal gray**, tectal plates, **medial thalami**, **mammillary bodies**, walls of the third and fourth ventricles, cerebellar vermis, pons, medulla, dentate nuclei, cranial nerve nuclei and vestibular nuclei.
- ▶ Eye signs reflect involvement of **cranial nerve III, VI and VIII nuclei**, medial longitudinal fasciculus and periaqueductal/brainstem ocular motor pathways.
- ▶ Gait ataxia reflects combined involvement of the **cerebellar vermis**, vestibular pathways and often peripheral neuropathy; truncal/gait ataxia is more prominent than limb ataxia.
- ▶ Autonomic features such as **hypothermia** and **postural hypotension** reflect hypothalamic and brainstem autonomic pathway involvement.

- ▶ Korsakoff amnesia reflects damage in the **mammillary bodies, mammothalamic tract, medial dorsal/anterior thalamic nuclei, hippocampal-parahippocampal circuits and related limbic memory pathways.**
- ▶ Pathology evolves from congestion and **petechial hemorrhages** to glial proliferation, myelin pallor, shrinkage and discoloration in the same regions seen on MRI.

Clinical features

Component	Exam-ready points
Mental status	Confusion is the commonest feature, developing over days to weeks: inattention, apathy, disorientation, impaired short-term memory and reduced mental control. Stupor or coma is uncommon but possible.
Ocular signs	Horizontal gaze-evoked nystagmus, vertical nystagmus on upgaze, bilateral lateral rectus weakness/sixth nerve palsy, conjugate gaze palsy, ophthalmoplegia; sluggish pupils and light-near dissociation may occur.
Ataxia	Broad-based gait, truncal instability, inability to stand/walk unaided; limb ataxia is less prominent. Vertigo may be absent despite vestibular nuclear involvement.
Peripheral/autonomic	Peripheral neuropathy, pain/paresthesia, reduced reflexes, hypothermia, postural hypotension; look for malnutrition, liver disease and alcohol withdrawal.
Korsakoff syndrome	Usually follows repeated or inadequately treated Wernicke episodes: severe anterograde and retrograde amnesia, impaired learning, disorientation to time/place and early confabulation, with relative preservation of alertness, attention and social behavior.

- ▶ The classic triad is useful but insensitive: Bradley notes all three elements in fewer than half of patients; a Spanish series found the triad in 39% of alcoholic and 29% of non-alcoholic patients.
- ▶ In alcohol use disorder, Wernicke encephalopathy may coexist with withdrawal delirium, hepatic encephalopathy, head injury, subdural hematoma, hypoglycemia, sepsis and electrolyte disturbances.

Diagnosis and investigations

- ▶ **Diagnosis is clinical and urgent.** Do not wait for laboratory confirmation before giving parenteral thiamine.

- ▶ **Caine criteria:** suspect Wernicke encephalopathy when any **two of four** are present: (1) dietary deficiency/malnutrition, (2) oculomotor abnormality, (3) cerebellar dysfunction or impaired gait, (4) altered mental status or memory impairment. These criteria are more sensitive than requiring the full triad.
- ▶ **Therapeutic response** supports the diagnosis: improvement in ocular signs or confusion within 1-2 days is strongly suggestive, but absence of immediate full recovery does not exclude the diagnosis.
- ▶ **Laboratory tests:** draw blood before treatment if feasible, but never delay therapy. Tests include whole-blood/serum thiamine, urinary thiamine excretion, erythrocyte transketolase activity before and after thiamine pyrophosphate, and serum pyruvate. Harrison uses >25% stimulation of transketolase activity after thiamine pyrophosphate as abnormal.
- ▶ **MRI brain** is the best imaging test when available: symmetric T2/FLAIR and diffusion abnormalities in periaqueductal regions, tectal plates, medial thalami and mammillary bodies; cerebellar vermis, pons, medulla, dentate nuclei, basal ganglia and cranial nerve nuclei may be involved. SWI may show petechial hemorrhage in mammillary bodies.
- ▶ **CT brain** is much less sensitive but may be needed to exclude trauma, hemorrhage, hydrocephalus or stroke. CSF is usually normal or shows only mild protein elevation.
- ▶ **Differential diagnosis:** alcohol intoxication or withdrawal delirium, hepatic encephalopathy, uremic encephalopathy, sepsis-associated encephalopathy, hypoglycemia, stroke/posterior circulation disease, encephalitis, sedative/opioid intoxication, electrolyte disorders and Marchiafava-Bignami disease.

Management

Situation	Treatment
Suspected/established Wernicke encephalopathy	Give thiamine immediately before glucose. CMDT recommends empiric thiamine 500 mg IV three times daily for 3-5 days when Caine criteria are met; Bradley gives 500 mg IV acutely followed by 100 mg three times daily during the first week. Harrison recommends 200 mg IV three times daily in acute thiamine deficiency with neurologic signs until no further acute improvement, then oral thiamine.
At-risk coma/intoxication or emergency dextrose	Give IV thiamine first; CMDT coma protocol gives thiamine 100 mg IV , followed by 50% dextrose 25 g and naloxone when indicated.
Alcohol withdrawal prophylaxis	Hydration, electrolyte correction and vitamins; CMDT uses thiamine 100 mg IV daily for 3 days , then oral thiamine for prevention. Harrison advises

Situation	Treatment
	oral multivitamins with 50-100 mg oral thiamine daily for a week or more in withdrawal.
After acute phase	Continue oral thiamine until nutrition is secure; correct diet, protein-calorie malnutrition and coexisting B-vitamin deficiencies.

- ▶ **Magnesium repletion is essential** because magnesium is required for thiamine activation; thiamine response may be poor if magnesium is low.
- ▶ Treat associated alcohol withdrawal with benzodiazepines when indicated, correct hypokalemia/hypomagnesemia/hypophosphatemia, screen for trauma, infection, hypoglycemia and liver disease, and arrange alcohol-use-disorder treatment and nutritional rehabilitation.
- ▶ Oral thiamine alone is inadequate initially in suspected Wernicke encephalopathy because absorption is unreliable in debilitated and alcoholic patients.

Prognosis, complications and prevention

- ▶ Untreated Wernicke encephalopathy is progressive and may cause death, coma or permanent Korsakoff syndrome.
- ▶ Even with treatment, early studies reported mortality of **10-20%**; delayed recognition is common because the full triad is often absent and non-alcoholic cases are overlooked.
- ▶ Ocular signs usually improve rapidly, often within hours to 24 h, although fine horizontal nystagmus may persist in about **60%**. Gait improves slowly and may remain abnormal for months in more than one-third of patients.
- ▶ Korsakoff syndrome is often persistent; treatment is mainly supportive supervision and rehabilitation, as controlled evidence for cholinesterase inhibitors or memantine is not consistent.
- ▶ Prevention is mandatory in all high-risk patients: give thiamine before carbohydrate, during alcohol withdrawal, before/with refeeding, after bariatric surgery, during prolonged vomiting or hyperemesis, and in dialysis patients with unexplained encephalopathy.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Triad and lesion-map diagram:** central label “Thiamine deficiency”; arrows to “Confusion”, “Ophthalmoplegia/nystagmus”, “Gait/truncal ataxia”; side labels “mammillary bodies”, “medial thalami”, “periaqueductal gray”, “tectal plate”, “CN III/VI/VIII nuclei”, “cerebellar vermis”, “hypothalamic autonomic pathways”.
- ▶ **Emergency treatment flowchart:** “At-risk delirium/coma/malnutrition/alcohol use” -> “Draw thiamine labs if feasible” -> “Thiamine IV before glucose” -> “High-dose IV

thiamine + Mg/B-complex/electrolytes” -> “MRI if needed; exclude trauma/sepsis/hepatic/uremic causes” -> “Oral thiamine + nutrition + abstinence plan”.

Clinical / Diagnostic significance

- ▶ Wernicke encephalopathy is a **medical emergency**, not a retrospective diagnosis; treatment is safe, inexpensive and should precede imaging and laboratory confirmation.
- ▶ The most important diagnostic trap is waiting for the full triad; use **Caine criteria** in any malnourished, alcoholic, hyperemesis, post-bariatric, refeeding or dialysis patient with delirium, ataxia or ocular signs.
- ▶ Always give **thiamine before dextrose** in at-risk patients; glucose administration increases thiamine requirement and may precipitate or worsen Wernicke-Korsakoff syndrome.
- ▶ MRI helps confirmation but a negative CT or absent MRI lesion does not exclude the diagnosis.
- ▶ Distinguish from delirium tremens: DT has autonomic hyperactivity, tremor, hallucinations and withdrawal timing; Wernicke has nutritional risk plus ocular motor signs and gait ataxia, and both can coexist.
- ▶ Persistent amnesia after the acute delirium clears suggests **Korsakoff syndrome**.

High-yield exam pointers

- ▶ Write the triad: **confusion + ophthalmoplegia/nystagmus + gait ataxia**.
- ▶ Mention that the full triad is absent in many cases; use **two of four Caine criteria**.
- ▶ Never give glucose first in an at-risk patient; **thiamine before dextrose** is a must-write line.
- ▶ High-dose parenteral thiamine is required for suspected disease: **500 mg IV three times daily for 3-5 days** is the current empiric emergency regimen.
- ▶ Add **magnesium correction**, B-complex vitamins, nutrition and alcohol-withdrawal management.
- ▶ MRI lesions: **mammillary bodies, medial thalami, periaqueductal gray/tectal plate**.
- ▶ Korsakoff syndrome: **anterograde and retrograde amnesia with confabulation** after repeated or undertreated episodes.
- ▶ Prevention is needed in alcohol use disorder, hyperemesis, bariatric surgery, starvation/refeeding, prolonged IV feeding and dialysis.

Infectious diseases

Management of a Cat Bite — Wound Care, Antimicrobial Therapy and Infection Prophylaxis (Rabies & Tetanus)

Asked in: Paper II 08 Apr 2026 — RGUHS MD General Medicine

Definition / Introduction — An animal bite is a breach of the skin’s protective barrier that inoculates the biting animal’s oropharyngeal flora into deeper, susceptible tissues, converting the wound into a contaminated, often deep, polymicrobial injury. Cat bites are clinically deceptive: although the external wound is small, the cat’s *narrow, sharp canine teeth* drive bacteria deep, so that **more than half of all cat bites become infected** — a far higher rate than dog bites — with a strong predilection for **septic arthritis and osteomyelitis** when punctures overlie a joint, especially of the hand. The dominant pathogen is *Pasteurella multocida*, which advances within hours. Management therefore rests on four pillars: structured assessment, aggressive local wound care, appropriate antibiotic therapy, and prophylaxis against rabies and tetanus.

Microbiology — why a cat bite is dangerous

Cat-bite infections are **polymicrobial**, reflecting the feline oropharynx plus skin/soil organisms; cultures yield a mix of aerobes and anaerobes.

Organism	Note
* <i>Pasteurella multocida</i> *	Small gram-negative coccobacillus; normal feline oral flora; the single commonest isolate (~75% of cat-bite infections); causes rapidly advancing cellulitis with purulent drainage and adenitis, often within hours
<i>Staphylococcus aureus</i> (incl. MRSA)	Skin/oral flora; consider empirical MRSA cover in high-risk wounds
β-hemolytic streptococci	Common aerobic co-pathogen
Anaerobes — <i>Bacteroides</i> , <i>Fusobacterium</i> , <i>Prevotella</i> , <i>Porphyromonas</i>	Especially in deep punctures; many produce β-lactamase

Organism	Note
* <i>Capnocytophaga canimorsus</i> *	Fulminant sepsis, DIC, renal failure in asplenic, cirrhotic or immunosuppressed hosts
<i>Bartonella henselae</i>	Cat-scratch disease — late consequence (see below)
<i>Francisella tularensis</i> (tularemia); <i>Sporothrix schenckii</i> (sporotrichosis)	Reported after cat bites/scratches

Approach to the patient — focused assessment

- ▶ **History:** type of animal, *provoked vs unprovoked* attack (unprovoked raises rabies suspicion), **time elapsed** since injury, the animal's vaccination/ownership status and current whereabouts.
- ▶ **Host risk factors:** diabetes mellitus, liver disease/cirrhosis, **splenectomy/asplenia**, immunosuppression (glucocorticoids, SLE, leukaemia), mastectomy or lymphoedema of the involved limb, prosthetic joints/valves — all favour antibiotics and predict severe disease.
- ▶ **Wound examination:** type (puncture/laceration/scratch), depth, and crucially **joint, tendon, nerve or bone involvement** — hand wounds warrant **hand-surgery consultation**. Document with a diagram or photograph. Assess for established infection (redness, exudate, foul odour, lymphangitis, lymphadenopathy).
- ▶ **Investigations:** **radiograph** of penetrating/hand wounds for fracture, retained tooth or foreign body and to baseline for osteomyelitis; **Gram stain and aerobic + anaerobic culture** of all infected wounds (use a small-tipped swab in deep punctures); WBC count and **blood cultures** if systemic infection is suspected. Notify the laboratory if fastidious organisms (e.g. *Capnocytophaga*) are suspected, as they need prolonged incubation.

Wound management (local care) — the most important step

- ▶ **Copious irrigation** with normal saline and **debridement** of devitalised tissue; remove foreign bodies; drain all abscesses. Thorough cleansing/irrigation is the single most important factor in reducing infection.
- ▶ **Wound closure is controversial and generally avoided** in bite wounds. **Cat-bite puncture wounds should be left unsutured** because of their very high infection rate; small uninfected wounds heal by secondary intention, and **delayed primary closure** is used once the risk of infection has passed.
- ▶ **Facial wounds** are an exception — usually sutured after meticulous cleaning, because of excellent blood supply, low infection risk and cosmetic importance.
- ▶ Wounds **>12 h old** (arm/leg) or **>24 h old** (face) and **all hand wounds** should not be closed primarily.
- ▶ **Elevate and immobilise** the part (especially the hand) — a valuable adjunct to antimicrobial therapy.

Antibiotic therapy

Cover must target *S. aureus*, *Pasteurella*, *Capnocytophaga*, streptococci and oral anaerobes. **Avoid monotherapy with dicloxacillin, cephalexin, macrolides or clindamycin** — all lack reliable *Pasteurella* activity; azithromycin and 1st/2nd-generation cephalosporins are inadequate. **TMP-SMX has poor anaerobic activity** and must be paired with an anti-anaerobe.

Scenario	Regimen
Prophylaxis (early uninfected cat bite — <i>usually advised</i> , see below)	Amoxicillin-clavulanate 875/125 mg PO q12h (or 500 mg PO TID) for 3–5 days
Penicillin-allergic	Clindamycin or metronidazole <i>plus</i> (doxycycline 100 mg BD or double-strength TMP-SMX BD or a fluoroquinolone, e.g. ciprofloxacin 500 mg BD); or moxifloxacin 400 mg OD monotherapy
Established infection	Amoxicillin-clavulanate PO; or ampicillin-sulbactam 1.5–3.0 g IV q6–8h; or ceftriaxone + metronidazole; or ertapenem 1 g IV daily
* <i>Serious P. multocida</i> *** (pneumonia/sepsis/meningitis)	IV penicillin G (alternatives: 2nd/3rd-gen cephalosporin, ciprofloxacin)
** <i>C. canimorsus</i> bacteraemia**	2-week course of IV penicillin G or ampicillin-sulbactam, then step-down oral

- **Duration:** established skin/soft-tissue infection generally 5–7 days (up to 2–3 weeks per CMDT); septic arthritis 4 weeks, osteomyelitis 6 weeks.
- **Prophylaxis is recommended for essentially all cat bites**, particularly hand bites, because of their high infection rate; also for severe/crush/deep wounds, possible bone/joint involvement, genital wounds, delayed care (>8 h), and the immunocompromised/comorbid host. A meta-analysis showed prophylaxis halves the infection rate.

Rabies post-exposure prophylaxis (PEP)

Rabies is almost uniformly fatal but **nearly always preventable** by prompt PEP — *more cats than dogs are reported rabid each year* in the USA, so a cat bite mandates a deliberate rabies decision in consultation with public-health authorities.

- **Risk stratification:** a healthy-appearing **dog, cat or ferret** may be **confined and observed for 10 days** — PEP is not needed if the animal stays healthy; if it sickens, euthanise and test the brain by **direct fluorescent antibody (DFA)**. If the animal escaped, is unprovoked, or rabies is endemic, **start PEP without delay**.
- **Local wound care:** wash thoroughly with **soap and water**, debride — must not be delayed.
- **Passive immunisation** (previously unvaccinated only): **Human Rabies Immune Globulin (HRIG)** 20 IU/kg — infiltrate **as much as anatomically possible into and around the wound**, remainder IM at a distant site. If HRIG is unavailable, **equine RIG** 40 IU/kg. RIG must be given

no later than day 7 after the first vaccine dose; never give RIG and vaccine at the same site/syringe.

- ▶ **Active immunisation:** four 1-mL doses of cell-culture rabies vaccine IM in the deltoid (anterolateral thigh in children) on days 0, 3, 7 and 14; a 5th dose on day 28 only in the immunocompromised. Never give in the gluteus (vaccine failures).
- ▶ **Previously vaccinated patient:** two booster doses on days 0 and 3; no RIG.

Tetanus & other prophylaxis

A bite is a contaminated, tetanus-prone wound.

- ▶ **Booster (Td/Tdap):** indicated if primary immunisation is incomplete/unknown or if the last booster was >5 years ago (bite wounds), as opposed to the >10-year rule for clean minor wounds.
- ▶ **Human Tetanus Immune Globulin (TIG):** given (with the vaccine, at a separate site) to patients who have not completed primary immunisation or whose status is unknown.
- ▶ **Hepatitis B:** for human-bite exposure to blood-tinged saliva, give hepatitis B vaccine ± HBIG (not generally required after animal bites).

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Rabies PEP decision algorithm** — boxes/labels: “Bite or saliva contaminating wound/mucosa?” → “Rabies endemic in species & area?” → “Animal captured?” → if a normally-behaving dog/cat/ferret → “Observe 10 days” (well → No prophylaxis; ill/DFA-positive → RIG + vaccine); if escaped/wild/abnormal → RIG + vaccine.
- ▶ **Cat-bite hand puncture (cross-section)** — labels: narrow deep puncture, epidermis/dermis, metacarpophalangeal joint, tendon sheath, deep inoculation of *Pasteurella multocida*, small external wound belying deep penetration.

Clinical / Diagnostic significance

- ▶ The small external wound of a cat bite belies deep inoculation — a low threshold for imaging, prophylaxis and hand-surgery referral prevents missed septic arthritis/osteomyelitis.
- ▶ **Asplenic/cirrhotic patients** are at risk of fulminant *Capnocytophaga canimorsus* sepsis with purpura fulminans and DIC — counsel and treat aggressively.
- ▶ **Cat-scratch disease** (*B. henselae*) is a late consequence: subacute, painful regional lymphadenopathy (axillary/epitrochlear) with a primary inoculation papule; usually self-limited. Aspirate (do not incise) suppurative nodes; treat extensive lymphadenopathy with **azithromycin 500 mg day 1 then 250 mg OD ×4 days**. Atypical forms include *Parinaud’s oculoglandular syndrome* and *neuroretinitis* (macular star).

- ▶ Failure to respond to antibiotics should prompt re-evaluation for **retained foreign body**, **abscess**, or **deep-space infection** needing surgical drainage.

High-yield exam pointers

- ▶ **>50% of cat bites become infected**; deep, narrow puncture → joint/bone risk.
- ▶ ****Pasteurella multocida* = commonest pathogen**; infection within hours; treat with **amoxicillin-clavulanate**.*.
- ▶ **Never use clindamycin, macrolides, cephalexin or dicloxacillin alone** (no *Pasteurella* cover).
- ▶ **Do NOT primarily suture cat-bite punctures** — irrigate, debride, leave open / delayed closure.
- ▶ **Rabies PEP**: wound wash + **HRIG 20 IU/kg infiltrated into wound** + vaccine IM deltoid on **days 0, 3, 7, 14** (4 doses); previously vaccinated → days 0 & 3 only, no RIG.
- ▶ **Healthy dog/cat/ferret** → observe **10 days** before committing to vaccine.
- ▶ **Tetanus**: bite = tetanus-prone → booster if last dose >5 yr; TIG if primary course incomplete.
- ▶ Cover MRSA empirically in high-risk wounds; **asplenia** → **Capnocytophaga** sepsis risk.
- ▶ **Cat-scratch disease** = *B. henselae*, tender regional nodes, **azithromycin**, aspirate not incise.

SOURCE & COVERAGE

- ▶ **Harrison's Principles of Internal Medicine, 22e** — “Infectious Complications of Bites” (microbiology, approach, wound management, antibiotic Table 146-1, prophylaxis); “Rabies and Other Rhabdovirus Infections” (post-exposure prophylaxis — HRIG 20 IU/kg, 4-dose vaccine schedule, 10-day observation); “Tetanus” (wound management, HTIG, prevention); “Bartonella Infections, Including Cat-Scratch Disease” (cat-scratch disease, azithromycin).
- ▶ **CMDT 2026** — “Common Problems in Infectious Diseases & Antimicrobial Therapy: Animal & Human Bites” (current prophylaxis/treatment regimens, durations, indications).

Coverage note: The standard tetanus wound-prophylaxis decision (Td/Tdap if last booster >5 years for tetanus-prone wounds; TIG ~250 IU IM if primary immunisation incomplete) is universally accepted internal medicine; Harrison Ch 146/157 explicitly supports the >5-year booster rule for bites and TIG for incomplete primary immunisation, while the exact prophylactic TIG dose is conventional. All organism names, drug regimens and doses above are taken verbatim from the cited chapters.

Scrub Typhus presenting as Acute Undifferentiated Febrile Illness with an Eschar and Multi-Organ Dysfunction

Asked in: Paper II 08 Apr 2026 — RGUHS MD General Medicine

Definition / Introduction — Scrub typhus is an acute, mite-borne rickettsiosis caused by the obligate intracellular bacterium **Orientia tsutsugamushi*, characterised by fever, an inoculation eschar, regional lymphadenopathy and rash, and a propensity to evolve into life-threatening multi-organ dysfunction. This 34-year-old farmer with 7 days of high-grade fever and headache, a 0.5 cm punched-out black scabbed lesion (eschar) in the warm, moist left axilla, worsening breathlessness (interstitial pneumonitis/ARDS) and the triad of thrombocytopenia + acute kidney injury + transaminitis is a near-textbook presentation of severe scrub typhus with multi-organ involvement*. The disease responds dramatically to tetracyclines, so early empirical recognition is life-saving.

(a) Diagnosis and differential diagnosis

- ▶ **Most probable diagnosis:** Severe scrub typhus (*Orientia tsutsugamushi* infection) complicated by multi-organ dysfunction — pneumonitis/ARDS (breathlessness), AKI (raised creatinine), hepatitis (raised transaminases) and thrombocytopenia.
- ▶ **Clinching clues:** rural/agricultural exposure; week-long undifferentiated fever with headache; eschar in an intertriginous covered site (axilla — chiggers preferentially feed on warm, moist, occluded skin); and the classic laboratory triad of thrombocytopenia, elevated hepatic aminotransferases and azotaemia with (often) hyponatraemia — the shared signature of rickettsioses.
- ▶ **Differential diagnosis of acute febrile illness in this setting (CMDT/Harrison):** leptospirosis, dengue, enteric (typhoid) fever, malaria, Q fever, other rickettsioses (murine/endemic typhus, Indian tick typhus/spotted fever), viral haemorrhagic fevers/hantavirus, viral hepatitis, meningococcaemia and bacterial sepsis. Co-infection with malaria or leptospirosis can coexist.
- ▶ **Differential diagnosis of a black eschar (tâche noire):** other rickettsioses — Mediterranean spotted fever (*R. conorii*), African tick-bite fever (*R. africae*, often multiple eschars), rickettsialpox (*R. akari*); cutaneous anthrax, ecthyma gangrenosum, necrotic spider bite, and tularaemia/cutaneous leishmaniasis. The combination of eschar + lymphocytosis + raised CRP helps separate scrub typhus from dengue.

(b) Organism and vector

Feature	Detail
Organism	<i>*Orientia tsutsugamushi</i> (formerly <i>Rickettsia tsutsugamushi</i>) — small, obligately intracellular gram-negative coccobacillus; genetically and structurally distinct from <i>Rickettsia</i> — it lacks lipopolysaccharide* (and peptidoglycan) in its cell wall
Antigenic behaviour	Marked antigenic diversity; immunity to a homologous strain wanes over 1–3 years and cross-protection can be lost within a month, allowing

Feature	Detail
	reinfection. Related species: <i>O. chuto</i> (SW Asia/Africa), <i>Candidatus O. chiloensis</i> (Chile)
Vector	Larval trombiculid mite (chigger) — * <i>Leptotrombidium deliense</i> and related species; the larva is the only host-feeding stage*
Reservoir/maintenance	The mite is both vector and reservoir — maintained by transovarial (and transstadial) transmission ; humans are incidental hosts. Chiggers abound in heavy scrub vegetation during the wet season
Geography	Endemic across the “ tsutsugamushi triangle ” — eastern/southern Asia (India, China), northern Australia, and western Pacific & Indian Ocean islands; reemerging

(c) How to confirm the diagnosis

- ▶ **Identify the eschar** — clinically pathognomonic when present; deliberately search axillae, groin, genitalia, waistband and skin folds (eschar is recognised in only ~19% in some series, so absence does not exclude). Look for regional lymphadenopathy.
- ▶ **Serology (mainstay/reference standard):** Indirect fluorescent antibody (IFA) and indirect immunoperoxidase assays are the *gold standard*; demonstrate a **four-fold rise in titre** between acute and convalescent sera. ELISA detects *Orientia*-specific IgM/IgG; **rapid lateral-flow chromatographic tests** aid point-of-care diagnosis.
- ▶ **Molecular:** PCR amplification of *Orientia* genes is the **most sensitive test in early illness** and is **higher-yield from the eschar than from blood**; obtain samples **before starting doxycycline**. CMDT recommends combined ELISA + PCR.
- ▶ **Culture:** feasible from early blood but needs a **BSL-3** specialised laboratory; rarely done.
- ▶ **Supportive laboratory findings:** thrombocytopenia, normal/low WBC, elevated transaminases and bilirubin, raised creatinine, hyponatraemia.
- ▶ **Weil–Felix test** (*Proteus* OX-K agglutination): cheap and widely used in resource-limited settings but **insensitive/non-specific** — only supportive (*see Coverage note*).

(d) How would you treat this patient

- ▶ **Drug of choice** — Doxycycline 100 mg twice daily, PO or IV (IV given the vomiting/severe illness), for 7–15 days; continue **at least 3 days after defervescence** — shorter courses risk relapse. Rapid clinical response (defervescence often within ~48 h) supports the diagnosis.
- ▶ **Severe / multi-organ disease (this patient): combination therapy.** Both Harrison and CMDT note that in severe scrub typhus, the combination of IV doxycycline + azithromycin is superior

to either as monotherapy (***INTREST trial**, *Varghese et al*, NEJM* 2023 — lower 28-day mortality, fewer day-7 complications, less persistent fever than monotherapy).

- ▶ **Azithromycin** 500 mg once daily for 3 days — preferred in **pregnancy, children and doxycycline allergy/intolerance**; efficacy similar to doxycycline with fewer adverse effects.
- ▶ **Chloramphenicol** 500 mg four times daily (7–15 days) — alternative, including pregnancy.
- ▶ **Rifampin** — reserved for the doxycycline/chloramphenicol **poorly-responsive strains** described in northern Thailand (responds to azithromycin and rifampin).
- ▶ **Aggressive supportive/organ care**: ICU admission; **lung-protective mechanical ventilation** for ARDS, judicious fluid resuscitation (avoid precipitating non-cardiogenic pulmonary oedema), **renal replacement therapy** for severe AKI, platelet support if bleeding, vasopressors for shock.

(e) Complications to anticipate

- ▶ **Respiratory**: interstitial **pneumonitis** progressing to **ARDS** (this patient's worsening breathlessness) — a leading cause of death.
- ▶ **Renal**: **acute kidney injury** (already present); may need dialysis.
- ▶ **Hepatic**: hepatitis/transaminitis, hyperbilirubinaemia.
- ▶ **Neurological**: **meningoencephalitis / aseptic meningitis**.
- ▶ **Cardiac**: myocarditis.
- ▶ **Haematological/systemic**: DIC, severe thrombocytopenia with bleeding, **septic/toxic shock and multi-organ failure**, and **haemophagocytic lymphohistiocytosis (haemophagocytosis)** — the latter, like ARDS, tends to appear in the **2nd–3rd week**.
- ▶ **Death**: untreated classic case-fatality ~6% (Harrison), reported up to **10–30%** in severe series (CMDT). **Poor-prognostic markers**: hypotension requiring vasopressors, ICU need, **age >60 years**, **absence of an eschar** (delays diagnosis), pregnancy, leukocytosis and hypoalbuminaemia.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **The eschar (labelled)**: central **black necrotic scab/crust** → surrounding **erythematous halo** → at a covered intertriginous site (axilla/groin) → with **draining regional lymphadenopathy**. Labels: *Black eschar (tâche noire)*, *Erythematous rim*, *Site = warm moist skin fold*, *Regional lymph node*.
- ▶ **Transmission cycle**: *Leptotrombidium* mite eggs → **larva (chigger)** — **only feeding stage** bites human → inoculates *O. tsutsugamushi* → **transovarial transmission** maintains infection in mite (mite = vector + reservoir); human = incidental host. Labels: *Egg*, *Larva/chigger*, *Nymph*, *Adult mite*, *Transovarial transmission*, *Human (incidental host)*.

Clinical / Diagnostic significance

- ▶ Scrub typhus is a leading, treatable cause of **acute undifferentiated febrile illness** and of **fever of unknown origin** in India and Asia — always sought in a febrile farmer/agricultural worker.
- ▶ The **eschar is the single most useful clinical clue**; a focused search of skin folds changes management instantly.
- ▶ **Empirical doxycycline must not await serology** — acute-phase antibody tests are frequently negative early; treatment is started on clinical-epidemiological suspicion.
- ▶ The classic biochemical triad (**thrombocytopenia + transaminitis + AKI**) in a febrile patient with an eschar should trigger antirickettsial therapy and ICU-level vigilance for ARDS/MODS.

High-yield exam pointers

- ▶ **Organism:** *Orientia tsutsugamushi* — intracellular gram-negative, **lacks LPS**; strains show wide antigenic diversity (no lasting cross-immunity → reinfection).
- ▶ **Vector & reservoir:** larval *trombiculid mite/chigger* (*Leptotrombidium deliense*); *maintained by transovarial transmission* — mite is both* vector and reservoir.
- ▶ **Eschar** = inoculation site; favours warm, moist, covered areas (axilla, groin, waist); often missed → search deliberately. **Relative bradycardia** is a clue.
- ▶ **Geography:** “tsutsugamushi triangle”; endemic and reemerging in India.
- ▶ **Diagnosis:** IFA = gold standard (4-fold titre rise); **PCR from eschar = most sensitive early test**; obtain samples **before doxycycline**; Weil-Felix OX-K only supportive.
- ▶ **Treatment:** **doxycycline 100 mg BD** (drug of choice); **azithromycin** in pregnancy/children; **doxycycline + azithromycin for severe disease** (INTREST trial); treat ≥3 days post-defervescence.
- ▶ **Lethal complications:** ARDS, AKI, myocarditis, meningoencephalitis, DIC, HLH, MODS — many in week 2–3.
- ▶ **Poor prognosis:** vasopressor-dependent shock, age >60, **absent eschar**, pregnancy, hypoalbuminaemia.

SOURCE & COVERAGE

- ▶ **Harrison's Principles of Internal Medicine, 22e** — “Rickettsial Diseases” (Scrub Typhus section: organism, *Leptotrombidium*/chigger vector, transovarial maintenance, clinical features, IFA/PCR diagnosis, doxycycline/azithromycin/chloramphenicol regimens and the severe-disease combination; rickettsial laboratory triad and eschar differential).
- ▶ **CMDT 2026** — “Viral & Rickettsial Infections” (Scrub Typhus: essentials, tsutsugamushi triangle, eschar yield, relative bradycardia, ELISA+PCR strategy, doxycycline/minocycline/azithromycin treatment, INTREST trial [Varghese et al, *NEJM* 2023], poor-prognostic factors, differential diagnosis and complications).

- **Coverage note:** The Weil-Felix (Proteus OX-K) agglutination test and the named antigenic serotypes Karp/Kato/Gilliam are *universally accepted standard rickettsiology* but are **not explicitly described in the corpus chapters consulted**; Harrison/CMDT instead emphasise IFA/immunoperoxidase, ELISA and PCR. The chigger's preference for moist intertriginous skin (axilla/groin) is standard teaching consistent with, though not verbatim in, the corpus.

Pulmonary Nocardiosis in a Diabetic with Non-resolving Pneumonia — CT Thorax Findings and Management

Asked in: Paper II 08 Apr 2026 — RGUHS MD General Medicine

Definition / Introduction — *Nocardiae* are aerobic, Gram-positive, weakly (partially) acid-fast, catalase-positive filamentous bacteria that are ubiquitous saprophytes of soil and water, acquired chiefly by **inhalation**. Pulmonary nocardiosis is a subacute, **non-resolving necrotising pneumonia** that classically arises in hosts with impaired cell-mediated/phagocyte defence and has a strong tendency to **cavitate, cross tissue planes (pleura/chest wall) and disseminate haematogenously to the brain and skin**. A BAL culture growing *Nocardia* in this 45-year-old diabetic with a pneumonia failing to clear is therefore not a contaminant but a call to define disease extent (especially occult brain abscess) and start prolonged, susceptibility-guided combination therapy led by trimethoprim-sulfamethoxazole.

Why suspect *Nocardia* in this patient (microbiology and host risk)

- **Organism:** Gram-positive, beaded, **branching filaments** ~1 µm wide, up to 50 µm long that fragment into cocco-bacillary forms; **weakly/partially acid-fast** on modified Kinyoun, Ziehl-Neelsen or Fite-Faraco stains (weak-acid decolouriser) — hence frequent confusion with *Mycobacterium tuberculosis*. Cell wall contains mycolic acids; grows as chalky, wrinkled, white-yellow/orange colonies.
- **Common pathogenic species:** *N. farcinica*, *N. cyriacigeorgica*, *N. nova* complex, *N. abscessus*, *N. brasiliensis* (mostly cutaneous), *N. otitidiscaviarum*, *N. transvalensis*. *N. farcinica* has a special predilection for CNS spread and is often ceftriaxone-resistant.
- **Host defects predisposing to invasive disease:** defects of **cell-mediated immunity and phagocytes** — solid-organ or haematopoietic stem-cell transplantation, **systemic corticosteroids/Cushing syndrome**, immunosuppressive therapy, HIV, chronic granulomatous disease (CGD), IL-12/IL-12R deficiency, pulmonary alveolar proteinosis with **anti-GM-CSF autoantibodies**.

- ▶ **Structural lung disease / bronchiectasis** predisposes to airway *colonisation*; a positive respiratory culture must be read in clinical context, but in an immunosuppressed host it usually reflects true disease and warrants empirical therapy.
- ▶ *Diabetes mellitus* (this patient) is a widely recognised predisposing condition through impaired neutrophil/phagocyte function — see Coverage note.

Pleuropulmonary clinical picture (the “non-resolving pneumonia”)

- ▶ **Subacute onset** over days to weeks; in the severely immunocompromised it may be acute. **Cough productive of small amounts of thick, purulent, non-malodorous sputum** is prominent.
- ▶ Fever, anorexia and malaise are common; **weight loss, dyspnoea, pleuritic pain and haemoptysis are less common.**
- ▶ Without definitive therapy there are characteristic **remissions and exacerbations over weeks to months** — the classic “non-resolving / relapsing” pneumonia that fails standard antibiotics and mimics TB, fungal infection or malignancy.
- ▶ **Dissemination occurs in up to one-third** of pulmonary cases — CNS (brain abscess) and skin/subcutaneous tissue are the commonest metastatic sites.

CT thorax — what you would find

Finding	Detail
Nodules and masses	Solid pulmonary nodules and mass lesions in one or more lobes (often multifocal/multilobar)
Cavitation	Nodules and masses frequently cavitate — thick-walled cavities are characteristic
Consolidation / infiltrates	Dense lobar or patchy air-space consolidation
Pleural disease	Pleural effusion or empyema in ~one-third of cases (empyema may occur even without parenchymal disease)
Chest-wall extension	Direct invasion through the ribs and chest wall with chest-wall abscess (non-respect of tissue planes)
Pattern	Multifocal, indolent, progressive; radiologically mimics TB, fungal pneumonia, metastases or bronchogenic carcinoma

- ▶ Representative CT (Harrison Fig. 179-3): solid nodules, a cavitated nodule, an ipsilateral pleural effusion and a chest-wall abscess.
- ▶ *Practical pearl*: the combination of **cavitating nodules/masses + effusion/empyema + chest-wall involvement** in an immunocompromised or diabetic host with a non-resolving pneumonia should raise nocardiosis specifically.

Establishing the diagnosis and staging extent

- ▶ **Microbiology is the cornerstone.** Sputum smears are *often negative*, so **BAL fluid or lung biopsy** (as done here) is the higher-yield specimen.
- ▶ **Stains:** Gram stain (beaded branching filaments) plus a **modified acid-fast stain** (weak-acid decolourisation); organisms may take up silver stains.
- ▶ **Culture:** grows on most fungal/mycobacterial and routine media but **slowly** — **colonies in up to 2 weeks, typical morphology by 4 weeks**; alert the laboratory to incubate longer and to **avoid mycobacterial decontamination procedures** (they kill *Nocardia*). Selective media (colistin-nalidixic acid, modified Thayer-Martin, BCYE) improve recovery from mixed flora.
- ▶ **Speciation and susceptibility:** identify at least to complex level by **MALDI-TOF MS or gene sequencing** (16S rRNA, *secA1*, *hsp65*, *gyrB*); perform **susceptibility testing** by CLSI-approved **broth microdilution** (E-tests less reliable) — species-directed therapy matters because susceptibilities differ markedly.
- ▶ **Mandatory search for disseminated disease — image the brain.** Every patient with pulmonary/systemic nocardiosis, **regardless of CNS symptoms**, must have **contrast-enhanced brain imaging** to exclude occult abscess (one-third of CNS cases are asymptomatic). **MRI with gadolinium is preferred** (more sensitive); CT is reserved for when MRI is not possible. Nocardial brain abscesses are typically **multiple, multilobulated, ring-enhancing**.
- ▶ **Identify the immune defect:** test for **HIV**; in the absence of an obvious risk factor consider **CGD** and anti-GM-CSF autoantibodies; optimise/document the diabetic and any iatrogenic immunosuppression.

Management

Principles: susceptibility-guided, **prolonged** (months), **combination therapy** for **severe/disseminated/CNS disease** then de-escalation to a single oral agent, plus **source control** (drainage of empyema/abscess) and **correction of host factors** (glycaemic control, reduce immunosuppression where feasible).

Agent	Dose	Role / caveats
Trimethoprim-sulfamethoxazole (TMP-SMX)	TMP 10–20 mg/kg + SMX 50–100 mg/kg per day in 2 divided doses initially; maintenance down to TMP 5 / SMX 25 mg/kg	Drug of choice; sulfa allergy → desensitisation
Linezolid	600 mg PO/IV q12h	Uniformly active against all species; cytopenias/neuropathy limit therapy after 2–3 weeks (tedizolid less toxic)
Amikacin	5–7.5 mg/kg q12h or 15 mg/kg q24h	Active vs nearly all species (except <i>N. transvalensis</i> , some <i>N.</i>

Agent	Dose	Role / caveats
		<i>pseudobrasiliensis</i>); monitor levels/renal function
Imipenem / Meropenem	Imipenem 500 mg IV q6h; meropenem 2 g IV q8h	β-lactam for combination; meropenem preferred if CNS involved (lower seizure risk)
Ceftriaxone	—	Useful but <i>*not active against N. farcinica***</i>
Amoxicillin-clavulanate	875/125 mg bid	Effective in <i>N. brasiliensis</i> , some <i>N. farcinica</i>
Moxifloxacin / Minocycline	Minocycline 100–200 mg bid	Oral options; moxifloxacin most active quinolone

- ▶ **Severe disease (as here, non-resolving pneumonia ± dissemination):** empirical combination of two or three of TMP-SMX, linezolid, amikacin and a carbapenem (imipenem, or meropenem if CNS). Clinical improvement usually appears in 1–2 weeks (may be slower).
- ▶ **De-escalation:** after definite improvement, continue with a single oral drug, usually TMP-SMX.
- ▶ **Duration:** pulmonary/systemic with intact host defences 6–12 months; with deficient host defences 12 months (indefinite in AIDS with CD4 <200/μL or CGD); CNS disease 12 months (6 months if all CNS disease excised); primary cutaneous 2 months.
- ▶ **Surgery:** drain empyema and chest-wall/soft-tissue abscesses; **brain abscesses** aspirated/drained/excised if diagnosis unclear, large, or failing medical therapy; repeat imaging to confirm resolution (radiographic lag is expected).
- ▶ **Diabetes-specific:** tight glycaemic control and treating any concomitant immunosuppression are integral to cure; **do not give topical corticosteroids** if nocardial keratitis coexists.
- ▶ **Prognosis:** mortality <10% for localised pulmonary disease; higher with dissemination, worst with CNS involvement and delayed therapy.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **CT thorax (axial) schematic of pulmonary nocardiosis** — labels: *thick-walled cavitating nodule, multiple solid nodules, lobar consolidation, pleural effusion/empyema, chest-wall abscess invading through rib, (absence of significant hilar lymphadenopathy).*
- ▶ **Modified acid-fast (Kinyoun/ZN) smear of BAL** — labels: *beaded, branching, partially acid-fast filaments ~1 μm wide, fragmentation into cocco-bacillary forms, neutrophilic background.*

Clinical / Diagnostic significance

- ▶ Treat *Nocardia* in BAL of an immunosuppressed/diabetic patient with a non-resolving pneumonia as **true infection**, not colonisation, and act on it.
- ▶ The single highest-yield staging step is **brain imaging (MRI preferred)** to catch silent abscesses that change duration and the choice of carbapenem.
- ▶ **Alert the microbiology lab** (slow grower; avoid mycobacterial decontamination) and obtain **species ID + susceptibilities** — they directly dictate the regimen (e.g., ceftriaxone fails *N. farcinica*).
- ▶ Differentiate from TB (both acid-fast, both cavitate) by branching filament morphology and culture/molecular ID — clinically important because mismanagement as TB delays cure.

High-yield exam pointers

- ▶ *Nocardia* = aerobic, **weakly acid-fast, branching beaded Gram-positive filaments**; acquired by **inhalation**; opportunist of impaired cell-mediated immunity.
- ▶ CT hallmark: **multifocal cavitating nodules/masses + pleural effusion/empyema ($\sim\frac{1}{3}$) + chest-wall invasion**.
- ▶ **Sputum often negative** → BAL/biopsy; cultures slow (up to 2–4 weeks) — *tell the lab*.
- ▶ **TMP-SMX is the drug of choice**; severe disease → **2–3 drug combination** (add linezolid/amikacin/carbapenem).
- ▶ **Meropenem over imipenem if CNS**; **ceftriaxone not active against N. farcinica****.
- ▶ **Always image the brain** even if asymptomatic; nocardial brain abscess = **multiple, multilobulated, ring-enhancing**.
- ▶ Prolonged therapy: **6–12 months (intact), 12 months (immunosuppressed/CNS)**.
- ▶ Linezolid is uniformly active but toxicity limits use after **2–3 weeks**; monitor counts.

SOURCE & COVERAGE

- ▶ **Harrison's Principles of Internal Medicine, 22e** — “Nocardiosis” (microbiology, risk factors, pulmonary/CT features incl. Figs 179-2/179-3, diagnosis, drug doses, treatment-duration Table 179-1).
- ▶ **CMDT 2026** — “Nocardiosis” (Bacterial & Chlamydial Infections) and “Pulmonary Disorders” (essentials of diagnosis, chest-wall invasion, TMP-SMX dosing 15 mg/kg/day, imipenem/meropenem/amikacin/linezolid/minocycline doses, brain-imaging rule, 6–12-month duration).

Coverage note: The corpus describes CT findings qualitatively (nodules, masses, cavitation, effusion/empyema, chest-wall invasion) but does not enumerate finer CT signs (e.g., halo sign, ground-glass, tree-in-bud), so these are deliberately omitted. Harrison's explicit major risk-factor list emphasises T-cell/phagocyte immunosuppression (transplant, corticosteroids, HIV, CGD)

rather than diabetes specifically; **diabetes mellitus as a predisposing condition** is included here as universally accepted internal medicine and is supported indirectly by the chapter's "impaired host-defence" framing.

A 45-year-old man from Chhattisgarh with 6 months of intermittent fever, anorexia, weight loss and massive splenomegaly: differential diagnosis, confirmatory investigations, and treatment of rK39-positive visceral leishmaniasis

Asked in: Paper II May 2025 — RGUHS MD General Medicine

Definition / Introduction — A middle-aged man from a leishmaniasis-endemic part of India presenting with chronic intermittent fever, constitutional symptoms and *massive splenomegaly* most often has **visceral leishmaniasis (VL, kala-azar)**, a systemic protozoal infection of the reticuloendothelial system caused by the **Leishmania donovani complex** and transmitted by phlebotomine sandflies. "Massive splenomegaly" (spleen palpable >8 cm below the left costal margin or weighing ≥1000 g) sharply narrows the differential, and a positive **rK39 rapid diagnostic test** in this setting effectively confirms VL. The answer below addresses (a) the differential diagnosis and confirmatory work-up, and (b) treatment once rK39 is positive.

(a) Differential diagnosis — fever + weight loss + massive splenomegaly

The combination of a chronic febrile illness with constitutional decline and a *huge* spleen narrows a long list considerably. Causes are grouped below.

Category	Conditions to consider	Discriminating features
Chronic infections (tropical)	Visceral leishmaniasis (kala-azar) — top of the list in an endemic Indian patient; chronic/relapsing malaria & hyper-reactive malarial (tropical) splenomegaly syndrome; disseminated/miliary tuberculosis; enteric (typhoid) fever; brucellosis; schistosomiasis; disseminated histoplasmosis; subacute infective endocarditis	VL: progressive <i>massive</i> spleen, pancytopenia, hypergammaglobulinaemia, skin hyperpigmentation

Category	Conditions to consider	Discriminating features
Haematological / neoplastic (classic massive-spleen causes, Table 70-3)	Chronic myeloid leukaemia (CML); myelofibrosis with myeloid metaplasia; non-Hodgkin lymphoma / chronic lymphocytic leukaemia / hairy cell leukaemia; polycythaemia vera; Gaucher disease; autoimmune haemolytic anaemia	Leucocytosis/immature myeloid cells (CML), leucoerythroblastic film + teardrop cells (myelofibrosis), lymphadenopathy/lymphocytosis (lymphoma/CLL)
Congestive / other	Portal hypertension from chronic liver disease (congestive splenomegaly); sarcoidosis; thalassaemia major	Stigmata of chronic liver disease, varices; transfusion-dependent anaemia

- **Why VL is the leading diagnosis here:** an endemic Indian origin, 6-month indolent course, intermittent fever with the characteristic double-rise pattern, progressive *massive* splenomegaly (the single most important sign of VL), and constitutional wasting. Per Harrison, VL is **easily mistaken for malaria**, and the other key mimics it explicitly lists are **typhoid, tuberculosis, brucellosis, schistosomiasis and histoplasmosis**; splenomegaly from **portal hypertension, CML, tropical splenomegaly syndrome and schistosomiasis** can also be confused with VL.
- **Pointers that strongly suggest VL:** *fever with neutropenia or pancytopenia* in a patient from an endemic region; **hypergammaglobulinaemia** (polyclonal) in long-standing illness; moderate hepatomegaly following the splenomegaly; lymphadenopathy is *uncommon on the Indian subcontinent* (helps distinguish from African VL and from lymphoma).

(a) Investigations to confirm the diagnosis

1. **Demonstration of the parasite (gold standard).** Amastigotes (**Leishman–Donovan bodies**, 2–4 µm, each with a nucleus and a kinetoplast) within macrophages on Giemsa-stained tissue aspirate smears:

- **Splenic aspirate** — highest sensitivity >95%, but invasive and potentially dangerous (haemorrhage) in untrained hands; avoid with deranged coagulation/thrombocytopenia.
- **Bone marrow aspirate** — sensitivity 60–85%; safer and most commonly used in practice.
- **Lymph node aspirate** — sensitivity ~50%.
- **Culture** of the aspirate (e.g. NNN medium) raises yield; **PCR / real-time PCR** and **LAMP** are highly sensitive, allow species identification, and outperform microscopy on blood, but are confined to reference laboratories.

2. **Serology / antigen-based tests.**

- **rK39 immunochromatographic rapid diagnostic test** — detects antibody to a 39-amino-acid recombinant antigen from the kinesin region of *L. infantum*; needs only a drop of finger-prick blood, read in **15 min**; in immunocompetent patients sensitivity ~98% and specificity ~90% (both lower in East Africa). It is the field test of choice.

- ▶ ELISA and indirect immunofluorescent antibody test (IFAT) in equipped laboratories.
- ▶ **Caveat:** antibody tests (including rK39) **stay positive for years after cure**, so they *cannot* be used to confirm cure or detect relapse.

3. Supportive laboratory findings. Pancytopenia (early leukopenia and anaemia, later thrombocytopenia from marrow infiltration/hypersplenism); marked **polyclonal hypergammaglobulinaemia** (basis of the classic bedside **aldehyde/formol-gel test**, non-specific); raised aminotransferases $\pm$ bilirubin; hypoalbuminaemia in advanced disease. Always exclude **HIV co-infection**, which alters diagnosis (serology may be negative in up to 50%) and treatment.

(b) Treatment when the rK39 test is positive — VL in India

A positive rK39 in this clinical context confirms VL; institute supportive care plus a specific antileishmanial regimen tailored to **India**, where there is **widespread resistance to pentavalent antimonials** (cure <50% in Bihar) so antimonials are *not* first-line.

Drug / regimen	Dose & schedule	Notes
Liposomal amphotericin B (LAmB) — <i>drug of choice in India</i>	Single dose 10 mg/kg IV (96% cure; used in the national elimination programme). FDA-approved regimen: 3 mg/kg on days 1–5, 14 and 21 (total 21 mg/kg). Asian total-dose requirement only 10–15 mg/kg	Best safety profile; reticuloendothelial uptake; mild infusion reactions, backache, reversible nephrotoxicity
Amphotericin B deoxycholate	0.75–1.0 mg/kg on alternate days $\times$ 15 infusions	Effective but toxic — infusion fever/chills, nephrotoxicity, hypokalaemia; premedicate with chlorpheniramine + paracetamol
Miltefosine (first oral drug)	28 days: 50 mg/day if <25 kg; 50 mg twice daily if $\geq$ 25 kg; 2.5 mg/kg/day for children 2–11 yr	~94% cure (declining); GI upset; teratogenic — contraindicated in pregnancy , contraception $\geq$ 5 months; give as directed observed therapy
Paromomycin (aminosidine)	11 mg/kg base IM daily $\times$ 21 days	Cure ~94.6%; ototoxicity, reversible hepatotoxicity
Pentavalent antimonials (SbV) — <i>not first-line in India</i>	20 mg/kg/day IV/IM $\times$ 28–30 days	Cure >90% in Africa/Americas but <50% in Bihar ; monitor ECG — QTc >0.5 s risks fatal arrhythmia; pancreatitis, arthralgia

- ▶ **Preferred for this patient:** a single 10 mg/kg dose of liposomal amphotericin B, the regimen adopted by the Indian subcontinent VL elimination programme — short, well-tolerated and highly effective.

- ▶ **Multidrug (combination) therapy** is increasingly favoured for shorter courses, lower toxicity and reduced resistance: in India, **single-dose LAmB 5 mg/kg followed by miltefosine for 7 days, or paromomycin for 10 days, or miltefosine + paromomycin together for 10 days** each give cure rates >97%.
- ▶ **Supportive care:** correct severe anaemia with transfusion; treat intercurrent infections (pneumonia, TB, dysentery); nutritional support.
- ▶ **If HIV co-infected:** LAmB is the drug of choice; WHO now recommends **LAmB total 30 mg/kg (5 mg/kg on days 1,3,5,7,9,11) plus oral miltefosine 100 mg/day for 14 days** in the Indian subcontinent, alongside antiretroviral therapy (restoring CD4 >200/ μ L reduces relapse). Relapse within a year is common; prolonged follow-up is essential.
- ▶ **Response & follow-up:** defervescence, regression of splenomegaly, weight gain and haematological recovery occur within ~1 week; **continued improvement over 12 months indicates cure**. rK39 cannot be used to judge cure. Watch for **post-kala-azar dermal leishmaniasis (PKDL)** in 5–15% of Indian patients 6 months–3 years later (hypopigmented macules/nodules) — treated with miltefosine for 12 weeks; PKDL patients are a human reservoir, important for elimination.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Sandfly–human life cycle of *Leishmania donovani*:** label *Phlebotomus argentipes* sandfly, **promastigote** (flagellate, 10–20 μ m, in sandfly midgut), bite/inoculation into skin, uptake by **neutrophils** → **macrophages**, transformation to **amastigote** (2–4 μ m, intracellular), multiplication and rupture of macrophages, reticuloendothelial spread to **spleen, liver, bone marrow, lymph nodes**, and re-uptake by feeding sandfly.
- ▶ **Giemsa-stained splenic/marrow smear:** macrophage containing multiple **amastigotes** (**Leishman–Donovan bodies**), each labelled with **nucleus** and rod-shaped **kinetoplast**; a few extracellular parasites.

Clinical / Diagnostic significance

- ▶ **Massive splenomegaly** + fever + pancytopenia + hypergammaglobulinaemia in an endemic Indian patient is the classic VL pentad; bone marrow aspirate is the practical confirmatory test, rK39 the field test.
- ▶ Untreated VL is fatal in the majority (and historically ~90% mortality); early diagnosis and treatment cut mortality to 2–5%.
- ▶ Antimonial **resistance in Bihar** is the single most important reason LAmB/miltefosine displaced antimonials as first-line in India — a frequent exam discriminator.
- ▶ Always screen for **HIV**: it changes prognosis (atypical sites, seronegative serology, high relapse) and the specific regimen.

- ▶ VL is targeted for **elimination as a public-health problem** in India (reported 98.7% decline); single-dose LAmB and active PKDL detection underpin the programme.

High-yield exam pointers

- ▶ **Massive splenomegaly** = spleen >8 cm below LCM or ≥ 1000 g; classic causes — CML, myelofibrosis, kala-azar, chronic malaria (tropical splenomegaly), lymphoma/CLL, hairy cell leukaemia, Gaucher disease, thalassaemia major.
- ▶ Kala-azar = *L. donovani* complex; vector in India **Phlebotomus argentipes**; transmission **anthroponotic** (humans reservoir); incubation ~2–6 months.
- ▶ **Splenic aspirate sensitivity** >95% > bone marrow 60–85% > lymph node ~50%.
- ▶ **rK39**: 39-aa kinesin antigen, ~98% sensitive/~90% specific; stays positive after cure — *not* for test-of-cure.
- ▶ **First-line in India** = **liposomal amphotericin B**, single dose 10 mg/kg; antimonials fail (<50% cure) due to Bihar resistance.
- ▶ **Miltefosine** = first oral drug, 28 days, **teratogenic** (avoid in pregnancy).
- ▶ **PKDL** follows treated Indian VL in 5–15% (6 months–3 years); reservoir for transmission.
- ▶ Cure judged **clinically over 12 months** (defervescence, shrinking spleen, count recovery), not by serology.

SOURCE & COVERAGE

- ▶ **Harrison's Principles of Internal Medicine, 22e** — “Leishmaniasis” (visceral leishmaniasis: epidemiology, immunopathogenesis, clinical features, rK39 and parasitological diagnosis, differential diagnosis, and full treatment/regimen detail including LAmB, miltefosine, paromomycin, antimonials, combination therapy, HIV co-infection, PKDL); and “Enlargement of Lymph Nodes and Spleen” (Table 70-3, diseases associated with massive splenomegaly).
- ▶ **CMDT 2026** — “Protozoal & Helminthic Infections: Leishmaniasis” (current management: liposomal amphotericin B dosing in India, miltefosine, paromomycin, combination regimens; rK39 and splenic/marrow aspiration diagnosis; mortality figures).

Coverage note: The patient's specific state (Chhattisgarh) is not named in the corpus; the answer is grounded in the corpus's “Indian subcontinent” VL data, which applies. The **aldehyde (formol-gel) test** is included as universally accepted classic Indian bedside teaching for the hypergammaglobulinaemia that Harrison documents; it is non-specific and not a confirmatory test.

Abdominal tuberculosis

Asked in: Paper I May 2019 — RGUHS MD General Medicine

Definition / Introduction — Abdominal tuberculosis is *Mycobacterium tuberculosis* (and occasionally *M. bovis*) infection involving the gastrointestinal tract, peritoneum, mesenteric/omental lymph nodes and solid abdominal viscera. It is one of the commonest forms of extrapulmonary TB in endemic regions such as India, classically affecting the **ileocaecal region** and the **peritoneum**. Active pulmonary disease is demonstrable in fewer than half of patients, and the indolent, non-specific presentation (chronic pain, fever, weight loss, ascites, subacute obstruction) makes it a notorious mimic of Crohn disease and malignancy — hence a “great diagnostic challenge.”

Epidemiology, pathogenesis & routes of spread

- ▶ In Harrison’s descending order of extrapulmonary frequency, the **peritoneum** ranks among the major sites; **gastrointestinal TB** accounts for ~3.5% of extrapulmonary cases in low-burden settings but is far commoner in endemic India and in untreated AIDS/immigrant groups.
- ▶ **Four mechanisms of seeding:**
 - **Swallowing of infected sputum** with direct mucosal seeding (in active pulmonary TB).
 - **Haematogenous spread** from a pulmonary or miliary focus.
 - **Ingestion of milk** from cattle with bovine TB (*M. bovis*) — historical, now rare.
 - **Contiguous spread** from adjacent organs (e.g., ruptured mesenteric nodes, female genital TB).
- ▶ The **terminal ileum and caecum** are most often involved because of abundant lymphoid (Peyer’s patch) tissue, physiological stasis and greater contact time for bacillary penetration.

Clinical forms of abdominal TB

Form	Site / pathology	Typical features
Intestinal (luminal) TB	Terminal ileum & caecum most common; any segment possible	Chronic abdominal pain (may mimic appendicitis), subacute/recurrent obstruction , palpable abdominal mass , weight loss, diarrhoea, hematochezia ; ulcers/fistulae may simulate Crohn disease
Tuberculous peritonitis	Peritoneum, omentum, mesentery	Non-specific abdominal pain, fever and ascites ; “doughy abdomen”; SAAG <1.1, lymphocytic exudate
Glandular (nodal)	Mesenteric & retroperitoneal lymph nodes	Massive lymphadenopathy, central necrosis on CT; may cause obstruction or fistulae

Form	Site / pathology	Typical features
Visceral	Liver, spleen, pancreas (part of disseminated/miliary disease)	Hepatosplenomegaly, granulomas on biopsy; rare isolated organ involvement

- ▶ **Morphological subtypes of intestinal TB (standard surgical classification):** *ulcerative* (transverse/circumferential “girdle” ulcers, bleeding, perforation-prone), *hypertrophic* (mass-forming, mimics carcinoma), and *ulcero-hypertrophic* (mixed).
- ▶ **Complications:** intestinal obstruction (commonest), perforation, haemorrhage, fistula and stricture formation; **anal/perianal fistulae** should prompt evaluation for rectal TB.

Tuberculous peritonitis — types & ascitic fluid analysis

- ▶ **Three classical morphological types:** **wet (ascitic)** — free fluid; **dry/plastic (fibroadhesive)** — adhesions, mesenteric thickening, “doughy abdomen”; **fibrotic/encysted (loculated)** — omental masses and loculated collections.
- ▶ **Ascitic fluid (paracentesis) — hallmark findings:**
 - **Exudative, high protein** (>2.5 g/dL) fluid.
 - **Low SAAG** (<1.1 g/dL) — a “diseased peritoneum” pattern; *caveat:* coexistent cirrhosis produces **mixed ascites** with a high SAAG, complicating the diagnosis.
 - **Lymphocyte-predominant leukocytosis** (neutrophils occasionally predominate early).
 - **Elevated adenosine deaminase (ADA)** — useful supportive marker for tuberculous peritonitis.
 - **Low smear/culture yield** — direct AFB smear is usually negative; culturing a **large volume** of fluid increases yield.
- ▶ **Peritoneal/omental biopsy — best obtained at laparoscopy** — is often required for definitive diagnosis (caseating granuloma, AFB, culture). Laparoscopy is specifically recommended for low-SAAG/mixed ascites with non-diagnostic CT and cytology.

Diagnostic approach / investigations

- ▶ **Imaging:**
 - **Contrast CT abdomen** — wall thickening of the **caecum and ileocaecal valve**, **massive (necrotic, low-attenuation) lymphadenopathy**, omental/mesenteric thickening, ascites; CT helps interpret questionable plain-film findings and define intra-abdominal disease.
 - **Ultrasound** confirms ascites and guides paracentesis; barium studies may show strictures, “string sign,” and a contracted caecum.
- ▶ **Colonoscopy + biopsy** — ileocaecal ulcers with steep/undermined edges, adjacent sessile pseudopolyps, small ulcers/erosions or pseudodiverticula; obtain multiple biopsies for histology, AFB, culture and PCR.

- ▶ **Microbiological/histological confirmation** (any one is diagnostic):
 - Caseating granuloma on histology.
 - Acid-fast bacilli on smear/stain.
 - Positive mycobacterial culture (gold standard) of biopsy/fluid.
 - Nucleic acid amplification (PCR / Xpert MTB/RIF) — now the *most sensitive* means of detecting bacilli in biopsy specimens and also reports rifampin resistance.
- ▶ **Tuberculin skin test (PPD)** may be **negative**, especially with weight loss or AIDS — a negative test does *not* exclude the diagnosis.
- ▶ Because surgery is needed in many obstructive/complicated cases, the diagnosis is frequently established on **intraoperative histology and culture**.

Differential diagnosis — intestinal TB vs Crohn disease

Feature	Intestinal TB	Crohn disease
Ulcer orientation	Transverse / circumferential (“girdle”)	Longitudinal, cobblestoning, aphthous
Distribution	Ileocaecal, short segment, contracted caecum	Segmental “skip lesions”, longer involvement
Granuloma	Caseating, confluent, larger	Non-caseating, small, discrete
Microbiology	AFB / culture / PCR positive	Negative
Serology / markers	—	ASCA may be positive

- ▶ Other mimics: **carcinoma**, **lymphoma**, **intestinal amoebiasis**, appendiceal mass, and (for peritoneal disease) **peritoneal carcinomatosis** and ovarian malignancy. A therapeutic ATT trial with response assessment is sometimes used when distinction from Crohn disease is impossible.

Management

- ▶ **First-line anti-tubercular therapy (ATT)** — abdominal (extrapulmonary) TB is treated with the **same regimen as drug-susceptible pulmonary TB**: a 2-month intensive phase of isoniazid + rifampin + pyrazinamide + ethambutol followed by a 4-month continuation phase of isoniazid + rifampin — **2HRZE / 4HR (6 months total)**, curative in >90%.
 - Footnote caveat (Harrison Table 183-4): standard 6 months suffices for extrapulmonary TB except CNS, bone or joint disease, which need longer (CMDT: many experts give **9–12 months** for miliary, meningeal, bone/joint TB).

Drug (daily, adult)	Dose	Max
Isoniazid (H)	5 mg/kg	300 mg
Rifampin (R)	10 mg/kg	600 mg

Drug (daily, adult)	Dose	Max
Pyrazinamide (Z)	25 mg/kg	2 g
Ethambutol (E)	15 mg/kg	—

- ▶ **Adjuncts:** pyridoxine with isoniazid to prevent peripheral neuropathy; daily (not intermittent) dosing is preferred; monitor for **drug-induced liver injury**, optic neuritis (ethambutol) and adherence.
- ▶ **Surgery** is reserved for complications — obstruction not relieved by ATT, perforation, uncontrolled haemorrhage, fistula and abscess. Steroids have an established role only in **TB pericarditis and meningitis**, not in routine intestinal/peritoneal disease (corticosteroids are sometimes used to reduce adhesion/obstruction risk in peritoneal TB — see Coverage note).

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Ileocaecal tuberculosis** (line diagram of the terminal ileum, ileocaecal valve and caecum). Labels: *Terminal ileum, Thickened/incompetent ileocaecal valve, Contracted/conical caecum, Transverse (circumferential) ulcers, Hypertrophic mass, Stricture causing obstruction, Enlarged caseating mesenteric lymph nodes.*
- ▶ **Tuberculous peritonitis — ascitic fluid analysis flow box.** Labels: *Paracentesis → Exudate, protein >2.5 g/dL, SAAG <1.1 g/dL, Lymphocytic leukocytosis, Raised ADA, Low AFB smear/culture yield, Laparoscopic peritoneal biopsy = confirmatory.*

Clinical / Diagnostic significance

- ▶ **Index of suspicion** in any patient from an endemic area with chronic abdominal pain, fever, weight loss, ascites or subacute obstruction — abdominal TB is treatable and curable but lethal if missed.
- ▶ The low-SAAG, lymphocytic, ADA-rich exudate plus **necrotic mesenteric nodes on CT** is a classic triad pointing to peritoneal TB; remember “mixed ascites” when cirrhosis coexists.
- ▶ **Ileocaecal TB closely mimics Crohn disease** — empirical immunosuppression/biologics for misdiagnosed Crohn can be catastrophic, so excluding TB (caseation, AFB, PCR, culture) before starting anti-TNF therapy is mandatory.
- ▶ **PCR/Xpert MTB/RIF** on biopsy improves yield and simultaneously screens for rifampin resistance, shortening time to appropriate therapy.

High-yield exam pointers

- ▶ Commonest sites: **ileocaecum** (luminal) and **peritoneum**; <50% have active pulmonary TB.
- ▶ Four routes: **swallowed sputum, haematogenous, ingested (M. bovis) milk, contiguous spread**.
- ▶ Intestinal subtypes: **ulcerative, hypertrophic, ulcero-hypertrophic**; commonest complication = **obstruction**.

- ▶ Peritoneal types: wet (ascitic), dry/plastic, fibrotic/encysted; “doughy abdomen.”
- ▶ Ascites: exudate, SAAG <1.1, high protein, lymphocytic, high ADA, low smear yield; laparoscopic biopsy is most reliable.
- ▶ CT clues: ileocaecal/valve thickening + massive necrotic lymphadenopathy.
- ▶ Diagnosis confirmed by caseating granuloma / AFB / culture / PCR; PPD may be negative.
- ▶ Treatment = 2HRZE/4HR (6 months) — same as pulmonary; longer only for CNS/bone/joint; surgery for complications.
- ▶ Key differential = Crohn disease (transverse vs longitudinal ulcers; caseating vs non-caseating granuloma) — exclude TB before biologics.

SOURCE & COVERAGE

- ▶ Harrison’s Principles of Internal Medicine, 22e — “Tuberculosis” (extrapulmonary TB: Gastrointestinal TB and Tuberculous peritonitis; treatment regimens and drug-dose Tables 183-2/183-4).
- ▶ CMDT 2026 — “Gastrointestinal Disorders” (Intestinal Tuberculosis; Ascites — SAAG classification, ascitic-fluid analysis, ADA, laparoscopy) and “Pulmonary Disorders” (extrapulmonary TB treatment duration; pyridoxine).
- ▶ Coverage note: The morphological subclassifications (intestinal: ulcerative/hypertrophic/ulcero-hypertrophic; peritoneal: wet/dry/fibrotic), the Crohn-vs-TB ulcer-orientation/granuloma contrasts, ASCA, and a specific numerical ADA cut-off are universally accepted standard internal-medicine teaching but are not stated verbatim in the cited corpus, which confirms the underlying findings (lymphocytic exudate, raised ADA, ileocaecal site, Crohn mimicry, caseating granuloma) in narrative form. Routine corticosteroid use in peritoneal TB to reduce adhesions is variably practised and is *not* endorsed by the corpus (which supports steroids only for TB pericarditis and meningitis).

Acute pyelonephritis

Asked in: Paper IV Nov 2021 — RGUHS MD General Medicine

Definition / Introduction — Acute pyelonephritis is a symptomatic, **tissue-invasive infection of the renal parenchyma, calyces and pelvis**, and is the prototype of a *complicated urinary tract infection (UTI)* because infection has extended beyond the bladder. It usually develops as an **ascending infection** from the bladder, so its microbiology mirrors that of acute cystitis. Affected patients are often systemically ill, and fever is the cardinal feature distinguishing it from cystitis.

Etiology and microbiology

- ▶ **Escherichia coli is the predominant uropathogen across the whole UTI spectrum; the microbiology of pyelonephritis is similar to that of acute cystitis** since it arises by ascent.
- ▶ Other **Enterobacterales** — *Klebsiella*, *Proteus*, *Enterobacter*, *Citrobacter* — and *Staphylococcus saprophyticus* account for most of the remainder.
- ▶ *Staphylococcus aureus* or *Salmonella* in urine should raise suspicion of **haematogenous seeding** and concomitant bacteraemia.
- ▶ **Rising antimicrobial resistance:** surveillance shows >20% resistance to TMP-SMX, fluoroquinolones and nitrofurantoin in many regions; ~9% of isolates produce **extended-spectrum β -lactamase (ESBL)** and ~6% are resistant to ≥ 3 antibiotic classes — hence the value of *local antibiogram* data.

Pathogenesis

- ▶ The urinary tract is a continuous urine column from kidney to urethra; in most UTIs bacteria **ascend** urethra $\rightarrow$ bladder $\rightarrow$ ureter $\rightarrow$ renal parenchyma. **Haematogenous infection accounts for <2% of UTIs.**
- ▶ The **flushing action of normal voiding** is the key host defence; anything causing stasis or obstruction predisposes to infection.
- ▶ **Vesicoureteral reflux** and **inhibition of ureteral peristalsis / decreased ureteral tone** promote ascent — these are central to pyelonephritis in **pregnancy**.
- ▶ **Microbial virulence factors:** *P fimbriae* (bind the blood-group P antigen on renal epithelium) are important in the pathogenesis of pyelonephritis and subsequent **bloodstream invasion**; *type 1 pili* mediate bladder attachment (bind mannose). Toxins, iron-acquisition systems, biofilm and capsule also contribute.
- ▶ **Host factors:** familial/maternal predisposition; mutations in innate-immune genes (**Toll-like receptors, IL-8 receptor**) linked to recurrent UTI and pyelonephritis; non-expression of certain blood-group antigens (non-secretor) increases uroepithelial adherence of *E. coli*.

Predisposing / risk factors

- ▶ **Obstruction & stasis:** renal/staghorn calculi, benign prostatic hypertrophy, neurogenic bladder, vesicoureteral reflux, urinary-diversion surgery, congenital anomalies, cystocele/pelvic-organ prolapse.
- ▶ **Foreign bodies:** indwelling/intermittent catheters, stents, nephrostomy tubes — provide an inert surface for **biofilm** and act as a nidus.
- ▶ **Diabetes mellitus** (2–3 $\times$ higher UTI/ASB rate; predisposes to emphysematous pyelonephritis); **pregnancy**; female anatomy (**short urethra**); sexual activity and **spermicide** use; immunocompromise.

Clinical features

- ▶ **Acute onset**, with or without preceding cystitis symptoms (dysuria, frequency, urgency).
- ▶ ****Mild** pyelonephritis — **low-grade fever ± lower-back or costovertebral-angle (flank) pain****.
- ▶ ****Severe** pyelonephritis — high fever, rigors, nausea, vomiting and flank pain**; may progress to bacteraemia and sepsis.
- ▶ Fever, rigors and unilateral back/flank pain in a patient with “cystitis” are **inconsistent with simple cystitis** and mandate evaluation for infection beyond the bladder.

Complications

Complication	Key features (per source)
Acute papillary necrosis	Sloughed papillae obstruct the ureter → obstructive uropathy; also seen in sickle cell disease and analgesic nephropathy ; <i>bilateral</i> necrosis → rapid rise in serum creatinine
Emphysematous pyelonephritis	Severe form with gas in renal/perinephric tissue ; occurs almost exclusively in poorly controlled diabetes (often <i>E. coli</i> , a gas-forming facultative anaerobe)
Xanthogranulomatous pyelonephritis (XGP)	Chronic obstruction (often staghorn calculus) + chronic infection → suppurative destruction; residual tissue is yellow with lipid-laden macrophages ; can mimic renal malignancy
Intraparenchymal / perinephric / renal cortical abscess	Suspect with continued fever and/or bacteraemia despite antibiotics

Diagnosis / investigations

- ▶ **Urinalysis**: pyuria (>10 WBC/HPF is the accepted standard for pyuria), **nitrite** (only Enterobacterales convert nitrate→nitrite) and **leukocyte esterase** on dipstick; haematuria in ~30%.
- ▶ **Urine culture** before therapy — provides organism identification and **susceptibilities to guide therapy** (essential in pyelonephritis, men, pregnancy and recurrent/resistant cases).
- ▶ **Blood cultures** in systemically ill / febrile patients.
- ▶ **Imaging (CT or ultrasound)** for febrile UTI and febrile UTI in men — to detect **obstruction, abscess, calculi or anatomic abnormalities**; CT also demonstrates gas in emphysematous pyelonephritis.

Treatment

- ▶ **Principle**: empirical therapy must be reliable and **rapidly reach therapeutic levels in renal parenchyma and blood**; nitrofurantoin, fosfomycin and pivmecillinam achieve poor renal-tissue levels and **must not be used** for pyelonephritis.

Setting	Recommended regimen (per source)
Hospitalised patients	Empirical IV β -lactam, chosen by local antibiogram and avoiding agents to which the patient recently had a resistant isolate
Outpatient (not requiring admission)	Empirical TMP-SMX, ciprofloxacin, or levofloxacin per local antibiogram + urine culture + short-term follow-up; an initial IV/IM β -lactam or aminoglycoside dose can be added where feasible
Susceptible isolate, oral therapy	5–7 days of an oral fluoroquinolone OR 7–14 days of oral TMP-SMX; oral β -lactams are less effective → use with caution and close follow-up
Parenteral options (uncomplicated PN)	Late-generation cephalosporin (ceftriaxone, cefepime), piperacillin-tazobactam, a carbapenem, or fluoroquinolone; alternatives — novel β -lactam/ β -lactamase inhibitors (e.g., meropenem-vaborbactam) and aminoglycosides
Pregnant patients with pyelonephritis	Parenteral β -lactam therapy $\pm$ aminoglycoside (based on limited data)

- ▶ **Admit** ambulatory patients who cannot tolerate oral medication (vomiting) or are unlikely to adhere to follow-up.
- ▶ **Step-down:** once a clinical response is achieved, switch parenteral → **oral**; therapy may be concluded at **7 days** in responders treated with a fluoroquinolone or TMP-SMX (oral β -lactams may need longer).
- ▶ **No clinical response within 72 h** → evaluate for an **uncontrolled source** (obstruction, abscess).
- ▶ **Source control:** papillary necrosis with obstruction needs intervention to relieve obstruction; perinephric/cortical abscess → **percutaneous drainage**; **emphysematous pyelonephritis** → percutaneous drainage initially, then **elective nephrectomy** as needed; **XGP** → usually **nephrectomy** with individualized antibiotic duration, in collaboration with urology.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Diagram 1 — Ascending pathogenesis of pyelonephritis:** vertical urinary tract with labels — Urethra → Bladder (cystitis) → Vesicoureteral reflux → Ureter → Renal pelvis/calices → Renal parenchyma (pyelonephritis); annotate *P fimbriae* adhesion to renal epithelium, *Type 1 pili* (bladder), and *Haematogenous seeding* (<2%: *S. aureus*, *Salmonella*).
- ▶ **Diagram 2 — Labelled kidney showing complications:** cross-section with labels — Cortical abscess, Perinephric abscess, Papillary necrosis (sloughed papilla obstructing ureter), Gas in parenchyma (emphysematous PN), Staghorn calculus with destruction (XGP).

Clinical / Diagnostic significance

- ▶ **Fever + flank/CVA tenderness** in a UTI patient = pyelonephritis until proven otherwise; reclassify “cystitis with fever” as a complicated UTI.
- ▶ Persistent fever/bacteraemia despite appropriate antibiotics signals **abscess or obstruction** — image and arrange drainage.
- ▶ **Diabetic + severe pyelonephritis + gas on imaging** = emphysematous pyelonephritis, a urological emergency.
- ▶ **Pregnancy**: untreated asymptomatic bacteriuria predisposes to pyelonephritis, **preterm delivery and low birth weight** — justifying routine **ASB screening and treatment** by urine culture in pregnancy.
- ▶ **Avoid** nitrofurantoin/fosfomycin/pivmecillinam for upper-tract disease — they fail to reach renal tissue.

High-yield exam pointers

- ▶ Pyelonephritis = **tissue-invasive complicated UTI**; *E. coli* is the commonest organism; ascent is the usual route (<2% haematogenous).
- ▶ **P fimbriae** = key virulence factor for pyelonephritis and bloodstream invasion; **type 1 pili** for bladder attachment.
- ▶ **Triad of severe disease**: high fever + rigors + flank pain, often with nausea/vomiting.
- ▶ **Emphysematous pyelonephritis** → poorly-controlled diabetes; **XGP** → staghorn calculus + lipid-laden macrophages, mimics tumour; **papillary necrosis** → also sickle cell disease & analgesic nephropathy.
- ▶ Always **send urine culture (± blood cultures)** before empirical antibiotics; image febrile UTI/men with CT or US.
- ▶ Outpatient empirical: **TMP-SMX / ciprofloxacin / levofloxacin** by antibiogram; hospitalised: **IV β-lactam**.
- ▶ Oral course for susceptible isolate: **5–7 days fluoroquinolone or 7–14 days TMP-SMX**; reassess at **72 h** if no response.
- ▶ **Pregnant pyelonephritis** = admit + **parenteral β-lactam ± aminoglycoside**.

SOURCE & COVERAGE

Harrison 22e — Ch 140 “Urinary Tract Infections: Cystitis, Prostatitis, and Pyelonephritis.”

Coverage note: This chapter does not state a specific clean-catch colony-count threshold for diagnosing pyelonephritis (it gives $>10^2$ CFU/mL as a sensitive cystitis cut-off and $\geq 10^3$ CFU/mL for CAUTI); the classic $\geq 10^5$ CFU/mL clean-catch criterion is universally accepted standard textbook medicine. Quantified imaging grading (e.g., Huang–Tseng classes of emphysematous pyelonephritis) is also outside the provided text.

Amoebic Liver Abscess

Asked in: Paper II Dec 2023 — RGUHS MD General Medicine

Definition / Introduction — Amoebic liver abscess (ALA) is the most common extraintestinal manifestation of infection with *Entamoeba histolytica*, produced by portal venous spread of invasive trophozoites from the colon to the liver. It usually presents as a febrile hepatic space-occupying lesion with right-upper-quadrant pain, often without active dysentery. It is a treatable medical emergency because rupture into the pleura, peritoneum, or pericardium may be fatal.

Etiology and Epidemiology

- ▶ **Agent:** *E. histolytica* is the pathogenic species in the *Entamoeba* complex; *E. dispar*, *E. moshkovskii*, and other species may be morphologically indistinguishable on microscopy but do not explain classic invasive disease.
- ▶ **Transmission:** ingestion of mature cysts from fecally contaminated water, food, hands, or mechanically contaminated food; less commonly via oral-anal sexual practices. Trophozoites are killed by gastric acid and air and do not transmit infection.
- ▶ **Reservoir:** humans are the established host; asymptomatic carriers may shed large numbers of cysts.
- ▶ **Geography:** common in tropical and subtropical areas with poor sanitation, crowding, and poor nutrition; important in the Indian subcontinent, Africa, parts of East Asia, Mexico, Colombia, and other endemic regions.
- ▶ **Risk groups:** residents of endemic areas, returning travelers, recent immigrants, men who have sex with men, institutional inmates, and persons exposed to unsafe water or food.
- ▶ **Sex and age:** invasive colitis and liver abscess are much more common in men; Harrison notes that men aged 30-60 years are affected 10-12 times more often than women of the same age.
- ▶ In travelers who develop ALA after leaving an endemic area, most present within 5 months.

Pathogenesis and Pathology

- ▶ After cyst ingestion, **excystation** occurs in the small intestine; trophozoites colonize the large bowel. In most persons infection remains asymptomatic, but trophozoites may invade the colonic mucosa.
- ▶ Virulence depends on **Gal/GalNAc adherence lectin**, cysteine proteinases, glycosidases, contact-dependent cytotoxicity, trophocytosis, inflammatory-cell lysis, and resistance to oxidative and complement-mediated killing.
- ▶ Intestinal disease produces **flask-shaped ulcers** with trophozoites at the margin of viable and necrotic tissue; glucocorticoid exposure can convert unrecognized amebiasis into severe colitis or toxic megacolon.

- ▶ ALA is **always preceded by intestinal colonization**, often asymptomatic. Trophozoites enter mesenteric venules and reach the liver via the **portal venous system**.
- ▶ In the liver, vessel-wall lysis, thrombosis, neutrophil recruitment, neutrophil lysis, and hepatocyte necrosis produce a cavity of necrotic debris surrounded by a thin rim of congested liver.
- ▶ The aspirate is classically described as “**anchovy paste**”, but color is variable. It is usually **bacteriologically sterile**, granular, and poor in cells; trophozoites are uncommon in the aspirated center and are more often near the abscess capsule.

Clinical Features

- ▶ **Classical triad**: fever, right-upper-quadrant abdominal pain, and tender hepatomegaly.
- ▶ Onset may be acute or gradual. Pain is often dull or pleuritic and may radiate to the right shoulder; point tenderness over the liver and **intercostal tenderness** are useful bedside clues.
- ▶ **Fever** is common; **jaundice is rare** and, if prominent, suggests large abscess, biliary obstruction, cholangitis, or alternative diagnosis.
- ▶ Gastrointestinal symptoms are absent in many patients: fewer than one-third have active diarrhea despite colonic origin of infection. Anorexia, malaise, weight loss, nausea, cough, and hiccups may occur.
- ▶ **Right pleural effusion** or elevated right hemidiaphragm may accompany superior right-lobe abscesses.
- ▶ Older patients from endemic areas may present subacutely over months with weight loss and hepatomegaly; 10-15% may present only as fever of unknown origin.

Pattern	Exam clue	Significance
Acute ALA	Fever, RUQ pleuritic pain, tender liver, leukocytosis	Usually symptomatic for <10 days; multiple lesions are more likely early
Subacute/chronic ALA	Weight loss, hepatomegaly, variable fever	Common diagnostic trap in endemic-area patients
Left-lobe abscess	Epigastric pain, pericardial risk	Needs early drainage consideration
Superior right-lobe large abscess	Pleural pain, effusion, basal lung signs	Risk of pleuropulmonary rupture

Investigations and Diagnosis

- ▶ **CBC/LFT**: leukocytosis is common; Harrison notes leukocytosis >10,000 cells/microliter in about three-fourths of ALA. Eosinophilia is not a feature. Liver enzymes may be normal or minimally raised; **alkaline phosphatase** is most often elevated and may remain high for months.

- ▶ **Stool tests:** often negative in isolated ALA. If intestinal symptoms are present, examine at least **three fresh stool specimens**; hematophagous trophozoites are diagnostic, but routine microscopy cannot distinguish *E. histolytica* from nonpathogenic *Entamoeba* species.
- ▶ **Serology:** anti-amebic antibody testing is positive in **>90%** of invasive amebiasis including liver abscess. Early ALA may be seronegative in up to **10%**, so repeat testing after about a week if suspicion remains high.
- ▶ **Antigen/PCR:** stool or aspirate antigen assays targeting *E. histolytica* improve specificity; PCR-based gastrointestinal panels have very high sensitivity and specificity where available. In hepatic abscess, stool antigen is frequently negative, while aspirate antigen is highly diagnostic if aspiration is done.
- ▶ **Imaging:** ultrasonography, CT, and MRI detect round or oval hypoechoic or low-density nonhomogeneous lesions. More than **80%** of patients symptomatic for **>10 days** have a **single right-lobe abscess**; about **50%** of those symptomatic for **<10 days** may have multiple abscesses.
- ▶ **Important limitation:** imaging cannot reliably distinguish amoebic from pyogenic abscess; use epidemiology, serology, cultures when aspirated, and therapeutic response.
- ▶ **Differential diagnosis:** pyogenic liver abscess, cholangitis, acute cholecystitis, hepatocellular carcinoma with necrosis/infection, hydatid cyst, tuberculosis, malaria, typhoid fever, right lower-lobe pneumonia, subphrenic abscess, and inflammatory bowel disease with hepatic sepsis.

Treatment

- ▶ **Principle:** treat both tissue invasion and intestinal carriage. A tissue amebicide alone improves the abscess but does not eradicate bowel cysts; hence add a **luminal amebicide** after or along with nitroimidazole therapy.

Clinical setting	Preferred regimen
Amoebic hepatic abscess	Metronidazole 750 mg orally three times daily for 10 days; if oral therapy is not possible, metronidazole 500 mg IV every 6 hours for 10 days
Alternative	Tinidazole 2 g orally daily for 5 days
Luminal eradication	Diloxanide furoate 500 mg orally three times daily for 10 days or iodoquinol 650 mg orally three times daily for 21 days or paromomycin 10 mg/kg orally three times daily for 7 days

- ▶ Avoid alcohol with metronidazole/tinidazole because of a disulfiram-like reaction; nausea, metallic taste, vomiting, epigastric discomfort, and headache may occur.
- ▶ More than **90%** respond dramatically to metronidazole, with reduction in pain and fever within **72 hours**. With early diagnosis and treatment, mortality from uncomplicated ALA is **<1%**.

- ▶ **No routine aspiration** is required for typical, uncomplicated ALA responding to therapy; aspiration does not hasten healing even for large abscesses up to about 10 cm.
- ▶ **Aspirate/drain if:** pyogenic abscess must be excluded, especially with multiple lesions; no clinical response in **3-5 days**; very large abscess with threatened rupture; left-lobe abscess at risk of pericardial rupture; frank pleural or peritoneal rupture; or the patient is toxic/very ill.
- ▶ **Surgery:** reserve for bowel perforation and rupture into the pericardium; percutaneous drainage may suffice for many ruptured hepatic abscesses.
- ▶ Abscess cavities resolve slowly. Imaging abnormalities may persist despite clinical cure; complete resolution by 6 months occurs in about two-thirds, and 10% may have abnormalities for a year.

Complications and Prevention

- ▶ **Pleuropulmonary complications** are the commonest, reported in **20-30%**: sterile effusion, contiguous spread, rupture into pleural space, lung abscess, or hepatobronchial fistula with expectoration of necrotic material.
- ▶ **Peritoneal rupture** may present as indolent leak or acute abdomen and needs drainage plus medical therapy.
- ▶ **Pericardial rupture**, usually from left-lobe abscess, has the worst prognosis and requires urgent surgical drainage.
- ▶ Rare extraintestinal sites include lung, brain, genitourinary tract, and painful punched-out genital ulcers due to direct extension or hematogenous spread.
- ▶ **Prevention:** safe water, sanitary disposal of feces, hand hygiene, adequate cooking of food, protection of food from flies, avoidance of unpeeled fruits/vegetables in endemic areas, bottled/boiled/filtered water, and treatment of cyst carriers.
- ▶ Cysts resist standard chlorination; iodine treatment or boiling/filtration is more reliable. There is **no effective chemoprophylaxis**.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Life cycle and hepatic spread of *E. histolytica*:** ingestion of cysts, excystation in small intestine, colonization of colon, flask-shaped colonic ulcer, portal venous spread, right-lobe liver abscess; labels: cyst, trophozoite, colon, portal vein, liver abscess, asymptomatic cyst passage.
- ▶ **Anatomical complications of ALA:** right-lobe abscess, pleural effusion/rupture, hepatobronchial fistula, peritoneal rupture, left-lobe abscess, pericardial rupture.

Clinical / Diagnostic significance

- ▶ ALA is a classic cause of **fever with right-upper-quadrant pain** in Indian exams and must also be considered in FUO with epidemiologic risk.

- ▶ Absence of diarrhea does **not** exclude ALA; most patients with hepatic disease have no active intestinal symptoms.
- ▶ Positive serology plus compatible imaging and clinical syndrome is usually sufficient for diagnosis; aspiration is mainly for uncertainty, poor response, or rupture risk.
- ▶ Differentiate from pyogenic abscess: pyogenic abscess patients are often older, have biliary disease, bowel disease, diabetes, recent surgery, polymicrobial cultures, and need antibacterial therapy plus drainage.
- ▶ Rule out amebiasis before giving glucocorticoids for presumed inflammatory bowel disease in endemic settings.
- ▶ Do not chase radiologic resolution too frequently: clinical response is more important early because abscess size can lag behind cure.

High-yield exam pointers

- ▶ Most common extraintestinal site of amebiasis is the **liver**.
- ▶ **Right-lobe, solitary abscess in a young/middle-aged man** with fever and RUQ pain is the prototype.
- ▶ **Jaundice is uncommon** in uncomplicated ALA.
- ▶ Stool examination is often negative in ALA; **serology is the key test**.
- ▶ Aspirate is classically **anchovy-paste**, sterile, and poor in cells; trophozoites are usually not seen in the center.
- ▶ Treat with **metronidazole/tinidazole plus luminal agent**; metronidazole alone risks persistent intestinal carriage.
- ▶ Clinical response should occur within **72 hours**; lack of response by **3-5 days** is an aspiration/drainage indication.
- ▶ Left-lobe abscess is dangerous because of **pericardial rupture**.
- ▶ Standard chlorination is unreliable against cysts; emphasize sanitation, boiling/iodination/filtration, and safe food.

Harrison 22e — “Amebiasis and Infection with Free-Living Amebae”; CMTD 2026 — “Protozoal & Helminthic Infections” and “Liver, Biliary Tract, & Pancreas Disorders”.

Anaerobic organisms infections

Asked in: Paper II Jul 2021 — RGUHS MD General Medicine

Definition / Introduction — **Anaerobic bacteria** are organisms that grow optimally in the absence of oxygen and constitute the predominant class of the normal human microbiota residing on mucous membranes. They cause disease chiefly after **breakdown of a mucosal barrier** allows the microbiota to leak into normally sterile tissue, producing infections that are typically **polymicrobial** (mixed anaerobic + facultative/microaerophilic species). Because they are fastidious and hard to culture, the anaerobic aetiology is frequently *unproven*, so the diagnosis often rests on clinical pattern recognition. Treatment hinges on **appropriate antibiotics plus surgical drainage/debridement**.

Classification of anaerobes by oxygen tolerance and morphology

- ▶ **Obligate (strict) anaerobes** — killed in the presence of $\geq 0.5\%$ oxygen (lack superoxide dismutase/catalase).
- ▶ **Aerotolerant anaerobes** — tolerate oxygen but cannot use it for growth; *most clinically relevant anaerobes* (*Bacteroides fragilis*, *Prevotella melaninogenica*, *Fusobacterium nucleatum*) are relatively aerotolerant.
- ▶ **Facultative anaerobes** — grow with or without oxygen (e.g. *E. coli*); preferentially use oxygen when available.
- ▶ **Microaerophilic organisms** — require low O_2 (2–10%) and are damaged by atmospheric $\sim 21\%$.
- ▶ Oxygen tolerance correlates with expression of **superoxide dismutase and catalase** (detoxify O_2^- and H_2O_2). Energy is generated by less-efficient **anaerobic respiration** (acceptors: sulfate, nitrate, CO_2 , fumarate) or **fermentation** ($\sim 5\%$ of the ATP yield of aerobic respiration).

Microbiological group	Representative pathogens
Gram-negative bacilli	<i>Bacteroides fragilis</i> group (25 species), <i>Prevotella</i> , <i>Porphyromonas</i> , <i>Fusobacterium</i> spp.
Gram-negative cocci	<i>Veillonella</i> spp. (few of the gram-neg cocci causing disease)
Gram-positive cocci	Peptostreptococci (<i>P. micros</i> , <i>P. anaerobius</i>), <i>Finegoldia magna</i> (ex- <i>Peptostreptococcus magnus</i>)
Gram-positive spore-forming bacilli	<i>Clostridium</i> spp. (covered separately)
Gram-positive non-spore-forming bacilli	<i>Cutibacterium acnes</i> (ex- <i>Propionibacterium</i>), <i>Actinomyces</i> spp.

Sites of normal anaerobic microbiota and the organisms they seed

- ▶ The **lower GI tract (colon)** is the major reservoir — anaerobe:aerobe ratio $\sim 1000:1$, $\sim 10^{11}$ – 10^{12} organisms/g; *Bacteroides* group, *Prevotella*, *Clostridium*.
- ▶ **Oral cavity / gingival crevices** — ratio up to 1000:1; *Prevotella*, *Porphyromonas*, *Fusobacterium*, *Peptostreptococcus*, *Actinomyces* → odontogenic, peripharyngeal, sinus and pleuropulmonary infections.

- ▶ **Female genital tract** — ratio ~10:1; *Prevotella bivia*, *P. disiens*, *Bacteroides* → pelvic infections.
- ▶ **Skin** — *Cutibacterium acnes* predominant → foreign-body/prosthetic infections.
- ▶ Infections “reflect the neighbouring microbiota”: e.g. **B. fragilis** + **E. coli** dominate intra-abdominal abscesses; oral flora dominate lung abscess.

Pathogenesis and virulence factors

- ▶ **Prerequisite** = an anaerobic micro-environment with lowered oxidation–reduction (redox) potential — created by ischaemia, trauma, surgery, a perforated viscus, or by facultative organisms consuming oxygen (basis of synergy).
- ▶ **Adhesion** — *P. gingivalis* fimbriae; *F. nucleatum* acts as a “bridge” binding almost all oral bacteria; *B. fragilis* pili/fimbriae/haemagglutinins.
- ▶ **Exoproteins/toxins** — *P. gingivalis* collagenase; clostridial exotoxins are among the most potent in nature.
- ▶ **Endotoxin (lipid A)** of *B. fragilis*/*Prevotella*/*Porphyromonas* is **100–1000× less biologically potent** than aerobic gram-negative LPS → explains the *lower rates of DIC, purpura and septic shock* in anaerobic gram-negative bacteraemia. (Exception: *Fusobacterium* LPS, contributing to severe Lemierre’s syndrome.)
- ▶ *****B. fragilis* capsular polysaccharide complex** — **the best-studied anaerobic virulence factor**; ≥8 **distinct capsules**; PSA and PSB are zwitterionic (**free amino + carboxyl groups**). **PSA induces abscesses by stimulating peritoneal macrophages (via TLR-2) to release IL-8, IL-17 and TNF-α, driving PMN chemotaxis and adhesion to ICAM-1****-expressing mesothelium — the abscess nidus.
- ▶ **Bacterial synergy** — infections characteristically involve **3–6 organisms**; facultatives lower redox potential, supply growth factors (e.g. vitamin K for *P. melaninogenica*) and impair phagocytosis (short-chain/succinic acids).

Clinical syndromes by anatomical site

- ▶ **Mouth, head & neck** — dental caries, periodontitis; **Ludwig’s angina** (submandibular/sublingual/submental space cellulitis from molar abscess, tongue elevation, airway threat); **acute necrotizing ulcerative gingivitis** (*trench mouth* / *Vincent’s stomatitis* — painful bleeding gums, grey pseudomembrane); **noma (cancrum oris)** — gangrenous orofacial destruction in malnourished children (sub-Saharan Africa, 70–90% untreated mortality, driven by *F. necrophorum*/*P. intermedia*); **peritonsillar abscess (quinsy)** and **retropharyngeal abscess**; **chronic sinusitis & suppurative otitis media** (anaerobes spare the *acute* forms).
- ▶ **Lemierre’s syndrome** — *F. necrophorum* oropharyngeal infection → **septic thrombophlebitis of the internal jugular vein** with septic pulmonary emboli.

- ▶ **CNS** — anaerobes recovered in ~30% of **brain abscesses**, ~20% of epidural abscesses, ~10% of subdural empyemas (usually by contiguous spread from oto-/odonto-/sinogenic foci); anaerobic meningitis is rare.
- ▶ **Pleuropulmonary** (from microaspiration of oral flora; indolent course) — **aspiration pneumonia** (dependent segments), **lung abscess** (foul sputum, ~90% yield an anaerobe, 3–6 isolates), **empyema** — distinguish from simple parapneumonic effusion:

Feature	Parapneumonic effusion	Anaerobic empyema
WBC (cells/mL)	~5,000	~55,000
LDH (IU/L)	>200	>1000
pH	~7.4	<7.2
Character	thin exudate	foul, thick pus, loculated, pleural peel

(Contrast with **Mendelson syndrome** — *chemical* aspiration pneumonitis from gastric acid, evolving within 4–6 h, needing no antibiotics unless superinfected.)

- ▶ **Intra-abdominal** — peritonitis/abscess after perforation; *E. coli* + *B. fragilis* group; **neutropenic enterocolitis (typhlitis)** — caecal wall thickening >4 mm post-chemotherapy; *Clostridium septicum* bacteraemia flags occult **colon cancer**.
- ▶ **Pelvic** — PID, tubo-ovarian abscess, septic abortion, endometritis (*P. bivia*, *P. disiens*, *B. fragilis*); **bacterial vaginosis** (loss of lactobacilli, overgrowth of *Gardnerella/Prevotella/Mobiluncus*).
- ▶ **Skin/soft tissue** — **gas gangrene** (clostridial), **progressive bacterial synergistic (Meleney) gangrene**, **synergistic necrotizing cellulitis / Fournier gangrene** (scrotum–perineum–abdominal wall), **necrotizing fasciitis, myositis** — foul odour, crepitus/subcutaneous gas, cutaneous anaesthesia.
- ▶ **Bone & joint** — *Actinomyces* “**lumpy jaw**” (cervicofacial, mandible > maxilla, sinus tracts); contiguous mixed osteomyelitis (diabetic foot, decubitus).
- ▶ **Bacteraemia / endocarditis** — *B. fragilis* is the anaerobe most often isolated from blood; mortality of untreated *B. fragilis* group bacteraemia ~60%; gram-negative anaerobic endocarditis carries 21–43% mortality.

Diagnosis

- ▶ **Clinical clues** — abscess formation, **putrid/foul-smelling** discharge (present in only 30–50%, often late), gas in tissues, septic thrombophlebitis, tissue necrosis, and **failure to respond to antibiotics inactive against anaerobes**.
- ▶ “**Sterile pus**” that yields no growth (or only a single aerobe) yet is **teeming with organisms on Gram stain** strongly implies anaerobes (lost on inadequate transport/culture).

- **Specimens** — sample normally sterile sites (blood, pleural/peritoneal fluid, aspirates/biopsy); avoid mucosal-surface swabs (mouth, vagina, faeces) that contain commensal anaerobes. Use **air-free syringe + anaerobic transport medium** and rapid transport. Prior antibiotics reduce recovery.

Treatment / Antimicrobial therapy

- **Two pillars:** (1) appropriate antibiotics active against *both* aerobes and anaerobes; (2) **surgical debridement of devitalized tissue + drainage** of abscesses, and prompt closure of any mucosal breach.
- **No useful anaerobic activity:** aminoglycosides, monobactams (aztreonam), trimethoprim-sulfamethoxazole.

Agent	Caveat
Metronidazole	First-line for gram-negative anaerobes; <i>unreliable</i> against gram-positive non-spore-formers (<i>Actinomyces</i> , <i>Cutibacterium</i> , <i>Peptostreptococcus</i> , <i>Lactobacillus</i>)
β -lactam/ β -lactamase-inhibitor (ampicillin-sulbactam, piperacillin-tazobactam)	Rising resistance in some gram-negatives; newer ceftolozane/ceftazidime-avibactam have limited anaerobic activity
Clindamycin	<i>B. fragilis</i> group resistance now 30–43% in USA → no longer first-line for intra-abdominal sepsis
Carbapenems (meropenem, imipenem, ertapenem, doripenem)	Very low resistance (<5%); rare carbapenemase-producing strains
Chloramphenicol	Occasional clinical failures despite in-vitro susceptibility

- **Above vs below the diaphragm** governs empirical choice:
 - **Above diaphragm** (orodental flora, *Prevotella*/*Porphyromonas*/*Fusobacterium*; >70% β -lactamase-producing): clindamycin, a β -lactam/ β -lactamase-inhibitor, or **metronidazole + penicillin** (for microaerophilic/aerobic streptococci). Penicillin alone is inadequate.
 - **Below diaphragm** (must cover *B. fragilis* + coliforms): single agent — **cefoxitin**, **moxifloxacin**, a β -lactam/ β -lactamase-inhibitor, or a **carbapenem**; or two-drug **metronidazole + cephalosporin/fluoroquinolone**; add ampicillin/vancomycin if enterococci suspected.
- **Representative CMDT 2026 regimens:** ampicillin-sulbactam 3 g IV q6h (then amoxicillin-clavulanate 875/125 mg PO BID); ceftriaxone + metronidazole 500 mg q6–8h; moxifloxacin 400 mg/day; **brain abscess** — ceftriaxone 2 g IV q12h + metronidazole 500 mg q8h for 6–8 weeks (imaging-guided); anaerobic/microaerophilic streptococcal **endocarditis** — penicillin G 12–18 MU/day for 4–6 weeks.

- ▶ **Failure to respond** → re-image for undrained focus, reculture, request susceptibility testing (reserved for serious/refractory/prolonged-therapy infections).

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **“Pathogenesis of an anaerobic abscess” flow diagram** — label: *Mucosal barrier breach (perforation/ischaemia/surgery) → Polymicrobial inoculation → Facultative organisms consume O₂ → lowered redox potential → Outgrowth of obligate anaerobes → B. fragilis PSA → TLR-2 on macrophages → IL-8/IL-17/TNF-α → PMN influx → ICAM-1 adhesion → ABSCESS.*
- ▶ **Lung abscess radiograph schematic** — label: *cavity with air–fluid level, dependent (posterior) segment, right upper-lobe posterior / lower-lobe superior segment, surrounding consolidation.*

Clinical / Diagnostic significance

- ▶ Suspect anaerobes whenever an infection arises **adjacent to a mucosal surface**, forms an abscess, is foul-smelling, contains gas, or fails broad-spectrum antibiotics lacking anaerobic cover.
- ▶ **Source control (drainage/debridement) is as important as antibiotics** — many synergistic infections resolve even if therapy targets only the dominant organisms, because resistant species do not survive without their co-pathogens.
- ▶ *B. fragilis* group **always implies significant underlying pathology** (colonic neoplasm, diverticulitis, perforation) when isolated from blood — investigate the gut.
- ▶ Low DIC/shock incidence is a *hint* (weak lipid A), but does not exclude serious infection.

High-yield exam pointers

- ▶ Three oxygen classes: **obligate** (killed $\geq 0.5\%$ O₂) / **aerotolerant** / **facultative**; tolerance = SOD + catalase.
- ▶ *B. fragilis* = commonest anaerobe in intra-abdominal abscess, bacteraemia and endocarditis; only ~0.5–1% of colonic flora yet dominant in disease — due to its **zwitterionic capsular polysaccharide (PSA)**.
- ▶ **Lemierre’s syndrome** = *F. necrophorum* + IJV septic thrombophlebitis + septic pulmonary emboli.
- ▶ **Ludwig’s angina, ANUG (Vincent’s), noma, quinsy** — classic head-and-neck anaerobic eponyms.
- ▶ **Meleney** (progressive synergistic) gangrene and **Fournier** gangrene are anaerobic synergistic soft-tissue infections.
- ▶ **Empyema** fluid: pH <7.2, LDH >1000, WBC ~55,000 → needs drainage.
- ▶ **Typhlitis** + *Clostridium septicum* bacteraemia → screen for **colon cancer**.

- ▶ Metronidazole fails against gram-positive non-spore-formers (Actinomyces, Cutibacterium, Peptostreptococcus).
- ▶ No anaerobic activity: aminoglycosides, aztreonam, co-trimoxazole.
- ▶ Above- vs below-diaphragm rule directs empirical antibiotics.

SOURCE & COVERAGE

Aspergillus Infections (Aspergillosis)

Asked in: Paper II Sep 2025 — RGUHS MD General Medicine

Definition / Introduction — *Aspergillosis* is the collective term for the spectrum of disease produced by the ubiquitous, hyaline, septate, branching mould *Aspergillus* (~50 pathogenic/allergenic species). *A. fumigatus* causes most invasive disease, >95% of chronic disease and most allergic syndromes; *A. flavus* predominates in sinus, cutaneous and keratitis disease (and granulomatous sinusitis of the Middle East/India); *A. terreus* and *A. nidulans* are intrinsically amphotericin-resistant. Only species growing at 37°C invade; spectrum runs from harmless saprophytic colonisation through devastating angioinvasive infection to allergic hypersensitivity. The clinical form is dictated by the **host immune state**.

Epidemiology, ecology and pathogenesis

- ▶ **Ecology**: worldwide; grows in decomposing plant matter (compost), hay and bedding, producing vast numbers of airborne **conidia**. Inhalation is the route of entry; daily exposure ranges from a few to millions of conidia. Intense exposure (construction, mouldy bark/hay, composting) can cause acute pulmonary aspergillosis even in the immunocompetent.
- ▶ **Incubation** of invasive disease is highly variable (2–90 days), so community-acquired strains often manifest during hospitalisation; outbreaks relate to contaminated air sources or **hospital construction**. **HEPA filtration** is protective and should guard operating rooms, burn units and high-risk wards.
- ▶ **Burden (global, 2024 estimates)**: invasive ~2.1 million; chronic ~6.1 million; allergic ~11.7 million.

- **Pathogenesis is host-determined:** profound neutropenia/phagocyte dysfunction → **angioinvasion**; an inadequate TH1 response with persistent inflammation → **chronic** cavitory disease; an exaggerated TH2/"allergic" response to *A. fumigatus* → **ABPA/SAFS**.

Risk factors (by disease form)

Form	Principal host setting / risk factors
Invasive	Profound, prolonged neutropenia ; high-dose glucocorticoids ; haematological malignancy/relapsed leukaemia; HSCT; chronic granulomatous disease (esp. <i>A. nidulans</i>); advanced HIV; immunomodulators — infliximab , ibrutinib (ibrutinib → cerebral disease); ICU patients (2–5%), severe influenza (8–25%), severe COVID-19 (~10%, "CAPA"), COPD (1.3–3.9%); severe liver disease
Chronic	Apparently immunocompetent but with prior lung damage — prior/active TB , NTM, sarcoidosis, prior pneumothorax/bullae, COPD, rheumatoid lung; subtle NK/IL-12/IFN- γ defects
Allergic (ABPA/SAFS)	Asthma and cystic fibrosis (incl. heterozygous <i>CFTR</i>); genetic TH2 predisposition; common in the Indian subcontinent
Saprophytic	Pre-existing pulmonary cavity (aspergilloma); maxillary sinus (fungal ball)

Classification and clinical manifestations

- **Invasive (acute ≤ 1 month / subacute 1–3 months):**
 - *Invasive pulmonary aspergillosis* — >80% of invasive disease; fever, cough, pleuritic discomfort, trivial **haemoptysis**, dyspnoea (often asymptomatic). Fever may respond transiently to steroids while disease progresses; a frequent **autopsy-only** diagnosis.
 - *Invasive sinusitis* — 5–10%, leukaemia/HSCT; nasal/facial pain, blocked nose, bloody discharge; endoscopy shows pale/dusky/necrotic mucosa.
 - *Tracheobronchitis* — lung-transplant and ventilated patients; ulcerative/pseudomembranous; mucous-plug obstruction.
 - *Disseminated/cerebral disease* — spread to **brain** (haemorrhagic infarction, abscess; rarely meningitis, mycotic aneurysm, granuloma), skin, thyroid, bone, kidney, GI tract, eye, heart valve; blood cultures almost always negative.
 - *Endocarditis* — usually prosthetic-valve (intra-operative contamination) or in PWID; large vegetations, culture-negative.
 - *Cutaneous* — purplish area → necrotic **eschar**; direct invasion at IV-catheter sites and in burns/trauma (esp. *A. flavus*).

- ▶ **Chronic pulmonary aspergillosis (CPA):**
 - *Chronic cavitary pulmonary aspergillosis (CCPA)* — one/more cavities expanding over months–years; >90% with prior lung disease; weight loss/fatigue may dominate; **life-threatening haemoptysis** is the key complication; untreated → *chronic fibrosing pulmonary aspergillosis* (“destroyed lung”). IgG positive in ~90%.
 - *Aspergilloma (fungal ball)* — fungal mass within a cavity; cough, haemoptysis, wheeze; ~10% resolve spontaneously.
 - *Aspergillus nodule* — 5–50 mm, may cavitate, mimics carcinoma; PET-avid; IgG positive ~65%.
- ▶ **Chronic sinusitis:** fungal ball of (maxillary) sinus — non-invasive, surgically curable; chronic invasive sinusitis — slowly destructive (ethmoid/sphenoid), *orbital apex syndrome* (**blindness + proptosis**), cavernous-sinus/carotid involvement; chronic granulomatous sinusitis — Middle East/India, *A. flavus*.
- ▶ **Allergic / saprophytic-allergic:**
 - *ABPA* — hypersensitivity to *A. fumigatus*; ~2.5% of referred asthmatics, up to 15% of CF teenagers; brown sputum casts, fleeting infiltrates, central **bronchiectasis**.
 - *Severe asthma with fungal sensitisation (SAFS)* — fungal sensitisation without full ABPA criteria; total IgE <1000 IU/mL. ABPA + SAFS = “fungal asthma.”
 - *Allergic fungal rhinosinusitis* — perennial sinusitis, nasal polyps, eosinophilic mucin, **Charcot-Leyden crystals**.
- ▶ **Superficial:** keratitis (sight-threatening; treat with topical **natamycin 5%**), onychomycosis (toenail, diabetes), otitis externa (often *A. niger*).

Diagnosis

- ▶ **Microscopy/histology:** hyaline, narrow, **septate hyphae branching at acute (45°) angles**; tissue shows vascular invasion with infarction (angioinvasion) or necrosis.
- ▶ **Galactomannan antigen** (cell-wall) in serum and especially **BAL** — high sensitivity (>80%); BAL more sensitive than serum and essential in ventilated ICU patients where radiology is nonspecific; serum antigen often precedes clinical/radiological signs by days; sensitivity falls with antifungal therapy; rising levels predict worse outcome.
- ▶ **Serum (1,3)- β -D-glucan** — supportive but non-specific (positive in many fungi).
- ▶ **Real-time PCR** (sputum/serum/BAL) — fast and more sensitive than culture; useful combined with antigen.
- ▶ **Culture** — positive in only **10–30%** of invasive disease; *request fungal media/high-volume culture*; vital for **azole-susceptibility testing** (especially during therapy).
- ▶ **Aspergillus IgG antibody** — cornerstone of **chronic** disease diagnosis with characteristic imaging (positive ~90% CCPA).

- ▶ **ABPA serology:** *Aspergillus*-specific IgE (or positive skin-prick) + elevated **total IgE** (usually >1000 IU/mL) + eosinophilia; hyperattenuated/high-density mucus is highly specific.
- ▶ **Imaging:** CT thorax — **halo sign** (ground-glass of haemorrhagic infarction around a nodule; early, ~7 days, good prognosis in neutropenia), nodules, wedge/pleural-based infarcts, later cavitation/**air-crescent sign** (aspergilloma). Sinus CT/MRI; brain MRI preferred for cerebral disease. *Definitive* diagnosis = positive culture from a sterile site, or positive histology **plus** culture/molecular confirmation from affected tissue.

Treatment

Indication	Primary	Alternatives / notes
Invasive aspergillosis	Voriconazole or isavuconazole (azoles ~20% higher response than AmB)	Posaconazole; lipid AmB; caspofungin/micafungin (2nd line). ID consult; therapy 3 months–years until immune reconstitution
Chronic pulmonary (CCPA)	Voriconazole or itraconazole	Posaconazole; IV AmB/micafungin. ≥12 months; avoid steroids (↑mortality ~240% unless antifungal cover)
ABPA / SAFS	Itraconazole + glucocorticoids (prednisone ~0.5 mg/kg/day, taper)	Voriconazole, posaconazole, inhaled AmB; long-term azole spares steroids
Single aspergilloma	Surgical resection (peri-operative antifungal cover)	Intracavitary AmB; medical Rx for multicavity disease
Sinus fungal ball / allergic sinusitis	Surgical removal ± endoscopic clearance	Local ± systemic steroids (allergic); ethmoidectomy if recurrent

- ▶ **Representative doses:** Voriconazole IV 6 mg/kg q12h ×2 loading then 4 mg/kg q12h (oral 200 mg bid); isavuconazole 200 mg q8h ×6 doses (2 days) then 200 mg daily; posaconazole tablet 300 mg daily; caspofungin 70 mg load → 50 mg/day; micafungin ≥150 mg/day (treatment); AmB deoxycholate 1 mg/kg/day; lipid AmB 3 mg/kg (AmBisome) or 5 mg/kg (Abelcet).
- ▶ **Therapeutic drug monitoring** is recommended for voriconazole, itraconazole, posaconazole and isavuconazole (variable absorption/metabolism, drug interactions).
- ▶ **Resistance:** multi-azole resistance in *A. fumigatus* ~3–20% (rising, esp. Southeast Asia; partly from agricultural azole fungicides); AmB inactive against **A. terreus* and *A. nidulans*; *A. niger** resistant to isavuconazole.
- ▶ **Adjuncts:** **bronchial artery embolisation** for problematic haemoptysis; reverse immunosuppression; surgery for endocarditis, brain abscess, keratitis, endophthalmitis, proximal-lung lesions.

- ▶ **Prophylaxis** (AML induction, GVHD, high-risk HSCT): **posaconazole** (most effective) or voriconazole/itraconazole solution/SUBA-itraconazole; IV micafungin if azole-contraindicated. *Fluconazole has no anti-Aspergillus activity.*

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **CT thorax spectrum of pulmonary aspergillosis** — label: (1) *halo sign* = nodule with surrounding ground-glass (early invasive/neutropenic); (2) *air-crescent sign* = crescent of air around a fungal ball (recovery); (3) *aspergilloma* = mobile fungal ball within an upper-lobe cavity with pleural thickening.
- ▶ **Tissue microscopy of Aspergillus** — label: hyaline **septate hyphae**, dichotomous **branching at 45° (acute) angle**, progressive width; inset of **conidiophore** with radiating chains of **conidia** (culture morphology); contrast note: broad, aseptate, right-angle hyphae = *Mucor* (differential).

Clinical / Diagnostic significance

- ▶ The single most useful discriminator is the **host**: neutropenia → invasive/angioinvasive; structurally damaged lung → chronic/aspergilloma; atopic asthma/CF → allergic.
- ▶ In India, CCPA is a **major mimic of, and sequel to, pulmonary TB** (follows treated TB in ~6–13%) — suspect in “smear-negative TB” or relapsing cavitary disease with weight loss; check **Aspergillus IgG**.
- ▶ In neutropenic/leukaemic and ICU/post-influenza/COVID patients, screen with **serum/BAL galactomannan** and urgent **CT thorax**; a *halo sign* warrants pre-emptive therapy.
- ▶ **ABPA** must be sought in poorly controlled asthma (total IgE >1000 IU/mL, specific IgE, eosinophilia, central bronchiectasis) — treatable, prevents fibrosis.
- ▶ Differentiate angioinvasive aspergillosis from **mucormycosis** (broad, aseptate, right-angle hyphae; AmB- rather than voriconazole-responsive) — management diverges sharply.

High-yield exam pointers

- ▶ *A. fumigatus* = most invasive/chronic/allergic disease; *A. flavus* = sinus/cutaneous/keratitis & granulomatous sinusitis (India/Middle East).
- ▶ **Septate hyphae, acute-angle (45°) dichotomous branching** — the classic histology buzz-phrase.
- ▶ **Galactomannan** (serum/BAL) and **β-D-glucan** are key non-culture markers; culture positive in only 10–30% of invasive disease.
- ▶ Radiology: **halo sign** (early), **air-crescent sign** (recovery/aspergilloma).
- ▶ ABPA hallmark: **total IgE usually >1000 IU/mL + Aspergillus-specific IgE + central bronchiectasis + brown mucus plugs**.

- ▶ First-line invasive therapy: **voriconazole or isavuconazole**; voriconazole IV 6 mg/kg q12h load → 4 mg/kg q12h.
- ▶ *AmB does NOT cover *A. terreus* or *A. nidulans*; *A. niger* is isavuconazole-resistant; fluconazole has NO anti-*Aspergillus* activity.*
- ▶ **Surgery cures** single aspergilloma and sinus fungal ball; **bronchial artery embolisation** for massive haemoptysis.
- ▶ Mortality: invasive 30–70% if treated (**100% if missed**); CCPA ~15–20% at 1 year, ~40% at 5 years, 50–60% at 10 years.
- ▶ Avoid glucocorticoids in CCPA (mortality up ~240%) unless covered by antifungals.

SOURCE & COVERAGE

- ▶ **Harrison's Principles of Internal Medicine, 22e** — “Aspergillosis” (Denning), incl. Tables 223-1/2/3 (disease frequency & diagnostic sensitivity, manifestations, treatment).
- ▶ **CMDT 2026** — “Mycotic Infections” (Aspergillosis: allergic/chronic/invasive forms, diagnosis, prevention and IDSA/ESCMID-ECMM-ERS treatment regimens and doses).
- ▶ *Coverage note:* The *air-crescent sign* and the *Aspergillus-vs-Mucor* hyphal contrast are standard, universally accepted radiology/microbiology added for completeness; Harrison explicitly describes the halo sign, cavitation, 45° septate hyphae and the broad differential rather than naming the “air-crescent sign.” Detailed ISHAM/formal ABPA criteria beyond IgE thresholds are not enumerated in the corpus; the serological criteria given are those stated in Harrison/CMDT.

Brucellosis

Asked in: Paper II Jul 2020 — RGUHS MD General Medicine

Definition / Introduction — Brucellosis is a bacterial zoonosis transmitted directly or indirectly to humans from infected animals, predominantly domesticated ruminants and swine. It is known colloquially as *undulant fever* because of the remittent (waxing-and-waning) character of its pyrexia. Although it commonly presents as an acute febrile illness, the clinical manifestations are protean and definitive diagnostic signs may be lacking; thus the clinical impression must usually be confirmed by bacteriologic and/or serologic testing. It remains a major public-health problem in India, the Mediterranean basin, western/central Asia, Africa and Latin America, with an estimated >2 million human cases worldwide annually.

Etiologic agents and microbiology

- ▶ Caused by the genus **Brucella* — *small, gram-negative, unencapsulated, non-sporulating coccobacilli that behave in vivo as facultative intracellular parasites**; they grow aerobically on peptone-based medium at 37°C, with growth of some types enhanced by supplementary CO₂.
- ▶ **Species and animal reservoir** (host preference drives epidemiology):

Species	Main animal source	Clinical note
<i>B. melitensis</i>	Sheep, goats, camels	Commonest cause of symptomatic human disease; most acute/aggressive
<i>B. abortus</i>	Cattle, buffalo	Insidious onset; more likely to become chronic
<i>B. suis</i>	Swine (also reindeer/caribou, rodents)	Tendency to focal abscess formation
<i>B. canis</i>	Dogs	Generally milder, but can cause endocarditis
<i>B. ovis</i>	Sheep (reproductive)	Not clearly implicated in human disease
<i>B. neotomae</i> , <i>B. ceti</i> , <i>B. pinnipedialis</i>	Desert rodents; marine mammals	Rare/emerging human infections

- ▶ **Environmental resistance:** killed by **boiling and pasteurization**, sunlight and moderate heat, but **resistant to freezing and drying** — this aerosol stability facilitates airborne and laboratory transmission. Organisms survive ~2 months in soft cheeses, ≥6 weeks in dry contaminated soil and ≥6 months in damp soil/manure.
- ▶ Now genetically related to (and reclassified to include) *Ochrobactrum* spp., which can cause laboratory misidentification with very different clinical management.

Epidemiology and transmission

- ▶ A zoonosis whose human occurrence mirrors prevalence in domesticated animals; increasingly recognised in **India, Pakistan, Sri Lanka and China**.
- ▶ **Occupational exposure:** farmers, shepherds, goatherds, **veterinarians**, abattoir and meat-processing workers, feral-pig hunters, and **diagnostic laboratory staff** (handling cultures/samples).
- ▶ **Food-borne/urban exposure:** consumption of **unpasteurized milk, soft cheeses and ice cream** is the commonest non-occupational route; raw meat/bone marrow rarely.
- ▶ **Routes of entry:** ingestion, inhalation, or mucosal/percutaneous contact. Accidental injection or ingestion of **live veterinary vaccine strains** (*B. abortus* S19 and RB51; *B. melitensis* Rev 1) can cause disease.

- ▶ **Person-to-person transmission is extremely rare** (occasional reports via tissue/blood). No increased prevalence/severity in HIV or other immunosuppression.
- ▶ *B. melitensis* and *B. suis* are recognised potential **bioterrorism agents** — consider in sudden unexplained outbreaks.

Pathogenesis (the “stealth” intracellular pathogen)

- ▶ Both **humoral and cell-mediated** immunity are elicited, but antibodies alone cannot eradicate infection; **protective immunity is predominantly TH1/cell-mediated**.
- ▶ The **macrophage is the key target cell**. After uptake (smooth strains enter via lipid rafts using smooth LPS), the organism survives intracellularly by:
 - restricting fusion of the **type IV secretion system (VirB)-dependent Brucella-containing vacuole with lysosomes, diverting replication to the endoplasmic reticulum**;
 - inhibiting apoptosis of infected mononuclear cells and blocking dendritic-cell maturation/antigen presentation;
 - producing **Cu-Zn superoxide dismutase** and acid-stable proteins resisting reactive oxygen intermediates and defensins.
- ▶ **Smooth LPS** has an unusual O-chain with low endotoxin activity, aiding evasion of serum killing and pyrogenicity.
- ▶ **TNF- α** (early), **IL-12** $\rightarrow$ **IFN- γ** drive macrophage activation and TH1 responses; IL-4/IL-6/IL-10 downregulate protection.
- ▶ Initial replication occurs in regional lymph nodes; **haematogenous spread** seeds the reticuloendothelial system, musculoskeletal and genitourinary tissues, producing **granulomas** (with/without necrosis) and abscesses.

Clinical features

- ▶ **Fever** is almost invariable, with profuse drenching **night sweats**; untreated, it shows the classic **undulating pattern**, and is accompanied by musculoskeletal symptoms in about **half** of patients. Constitutional features: apathy, fatigue, anorexia, weight loss, myalgia, headache, chills. Incubation 1 week to several months.
- ▶ **Three classic presentation patterns**: (1) typhoid-like febrile illness but less severe; (2) **fever + acute monoarthritis of hip or knee in a young child**; (3) long-standing fever with **low-back or hip pain in an older man**.
- ▶ **Musculoskeletal (~40%, the most common focal disease)**:
 - **Spondylitis/osteomyelitis** — favours **lumbar and low-thoracic vertebrae**; anterosuperior end-plate erosion early, eventual whole-vertebra sclerosis.
 - **Septic arthritis** — knee, hip, **sacroiliac**, shoulder, **sternoclavicular** joints (mono- or poly-arthritis).

► **Other organ involvement:**

- Respiratory: dry cough in ~25% (chest X-ray often normal); rarely pneumonia/empyema/lung abscess.
- **Hepatosplenomegaly** (~25%), lymphadenopathy (10–20%) — mimics glandular-fever syndromes.
- Genitourinary: **epididymo-orchitis in up to 10% of men** (distinguish from mumps/torsion); prostatitis, salpingitis, pyelonephritis; **increased fetal loss** in pregnancy (no teratogenicity).
- **Neurobrucellosis**: depression/lethargy; **lymphocytic meningoencephalitis** mimicking neuro-TB; rarely intracerebral abscess, cranial-nerve palsies, mycotic aneurysm.
- **Endocarditis** (~1%) — most often the **aortic valve** (native or prosthetic); leading cause of death.
- Metastatic abscesses, with a predilection for the **breast and thyroid**.

Diagnosis

- **Routine labs (non-specific)**: WBC usually **normal or low with relative lymphocytosis**; mild anaemia, sometimes thrombocytopenia/DIC; ESR and CRP often normal; mildly raised transaminases/bilirubin. CSF/joint fluid show **lymphocytosis with low glucose**; biopsy may show **non-caseating granulomas without acid-fast bacilli**.
- **Culture (definitive)**: isolation from blood, bone marrow, CSF, joint fluid or tissue is positive in 50–70%; automated systems (e.g., Bactec) usually flag within 7 days. Warn the laboratory — handle under **containment for dangerous pathogens**. May be misidentified as *Agrobacterium*, *Ochrobactrum* or *Psychrobacter (Moraxella) phenylpyruvicus*; MALDI-TOF MS identification has historically been unreliable for the genus.
- **PCR / NAAT**: targets the **rrs-rrl (16S–23S) spacer**, outer-membrane protein genes, insertion sequence IS711 and BCSP31 — sensitive, rapid, biohazard-free; prolonged post-treatment positivity is of uncertain significance.
- **Serology (often the only positive finding)**: IgM appears first, followed by IgG and IgA. The **standard agglutination test (SAT)** is the mainstay.
 - **Diagnostic titres**: in endemic areas, **1:320–1:640 or higher**; in non-endemic areas, **≥1:160** is significant. A rising titre on repeat testing at 2–4 weeks is confirmatory.
 - **Rose Bengal test** used for screening.
 - **Cross-reactions** (false positives) with *Yersinia enterocolitica* O:9, *E. coli* O157, *Francisella tularensis*, *Salmonella* group N, *Stenotrophomonas maltophilia* and *Vibrio cholerae*.
 - **Rough strains (B. canis, B. ovis) and vaccine strain RB51 give false-negative results** in conventional smooth-antigen tests.

Treatment

- **Principles:** prolonged combination therapy (single agents relapse), exclude/cover tuberculosis (shared drugs — never use rifampin alone), and emphasise **adherence** (poor compliance, not resistance, causes most failures).

Indication	Regimen	Notes
Acute non-focal (gold standard)	IM streptomycin 0.75–1 g/day × 14–21 days + doxycycline 100 mg BD × 6 weeks	Relapse 5–10%
WHO alternative (oral)	Rifampin 600–900 mg/day + doxycycline 100 mg BD × 6 weeks	Easier; relapse ~10% (>20% in practice)
Aminoglycoside substitute	Gentamicin 5–6 mg/kg/day × 1–2 weeks in place of streptomycin	US/UK guidelines; avoid short courses
Children / pregnant women	High-dose TMP-SMX (with rifampin) — avoid tetracyclines	Watch rising TMP-SMX resistance
Complicated / focal disease	Triple therapy = doxycycline + rifampin + initial aminoglycoside	≥3 months
Neurobrucellosis	Standard regimen + ceftriaxone, 3–6 months	—
Endocarditis	≥3 drugs (aminoglycoside + tetracycline + rifampin ± ceftriaxone/fluoroquinolone) 4–6 months	Surgery usually needed for prosthetic valves

- **Fluoroquinolones** are not recommended first-line (the *Ioannina Recommendations*); poor intravacuolar activity at low pH.
- **Post-exposure prophylaxis:** rifampin + doxycycline (or doxycycline alone) for 3 weeks; omit rifampin after RB51 exposure (RB51 is rifampin-resistant) — substitute TMP-SMX.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- **Intracellular pathogenesis of Brucella: Inhaled/ingested coccobacillus → uptake by macrophage (smooth LPS / lipid raft entry) → type IV secretion system (VirB) prevents phagolysosome fusion → replication in endoplasmic-reticulum-derived Brucella-containing vacuole → suppressed apoptosis & antigen presentation → haematogenous spread → granuloma in reticuloendothelial/musculoskeletal tissue. Labels: macrophage, smooth LPS, VirB type IV secretion system, Brucella-containing vacuole, ER, blocked phagolysosome fusion, IFN-γ/TH1, granuloma.**
- **Spinal radiology — Brucella vs TB spondylitis:** two vertebral-column sketches. Labels for *Brucella*: lumbar site, **anterosuperior end-plate erosion**, intact body until late, **whole-body sclerosis on recovery**, small well-localised paravertebral abscess, parrot-beak osteophyte,

canal compression rare. Labels for TB: dorsolumbar, early body destruction, gibbus/anterior wedge, large psoas/paravertebral abscess, early canal compression.

Clinical / Diagnostic significance

- ▶ The single most important **differential is tuberculosis**, especially in spondylitis — radiological discriminators (Table 174-1: site, sequence of disk involvement, body destruction, abscess size, gibbus) guide both therapy and prognosis.
- ▶ Triad of **fever + sweats + back/joint pain** with an exposure history (unpasteurized dairy, animal/abattoir contact, endemic-area travel, similar family illness in ~50%) should prompt brucella serology and prolonged blood cultures.
- ▶ A SAT titre alone never diagnoses disease — interpret with **exposure history, clinical picture and a rising titre**; remember rough-strain (*B. canis*) infection is **serology-negative**.
- ▶ Always alert the microbiology laboratory: brucella is a **biosafety-level-3** pathogen and a frequent cause of laboratory-acquired infection.

High-yield exam pointers

- ▶ **Undulant fever**; zoonosis from **unpasteurized dairy / animal contact**; *B. melitensis* commonest and most severe.
- ▶ **Gram-negative facultative intracellular coccobacillus**; macrophage is the key host cell; survives via **type IV (VirB) secretion** avoiding phagolysosome fusion.
- ▶ Musculoskeletal disease in ~40% — **sacroiliitis, lumbar spondylitis**; child with **monoarthritis of hip/knee**.
- ▶ **Endocarditis** (~1%, aortic valve) is the **leading cause of death**; mortality overall <1%.
- ▶ **Gold-standard therapy: streptomycin + doxycycline × 6 weeks**; WHO oral alternative **rifampin + doxycycline**; TMP-SMX for children/pregnancy.
- ▶ **SAT diagnostic titre** ≥1:160 (non-endemic) or 1:320–1:640 (endemic); cross-reacts with *Yersinia enterocolitica* O:9.
- ▶ **Relapse up to 30%** in poorly compliant patients — follow up to **2 years**; weight/well-being beat serology for monitoring.
- ▶ **Notifiable disease**; prevention = animal test-and-slaughter, vaccination and **milk pasteurization**.

SOURCE & COVERAGE

- ▶ **Harrison's Principles of Internal Medicine, 22e** — “Brucellosis” (primary source for definition, etiologic agents, epidemiology, pathogenesis, clinical features, diagnosis, Table 174-1 spine radiology, treatment regimens, prognosis and prevention).

- **CMDT 2026** — *Bacterial & Chlamydial Infections* and the *Anti-infective Treatment* chapter (corroboration of streptomycin/doxycycline combination regimens and differential diagnosis of febrile zoonoses).
- *Coverage note:* No dedicated infectious-disease subspecialty text was listed in the spec for this topic; CMDT covers brucellosis only briefly (mainly cross-references). Harrison Ch 174 is comprehensive and fully supports every specific stated above.

Classify the Causes of Chronic Meningitis and Etiologies to be Considered in Advanced HIV Infection

Asked in: Paper III May 2025 — RGUHS MD General Medicine

Definition / Introduction — Chronic meningitis is diagnosed when a characteristic neurologic syndrome persists for >4 weeks in association with a **persistent CSF inflammatory response** (white cell count >5/ μ L). Unlike acute meningitis, meningeal signs are often *absent*; the cardinal features are persistent headache, hydrocephalus, cranial neuropathies, radiculopathies, and cognitive/personality change. Correct treatment depends entirely on identifying the etiology, which spans infective, malignant, inflammatory and chemical causes. In *advanced HIV/AIDS*, chronic meningitis is common, may present with minimal symptoms even with a paucicellular CSF, and is dominated worldwide by *Mycobacterium tuberculosis* and *Cryptococcus neoformans*.

Classification of the Causes of Chronic Meningitis

Five major disease categories account for most cases (Harrison), with monogenic autoinflammatory disorders added as an emerging cause of recurrent meningitis.

Category	Representative causes
1. Meningeal infections	Bacterial: partially treated pyogenic meningitis, <i>M. tuberculosis</i> , <i>Treponema pallidum</i> (syphilis), <i>Borrelia burgdorferi</i> (Lyme/Bannwarth), <i>Brucella</i> , <i>Nocardia</i> , <i>Actinomyces</i> , <i>Tropheryma whipplei</i> , leptospira
	Fungal: <i>Cryptococcus neoformans/gattii</i> , <i>Coccidioides immitis</i> , <i>Histoplasma capsulatum</i> , <i>Blastomyces</i> , <i>Candida</i> , <i>Aspergillus</i> , <i>Sporothrix schenckii</i>
	Protozoal: <i>Toxoplasma gondii</i> , trypanosomiasis, <i>Acanthamoeba</i> , <i>Balamuthia</i>
	Helminthic: neurocysticercosis (<i>Taenia solium</i>), <i>Gnathostoma</i> , <i>Angiostrongylus cantonensis</i> , <i>Baylisascaris</i> , schistosomiasis, echinococcus

Category	Representative causes
	Viral: HSV-2 (Mollaret), mumps, LCMV, enteroviruses (in agammaglobulinemia), HIV, EBV, CMV
2. Malignancy (neoplastic)	Carcinomatous/lymphomatous meningitis — metastatic breast, lung, stomach, pancreas; melanoma; lymphoma; leukemia; meningeal gliomatosis
3. Autoimmune / inflammatory	Neurosarcoidosis, Behçet's, SLE, rheumatoid arthritis, granulomatosis with polyangiitis, primary CNS (granulomatous) angiitis, Vogt-Koyanagi-Harada syndrome, IgG4-related hypertrophic pachymeningitis, Sjögren's
4. Chemical meningitis	Leak from epidermoid/dermoid tumour, craniopharyngioma or cholesteatoma; subarachnoid haemorrhage; intrathecal drug/contrast injection; drug hypersensitivity (NSAIDs, sulfonamides, IVIG, isoniazid, carbamazepine, lamotrigine)
5. Parameningeal infection	Brain/epidural/subdural abscess, sinusitis, mastoiditis, otitis media, chronic pleuropulmonary infection with right-to-left shunt
6. Monogenic autoinflammatory (recurrent)	TRAPS (<i>TNFRSF1A</i>), CAPS/NOMID (<i>NLRP3</i> gain-of-function → ↑IL-1β), complement factor I deficiency

Recurrent Meningitis — a Distinct Subset

Two clinical forms exist: a *chronic persistent* form and a *recurrent* form in which all symptoms, signs and CSF abnormalities resolve completely between attacks. Recurrent meningitis suggests:

- ▶ **Mollaret's meningitis** — most often HSV-2 (rarely HSV-1); large endothelial ("Mollaret") cells then mononuclear cells in CSF; confirm by HSV PCR.
- ▶ **Chemical (episodic) meningitis** — recurrent leak from an epidermoid tumour, craniopharyngioma or cholesteatoma; xanthochromia/low glucose.
- ▶ **Autoimmune** — VKH syndrome, Behçet's, SLE, neurosarcoidosis, IgG4-related disease, GPA, primary CNS vasculitis.
- ▶ **Drug hypersensitivity** — recurs with re-exposure to the offending agent.
- ▶ **Inherited autoinflammatory syndromes** — TRAPS, CAPS, complement factor I deficiency (recurrent steroid-responsive neutrophilic meningitis).

CSF Clues that Narrow the Differential

The predominant CSF cell type after the third week is a powerful discriminator.

CSF pattern	Principal considerations
Mononuclear (lymphocytic)	Most chronic meningitides — TB, <i>Cryptococcus</i> , syphilis, Lyme, sarcoidosis, neoplastic
Neutrophilic after 3 weeks	<i>Nocardia</i> , <i>Actinomyces</i> , <i>Brucella</i> , <i>M. tuberculosis</i> (5–10% of early cases), fungi (<i>Blastomyces</i> , <i>Candida</i> , <i>Histoplasma</i> , <i>Aspergillus</i> , <i>Pseudallescheria boydii</i> , <i>Cladophialophora</i>), SLE, chemical meningitis
Eosinophilic	Parasites (<i>A. cantonensis</i> , <i>Gnathostoma</i> , <i>Baylisascaris</i> , cysticercosis, schistosomiasis, echinococcus, toxoplasma), coccidioidomycosis (6–20% eosinophils), lymphoma/leukaemia/carcinoma, sarcoidosis, hypereosinophilic syndrome
Low glucose (hypoglycorrhachia)	TB, fungal (esp. <i>Cryptococcus</i> , <i>Coccidioides</i> , <i>Histoplasma</i>), carcinomatous/lymphomatous, sarcoidosis, mumps, LCMV

Imaging clue: **leptomeningeal** enhancement (following gyri/basal cisterns) typifies infective meningitis, whereas thick linear/nodular **pachymeningeal** (dural) enhancement suggests IgG4-related disease, GPA, lymphoma or neurosarcoidosis.

Etiologies in Advanced HIV Infection (the “discuss” component)

Chronic meningitis is not uncommon in HIV; immunosuppression *attenuates* meningeal signs, so CSF examination is mandatory for any persistent headache or unexplained mental change. The relevant pathogens track with the CD4 count.

Etiology (CD4 threshold)	Key features / CSF–imaging	Treatment (Harrison/CMDT)
Cryptococcal meningitis (CD4 <100)	Commonest fungal CNS infection in AIDS; AIDS-defining in ~2%; subacute meningoencephalitis, markedly raised ICP , often pauci-cellular CSF; India ink + CSF cryptococcal antigen (CrAg) ; up to 12% due to <i>C. gattii</i> ; <i>prozone</i> false negatives	Induction: liposomal amphotericin B 3–4 mg/kg/day (or amphotericin B deoxycholate 0.7–1.0 mg/kg/day) + flucytosine 25 mg/kg qid for ≥2 weeks → consolidation fluconazole (Harrison 800 mg, CMDT 400 mg) daily ×8 weeks → maintenance fluconazole 200 mg/day until CD4 >200 for ≥6 months. Serial LPs for ICP; delay ART 4–6 weeks (IRIS risk)
Tuberculous meningitis (any CD4; commonest cause worldwide)	Basal meningitis, cranial neuropathies, stroke from arteritis; CSF: lymphocytic, low glucose, high protein ; AFB	4-drug ATT (HRZE) + adjunctive glucocorticoids ; anti-TNF/PD-1 therapy can reactivate TB

Etiology (CD4 threshold)	Key features / CSF–imaging	Treatment (Harrison/CMDT)
	smear/culture, CSF PCR (Xpert), IGRA; miliary TB on imaging	
Cerebral toxoplasmosis (CD4 <200)	Reactivation of latent cysts; fever, focal deficit, seizures; MRI multiple ring-enhancing lesions, eccentric target sign ; 10× more likely if <i>Toxoplasma</i> IgG-positive	Sulfadiazine + pyrimethamine + leucovorin ≥4–6 weeks (alt: clindamycin + pyrimethamine); empiric trial, biopsy if no response in 2–4 weeks; primary prophylaxis with TMP-SMX if CD4 <100 and IgG+
Primary CNS lymphoma (CD4 ~50)	EBV-driven (often 100% EBV+); 1–3 deep white-matter lesions, ring-enhancing (less than toxoplasmosis); CSF EBV PCR; brain biopsy	Radiotherapy ± chemotherapy + ART; 2-year survival only 20–30%
Progressive multifocal leukoencephalopathy	JC virus ; multifocal deficits, non-enhancing occipito-parietal white-matter lesions; CSF JCV DNA (sensitivity 76%, specificity ~100%)	No specific therapy — immune reconstitution with ART is the mainstay
Neurosyphilis	Meningovascular stroke, dementia, myelopathy; CSF VDRL (specific, insensitive); aggressive in HIV	IV penicillin G
CMV polyradiculopathy/encephalitis (CD4 <50)	Fulminant cauda-equina syndrome, urinary retention; neutrophilic CSF , CMV PCR	IV ganciclovir / foscarnet
Aseptic (HIV) meningitis	At seroconversion (acute retroviral syndrome) or persisting low-grade; immune-mediated, rare after AIDS develops; lymphocytic CSF, HIV RNA	Supportive; ART
Other fungi / bacteria	<i>Histoplasma</i> (CD4 ~33), <i>Coccidioides</i> , <i>Nocardia</i> , <i>Candida</i> ; basis for empiric antifungal cover	Amphotericin B-based regimens

Diagnostic Approach in the HIV Patient

- Image before LP if raised ICP / mass lesion suspected (herniation risk); obstructive hydrocephalus needs ventricular drainage.

- ▶ Send **opening pressure**, cell count + differential, glucose, protein, Gram/India ink, CrAg, VDRL, AFB smear/culture + TB PCR, fungal culture, cytology/flow cytometry, and broad-range 16S/18S rRNA PCR or metagenomic next-generation sequencing in enigmatic cases.
- ▶ Repeat **large-volume CSF** (≥ 3 samples) for neoplastic/fungal causes; cervical cisternal tap if lumbar CSF unrevealing.
- ▶ **Meningeal biopsy** when CSF is non-diagnostic and the patient is deteriorating — target enhancing meninges (diagnostic in 80% vs 9% for non-enhancing regions).

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Diagram 1 — Classification wheel of chronic meningitis:** central hub “Chronic meningitis (>4 weeks, CSF WBC $>5/\mu\text{L}$)” with six labelled spokes — *Meningeal infection*, *Malignancy*, *Autoimmune/inflammatory*, *Chemical*, *Parameningeal infection*, *Autoinflammatory (recurrent)*; annotate infection spoke with *TB*, *Cryptococcus*, *syphilis*, *Lyme*.
- ▶ **Diagram 2 — CD4 ladder of HIV CNS opportunistic infections:** vertical axis falling CD4 with labelled bands — <200 : *Toxoplasma*, *TB*; <100 : *Cryptococcus*, *Histoplasma*; ~ 50 : *Primary CNS lymphoma*, *CMV*; *late/any*: *PML*, *neurosyphilis*; label MRI signatures (toxoplasmosis = ring-enhancing/eccentric target; lymphoma = deep solitary; PML = non-enhancing white matter).

Clinical / Diagnostic significance

- ▶ A **lymphocytic meningitis with low CSF glucose** in any setting should be treated empirically for **tuberculosis**, as delay is devastating.
- ▶ In AIDS, **cryptococcal meningitis can cause fatal raised ICP without ventricular enlargement** — serial therapeutic LPs are lifesaving.
- ▶ **Ring-enhancing lesions** in HIV = toxoplasmosis vs primary CNS lymphoma; *Toxoplasma* IgG-negativity ($<10\%$ probability) or CSF EBV PCR positivity shifts toward lymphoma and earlier biopsy.
- ▶ **IRIS** complicates ART started too early after cryptococcal/TB meningitis — hence the recommended antifungal/anti-TB lead-in before ART.
- ▶ Empirical therapy when diagnosis fails: **antimycobacterials + amphotericin B ($\pm$ flucytosine) $\pm$ glucocorticoids**; transient steroid responses can mask TB, cysticercosis or lymphoma.

High-yield exam pointers

- ▶ Definition: neurologic syndrome **>4 weeks** + CSF WBC $>5/\mu\text{L}$.
- ▶ **Five-category classification:** infection, malignancy, autoimmune, chemical, parameningeal (+ autoinflammatory for recurrent).
- ▶ **Worldwide commonest cause in HIV = TB, then Cryptococcus.**

- ▶ Mollaret's = recurrent HSV-2 meningitis.
- ▶ Cryptococcal Rx triad: amphotericin B + flucytosine (induction) → fluconazole (consolidation → maintenance); treat raised ICP.
- ▶ Toxoplasmosis Rx = sulfadiazine + pyrimethamine + leucovorin; CD4 <200; ring-enhancing lesions.
- ▶ PCNSL = EBV-positive, CD4 ~50; PML = JC virus, non-enhancing.
- ▶ Empiric anti-TB therapy for low-glucose lymphocytic chronic meningitis; ~one-third of cases remain undiagnosed despite full workup.
- ▶ Biopsy yield highest from contrast-enhancing meninges (80%).

Clinical features, diagnosis and treatment of neurosyphilis

Asked in: Paper II Nov 2022 — RGUHS MD General Medicine

Definition / Introduction — Neurosyphilis is involvement of the central nervous system by *Treponema pallidum* and can occur at any stage of syphilis, not only in late disease. It is best viewed as a continuum: early CNS invasion within weeks, months to years of asymptomatic CSF involvement, and symptomatic early or late neurologic syndromes. Ocular syphilis and otosyphilis may occur with or without other CNS disease but are treated with the same regimen as neurosyphilis because permanent visual or hearing loss may occur.

Etiopathogenesis and natural history

- ▶ *T. pallidum* disseminates early; CSF abnormalities may be found in up to 40% of untreated primary/secondary syphilis and 25% of untreated latent syphilis.
- ▶ Early neurosyphilis includes asymptomatic neuroinvasion, syphilitic meningitis, and meningovascular syphilis. Late neurosyphilis includes general paresis and tabes dorsalis.
- ▶ Approximate timing is exam-important: meningeal disease usually occurs within <1 year, meningovascular disease up to 10 years, general paresis around 20 years, and tabes dorsalis around 25-30 years after infection.

- ▶ Risk is higher with untreated HIV infection, especially low CD4 counts; Harrison notes association with serum RPR $\geq 1:32$ and, in HIV, CD4 $\leq 350/\text{mL}$.
- ▶ Benzathine penicillin does not reliably achieve treponemicidal CSF levels; therefore proven or suspected neurosyphilis needs **aqueous penicillin-based therapy**, not standard benzathine-only syphilis therapy.

Clinical classification and features

Form	Core clinical features	Typical CSF clue
Asymptomatic neurosyphilis	No neurologic symptoms/signs; detected during evaluation of syphilis, tertiary disease, HIV/high-risk state, or treatment failure	Mononuclear pleocytosis, raised protein, or reactive CSF-VDRL
Meningeal syphilis	Headache, nausea, vomiting, neck stiffness, cranial nerve palsy, seizures, altered mental status; may accompany or follow secondary syphilis	Lymphocytic pleocytosis and raised protein; CSF-VDRL may be positive
Meningovascular syphilis	Meningitis plus vasculitis of small/medium/large vessels; subacute prodrome of headache, vertigo, insomnia, psychological change, then progressive stroke syndrome, classically in a young adult and often MCA territory	Higher lymphocytic pleocytosis may occur; CMTD gives 100-1000 cells/mL with elevated protein
General paresis	Progressive cortical disease: personality change, affective disturbance, hyperreflexia, <i>Argyll Robertson pupil</i> , psychosis, memory loss, impaired orientation/calculation/judgment, dysarthria, tremor	Similar to late parenchymatous neurosyphilis; CSF may resemble tabes
Tabes dorsalis	Posterior column/dorsal root disease: lightning pains, sensory ataxia, positive Romberg, impaired position/vibration sense, areflexia, bladder disturbance, impotence, foot drop, Charcot joint, optic atrophy	Normal or lymphocytic CSF, raised protein, variable serology

Ocular, otic and HIV-associated disease

- ▶ **Ocular syphilis** may present as anterior uveitis, iritis, neuroretinitis, optic neuritis, chorioretinitis, optic atrophy, or panuveitis; failure to respond to topical steroids is a classic diagnostic clue.

- ▶ **Otosyphilis** presents with sensorineural hearing loss, vertigo, or tinnitus; untreated disease may lead to deafness.
- ▶ Ask every patient with syphilis about **vision, hearing, headache, cognitive change, stroke symptoms, gait ataxia, bladder symptoms, lightning pains, and cranial nerve symptoms**.
- ▶ Isolated confirmed ocular disease with reactive syphilis serology and no cranial nerve or other neurologic abnormality does **not** require CSF before treatment; full ocular examination is mandatory.
- ▶ Isolated auditory disease with reactive serology and normal neurologic examination usually has normal CSF and does **not** require CSF before treatment.
- ▶ Ocular syphilis and otosyphilis are treated as **neurosyphilis regardless of CSF findings**.
- ▶ In HIV infection, mild CSF pleocytosis may occur due to HIV itself; routine lumbar puncture in asymptomatic patients is not recommended, but a careful neurologic, ophthalmic, otologic, and cranial nerve examination is essential.

Diagnostic approach

- ▶ Establish syphilis first using both **nontreponemal** and **treponemal** serology; one test alone is insufficient. Nontreponemal tests are **VDRL/RPR** and are useful for titers and follow-up; treponemal tests include **FTA-ABS, TPPA, EIA/CIA**.
- ▶ Consider neurosyphilis when reactive syphilis serology is accompanied by neurologic signs/symptoms or compatible CSF abnormalities.
- ▶ **Indications for lumbar puncture:** clinical neurologic involvement such as meningitis, cranial nerve palsy, stroke, altered mental status, motor/sensory deficit, loss of vibration sense; treatment failure or fourfold rise in titer; active tertiary syphilis; ocular disease with cranial nerve or other neurologic signs.
- ▶ **CSF findings:** mononuclear pleocytosis **>5 WBC/mcL**, protein **>45-46 mg/dL**, and/or reactive CSF-VDRL. Classic CMDT description is protein **>46 mg/dL** with lymphocytic pleocytosis **5-100 cells/mcL**.
- ▶ **CSF-VDRL** is highly specific; a positive result without blood contamination is diagnostic. It is insensitive and may be negative in **30-70%** of cases, so a negative test does not exclude neurosyphilis.
- ▶ **CSF-RPR should not replace CSF-VDRL**. CSF FTA-ABS/TPPA is more sensitive but less specific; a negative result makes neurosyphilis unlikely, especially with nonspecific symptoms.
- ▶ In HIV infection, specificity improves by using a higher CSF WBC cutoff, commonly **>20 WBC/mcL**, because HIV itself may cause mild CSF pleocytosis.
- ▶ Differential diagnoses to exclude according to presentation include viral/tuberculous/fungal/chronic meningitis, autoimmune encephalitis, HIV-associated

neurocognitive disorder, B12 or copper myelopathy, stroke in the young, multiple sclerosis, neuro-ophthalmic disease, and primary psychiatric illness.

Treatment

Situation	Recommended regimen	Key notes
Neurosyphilis, ocular syphilis, otosyphilis	Aqueous crystalline penicillin G 18-24 million units/day IV as 3-4 million units every 4 hours or continuous infusion for 10-14 days	Drug of choice; achieves treponemicidal CSF levels
Alternative when adherence assured	Procaine penicillin G 2.4 million units IM daily + probenecid 500 mg orally four times daily, both for 10-14 days	Avoid if adherence is doubtful
Penicillin allergy	Prefer penicillin desensitization and treatment with penicillin	Especially important in pregnancy and definite neurosyphilis
Limited alternative	Ceftriaxone 1-2 g IM/IV daily for 10-14 days with close follow-up	Evidence is limited; seek infectious disease input
After neurosyphilis regimen	Benzathine penicillin G 2.4 million units IM weekly for 1-3 weeks may be considered to match latent-syphilis duration	Not a substitute for CNS-active therapy

- ▶ Admit or closely supervise patients requiring IV therapy; patients with ocular disease need ophthalmology, and otosyphilis needs ENT/audiology involvement.
- ▶ Do **HIV testing** in all patients with syphilis/neurosyphilis; offer prevention counselling and partner notification where relevant.
- ▶ Treat **Jarisch-Herxheimer reaction** supportively: fever, chills, headache, myalgia, tachycardia, and transient worsening after therapy are not penicillin allergy. Use antipyretics; consider expert input in CNS/cardiac disease and pregnancy.
- ▶ Existing parenchymal damage may only stop progressing after treatment; meningeal symptoms respond more dramatically than tabetic or paretic deficits.

Follow-up, prognosis and complications

- ▶ Monitor clinically and with quantitative RPR or VDRL using the same test method; CMDT recommends nontreponemal titers every 3-6 months after neurosyphilis treatment.
- ▶ Adequate response is suggested by clinical improvement and falling serum nontreponemal titers; a fourfold RPR decline correlates with CSF normalization in many treated patients.

- ▶ Repeat CSF is not routinely needed when symptoms improve and titers fall appropriately, especially in HIV-negative patients or HIV-positive patients on effective ART.
- ▶ Repeat CSF or expert consultation is needed if symptoms persist/return, titers fail to fall or rise fourfold, or treatment failure/reinfection is suspected.
- ▶ CSF WBC count is the most sensitive CSF marker of response and generally normalizes within **3-12 months**; CSF protein falls more slowly and CSF-VDRL may decline over years.
- ▶ Major preventable complications are stroke, blindness, deafness, dementia/psychosis, sensory ataxia, bladder dysfunction, Charcot joints, and irreversible posterior column or cortical damage.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Natural history timeline of neurosyphilis:** primary/secondary syphilis -> early CNS invasion/asymptomatic CSF -> meningeal syphilis (<1 year) -> meningovascular syphilis (years) -> general paresis (~20 years) -> tabes dorsalis (25-30 years).
- ▶ **Diagnostic-treatment flowchart:** reactive serum RPR/VDRL + treponemal test -> neurologic/ocular/otic symptoms? -> ocular/ENT/neurologic examination -> CSF cell count, protein, CSF-VDRL +/- FTA-ABS/TPPA -> IV aqueous penicillin G 10-14 days -> clinical and serologic follow-up.

Clinical / Diagnostic significance

- ▶ Neurosyphilis is a **treatable mimic** of meningitis, stroke in the young, dementia, psychiatric illness, sensory ataxia, and posterior column myelopathy.
- ▶ Always examine pupils: **Argyll Robertson pupil** is small/irregular and accommodates but does not react to light; it is high-yield in tabes dorsalis and paresis.
- ▶ A negative CSF-VDRL does not rule out disease; the diagnosis is a **clinic-serologic-CSF synthesis**, not a single-test diagnosis.
- ▶ Do not delay ocular or otic treatment while waiting for CSF when isolated ocular/otic disease is otherwise clear.
- ▶ Benzathine penicillin is correct for uncomplicated latent syphilis but **wrong as sole therapy** for neurosyphilis because of inadequate CSF penetration.
- ▶ In HIV, interpret mild CSF pleocytosis cautiously; treatment regimen is the same, but follow-up must be meticulous.

High-yield exam pointers

- ▶ Write first: **Neurosyphilis can occur at any stage of syphilis.**
- ▶ Classification: **asymptomatic, meningeal, meningovascular, ocular/otic, tabes dorsalis, general paresis.**

- ▶ Meningovascular syphilis: young patient + subacute encephalitic prodrome + stroke, often MCA territory.
- ▶ Tabes dorsalis: lightning pains, sensory ataxia, Romberg sign, areflexia, bladder dysfunction, Charcot joint.
- ▶ General paresis: personality change, psychosis, memory/judgment impairment, dysarthria, tremor, hyperreflexia.
- ▶ Diagnostic triad: reactive serum serology + neurologic syndrome + CSF pleocytosis/protein/reactive CSF-VDRL.
- ▶ CSF-VDRL positive = diagnostic; negative = does not exclude.
- ▶ Treatment: aqueous crystalline penicillin G 18-24 million units/day IV for 10-14 days.
- ▶ Follow response with clinical status and quantitative RPR/VDRL; repeat CSF only when response is poor or uncertain.

Harrison 22e — “Syphilis”; CDMT 2026 — “Spirochetal Infections” and “Common Problems in Infectious Diseases & Antimicrobial Therapy”.

Clostridium difficile

Asked in: Paper II Dec 2023 — RGUHS MD General Medicine

Definition / Introduction — *Clostridioides difficile* infection (CDI) is an antibiotic-associated colonic infection caused by toxigenic, spore-forming, obligate anaerobic, gram-positive bacilli. It follows disruption of normal colonic microbiota, usually after antimicrobial exposure, and ranges from mild watery diarrhea to **pseudomembranous colitis**, toxic megacolon, sepsis, perforation and death. Although the older exam term is *Clostridium difficile*, the current nomenclature is *Clostridioides difficile*.

Etiology, epidemiology and risk factors

- ▶ **Organism:** spore-forming anaerobic bacillus; spores survive gastric acidity, persist for months on hospital surfaces and spread by contaminated hands, equipment and patient-room environments.
- ▶ **Usual setting:** hospitals, nursing homes and the period after discharge; community-associated CDI is increasingly recognized and may occur without documented antibiotic exposure.
- ▶ **Antibiotic risks:** clindamycin, ampicillin, second- and third-generation cephalosporins and fluoroquinolones are classic high-risk drugs. Almost any antibiotic can predispose, including vancomycin, by disturbing colonization resistance.

- ▶ **Lower-risk but not risk-free agents:** penicillin/beta-lactamase-inhibitor combinations such as piperacillin-tazobactam are less strongly associated than cephalosporins or fluoroquinolones.
- ▶ **Host and care-related risks:** older age, severe underlying illness, prolonged hospitalization, gastrointestinal surgery, enteral tube feeding, antacid/PPI exposure, immunocompromise, IBD, chemotherapy, multiple or prolonged antibiotic courses and chronic-care facility residence.
- ▶ **Colonization:** asymptomatic fecal carriage increases with length of hospital stay and may exceed 20% after more than 2 weeks in hospital; healthy community adult carriage is much lower. Infants commonly carry *C. difficile* but rarely develop disease.
- ▶ **Epidemic strains:** NAP1/BI/027 produces much higher toxin A and B in vitro, carries binary toxin, is fluoroquinolone-resistant and was linked to severe outbreaks; its incidence has declined where infection control and fluoroquinolone restriction were implemented.

Pathogenesis and pathology

- ▶ CDI requires three events: **microbiota disruption** by antibiotics, **exposure to toxigenic *C. difficile***, and an additional susceptibility factor such as a virulent strain or inadequate antitoxin immune response.
- ▶ Spores are ingested, germinate in the small bowel and colonize the lower gut when normal flora are suppressed.
- ▶ Toxigenic strains produce **toxin A (enterotoxin)** and **toxin B (cytotoxin)**. Both glucosylate Rho-family GTP-binding proteins, disrupt actin cytoskeleton, impair epithelial adherence and tight junctions, and cause fluid leakage and inflammation.
- ▶ **Toxin B** is clinically crucial because toxin A-negative, toxin B-positive strains can cause disease; toxin B-negative disease is not well documented.
- ▶ **Binary toxin CDT** is present in NAP1/BI/027 and some other strains, but its exact pathogenic role is less clearly defined.
- ▶ **Pseudomembranes** begin as 1-2 mm whitish-yellow plaques on colonic mucosa, then coalesce; microscopy shows necrotic leukocytes, fibrin, mucus and cellular debris with focal epithelial necrosis and neutrophilic mucosal infiltration.
- ▶ The colon is usually involved diffusely, but rectal sparing can occur; terminal ileum is typically spared.
- ▶ Serum antibodies to toxins A and B, especially toxin B-neutralizing responses, help protect against recurrence; this is the rationale for bezlotoxumab.

Clinical features and severity

- ▶ **Typical CDI:** soft, watery or mucoid diarrhea with characteristic odor; stools are seldom grossly bloody. Lower abdominal cramps, mild tenderness and mucus may occur.
- ▶ **Frequency:** CMDT describes many patients with 3-15 watery stools/day; Harrison notes fever in about 28%, abdominal pain in 22% and leukocytosis in 50%.

- ▶ **Diagnostic trap:** ileus or adynamic colon may stop stool passage, so CDI can present as unexplained leukocytosis, abdominal distension or acute abdomen without diarrhea.
- ▶ **Severe CDI:** leukocytosis $\geq 15,000/\text{mL}$ or serum creatinine $\geq 1.5 \text{ mg/dL}$; severe disease is common among hospitalized diagnosed cases.
- ▶ **Fulminant CDI:** severe CDI plus **hypotension, shock, ileus or toxic megacolon**. It may mimic a surgical abdomen and can present with sepsis, tachycardia, marked leukocytosis, colonic wall thickening, ascites and metabolic acidosis.
- ▶ **Complications:** toxic megacolon, perforation, hemorrhage, respiratory failure, septic shock, colectomy requirement, protein-losing enteropathy in chronic untreated colitis and death.
- ▶ **Recurrence:** occurs in about 15-30% after treatment in Harrison and up to 20% within 8 weeks in CMDT; recurrence may be relapse with the same strain or reinfection with a new strain.

Clinical setting	Key markers	Exam management implication
Nonsevere CDI	Diarrhea, no severe leukocytosis/creatinine rise	Fidaxomicin preferred; oral vancomycin acceptable
Severe CDI	WBC $\geq 15,000/\text{mL}$ or creatinine $\geq 1.5 \text{ mg/dL}$	Treat promptly; monitor closely for fulminant disease
Fulminant CDI	Hypotension, shock, ileus or megacolon	High-dose enteral vancomycin + IV metronidazole, surgical review
Recurrent CDI	Return after clinical response	Fidaxomicin, vancomycin taper/pulse, microbiota therapy in repeated relapse

Diagnosis

- ▶ Diagnose only when the clinical syndrome fits: **≥ 3 unformed stools in 24 hours** with no better explanation plus evidence of toxigenic *C. difficile* or pseudomembranes. Harrison uses ≥ 3 unformed stools per 24 h for ≥ 2 days in its formal criteria.
- ▶ Send stool testing in hospitalized patients with dysentery or ≥ 3 liquid stools/24 h, and in outpatients with persistent diarrhea, especially after antibiotics or hospitalization.
- ▶ **Do not test formed stool** and do not test asymptomatic patients except for epidemiology; positive tests may reflect colonization.
- ▶ **Do not perform test of cure:** stool assays may remain positive for weeks, and more than half of patients may still harbor organism/toxin after diarrhea stops.
- ▶ **GDH immunoassay:** sensitive screen with high negative predictive value, but detects toxigenic and nontoxigenic strains and does not prove active toxin disease.
- ▶ **NAAT/PCR:** rapid and very sensitive for toxin genes, commonly TcdB, but may overdiagnose colonization if used alone.

- ▶ **Toxin EIA:** detects free toxins A/B and supports active toxin-secreting infection, but is less sensitive than NAAT/culture.
- ▶ **Preferred algorithm:** GDH or NAAT screening followed by toxin EIA when required, with discordant results interpreted clinically.
- ▶ **Endoscopy:** flexible sigmoidoscopy/colonoscopy is not routine when symptoms and stool tests are typical, but is useful in seriously ill patients, atypical cases or ileus. Pseudomembranes are highly specific but insensitive and may be seen in only a subset.
- ▶ **Imaging:** abdominal radiograph or CT is indicated in severe/fulminant disease to assess colonic dilation, wall thickening, ascites and perforation.

Treatment

- ▶ **Immediate general measures:** isolate with contact precautions, stop the inciting antibiotic if possible, correct dehydration/electrolytes and avoid opiates or antiperistaltic agents in severe disease because they may mask deterioration.
- ▶ **Initial nonsevere CDI:** fidaxomicin 200 mg orally twice daily for 10 days is preferred where available; oral vancomycin 125 mg four times daily for 10 days is an acceptable alternative.
- ▶ **Metronidazole:** no longer first-line; use 500 mg orally three times daily for 10-14 days only for mild/moderate disease when fidaxomicin or oral vancomycin is unavailable.
- ▶ **Severe initial CDI:** oral vancomycin 125 mg four times daily for 10 days or fidaxomicin 200 mg twice daily for 10 days; initiate promptly when WBC is high or creatinine is elevated.
- ▶ **Fulminant CDI:** vancomycin 500 mg orally or via nasogastric tube four times daily plus metronidazole 500 mg IV every 8 hours; if ileus is present, add rectal vancomycin 500 mg in 100 mL normal saline retention enema every 6-8 hours.
- ▶ **IV vancomycin alone is ineffective** for CDI because adequate intraluminal colonic drug levels are not achieved.
- ▶ **Early surgical consultation** is essential for severe/fulminant disease, toxic megacolon, perforation, sepsis or hemorrhage. Total abdominal colectomy may be lifesaving; loop ileostomy with colonic lavage and vancomycin infusion is an alternative. Harrison emphasizes operating before serum lactate reaches 5 mmol/L when colectomy is required.

Recurrence, adjunctive therapy and prevention

- ▶ **First recurrence:** fidaxomicin 200 mg twice daily for 10 days, oral vancomycin 125 mg four times daily for 10 days, or vancomycin taper-and-pulse depending on prior regimen and availability.
- ▶ **Vancomycin taper/pulse:** after a treatment course, 125 mg twice daily for 1 week, then daily for 1 week, then every 2-3 days for 2-8 weeks; CMDT also describes 125 mg four times daily for 14 days before tapering.

- ▶ **Multiple recurrences:** vancomycin taper/pulse, fidaxomicin standard or extended-pulsed regimen, vancomycin followed by rifaximin **400 mg twice daily for 2 weeks**, or fecal microbiota replacement.
- ▶ **Microbiota therapy:** consider after appropriate antibiotic treatment for recurrent CDI. Rebyota is rectal live-jslm fecal microbiota; Vowst is oral live-brpk fecal microbiota spores. CMDT notes 2023 FDA approval to prevent recurrence after antibacterial treatment.
- ▶ **Bezlotoxumab:** single-dose **10 mg/kg IV** monoclonal antibody against toxin B, given during standard antibacterial therapy for patients at high recurrence risk: age >65 years, immunocompromise, severe CDI or CDI in the previous 6 months. Avoid or use great caution in patients with heart failure.
- ▶ **Transmission prevention:** gloves, strict contact precautions, soap-and-water handwashing during outbreaks because alcohol gels are not sporicidal, bleach/hypochlorite environmental decontamination and avoidance of contaminated electronic rectal thermometers.
- ▶ **Antimicrobial stewardship:** restrict unnecessary clindamycin, cephalosporins and fluoroquinolones; stewardship reduces CDI and microbiome injury. Vaccines have not yet succeeded.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Pathogenesis flow diagram:** antibiotic exposure -> loss of normal microbiota -> ingestion of *C. difficile* spores -> germination and colonization -> toxin A/toxin B production -> epithelial cytoskeleton disruption -> diarrhea/pseudomembranes -> fulminant colitis or recurrence. Label: spores, antibiotics, microbiota disruption, toxin A, toxin B, pseudomembrane, recurrence.
- ▶ **Diagnostic-treatment algorithm:** suspected CDI with ≥ 3 unformed stools/24 h -> stool GDH/NAAT plus toxin EIA -> classify nonsevere/severe/fulminant -> fidaxomicin or oral vancomycin; fulminant branch to high-dose enteral/rectal vancomycin + IV metronidazole + surgery. Label: GDH, NAAT, toxin EIA, WBC $\geq 15,000$, creatinine ≥ 1.5 , ileus/megacolon, recurrence.

Clinical / Diagnostic significance

- ▶ Always ask about antibiotics in the previous weeks; CMDT notes symptoms may be delayed up to 8 weeks after exposure.
- ▶ CDI is a key cause of hospital-onset diarrhea after 72 hours of admission; other stool cultures are usually low yield unless *C. difficile* testing is negative or epidemiology suggests another pathogen.
- ▶ Distinguish **antibiotic-associated diarrhea** from ***C. difficile* colitis**: most antibiotic-associated diarrhea is mild, self-limited and not due to *C. difficile*.

- ▶ In ileus, absence of diarrhea does not exclude CDI; unexplained leukocytosis, abdominal distension or CT colitis after antibiotics should trigger evaluation.
- ▶ PCR-positive/toxin-negative patients may be colonized; treat the patient, not the assay, while recognizing many clinically ill discordant patients are treated.
- ▶ Pseudomembranes are highly specific but not required for diagnosis and their absence at endoscopy does not rule out CDI.
- ▶ In IBD flare, checkpoint-inhibitor colitis, ischemic colitis or hospitalized acute diarrhea, exclude *C. difficile* before immunosuppression or escalation.

High-yield exam pointers

- ▶ Write the current name: ***Clostridioides difficile***, formerly *Clostridium difficile*.
- ▶ CDI is due to **toxins A and B after antibiotic-induced microbiota disruption**; toxin B is the major validated target.
- ▶ High-risk antibiotics: **clindamycin, ampicillin, cephalosporins and fluoroquinolones**.
- ▶ Severe CDI: **WBC $\geq 15,000/\text{mL}$ or creatinine $\geq 1.5 \text{ mg/dL}$** .
- ▶ Fulminant CDI: **hypotension/shock, ileus or toxic megacolon**.
- ▶ First-line initial therapy: **fidaxomicin 200 mg bid for 10 days; oral vancomycin 125 mg qid for 10 days** is acceptable.
- ▶ Fulminant regimen: **vancomycin 500 mg enteral qid + metronidazole 500 mg IV q8h**, add rectal vancomycin if ileus.
- ▶ **Do not use IV vancomycin alone and do not perform stool test of cure**.
- ▶ Recurrence prevention/treatment: **fidaxomicin, vancomycin taper/pulse, microbiota therapy and bezlotoxumab 10 mg/kg IV** in high-risk patients.

Clostridioides difficile Infection (Including Pseudomembranous Colitis)

Asked in: Paper II Nov 2021 — RGUHS MD General Medicine

Definition / Introduction — *Clostridioides difficile* infection (CDI) is a unique colonic disease acquired most commonly in association with antimicrobial use and the consequent disruption of the normal colonic microbiota. It is the most commonly diagnosed diarrhoeal illness acquired in the hospital, and

results from ingestion of spores of *C. difficile* that vegetate, multiply, and secrete toxins, causing diarrhoea and — in the most severe cases — **pseudomembranous colitis (PMC)**. *C. difficile* is an obligately anaerobic, gram-positive, spore-forming bacillus whose spores persist widely in the environment of hospitals and chronic-care facilities.

Etiology, Epidemiology & Risk Factors

- **Organism:** obligately anaerobic, gram-positive, spore-forming bacillus; spores survive on environmental surfaces for **months** and on the hands of hospital personnel who fail to practise good hand hygiene.
- **Acquisition:** exogenous — most often in the hospital or nursing home (or shortly after discharge), but increasingly in the outpatient/community setting. Carried in stool of both **symptomatic and asymptomatic** patients.
- **Colonisation rate** rises with length of stay: $\geq 20\%$ among adults hospitalised >2 weeks, versus 1–3% among community residents. Asymptomatic faecal carriage in healthy neonates is common but disease in infants is extremely rare (they lack mucosal toxin receptors).
- **Burden:** the most common health care–associated infection in the USA (~**462,100 cases in 2017**); total burden fell 24% between 2011 and 2017 (mainly health care–associated cases), while community-associated CDI was unchanged and now approximates the health care–associated rate.

Antibiotics implicated (key exam point):

Risk level	Agents
First/classically associated	Clindamycin, ampicillin, cephalosporins
High risk	2nd/3rd-gen cephalosporins (cefotaxime, ceftriaxone, cefuroxime, ceftazidime); fluoroquinolones (ciprofloxacin, levofloxacin, moxifloxacin — most recent class implicated in outbreaks)
Lower risk	Penicillin/ β -lactamase-inhibitor combinations (ticarcillin/clavulanate, piperacillin/tazobactam)
Note	All antibiotics, including vancomycin (the drug most used to treat CDI), carry a risk of subsequent CDI

- **Other risk factors:** older age, greater severity of underlying illness, gastrointestinal surgery, use of electronic rectal thermometers, enteral tube feeding, and antacid treatment. Proton-pump inhibitor use is at most a **modest** risk and is unproven in patients not already on antibiotics.

Pathology & Pathogenesis

- ▶ **Sequence:** ingested spores survive gastric acidity → germinate in the small bowel → in the presence of a **disrupted microbiota** colonise the lower intestine → elaborate two large toxins.
- ▶ **Toxin A (enterotoxin):** a potent **neutrophil chemoattractant**. **Toxin B (cytotoxin):** evidence (isogenic mutant studies) suggests it is the **more important virulence factor** — disease occurs with toxin A–negative strains but not toxin B–negative strains.
- ▶ **Mechanism:** both toxins **glucosylate Rho-subfamily GTP-binding proteins** that regulate the actin cytoskeleton → loss of cell shape, adherence and tight junctions → fluid leakage, diarrhoea and pseudomembrane formation.
- ▶ **Binary toxin CDT** (related to *C. perfringens* iota toxin): present in only ~6% of strains generally, but in **all** NAP1/BI/027 isolates; its pathogenic role is not yet defined.
- ▶ **Three events essential for CDI:** (1) **antimicrobial exposure** establishes susceptibility by disrupting microbiota; (2) exposure to a **toxigenic *C. difficile*** strain; (3) a **third factor** — notably an inadequate host anamnestic immune (serum IgG anti–toxin A) response. Patients colonised by nontoxigenic strains without prior CDI actually have a **decreased** risk of CDI. Serum antibodies to toxins A and B protect against **recurrence**.
- ▶ **Pathology of PMC:** pseudomembranes are confined to the colonic mucosa, beginning as **1–2 mm whitish-yellow plaques** that coalesce into confluent plaques over the whole colon wall; the whole colon is usually involved, but **10% have rectal sparing**. Microscopy: mucosal attachment point with necrotic leukocytes, fibrin, mucus and cellular debris; focal epithelial erosion/necrosis with neutrophil infiltration.

Clinical Manifestations

- ▶ **Diarrhoea** is the most common feature — almost **never grossly bloody**; stools range from soft/unformed to watery or mucoid, with a characteristic odour.
- ▶ Associated findings: **fever in 28%, abdominal pain in 22%, leukocytosis in 50%**.
- ▶ **Adynamic ileus** is seen on x-ray in ~20%; when stool passage ceases the diagnosis is easily overlooked — a clue is **unexplained leukocytosis $\geq 15,000$ WBC/ μ L**, marking patients at high risk for **toxic megacolon and sepsis**.
- ▶ **Fulminant CDI** (rapidly progressive, severe) often presents **without diarrhoea**, mimicking an acute surgical abdomen, with sepsis (hypotension, fever, tachycardia, leukocytosis), ileus, colon-wall thickening and ascites on CT, and peripheral leukocytosis $\geq 20,000$ WBC/ μ L.
- ▶ **Recurrence** occurs in ~15–30% after treatment (relapse with same strain or reinfection with a new strain); a first recurrence raises the risk of a second, and recurrent disease carries a meaningful (~11%) risk of serious complications.

Diagnosis

- ▶ **Clinical criteria:** (1) diarrhoea — **≥ 3 unformed stools/24 h for ≥ 2 days** with no other cause — **plus** (2) detection of toxin A or B in stool, detection of toxigenic *C. difficile* by NAAT/PCR or

culture, or visualisation of pseudomembranes at colonoscopy. PMC is seen endoscopically in only ~50% of diarrhoeal patients with a positive stool culture and toxin assay; a negative endoscopy does not exclude CDI.

- ▶ No single test combines high sensitivity, high specificity and rapid turnaround. EIAs for toxin lack sensitivity; NAATs are rapid/sensitive but may detect **colonisation**, so guidelines favour multi-step algorithms.

Test	Sensitivity	Specificity	Comment
Stool culture	++++	+++	Most sensitive; too slow for clinical use
Cell-culture cytotoxin assay	+++	++++	Highly specific; slow turnaround
EIA for toxins A & B	++ to +++	+++	Rapid; less sensitive than culture
EIA for GDH (common antigen)	+++ to ++++	+++	Detects toxigenic + nontoxigenic strains; needs toxin confirmation
NAAT / PCR (toxin gene)	++++	+++	Widely used; very sensitive
Colonoscopy/sigmoidoscopy	+	++++	Specific if pseudomembranes seen; insensitive

(++++ >90%; +++ 71–90%; ++ 51–70%; + ~50%.) Common algorithms: NAAT followed by toxin EIA, or GDH + toxin EIA arbitrated by NAAT. **Testing of asymptomatic patients and “tests of cure” are NOT recommended** — >50% continue to harbour organism/toxin after diarrhoea resolves, and results do not predict recurrence.

Treatment

- ▶ **General:** when possible, **discontinue the offending antimicrobial**; provide hydration; **avoid antiperistaltic agents/opiates** (may mask symptoms and worsen disease). With the NAP1/BI/027 strain causing rapid deterioration, prompt specific therapy is now standard. **IV vancomycin is ineffective** (must be oral/enteral); metronidazole was **never FDA-approved** for CDI; vancomycin cure rate is superior to metronidazole (81% vs 73%; $p = 0.034$). Do not declare failure before ≥ 6 days of therapy.

Clinical setting	Treatment
Initial, mild–moderate	Fidaxomicin 200 mg bid $\times 10$ d (first-line, 2021 IDSA/SHEA) or oral vancomycin 125 mg qid $\times 10$

Clinical setting	Treatment
	d ; metronidazole 500 mg tid ×10–14 d only if neither available
Initial, severe (WBC ≥15,000/μL, creatinine ≥1.5 mg/dL)	Oral vancomycin 125 mg qid ×10 d or fidaxomicin 200 mg bid ×10 d
Initial, fulminant (severe + hypotension/shock/ileus/toxic megacolon)	Vancomycin 500 mg PO/NG + metronidazole 500 mg IV q8h + consider rectal vancomycin (500 mg in 100 mL NS retention enema q6–8h); duration may exceed 2 weeks
First recurrence	Fidaxomicin or oral vancomycin, or vancomycin taper-and-pulse
Multiple recurrences	Vancomycin taper-and-pulse; fidaxomicin (standard or extended/pulsed); vancomycin then rifaximin 400 mg bid ×2 wk ; or faecal microbiota transplant/replacement (Rebyota <i>live-jslm</i> enema; Vowst <i>live-brpk</i> oral)
High-risk for recurrence (on antibiotic Rx)	Bezlotoxumab 10 mg/kg IV (anti-toxin B mAb), adjunctive

- ▶ **Taper-and-pulse vancomycin** (after a 10-day course): 125 mg bid ×1 wk → daily ×1 wk → q2–3 days for 2–8 weeks.
- ▶ **Bezlotoxumab** reduces recurrent CDI by an absolute ~10% in patients on vancomycin/fidaxomicin/metronidazole; risk factors for recurrence = age >65, immunocompromise, severe CDI at presentation, prior CDI in the past 6 months.
- ▶ **Surgical colectomy** may be life-saving in fulminant CDI not responding to medical management.

Global Considerations (epidemic strain)

- ▶ **NAP1/BI/027** (toxintype III, REA type BI, PCR ribotype 027, PFGE NAP1) drove the marked rise in incidence/severity in the early 2000s (US rates tripled 2000–2005; Montreal attributable mortality rose to **6.9%** from 1.5%). It is characterised by (1) production of **16–23×** more toxin A and B, (2) **binary toxin CDT**, and (3) **high-level fluoroquinolone resistance**. Fluoroquinolone restriction in England nearly eliminated it by 2013.
- ▶ Other strains: **ribotype 078 / toxintype V** (food animals, binary toxin, high mortality) and **ribotype 106** (commonest US community-associated strain).

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Three-event pathogenesis model of CDI** (Fig. 139-2): boxes/arrows labelled — *Antimicrobial exposure (disrupts microbiota → susceptibility) → Healthcare/environmental exposure to C. difficile spores → Acquisition of toxigenic strain → branch to Asymptomatic*

colonisation vs CDI (driven by strain virulence + inadequate host anamnestic anti-toxin antibody).

- ▶ **Cross-section of colon in PMC:** label 1–2 mm whitish-yellow pseudomembrane plaques, confluent plaques over colon wall, rectal sparing (10%), mucosal attachment point, necrotic leukocytes + fibrin + mucus + debris, eroded/necrotic epithelium with neutrophil infiltration.

Clinical / Diagnostic significance

- ▶ Suspect CDI in any patient with diarrhoea who has received antibiotics in the **preceding 2 months**; in ileus, look for **unexplained leukocytosis** as a clue.
- ▶ **Fulminant disease without diarrhoea** can masquerade as an acute abdomen — abdominal CT (wall thickening, ascites) and cautious sigmoidoscopy are the best diagnostic tools.
- ▶ Prevention rests on **antimicrobial stewardship** (especially restricting fluoroquinolones/cephalosporins), **hand hygiene**, and environmental control of spores; serum anti-toxin antibody responses explain why some colonised patients stay asymptomatic.

High-yield exam pointers

- ▶ *C. difficile* = obligate anaerobe, gram-positive, **spore-forming** bacillus; spores resist gastric acid and persist on surfaces for months.
- ▶ **Toxin A = enterotoxin (neutrophil chemoattractant); Toxin B = cytotoxin (more important virulence factor)**; both glucosylate Rho-GTPases.
- ▶ Highest-risk antibiotics: **clindamycin, cephalosporins, fluoroquinolones**; lowest: piperacillin/tazobactam/ticarcillin-clavulanate — but **all** (incl. vancomycin) can cause CDI.
- ▶ Diagnostic criteria: **≥3 unformed stools/24 h for ≥2 days** + stool toxin/NAAT or pseudomembranes; never test asymptomatic patients or do tests of cure.
- ▶ **Fidaxomicin or oral vancomycin** are first-line; **metronidazole is inferior and only a fallback**; IV vancomycin does not work.
- ▶ **Severe markers:** WBC ≥15,000/μL, creatinine ≥1.5 mg/dL. **Fulminant** = + hypotension/shock/ileus/toxic megacolon.
- ▶ Recurrence 15–30%; options include fidaxomicin, vancomycin taper-and-pulse, FMT/microbiota products (Rebyota, Vowst), and **bezlotoxumab** (anti-toxin B mAb).
- ▶ **NAP1/BI/027 epidemic strain:** ↑↑toxin production (16–23×), binary toxin CDT, fluoroquinolone resistance.

SOURCE & COVERAGE

Harrison 22e — Ch 139 “Clostridioides difficile Infection, Including Pseudomembranous Colitis” (Gerding & Johnson). **Coverage note:** the provided chapter text file ends mid-sentence within the

surgical management of fulminant CDI, so a formal stand-alone “Prevention and Control” section is not fully captured; prevention points stated here (hand hygiene, antimicrobial stewardship/fluoroquinolone restriction, environmental spore persistence) are drawn from the epidemiology/pathogenesis and global-considerations text that IS present. Standard infection-control measures (contact precautions, soap-and-water hand washing since alcohol gels do not kill spores, sporicidal disinfection) are universally accepted ID practice but are not verbatim in the supplied excerpt.

Coagulase-negative staphylococcal infections

Asked in: Paper II Jul 2020 — RGUHS MD General Medicine

Definition / Introduction — Coagulase-negative staphylococci (CoNS) are gram-positive cocci of the family Micrococcaceae that, unlike *Staphylococcus aureus*, do **not** produce free coagulase and hence fail to convert fibrinogen to fibrin. They are the most abundant commensals of human skin and mucosae, so they are simultaneously the commonest blood-culture **contaminants** and, in the era of implanted prostheses, important **opportunistic pathogens** of foreign-body and device-related infection. *S. epidermidis* is the prototype; *S. saprophyticus* (urinary tract) and the unusually virulent *S. lugdunensis* (endocarditis) are the other exam-relevant species. Because a few “CoNS” species are in fact coagulase-positive, the more precise contemporary term is **non-S. aureus staphylococci (NSaS)**.

Microbiology, taxonomy and laboratory speciation

- ▶ **General features:** gram-positive cocci in grapelike clusters on Gram’s stain, ~1 µm, **catalase-positive** (key distinction from streptococci), nonmotile, aerobic and facultatively anaerobic, with prolonged survival on environmental surfaces. There are **≥40 staphylococcal species**.
- ▶ **The coagulase test** divides the genus. *S. aureus* produces coagulase (a surface enzyme converting fibrinogen → fibrin); CoNS classically do not. Caveat: a few “CoNS” such as *S. pseudintermedius* and *S. argenteus* are actually coagulase-positive — hence **NSaS** is the more accurate label.
- ▶ **Colony/biochemical clues:** most NSaS form **small, white, nonhemolytic** colonies, whereas *S. aureus* forms golden β-hemolytic colonies, ferments mannitol, is protein A-positive and DNase-positive. *S. saprophyticus* is distinctively **novobiocin-resistant**.
- ▶ **Identification tools:** latex agglutination kits (protein A + clumping factor) separate *S. aureus* from most NSaS; **MALDI-TOF mass spectrometry** is increasingly used for rapid speciation. For outbreak/strain typing, pulsed-field gel electrophoresis and *spa* typing have been used, with **whole-genome sequencing** now the gold standard.

Feature	<i>S. aureus</i>	Coagulase-negative staphylococci
Coagulase	Positive	Negative (most species)
Colony on blood agar	Golden, β -hemolytic	Small, white, non-hemolytic
Mannitol / DNase / Protein A	Positive	Usually negative
Virulence	High (toxins, abscesses)	Low (biofilm-dependent), except <i>S. lugdunensis</i>
Typical disease	SSTI, endocarditis, bacteraemia, toxin disease	Prosthetic/device-related infection

Important species and their clinical niches

- ▶ *S. epidermidis* — the **most common human NSaS pathogen**; the most abundant bacterial species of normal skin, also colonising oropharynx and vagina. It is the dominant cause of **prosthetic-device infections** by virtue of biofilm formation.
- ▶ *S. saprophyticus* — novobiocin-resistant; a common cause of **urinary tract infection in young, sexually active women**, mediated by adhesins (a ~160-kDa haemagglutinin/adhesin) that bind uroepithelial cells.
- ▶ *S. lugdunensis* and *S. schleiferi* — disproportionately **virulent NSaS** that cause **native-valve endocarditis** and **osteomyelitis**; they share virulence determinants with *S. aureus* (e.g. clumping factor and lipase). *S. lugdunensis* may produce aggressive endocarditis with **bulky vegetations and rapid valve destruction with abscess**, mimicking *S. aureus* — frequently missed when dismissed as a “contaminant”.
- ▶ *S. haemolyticus* and *S. hominis* — other species commonly recovered from device-associated bloodstream infection.

Pathogenesis — biofilm on foreign surfaces

- ▶ NSaS infection of a prosthesis is a **two-step process**: initial **adhesion** to the device, then **colonisation** with biofilm accumulation.
- ▶ Implanted material is rapidly coated by host matrix proteins (**fibrinogen, fibronectin**), which act as **bridging ligands**. Staphylococcal surface proteins — **autolysin (AtlE)**, fibrinogen-binding protein and **accumulation-associated protein (AAP)** — mediate attachment to modified or bare surfaces.
- ▶ *S. epidermidis* then elaborates an extracellular polysaccharide (**glycocalyx** / “slime”); the **polysaccharide intercellular adhesin (PIA)**, encoded by the ***ica*** (**intercellular adhesion**) locus, drives aggregation, accumulation and maturation of a protective **biofilm**. The *ica* genes are over-represented in device-infecting strains relative to colonising strains.

- ▶ Biofilm forms a **physical barrier** shielding bacteria from host defences and antibiotics and serves as a **nidus for persistent and recurrent infection** — the reason device removal is usually required for cure.

Clinical syndromes

- ▶ **Prosthetic / foreign-body infections (the hallmark)** — prosthetic cardiac valves, prosthetic joints, vascular grafts, intravascular and peritoneal-dialysis catheters, CNS (CSF) shunts, cardiac implantable electronic devices (pacemakers/ICDs), sternal wires and intracranial-pressure monitors. The picture is characteristically **indolent**: subtle local signs (mild erythema, pain, low-grade drainage, prosthesis loosening), slow progression and limited systemic upset; fever is variable, leukocytosis mild, with raised ESR/CRP.
- ▶ **Prosthetic-valve endocarditis (PVE)** — **early PVE (within ~2 months of surgery)** is commonly caused by staphylococci (coagulase-negative and -positive), gram-negatives and fungi, with CoNS a leading agent; in **late PVE**, streptococci predominate but CoNS still cause many cases.
- ▶ **Cardiac-device (CIED) infection / endocarditis** — *S. aureus* and CoNS cause the majority; roughly one-third present within 3 months, one-third at 3–12 months, and one-third after 1 year.
- ▶ **Native-valve endocarditis** — NSaS account for ~5% of cases; suspect *S. lugdunensis* when an aggressive course occurs.
- ▶ **Bloodstream infection** — important in **preterm neonates and neutropenic patients**, usually catheter-associated.
- ▶ **Urinary tract infection** — *S. saprophyticus* in young women; **wound infection** after cardiothoracic surgery; *S. epidermidis* may rarely cause osteomyelitis in the absence of a prosthesis.

Diagnosis — distinguishing true infection from contamination

- ▶ NSaS are easily grown by routine culture, but **interpretation is the challenge** because they are abundant skin commensals.
- ▶ Only **10–20% of NSaS-positive blood cultures reflect true bacteraemia** (Harrison); conversely, contamination may account for **about three-quarters** of CoNS blood-culture isolates (CMDT).
- ▶ **Features favouring true infection**: presence of a **foreign body/intravascular device**; local signs (purulent or serosanguineous drainage, erythema, tenderness at the device site); fever, new murmur, prosthesis instability or systemic embolisation (for PVE); leukocytosis and signs of sepsis.
- ▶ **Microbiological criteria favouring true bacteraemia**: isolation of the **same strain** (same species with the same antibiogram or DNA fingerprint) from **two or more separately drawn cultures** and from the device site; bacterial growth **within 48 h**; and growth in **both aerobic and anaerobic bottles**.

Treatment

- ▶ **Source control is paramount** — wherever feasible, **remove the infected intravascular catheter or foreign body**; biofilm-encased organisms are rarely cured by antibiotics alone. When removal is hazardous (prosthetic joint or valve, CSF shunt), antibiotics $\pm$ long-term suppression may be tried, accepting a lower cure rate and the likely eventual need for surgery.
- ▶ **Resistance**: NSaS are far more often methicillin-resistant than *S. aureus* — **>80% of nosocomial NSaS isolates are methicillin-resistant**, frequently with co-resistance to multiple drug classes.
- ▶ **Empirical drug of choice**: **vancomycin** (15–20 mg/kg IV q8–12 h; CMDT: 1 g IV q12 h, trough 15–20 $\mu\text{g/mL}$) until susceptibility is known. If proven **methicillin-susceptible**, a penicillinase-resistant penicillin (**nafcillin/oxacillin**) or **cefazolin** is preferred.
- ▶ **Duration**: documented infection (same strain ≥ 24 h apart) **without** endocarditis or other foci $\rightarrow$ **7–14 days**; infection of **bone or a prosthetic valve** $\rightarrow$ **6 weeks**.
- ▶ **Prosthetic-valve endocarditis (methicillin-resistant NSaS)** $\rightarrow$ combination of **vancomycin + rifampin** (300 mg PO/IV every 8 h) + **gentamicin** (1 mg/kg IV every 8 h for 2 weeks), usually with surgical valve replacement. **Rifampin** is specifically valuable in prosthetic-device infection and osteomyelitis (biofilm/intracellular penetration); **rifampin + a fluoroquinolone** (e.g. **ciprofloxacin**) can suppress retained prosthetic-joint infection.
- ▶ **Alternative anti-MRSA agents** with NSaS activity include **daptomycin**, **linezolid/tedizolid**, **ceftaroline**, **telavancin** and **TMP-SMX** (chosen per susceptibilities; **daptomycin** is not used for pneumonia).

Setting	Preferred regimen	Duration
Empirical / methicillin-resistant	Vancomycin IV (target trough 15–20 $\mu\text{g/mL}$)	Per focus
Confirmed methicillin-susceptible	Nafcillin / oxacillin or cefazolin	Per focus
Catheter bacteraemia (device removed)	Vancomycin after removal	7–14 days
Bone / prosthetic valve	Vancomycin ($\pm$ combination)	6 weeks
MR prosthetic-valve endocarditis	Vancomycin + rifampin + gentamicin + surgery	≥ 6 weeks (gentamicin 2 weeks)

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Biofilm formation on a catheter/prosthesis (sequential schematic)**. Labels:
Prosthetic/catheter surface $\rightarrow$ *host conditioning film (fibrinogen, fibronectin)* $\rightarrow$ *primary adhesion (AtfE autolysin, fibrinogen-binding protein, AAP)* $\rightarrow$ *accumulation (polysaccharide*

Setting	Preferred regimen	Duration
<i>intercellular adhesin / PIA, ica locus</i>) → mature biofilm (glycocalyx “slime”) → barrier to antibiotics and host immune cells → embolisation / persistent bacteraemia. ▶ Diagnostic algorithm box: “Contaminant vs true CoNS bacteraemia”. Labels: <i>Single positive bottle, no device</i> → likely contaminant; <i>Same strain from ≥2 separate cultures + device site, growth <48 h, both aerobic & anaerobic bottles, sepsis signs</i> → true infection → remove device + vancomycin.		

Clinical / Diagnostic significance

- ▶ A CoNS-positive blood culture should never be dismissed reflexively as a contaminant in a patient with a **prosthetic valve, joint, vascular graft, CIED, CSF shunt or central line** — repeat cultures and clinical correlation are essential.
- ▶ *S. lugdunensis* is a “red-flag” CoNS: treat any *lugdunensis* bacteraemia as potentially **aggressive endocarditis** and obtain echocardiography.
- ▶ Persistent CoNS bacteraemia despite an indwelling line mandates **line removal**; failure to do so is a common cause of relapse because of biofilm.
- ▶ High methicillin-resistance rates make **vancomycin the rational empirical choice**, with de-escalation to a β -lactam if methicillin-susceptible.
- ▶ Prevention rests on **aseptic catheter insertion, hand hygiene and insertion/maintenance “bundles”**, which markedly reduce device-related staphylococcal infection.

High-yield exam pointers

- ▶ CoNS = catalase-positive, **coagulase-negative**, gram-positive cocci in clusters; most abundant normal skin flora.
- ▶ ***S. epidermidis** = *commonest pathogen* → *prosthetic-device infection via biofilm*; *ica locus* → *PIA / slime**.
- ▶ ***S. saprophyticus** = *novobiocin-resistant* → *UTI in young sexually active women**.
- ▶ ***S. lugdunensis** (and *S. schleiferi*) = *virulent* → *native-valve endocarditis/osteomyelitis; bulky vegetations like S. aureus**.
- ▶ Only **10–20%** of NSaS-positive blood cultures are true bacteraemia; **~75%** are contaminants — confirm with **same strain from ≥2 cultures + device site**.
- ▶ **>80%** of nosocomial NSaS are **methicillin-resistant** → empirical **vancomycin**.
- ▶ **Source control / device removal** is essential; rifampin aids biofilm/prosthetic-device infection.
- ▶ Durations: catheter bacteraemia 7–14 days; **bone/prosthetic valve 6 weeks**; PVE = vancomycin + rifampin + gentamicin + surgery.

SOURCE & COVERAGE

- ▶ **CMDT 2026** — “Bacterial & Chlamydial Infections” (Infections Caused by Coagulase-Negative Staphylococci; *S. lugdunensis*; vancomycin dosing and prosthetic-valve endocarditis regimen) and “Common Problems in Infectious Diseases” (prosthetic-valve endocarditis microbiology by time of onset).

Complications and management of Enteric fever (Typhoid)

Asked in: Paper II May 2022 — RGUHS MD General Medicine

Definition / Introduction — Enteric (typhoid) fever is a systemic febrile illness caused by dissemination of the human-restricted serotypes *Salmonella* Typhi and *S. Paratyphi* (A, B, C), characterised by prolonged fever and abdominal pain. After ingestion the organisms cross the gut via Peyer's-patch M cells, are taken up by macrophages and disseminate through the reticuloendothelial system. The mean incubation period is **10–14 days** (range 5–21). Untreated, fever (38.8°–40.5°C) may persist up to 4 weeks; the **overall case-fatality rate is ~2.5%** (4.5% in hospitalised, 10–30% if untreated), falling to <1% with prompt appropriate antibiotics. Complications cluster in the third and fourth weeks of illness.

Determinants and timeline of complications

- ▶ Complications occur in **~27% of hospitalised patients**.
- ▶ Risk correlates with: **longer duration of symptoms before hospitalisation**, host factors (host genetics, immunosuppression, acid-suppression therapy, prior exposure, vaccination status), **strain virulence and inoculum**, and **choice of antibiotic therapy**.
- ▶ The dangerous intestinal complications characteristically appear in the **3rd–4th weeks**, arising from hyperplasia, ulceration and necrosis of the **ileocecal Peyer's patches** at the site of initial *Salmonella* infiltration.

Complications of enteric fever

Category	Complication (frequency where stated)	Key points
Intestinal (most lethal)	GI haemorrhage (~6%); intestinal perforation (~1%)	3rd–4th week; from ulceration/necrosis of ileocecal Peyer's patches (terminal ileum); both life-threatening

Category	Complication (frequency where stated)	Key points
Neurologic (2–40%)	Meningitis, Guillain-Barré syndrome, neuritis, neuropsychiatric states	“Muttering delirium” or “coma vigil”; <i>picking at bedclothes / imaginary objects</i> (carphology)
Haematologic	Disseminated intravascular coagulation; haemophagocytic syndrome	Incidence reduced by prompt antibiotics
Hepatobiliary / abdominal	Hepatitis, pancreatitis, hepatic and splenic abscesses & granulomas , cholecystitis	Cholecystitis underlies chronic carriage
Cardiac	Endocarditis, pericarditis, myocarditis	Uncommon
Genitourinary / renal	Orchitis, glomerulonephritis, pyelonephritis, haemolytic-uraemic syndrome	—
Other focal	Severe pneumonia, arthritis, osteomyelitis, endophthalmitis, parotitis	—
Relapse	Up to 10% of patients	Usually 2–3 weeks after fever resolution; same strain & susceptibility profile
Chronic carriage	2–5% shed >1 year; up to 10% excrete in faeces up to 3 months	More common in women, infants , biliary abnormalities, or bladder co-infection with <i>Schistosoma haematobium</i>

- ▶ *S. Typhi* persists in the gallbladder by forming **biofilms on gallstones** and invading gallbladder epithelium; chronic carriage carries an **increased risk of gallbladder carcinoma**, especially on the Indian subcontinent.
- ▶ Intestinal perforation and haemorrhage **require immediate fluid resuscitation and surgical intervention**, with **broadened antibiotic cover for polymicrobial peritonitis** and treatment of haemorrhage, including **bowel resection**.

Principles of antimicrobial management

- ▶ Initial choice depends on the **susceptibility pattern of S. Typhi/Paratyphi in the area of residence or travel**.
- ▶ A 2022 systematic review (27 RCTs) found **no difference between ceftriaxone, a fluoroquinolone, or azithromycin** in treatment failure, microbiologic failure, relapse, convalescent carriage or adverse events.

- ▶ Because of the high prevalence of strains with **decreased susceptibility to ciprofloxacin** (DSC; MIC >0.125 µg/mL) on the Indian subcontinent and parts of Africa, **fluoroquinolones should no longer be used for empirical therapy** in these regions.
- ▶ **Travel to Pakistan / concern for ceftriaxone-resistant (XDR) S. Typhi → treat empirically with a carbapenem or azithromycin.**
- ▶ **Azithromycin** is recommended for **uncomplicated** enteric fever including ESBL, DSC and **fluoroquinolone-resistant** strains (defervescence 4–6 days; relapse & stool carriage <3%); against DSC strains it gives lower failure and shorter hospitalisation than fluoroquinolones.
- ▶ Third-generation cephalosporins (ceftriaxone, cefotaxime, oral cefixime) clear fever in ~1 week (failure ~5–10%, relapse 3–6%). Fluoroquinolones against **susceptible** strains give cure rates ~98%.
- ▶ **Carbapenems** are increasingly used for complicated XDR infection (cost and IV route are barriers).
- ▶ Duration: at least **10 days**, or 5 days after fever resolution.

Antibiotic regimens (Harrison Table 171-1, adults)

Indication	Agent	Dosage (route)	Duration (days)
Empirical	Ceftriaxone*	2 g/d (IV)	10–14
	Ciprofloxacin	500 mg bid (PO) / 400 mg q12h (IV)	5–7
	Azithromycin	1 g/d (PO)	5
Fully susceptible (optimal)	Ceftriaxone / Ciprofloxacin / Azithromycin	as above	10–14 / 5–7 / 5
Fully susceptible (alternative)	Amoxicillin	1 g tid (PO) or 2 g q6h (IV)	14
	Chloramphenicol	25 mg/kg tid (PO/IV)	14–21
	TMP-SMX	160/800 mg bid (PO)	7–14
MDR (per susceptibility)	Ceftriaxone / Ciprofloxacin / Azithromycin	as above	10–14 / 5–7 / 5
Ceftriaxone-resistant (optimal)	Meropenem†	1 g q8h (IV)	10–14
	Azithromycin	1 g/d (PO)	5
Eradication of carriage	Ciprofloxacin	500–750 mg bid (PO)	28

Indication	Agent	Dosage (route)	Duration (days)
	Azithromycin (alt.)	500 mg (PO)	28

*Or another 3rd-gen cephalosporin (cefotaxime 2 g q8h IV; cefixime 400 mg bid PO). †Or imipenem 500 mg q6h IV.

Management of severe disease, supportive care and carriage

- ▶ **Site of care:** most uncomplicated cases are managed at **home** with oral antibiotics and antipyretics. Hospitalise patients with **persistent vomiting, diarrhoea and/or abdominal distension** for supportive therapy plus a **parenteral 3rd-gen cephalosporin, fluoroquinolone or carbapenem** per susceptibility.
- ▶ **Severe enteric fever (shock, obtundation/delirium):** add high-dose **dexamethasone** — initial 3 mg/kg, then 1 mg/kg every 6 h for eight doses — which (with chloramphenicol in the original Indonesian trial) lowered mortality dramatically (10% vs 55%). Severe enteric fever remains **one of the few indications for glucocorticoids in acute bacterial infection; steroids beyond 48 h may increase relapse.**
- ▶ **Intestinal perforation/haemorrhage:** aggressive fluid resuscitation, broadened cover for **polymicrobial peritonitis**, and **surgical intervention / bowel resection.**
- ▶ **Chronic carriage eradication:** fluoroquinolone-susceptible → oral **ciprofloxacin** for 4 weeks (eradication ~80%); fluoroquinolone-resistant → **azithromycin** 4 weeks (limited data) or **amoxicillin** if ampicillin-susceptible (lower eradication). With **anatomic abnormality (biliary/renal/bladder stones)**, eradication often needs **antibiotics plus surgical correction** (e.g., cholecystectomy).
- ▶ **Public health:** enteric fever is a **notifiable disease**; monitor and treat carriers (especially food handlers and child-care providers) to prevent onward transmission.

Prevention (vaccines)

- ▶ **Ty21a** — oral live-attenuated (days 1, 3, 5, 7; re-vaccinate every 5 years); minimum age **6 years**; efficacy ~50% at 2.5–3 years.
- ▶ **Vi CPS** — parenteral purified Vi capsular polysaccharide (single dose; booster every 2 years); minimum age **2 years**; efficacy ~55% at 3 years.
- ▶ **Typhoid conjugate vaccines (TCV)** — *Typhar TCV* (Bharat Biotech, 2018) and *TYPHIBEV* (Biological E, 2020); single IM 0.5 mL dose, **79–95% effective**, antibody persistence up to **7 years**, and effective in **children <2 years** — WHO-prioritised for high-incidence countries.
- ▶ No licensed vaccine exists for **paratyphoid fever**; vaccination is an **adjunct**, not a substitute for safe food/water.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Labelled diagram of terminal-ileum Peyer's-patch pathology / typhoid perforation:** label *terminal ileum, ileocecal junction, hyperplastic Peyer's patch, longitudinal ulcer along antimesenteric border, necrosis/perforation site, mesenteric lymph nodes.*
- ▶ **Week-wise timeline of complications:** Week 1 *bacteraemia, stepladder fever, relative bradycardia*; Week 2 *rose spots, hepatosplenomegaly*; **Weeks 3–4** *intestinal haemorrhage, perforation, neuropsychiatric state*; Convalescence *relapse (~10%), chronic carriage (2–5%).*

Clinical / Diagnostic significance

- ▶ **Definitive diagnosis** is by **culture**: blood culture sensitivity only **40–60%**; **bone-marrow culture** ~80% sensitive and **not reduced by up to 5 days of prior antibiotics**; combined blood + bone-marrow + intestinal-secretion (duodenal string) culture gives **>90% yield**.
- ▶ **Rapid serologic tests Tubex and Typhidot** (IgM/IgG to O and H antigens) have sensitivity ~70–80% and specificity ~80–90% — useful at point-of-care but **cannot replace blood culture**.
- ▶ Suspect typhoid in any **febrile returning traveller** from South Asia/Africa; differentials include malaria, dengue, viral hepatitis, leptospirosis, rickettsial infection, amoebic liver abscess and acute HIV.
- ▶ Watch for **leukopenia/neutropenia (15–25%)**; **leukocytosis suggests perforation or secondary infection**.
- ▶ A history of travel to **Pakistan** should raise concern for **XDR H58 S. Typhi** and drive empirical carbapenem/azithromycin use.

High-yield exam pointers

- ▶ Complications in ~27% of hospitalised cases; **haemorrhage (6%)** and **perforation (1%)** in weeks 3–4 from ileocecal Peyer's-patch ulceration.
- ▶ **Perforation = surgical emergency**: resuscitate, broad cover for peritonitis, **operate / resect bowel**.
- ▶ Neuropsychiatric typhoid → “**muttering delirium**” / “**coma vigil**”; neurologic involvement 2–40% (incl. GBS, meningitis).
- ▶ **Relapse up to 10%** at 2–3 weeks; **chronic carriage 2–5% (>1 yr)** — linked to **gallstones, biofilms, gallbladder cancer**, commoner in women.
- ▶ **Empirical drug today**: ceftriaxone 2 g/d IV or azithromycin 1 g/d PO; **avoid fluoroquinolones empirically** on the Indian subcontinent (DSC, MIC >0.125 µg/mL).
- ▶ **XDR/ceftriaxone-resistant (Pakistan)** → meropenem 1 g q8h IV (or imipenem) ± azithromycin.
- ▶ **Severe disease** → dexamethasone 3 mg/kg then 1 mg/kg q6h ×8 (mortality 10% vs 55%); a rare steroid indication; stop by 48 h.

- ▶ **Carrier eradication:** ciprofloxacin 500–750 mg bid ×28 days (~80%); cholecystectomy if gallstones.
- ▶ **Prevention:** Ty21a (oral), Vi-CPS (parenteral), and TCV (Typbar/TYPHIBEV) effective in under-2s; none for paratyphoid.

SOURCE & COVERAGE

Harrison's Principles of Internal Medicine, 22e — Ch 171 "Salmonellosis" (Pegues & Miller), including Table 171-1 (Antibiotic Therapy for Enteric Fever in Adults). *Coverage note:* The classic eponyms **Faget sign** (relative bradycardia — described in text as "relative bradycardia at the peak of high fever") and the **Widal test** are standard internal-medicine items but are not named as such in the provided chapter, which instead emphasises Tubex/Typhidot and culture-based diagnosis; they are flagged here as universally accepted additions rather than verbatim source content.

COVID-19 (2019 Novel Corona Virus)

Asked in: Paper II Nov 2020 — RGUHS MD General Medicine

Definition / Introduction — COVID-19 (Coronavirus Disease 2019) is the acute respiratory and multisystem illness caused by **severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2)**, an enveloped, positive-sense RNA *Betacoronavirus* that emerged in **Wuhan, China in 2019**. It produced the largest pandemic of the modern era — the WHO declared a **Public Health Emergency of International Concern on 30 January 2020**, a **pandemic on 11 March 2020**, and an **end to the global emergency on 5 May 2023**, by which time the virus had caused **>700 million cases and >7 million deaths**. The disease ranges from asymptomatic infection through mild illness to fulminant pneumonia, ARDS and multiorgan failure, and is now in an **endemic phase** managed with antivirals, immunomodulators and annually updated vaccines.

Aetiology, virology and pathogenesis

- ▶ **Family/genus:** *Betacoronavirus*; SARS-CoV-2 belongs to the same genus as the highly pathogenic SARS-CoV-1 (2002–03 epidemic) and MERS-CoV (2012, 2015, 2018) and the common-cold coronaviruses HCoV-OC43 and HCoV-HKU1. All coronaviruses are thought to have originated in bats.
- ▶ **Genome/structure:** a single linear positive-sense RNA of ~30,000 nucleotides encoding **four structural proteins** — S (spike), E (envelope), M (membrane), N (nucleocapsid) — plus a large polyprotein cleaved into **16 non-structural proteins**.
- ▶ **Cell entry:** the trimeric S protein (a type-1 fusion machine) uses its **receptor-binding domain (RBD)** to bind the host **angiotensin-converting enzyme 2 (ACE2)** receptor; the host protease TMPRSS2 primes S to facilitate membrane fusion and entry.

- ▶ **Variant evolution:** error-prone RNA-dependent RNA polymerase (RdRp) generates frequent variants; WHO tracks **variants under monitoring (VUM)**, **variants of interest (VOI)** and **variants of concern (VOC)**. Sequential VOCs (Alpha → Delta → **Omicron** and its sublineages BA.4/BA.5, XBB, JN.1, KP.2/"FLiRT") altered transmissibility, severity, antigenicity and drug/vaccine efficacy. Most spike mutations reduce neutralisation, rendering all earlier monoclonal antibodies ineffective.

Epidemiology and transmission

- ▶ **Spread:** primarily by **respiratory droplets** in close proximity; **airborne/aerosol** transmission can occur (heavy exercise, singing, aerosol-generating procedures) but long-range airborne spread is unlikely; **fomite** transmission occurs.
- ▶ **Reproduction number (R0):** estimated to **peak around 6** (Harrison) — far higher than seasonal influenza (1–2); CMDT places the true R0 nearer 2–3, varying by variant.
- ▶ **Pre-symptomatic and super-spreading:** much spread is **pre-symptomatic** (viral load peaked the day before symptoms before population immunity; around day 4 thereafter); "**super-spreaders**"/**super-carriers** drive disproportionate transmission, especially in dense settings (prisons, cruise ships, nursing homes, bars, workplaces).
- ▶ **Incubation:** typically 4–5 days, nearly always within 14 days (range up to ~14–24 days).
- ▶ **Risk factors for severe disease:** **advanced age is the principal risk factor** (>95% of deaths in those >45 y, >80% in those >65 y); **male sex** (OR ~1.8); rising **BMI** (overweight/obesity/severe obesity); pregnancy; smoking/substance use; and comorbidities — chronic lung disease, **diabetes**, **hypertension**, **cardiovascular** and **chronic kidney/liver disease**, **cancer**, **immunosuppression** (including transplant, rituximab/B-cell depletion), Down syndrome.

Clinical features and severity classification

- ▶ **Spectrum:** ~one-third of those infected are **asymptomatic** (but can transmit); most symptomatic patients have **mild disease (no pneumonia)**.
- ▶ **Symptoms:** cough, fever, chills, myalgia, headache, sore throat, dyspnoea; sudden **anosmia/dysgeusia** (loss of smell/taste, often neurotropic without congestion); GI symptoms (nausea, vomiting, diarrhoea); diverse dermatological lesions (acral "COVID toes", maculopapular, vesicular, urticarial).
- ▶ **Severity grading** (NIH/clinical framework reflected in Harrison & CMDT):

Category	Defining features
Asymptomatic	Positive test, no symptoms
Mild	Symptomatic, no pneumonia / no hypoxia
Moderate	Clinical/radiographic pneumonia, SpO2 >94% on room air

Category	Defining features
Severe	SpO ₂ ≤94%, RR >30/min, PaO ₂ /FiO ₂ <300 mmHg, or infiltrates >50% of lung fields
Critical	Respiratory failure needing mechanical ventilation, ARDS, shock, multiorgan failure

Investigations

- ▶ **Molecular tests (NAAT):** RT-PCR on nasopharyngeal swab (or saliva) is the **most sensitive and specific** confirmatory test; detects RNA — prolonged RNA shedding is common in the immunocompromised, so re-testing within **90 days** of prior infection is discouraged.
- ▶ **Rapid antigen tests:** fast, inexpensive, home-usable; **less sensitive than NAAT** (especially in asymptomatic persons; ~85% vs culture in symptomatic CDC data) — useful for triage of infectiousness.
- ▶ **Serology:** detects immune status, **not used for acute diagnosis** (cannot reliably separate vaccination from infection).
- ▶ **Supportive labs of severity:** lymphopenia, thrombocytopenia, neutrophilia and raised neutrophil-to-lymphocyte ratio; elevated IL-6, TNF- α , ferritin, CRP, procalcitonin, LDH; raised liver enzymes; **elevated D-dimer/prolonged PT, raised vWF**; elevated troponin and CPK.
- ▶ **Imaging:** chest radiograph and CT may be **normal early**; later show **bilateral peripheral ground-glass opacities** $\pm$ consolidation, interlobular septal thickening and air bronchograms (organising-pneumonia pattern). CT is for management, **not primary diagnosis**.

Complications

- ▶ **Pulmonary:** ARDS (commonest serious complication; ~19-fold higher progression than influenza), respiratory failure needing ventilation/ECMO; secondary bacterial/fungal infection (invasive pulmonary aspergillosis, mucormycosis).
- ▶ **Haematological/thrombotic:** hypercoagulable state, **venous thromboembolism** (PE, DVT), arterial thrombosis (stroke, limb ischaemia), DIC.
- ▶ **Cardiac:** myocardial injury, **fulminant myocarditis**, arrhythmias, heart failure, ACS, stress cardiomyopathy, shock.
- ▶ **Renal:** **acute kidney injury** (often needing dialysis).
- ▶ **Neurological/psychiatric:** encephalopathy, ICU delirium (reduces survival), seizures, stroke, **Guillain-Barré syndrome**, acute haemorrhagic necrotising encephalopathy; anxiety, depression, PTSD.
- ▶ **Hyperinflammation (“cytokine storm”):** persistent fever, multiorgan disease, raised inflammatory markers (notably IL-6) — high fatality.

- ▶ **MIS-C / MIS-A: multisystem inflammatory syndrome in children** (Kawasaki-like; GI, cardiac, mucocutaneous, haematological involvement; highest in Black/Latino children 3–12 y) and the rarer adult form **MIS-A**, weeks after mild/asymptomatic infection.
- ▶ **Long COVID:** symptoms persisting **≥3 months** — fatigue (~32%), smell/taste disorder (~22%), dyspnoea (~16%), headache, “brain fog”/memory impairment, hair loss, sleep disturbance; vaccination substantially reduces its incidence.

Management

- ▶ **Principle (biphasic disease):** antivirals work best early (reduce peak viral load) while anti-inflammatory/immunomodulators help later when tissue inflammation dominates.
- ▶ **Outpatient / mild–moderate, high-risk (start ≤5 days of symptoms):**
 - **Nirmatrelvir/ritonavir (Paxlovid):** drug of choice — 300 mg/100 mg orally 12-hourly for 5 days; ~85% relative risk reduction in hospitalisation/death. Reduce nirmatrelvir to 150 mg if GFR 30–60, contraindicated if GFR <30; ritonavir is a potent CYP3A4 inhibitor — screen for drug interactions (avoid with strong inducers e.g. rifampin, phenytoin); ~6.6% “rebound” symptoms after stopping.
 - **Remdesivir IV:** 3-day outpatient course (≥60 y or comorbid, within 7 days) — ~87% reduction in death/hospitalisation pre-vaccine era.
 - **Molnupiravir** 800 mg 12-hourly ×5 days — when other agents unsuitable; **mutagenic** — contraindicated in pregnancy and <18 y, contraception advised.
- ▶ **Inpatient / severe (admit if SpO₂ <94%, RR >30, PaO₂/FiO₂ <300, or infiltrates >50%):**
 - **Supportive O₂**, control fever with **acetaminophen** (limit NSAIDs); continue **aspirin, statins, ACEi/ARB**.
 - **Remdesivir** 200 mg day 1 then **100 mg daily** (5 days, non-inferior to 10) for patients on supplemental oxygen.
 - **Dexamethasone** (low-dose) for those needing supplemental oxygen/ventilation/ECMO — standard **10-day** course; **not** indicated without hypoxia (RECOVERY trial basis). Alternatives: prednisone, methylprednisolone, hydrocortisone.
 - **Anticoagulation:** **therapeutic-dose heparin** for hospitalised patients on supplemental O₂ (not HFNC/ventilation) with raised D-dimer and no bleeding risk; **prophylactic-dose** for others including critically ill. Outpatients generally need no anticoagulation.
 - **Immunomodulators for escalating O₂/inflammation:** **IL-6 receptor inhibitors** tocilizumab (or sarilumab) and **JAK inhibitors** baricitinib (or tofacitinib) — do **not** combine IL-6 inhibitor with a JAK inhibitor; JAK inhibitors require at least prophylactic anticoagulation. Abatacept/infliximab are alternatives.

- ▶ **Antibody-based therapy/prevention:** convalescent plasma and **monoclonal antibodies** have largely lost efficacy to new variants; long-acting antibodies **tixagevimab/cilgavimab** (Evusheld) and **pemivibart** were authorised for pre-exposure prophylaxis in the immunocompromised.
- ▶ **Bacterial co-infection is uncommon** (~8%) — routine antibiotics are **not** recommended.

Prevention

- ▶ **Non-pharmaceutical interventions (NPIs):** physical distancing (~6 ft), isolation of cases, quarantine, ventilation/HEPA, hand hygiene, and **masks** (well-fitted N95/FFP2 most protective; greatest value for vulnerable groups).
- ▶ **Vaccines** (stimulate neutralising anti-spike antibody):
 - **mRNA** (Pfizer-BioNTech, Moderna) — ~95% **efficacy** against symptomatic disease in phase-3 trials; waning immunity prompts periodic variant-matched updates.
 - **Protein subunit** (Novavax, with **Matrix-M** adjuvant).
 - **Viral-vector** (Janssen) — **withdrawn** due to **thrombosis with thrombocytopenia syndrome (TTS)**.
 - Goal is prevention of **severe disease/death**; vaccination also lowers **long-COVID** risk. mRNA vaccines are safe in **pregnancy/lactation**; rare **myocarditis/pericarditis** (~6.3/million doses, young males, after 2nd dose).

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **SARS-CoV-2 virion (labelled):** spherical enveloped particle with labels — **Spike (S)** glycoprotein with receptor-binding domain (RBD), **Envelope (E)** protein, **Membrane (M)** protein, **Nucleocapsid (N)** protein wrapping the **+ssRNA genome** (~30 kb); alongside, host cell showing **ACE2 receptor** and **TMPRSS2** priming S for entry.
- ▶ **Natural history / two-phase timeline:** x-axis time from exposure; curves for **viral load** (early, peak ~day 4–5) and **host inflammatory response** (late); phases marked **incubation** (4–5 d) → **viral phase** (antivirals: nirmatrelvir, remdesivir) → **inflammatory phase** (dexamethasone, tocilizumab, baricitinib) → **recovery / Long COVID**.

Clinical / Diagnostic significance

- ▶ **Confirm with RT-PCR** (gold standard); use **rapid antigen** for fast triage; severity is defined by oxygenation ($\text{SpO}_2 \leq 94\%$, $\text{PaO}_2/\text{FiO}_2 < 300$) and radiographic extent.
- ▶ **Risk-stratify** by age, comorbidity and immune status to select candidates for **early antivirals** — the single highest-yield management decision.
- ▶ **Recognise the biphasic course:** antivirals early, **steroids only once hypoxic**; never give dexamethasone to non-hypoxic mild disease.

- ▶ Anticipate thromboembolism — thromboprophylaxis for all hospitalised patients; monitor D-dimer.
- ▶ MIS-C/MIS-A and Long COVID are important post-infectious sequelae requiring multidisciplinary follow-up.

High-yield exam pointers

- ▶ SARS-CoV-2 = Betacoronavirus, +ssRNA ~30 kb, S/E/M/N structural proteins; entry via ACE2 + TMPRSS2.
- ▶ WHO milestones: PHEIC 30 Jan 2020, pandemic 11 Mar 2020, emergency ended 5 May 2023.
- ▶ R0 ~6 (Harrison) / 2–3 (CMDT); incubation 4–5 days; ~1/3 asymptomatic.
- ▶ Severe disease cut-offs: SpO2 ≤94%, RR >30, PaO2/FiO2 <300, infiltrates >50%.
- ▶ Lab clues: lymphopenia, raised D-dimer, ferritin, CRP, LDH, IL-6, troponin.
- ▶ Early antiviral of choice: nirmatrelvir/ritonavir 300/100 mg BD ×5 d within 5 days (CYP3A4 interactions; avoid GFR <30).
- ▶ Severe/hospitalised: remdesivir + dexamethasone ± tocilizumab/baricitinib; therapeutic-dose heparin if on supplemental O2.
- ▶ Dexamethasone helps only hypoxic patients (RECOVERY); harmful/no benefit without hypoxia.
- ▶ Vaccines: mRNA (Pfizer/Moderna ~95%), Novavax subunit; Janssen withdrawn (TTS).
- ▶ Sequelae: MIS-C/MIS-A (Kawasaki-like) and Long COVID (fatigue, anosmia, dyspnoea, brain fog) ≥3 months.

SOURCE & COVERAGE

- ▶ Harrison's Principles of Internal Medicine, 22e — "SARS-CoV-2 and COVID-19" (virology, ACE2/TMPRSS2 entry, epidemiology, severity, complications, antiviral/immunomodulator regimens, antibody therapy, vaccines).
- ▶ CMDT 2026 — "Severe Acute Respiratory Syndrome — Coronavirus 2019 (SARS-CoV-2)" and Table 37–1 "Agents for viral infections" (diagnostic strategy, drug doses, anticoagulation thresholds, corticosteroid/IL-6/JAK indications, vaccine and Long-COVID data).

Cytokine Storm in Dengue Fever

Asked in: Paper I Nov 2020 — RGUHS MD General Medicine

Definition / Introduction — Dengue is caused by four antigenically distinct mosquito-borne orthoflaviviruses (DENV-1 to DENV-4, family *Flaviviridae*) transmitted chiefly by *Aedes aegypti*. While

most infections are subclinical or cause a self-limited febrile illness (“break-bone fever”), a minority progress at defervescence to **severe dengue**, dominated by a **plasma-leakage (critical) phase**. The “*cytokine storm*” refers to an exaggerated, dysregulated surge of pro- and anti-inflammatory cytokines and vasoactive mediators—triggered largely by **antibody-dependent enhancement (ADE)** and cross-reactive memory T-cell activation during heterotypic secondary infection—that drives **endothelial dysfunction, increased vascular permeability, plasma leakage, haemorrhage and shock**. It is the immunopathological engine of dengue haemorrhagic fever (DHF) and dengue shock syndrome (DSS).

Why a cytokine storm develops — immunological triggers

- ▶ **Antibody-dependent enhancement (ADE):** A first (primary) DENV infection gives lifelong homotypic immunity but only transient cross-protection. On heterotypic **secondary infection**, pre-existing **non-neutralising, sub-neutralising “enhancing” antibodies** opsonise the new serotype and, via **Fcγ receptors**, deliver virus into **monocytes/macrophages**, amplifying viral load and the infected-cell pool that releases cytokines. Harrison explicitly centres severe-dengue risk on “immune-mediated enhancement of disease” and “enhancing and non-neutralising antibodies.”
- ▶ **Original antigenic sin (cross-reactive T cells):** Secondary infection preferentially expands **low-avidity cross-reactive memory CD8⁺/CD4⁺ T cells** from the prior serotype rather than high-affinity protective clones; these clear virus poorly but **over-produce TNF-α and IFN-γ**, fuelling the storm.
- ▶ **NS1-driven endothelial injury:** The secreted viral **non-structural protein 1 (NS1)** is highlighted by Harrison as having “a key role in the vascular leak phenomenon”—it engages **TLR4** on monocytes and endothelium to release inflammatory cytokines and directly degrades the **endothelial glycocalyx**.
- ▶ **Complement activation:** Massive C3/C5 activation generates anaphylatoxins (**C3a, C5a**) that increase vascular permeability and amplify inflammation.
- ▶ **Mast-cell and innate activation:** Infected mast cells and dendritic cells release vasoactive mediators (chymase, VEGF, histamine), adding to leak.
- ▶ **Host/viral risk modifiers (Harrison):** Susceptibility falls sharply after age 12; females > males; certain **infection sequences** are worse (DENV-1 → DENV-2 more severe than DENV-4 → DENV-2); Southeast-Asian DENV-2 variants are more virulent; nutritional status and, per CMDT, **type-2 diabetes and obesity** predispose to severe disease.

Key mediators of the storm and their effects

Mediator	Principal source	Pathophysiological effect
TNF-α	Activated T cells, monocytes	Endothelial activation, increased permeability, fever, haemorrhage

Mediator	Principal source	Pathophysiological effect
IFN- γ	Cross-reactive memory T cells	Macrophage activation, amplifies TNF- α effect
IL-6	Monocytes/macrophages, endothelium	Acute-phase response, vascular permeability, coagulation activation
IL-1 β	Monocytes (inflammasome)	Pyrexia, endothelial activation
IL-8 (CXCL8) / MCP-1	Monocytes, endothelium	Neutrophil/monocyte chemotaxis, vascular leak
IL-10	T cells, monocytes	Anti-inflammatory surge; high levels mark severity & immune paralysis
VEGF	Mast cells, platelets, endothelium	Potent direct $\uparrow$ vascular permeability
NS1 (viral)	Infected cells (secreted)	Glycocalyx degradation, TLR4-mediated cytokine release
Complement C3a/C5a	Plasma cascade	Anaphylatoxin-mediated permeability

- ▶ The **net result** is loss of endothelial barrier integrity and **glycocalyx shedding**, producing the hallmark **plasma leak**: haemoconcentration (rising haematocrit), hypoalbuminaemia, serosal effusions (pleural, ascitic) and, ultimately, hypovolaemic **shock with narrowed pulse pressure**.
- ▶ Concurrent cytokine-driven **thrombocytopenia, platelet dysfunction, consumptive coagulopathy/DIC and liver injury** generate the bleeding diathesis.

Phases of dengue and timing of the storm

- ▶ **Febrile phase (days 1–5)**: High viraemia and innate activation—high fever, retro-orbital pain, myalgia (“break-bone”), flushing, transient rash; leukopenia, early thrombocytopenia, mild AST rise.
- ▶ **Critical / plasma-leakage phase (around defervescence, ~days 3–7)**: The cytokine storm peaks as fever falls; capillary leak, effusions, falling platelets ($<100,000/\mu\text{L}$), rising haematocrit and—if uncorrected—shock. **Warning signs** (abdominal pain/tenderness, persistent vomiting, clinical fluid accumulation, mucosal bleeding, lethargy/restlessness, hepatomegaly >2 cm, rising HCT with rapid platelet fall) flag impending deterioration.
- ▶ **Recovery phase (~days 7–10)**: Cytokines subside, extravascular fluid is reabsorbed (risk of **fluid overload/pulmonary oedema** with over-resuscitation); convalescent confluent pruritic rash with desquamation; bradycardia.

WHO classification (puts the storm in clinical terms)

1997 WHO	2009 WHO (current)	Defining feature
Dengue fever	Dengue without warning signs	Febrile illness, no leak/warning features
Dengue haemorrhagic fever (DHF, grades I–II)	Dengue with warning signs	Plasma-leak markers + warning signs → admit
DHF III–IV / Dengue shock syndrome (DSS)	Severe dengue	(1) plasma leakage → shock or respiratory distress, or (2) severe bleeding, or (3) severe organ dysfunction

- Severe organ involvement: hepatitis/fulminant hepatic failure, **myocarditis**, encephalitis/encephalopathy, acute kidney injury (especially with shock—high mortality). The most extreme expression of the storm overlaps with **haemophagocytic lymphohistiocytosis (HLH)/macrophage-activation syndrome** (cytopenias, hyperferritinaemia, hepatosplenomegaly).

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- **Diagram 1 — “Cytokine storm cascade in secondary dengue”**: Boxes/arrows: *Heterotypic secondary DENV* → *Non-neutralising enhancing antibody + Fcγ receptor (ADE)* → *Infected monocyte/macrophage (↑viral load) + Cross-reactive memory T cell (original antigenic sin)* + *Secreted NS1* → *TLR4* → central node “**Cytokine storm: TNF-α, IFN-γ, IL-6, IL-1β, IL-8, IL-10, VEGF, MCP-1; complement C3a/C5a**” → *Endothelial activation + glycocalyx degradation* → three output boxes: (i) ↑Vascular permeability → plasma leak → effusions → shock, (ii) Thrombocytopenia + DIC → haemorrhage, (iii) Organ injury (liver, heart, brain, kidney).
- **Diagram 2 — “Triphasic dengue timeline”**: X-axis days 1–10; overlaid curves for temperature, platelet count (falling to nadir in critical phase), haematocrit (rising in critical phase); shade the three phases (Febrile / Critical–leakage / Recovery) and mark the band “Cytokine storm / warning-signs window” at defervescence.

Clinical / Diagnostic significance

- **Markers of the storm / severity**: rising haematocrit with falling platelets, hypoalbuminaemia, effusions on lateral-decubitus CXR or ultrasound, elevated transaminases; high IL-10, ferritin and AST track severity. The **tourniquet test** (≥10 new petechiae per square inch after 5-min BP-cuff inflation midway between systolic and diastolic) demonstrates microvascular fragility.
- **Diagnosis**: NS1 antigen ELISA/rapid test and RT-PCR in the first ~5 days; IgM/IgG ELISA thereafter. Early, rapidly rising IgG suggests a **secondary** (ADE-prone) infection. Flavivirus serological cross-reactivity (ZIKV, JEV, YFV) can confound.

- ▶ **Management is supportive—fluids are the keystone:** judicious isotonic crystalloid/colloid guided by vitals, urine output and haematocrit, ideally **before shock**, with careful titration to avoid overload during recovery reabsorption. **Acetaminophen/paracetamol** for fever; **avoid NSAIDs and aspirin** (gastritis/bleeding). Platelet transfusion is reserved for **severe thrombocytopenia** ($<10,000/\mu\text{L}$) or active bleeding—prophylactic transfusion is not beneficial and may harm. Treat shock, DIC and organ failure in critical care.
- ▶ **Immunomodulation:** Routine corticosteroids/IVIG are **not** proven to alter outcome in severe dengue; targeted anti-cytokine therapy remains investigational. The cytokine-storm/ADE concept underpins **vaccine caution**.
- ▶ **Vaccine relevance of ADE:** CYD-TDV (Dengvaxia), built on the YFV-17D platform, *increased* severe dengue in **seronegative** recipients (vaccine acting as a “first serological hit”), mandating **pre-vaccination serostatus screening**; TAK-003 (Qdenga), a two-dose vaccine, shows benefit including in some seronegatives but with serotype caveats.

High-yield exam pointers

- ▶ Cytokine storm = **immunopathology**, not direct viral cytopathic lysis—peaks at **defervescence/critical phase**, not at peak fever.
- ▶ **Secondary heterotypic infection + ADE + cross-reactive T cells (original antigenic sin)** = core triggers; NS1 degrades glycocalyx and is the named driver of vascular leak.
- ▶ Dominant mediators to write: **TNF- α , IFN- γ , IL-6, IL-1 β , IL-8, IL-10, VEGF, complement C3a/C5a**.
- ▶ Cardinal consequence = **increased vascular permeability** $\rightarrow$ **plasma leak** $\rightarrow$ **haemoconcentration** $\rightarrow$ **DSS**; plus **thrombocytopenia/DIC** $\rightarrow$ **bleeding**.
- ▶ **Severe dengue (WHO 2009)** = plasma leakage (shock/respiratory distress) **or** severe bleeding **or** severe organ dysfunction.
- ▶ Triad to monitor: **rising HCT + falling platelets + warning signs**; effusions are an early leak sign.
- ▶ Treatment = **fluids + paracetamol**; **avoid NSAIDs/aspirin**; platelets only if $<10,000/\mu\text{L}$ or bleeding; **steroids/IVIG unproven**.
- ▶ **~500,000 severe dengue cases/year, CFR ~2.5%** (falls to ~1% with expert supportive care).
- ▶ **Dengvaxia ADE pitfall:** harm in seronegatives $\rightarrow$ screen serostatus before vaccinating.

SOURCE & COVERAGE

- ▶ **Harrison's Principles of Internal Medicine, 22e** — “Arthropod-Borne and Rodent-Borne Virus Infections” (Dengue, Severe Dengue and Viral Haemorrhagic Fever sections: ADE/immune enhancement, enhancing non-neutralising antibodies, NS1-driven vascular leak, plasma-leak/critical phase, severe-dengue criteria, host/viral risk factors, tourniquet test, vaccine ADE).

- ▶ **Harrison's 22e** — “Mechanisms of Regulation and Dysregulation of the Immune System” (general biology of pro-inflammatory cytokines TNF- α , IL-1, IL-6, IFN- γ and the anti-inflammatory IL-10/TGF- β axis underpinning immune dysregulation).
- ▶ **CMDT 2026** — “Viral & Rickettsial Infections” (Dengue: WHO 1997 vs 2009 classification, severe-dengue definition, laboratory monitoring, supportive treatment, NSAID avoidance, platelet-transfusion threshold, prognosis, comorbidity risk, vaccines).
- ▶ **Coverage note (spec gap = true):** The corpus grounds the *triggers* of the storm (ADE, secondary heterotypic infection, NS1-mediated vascular leak, T-cell dysregulation) and the *general* cytokine biology, but does **not** enumerate the dengue-specific cytokine cascade (TNF- α /IFN- γ /IL-6/IL-8/IL-10/VEGF, complement C3a/C5a, mast-cell/glycocalyx mechanisms) or use the phrase “cytokine storm” verbatim for dengue. Those mediator-level specifics are included as **universally accepted standard internal-medicine/infectious-disease teaching** and are flagged here for transparency.

Define and classify extended spectrum β -lactamases, list the risk factors for acquiring ESBL and its implications on antibiotic choice

Asked in: Paper I May 2025 — RGUHS MD General Medicine

Definition / Introduction — β -Lactamases are bacterial enzymes that hydrolyse the four-membered β -lactam ring and thereby inactivate β -lactam antibiotics; they are the commonest mechanism of β -lactam resistance in gram-negative bacteria. **Extended-spectrum β -lactamases (ESBLs)** are plasmid-encoded β -lactamases — usually evolved by point mutations from earlier penicillinases — that have an *expanded substrate profile* enabling them to degrade the oxyimino (third-generation) cephalosporins (ceftriaxone, cefotaxime, ceftazidime) and the monobactam aztreonam, while remaining **susceptible to β -lactamase inhibitors** (clavulanate, sulbactam, tazobactam) and (characteristically) **not** hydrolysing carbapenems or the cephamycins (cefoxitin). They are predominantly found in *Enterobacterales*, chiefly *Escherichia coli* and *Klebsiella pneumoniae*, and are a globally disseminated cause of multidrug-resistant infection.

Where ESBLs sit among β -lactamases — classification

Two complementary schemes are used: the **Ambler molecular classification** (based on amino-acid sequence/active site) and the **Bush–Jacoby functional classification** (based on substrate and inhibitor profile). ESBLs are predominantly **Ambler class A**, **Bush–Jacoby group 2be**.

Ambler class (active site)	Bush–Jacoby group	Enzyme examples	Hydrolyses	Inhibited by clavulanate?
A (serine)	2b / 2be (ESBL) / 2f	Early TEM-1, SHV-1 penicillinases → ESBLs: TEM-, SHV-, CTX-M-types; KPC carbapenemase (2f)	Penicillins, oxyimino-cephalosporins, aztreonam (ESBL); + carbapenems (KPC)	Yes (ESBL); KPC variably
B (metallo-, Zn ²⁺)	3	NDM, VIM, IMP (metallo-carbapenemases)	Penicillins, cephalosporins, carbapenems (not aztreonam)	No (and not avibactam)
C (serine)	1	AmpC (chromosomal in <i>Enterobacter</i> ; also plasmid)	Penicillins, cephalosporins including ceftioxin	No
D (serine)	2d	OXA -type (incl. OXA-ESBLs; OXA-48 carbapenemase)	Oxacillin/cloxacillin; some extended cephalosporins; OXA-48 → carbapenems	Variable / poorly

- ▶ **Phenotypic / practical classification** the candidate must also state: ESBLs are distinguished from the two great mimics — **AmpC cephalosporinases** (class C; not inhibited by clavulanate, *do* hydrolyse ceftioxin) and **carbapenemases** (KPC, NDM, OXA-48; hydrolyse carbapenems) — because the treatment differs sharply.
- ▶ **ESBL families**: the earliest were TEM- and SHV-derived; the now globally **predominant family** is CTX-M (e.g. CTX-M-15), which preferentially hydrolyses cefotaxime/ceftriaxone and drives community-onset ESBL *E. coli*.

Defining hydrolytic profile of ESBLs (substrate “fingerprint”)

- ▶ **Degraded (resistant)**: all penicillins; early- and extended-spectrum cephalosporins — ceftriaxone, cefotaxime, **ceftazidime**; and the monobactam **aztreonam**. Some ESBLs additionally degrade the fourth-generation cephalosporin **cefepime**, making cefepime unreliable.
- ▶ **Usually spared (treatment relevant)**: carbapenems (imipenem, meropenem, ertapenem, doripenem) are *not* degraded by ESBLs; cephamycins (ceftioxin) are also stable but are not used clinically for this.
- ▶ **Inhibited by**: clavulanate, sulbactam, tazobactam (and the newer diazabicyclooctanes avibactam, relebactam) — this *clavulanate susceptibility* is the basis of laboratory confirmation.

- ▶ **Co-resistance:** the ESBL plasmid frequently co-carries genes for **fluoroquinolone and aminoglycoside resistance**, so ESBL isolates are often resistant to ciprofloxacin and gentamicin as well — a key reason the carbapenems become indispensable.

Risk factors for acquiring an ESBL-producing organism

- ▶ **Prior antimicrobial exposure** — especially recent **third-generation cephalosporins and fluoroquinolones** (selection pressure favouring resistant strains); prior antibiotic therapy of any kind.
- ▶ **Prior infection or colonisation with a resistant pathogen**, and being part of a population with a large resistance reservoir.
- ▶ **Prior or prolonged hospitalisation**, particularly **ICU stay**; transfer from or residence in **long-term-care / nursing facilities**.
- ▶ **Invasive devices breaching host barriers** — indwelling **urinary catheters**, central venous/IV catheters, surgical drains, nasogastric and endotracheal tubes — a frequent source of health-care-associated gram-negative infection.
- ▶ **Cross-transmission** in health-care settings via the **contaminated hands of health-care workers** when hand hygiene/infection-control is inadequate.
- ▶ **Other widely accepted host factors:** recurrent or complicated urinary tract infection, recent surgery, haemodialysis, diabetes mellitus, immunosuppression, and **travel to / residence in highly endemic regions** (e.g. the Indian subcontinent for community-acquired CTX-M and for NDM carbapenemases).

Implications on antibiotic choice

- ▶ **Carbapenems are the drugs of choice** for serious ESBL infections (bacteraemia, pyelonephritis, intra-abdominal sepsis): they are *the most reliable agents* against ESBL producers. Use **meropenem/imipenem** for severe disease; **ertapenem** is a useful *carbapenem-sparing* once-daily option for stable, non-pseudomonal ESBL infection (preserves antipseudomonal carbapenems).
- ▶ **Do NOT rely on third-generation cephalosporins** even if the disk reports “susceptible” — there is an inoculum effect and high failure rate; ESBLs hydrolyse them *in vivo*.
- ▶ **β -Lactam/ β -lactamase-inhibitor combinations** (e.g. piperacillin-tazobactam) inhibit ESBLs *in vitro*, but their role in serious/bacteraemic ESBL infection is *debated* and they are generally inferior to carbapenems — reserve, if at all, for source-controlled, lower-acuity infection.
- ▶ **If a carbapenem cannot be used** (allergy, stewardship, carbapenemase co-existence): **ceftazidime-avibactam**, or possibly **ceftolozane-tazobactam** or **imipenem-cilastatin-relebactam** can be considered (avibactam/relebactam additionally cover KPC/AmpC, not metallo-enzymes).
- ▶ **Uncomplicated lower UTI (cystitis):** oral **nitrofurantoin** or **fosfomycin** are effective ESBL-active options that spare carbapenems (avoid in pyelonephritis/bacteraemia).

- ▶ **Fluoroquinolones and aminoglycosides are unreliable empirically** because of frequent plasmid-linked co-resistance — use only if susceptibility is confirmed; amikacin or **plazomicin** may remain active where gentamicin/tobramycin are not.
- ▶ **Salvage / extensively-resistant gram-negatives: cefiderocol** (siderophore cephalosporin) and the polymyxins (colistin) are options for carbapenem-resistant organisms.
- ▶ **Stewardship and empirical strategy:** in patients with ESBL risk factors who are septic, start **empirical carbapenem cover**, then **de-escalate** to the narrowest effective agent for the shortest course once cultures/susceptibilities return; restrict cephalosporin/fluoroquinolone over-use, enforce hand hygiene and contact precautions to limit spread.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Gram-negative cell-envelope schematic** showing the resistance site: outer membrane with porin channel, β -lactamase enzyme in the periplasmic space degrading the β -lactam before it reaches its target, and the inner-membrane **penicillin-binding proteins (PBPs/transpeptidases)**. Labels: *Outer membrane, Porin, Periplasmic space, β -lactamase (ESBL), β -lactam antibiotic, PBP/transpeptidase, Peptidoglycan, Inner (cytoplasmic) membrane, Efflux pump.*
- ▶ **Classification tree** of β -lactamases: β -lactamases $\rightarrow$ Ambler A (ESBL: TEM/SHV/CTX-M, KPC) / B (metallo – NDM, VIM, IMP) / C (AmpC) / D (OXA, OXA-48), with a side box: “ESBL = hydrolyses 3rd-gen cephalosporins + aztreonam; inhibited by clavulanate; spares carbapenems & ceftazidime.”

Clinical / Diagnostic significance

- ▶ **Laboratory detection** rests on the *clavulanate effect*: a **phenotypic confirmatory test** shows a ≥ 3 -doubling-dilution fall in the MIC of cefotaxime or ceftazidime when combined with clavulanate; the **double-disk synergy test** shows enhancement of the cephalosporin inhibition zone towards a co-placed amoxicillin-clavulanate disk. Distinguish from AmpC (no clavulanate synergy, ceftazidime-resistant).
- ▶ **Empirical choice is local-data-driven:** know the unit/hospital ESBL prevalence; obtain cultures **before** antibiotics; communicate rapid susceptibility results promptly to guide directed therapy.
- ▶ **Infection control:** ESBL producers are an *escalating, transmissible* threat (CDC “Serious” category — ESBL-producing *Enterobacterales*); contact precautions, hand hygiene, device removal and antimicrobial stewardship reduce acquisition and spread.
- ▶ **Prognostic impact:** ESBL infection independently delays appropriate therapy, prolongs hospital stay and increases mortality — hence the value of risk-stratified empirical carbapenem cover in the septic at-risk patient.

High-yield exam pointers

- ▶ **ESBL** = plasmid-mediated, Ambler class A / Bush–Jacoby 2be, clavulanate-inhibited enzyme that hydrolyses oxyimino-cephalosporins + aztreonam but spares carbapenems and ceftazidime.
- ▶ Commonest hosts: *E. coli* and *K. pneumoniae* (and other *Enterobacteriales*); dominant family now CTX-M (CTX-M-15).
- ▶ **Three mimics to separate**: ESBL (class A, clavulanate-sensitive), **AmpC** (class C, clavulanate-resistant, ceftazidime-resistant), **carbapenemase** (KPC/NDM/OXA-48).
- ▶ **Top risk factors**: prior cephalosporin/fluoroquinolone use, prior hospitalisation/ICU, long-term-care residence, indwelling catheters/devices, prior resistant-organism colonisation, endemic-area exposure.
- ▶ **Treatment of choice** = carbapenem (ertapenem for carbapenem-sparing; meropenem for severe); do not use cephalosporins despite “S” on the report.
- ▶ **Carbapenem-sparing alternatives**: ceftazidime-avibactam, ceftolozane-tazobactam, imipenem-relebactam; cystitis → nitrofurantoin/fosfomycin.
- ▶ **Co-resistance** to fluoroquinolones and aminoglycosides is common → narrows empirical options.
- ▶ **Detection**: double-disk synergy / clavulanate MIC reduction test.
- ▶ **Control**: stewardship + de-escalation + hand hygiene/contact precautions.

SOURCE & COVERAGE

- ▶ **Harrison’s Principles of Internal Medicine, 22e** — “Bacterial Resistance to Antimicrobial Agents” (β -lactamases, ESBL substrate profile, AmpC vs ESBL, carbapenemases KPC/NDM/OXA-48, β -lactamase inhibitors, ceftazidime; risk factors and epidemiology of resistance; CDC threat categories) and “Treatment and Prophylaxis of Bacterial Infections” (β -lactam mechanism, empirical vs directed therapy, antimicrobial stewardship).
- ▶ **CMDT 2026** — “Common Problems in Infectious Diseases & Antimicrobial Therapy” (ESBL → carbapenem; ceftazidime-avibactam / ceftolozane-tazobactam / imipenem-relebactam alternatives; ESBL *E. coli* co-resistant to cephalosporins, aminoglycosides, fluoroquinolones) and “Anti-infective Treatment: Antibiotic, Antifungal & Antiviral Agents” (carbapenems most reliable for ESBL; extended-spectrum penicillins; fosfomycin for UTI).

Coverage note: The Harrison/CMDT corpus describes ESBLs, AmpC, carbapenemases, the inhibitors and the management hierarchy in full, and supplies the risk-factor set (prior antibiotics, prior hospitalisation, prior resistant infection, invasive devices, cross-transmission). The **formal scheme names** (Ambler classes A–D; Bush–Jacoby group 2be), the **enzyme-family names** (TEM/SHV/CTX-M), and the **phenotypic confirmatory/double-disk synergy test** are universally

accepted standard infectious-disease microbiology added for completeness, though not spelled out verbatim in this Harrison/CMDT corpus; all such points are stated accurately.

Define shock. Discuss the pathophysiology and management of Septic shock

Asked in: Paper I Nov 2022 — RGUHS MD General Medicine

Definition / Introduction — Shock is the clinical condition of organ dysfunction resulting from an imbalance between cellular oxygen supply and demand, producing cellular and tissue hypoxia; it is a life-threatening state and a common reason for ICU admission. Organ dysfunction in early shock is often reversible with restoration of oxygen delivery, but untreated shock transitions to an irreversible phase with multisystem organ failure and death. **Septic shock** is the commonest cause of distributive shock and is defined (Sepsis-3, 2016) as the subset of sepsis in which profound circulatory, cellular, and metabolic abnormalities increase mortality risk beyond sepsis alone — operationally, a septic patient requiring vasopressors to maintain MAP ≥ 65 mmHg and with serum lactate > 2 mmol/L despite adequate fluid resuscitation.

Determinants of oxygen delivery and classification of shock

- ▶ Oxygen delivery: $DO_2 = CO \times CaO_2$, where $CO = HR \times SV$ and $CaO_2 = (Hb \times 1.34 \times SaO_2) + (PaO_2 \times 0.003)$; stroke volume $SV \propto (Preload \times Contractility) / SVR$.
- ▶ Any disturbance of HR, preload, contractility, SVR, SaO_2 or haemoglobin can reduce DO_2 and cause shock. Shock can also arise from increased consumption or impaired utilisation (e.g., cyanide poisoning uncouples oxidative phosphorylation).
- ▶ Four major physiologic types, each with a distinct haemodynamic profile:

Type	Primary derangement	CVP	PCWP	Cardiac output	SVR	Examples
Distributive	↓ SVR (vasodilation)	↓	↓	↑	↓	Septic shock, pancreatitis, severe burns, anaphylaxis, neurogenic, adrenal crisis
Cardiogenic	↓ CO (pump failure)	↑	↑	↓	↑	MI, myocarditis, arrhythmia, acute valvular failure

Type	Primary derangement	CVP	PCWP	Cardiac output	SVR	Examples
Obstructive	↓ CO (mechanical obstruction)	↑	↓/↑	↓	↑	Tension pneumothorax, tamponade, massive PE, aortic dissection
Hypovolemic	↓ preload	↓	↓	↓	↑	Haemorrhage (trauma, GI bleed), GI/renal/skin fluid losses

- ▶ **Mixed shock** is common: e.g., distributive septic shock with superimposed sepsis-induced cardiomyopathy adds a cardiogenic component. **Sepsis is the most common cause of distributive shock** and predominates in the ICU.

Stages of shock

- ▶ **Compensated (pre-shock)**: physiologic responses (tachycardia, rising CO in early sepsis; ↑SVR and ↑HR in haemorrhage) maintain perfusion; no overt organ dysfunction, perhaps mild lactate or creatinine rise.
- ▶ **Decompensated shock**: compensatory mechanisms overwhelmed → frank organ dysfunction (encephalopathy, oliguria). Still reversible with timely restoration of perfusion.
- ▶ **Irreversible shock**: permanent organ damage progressing to multisystem organ dysfunction and death.

Pathophysiology of septic shock

- ▶ **Trigger**: Pathogen-associated molecular patterns (PAMPs) — bacterial LPS, cell-wall components, pathogen nucleic acids — and host **damage-associated molecular patterns (DAMPs)** — histones, HMGB1, S100 proteins, extracellular DNA, ATP — are sensed by **pattern recognition receptors (PRRs)**: toll-like receptors (TLRs), C-type lectin receptors, RAGE, RIG-I-like and NOD-like receptors.
- ▶ **Dysregulated host response**: PRR activation on neutrophils, monocytes and macrophages triggers release of **pro-inflammatory cytokines/chemokines** (IL-1 β , IL-6, TNF- α), up-regulates vascular adhesion molecules and drives **emergency granulopoiesis**. Neutrophils release **neutrophil extracellular traps (NETs)**. Concurrent lymphoid exhaustion/apoptosis and myeloid-derived suppressor cells cause **immunosuppression**, predisposing survivors to secondary infection.

- ▶ **Endothelial activation:** breakdown of the endothelial **glycocalyx**, ↑ICAM/VCAM-1 expression, loss of VE-cadherin and tight junctions, and endothelial apoptosis cause **capillary leak**, interstitial oedema and increased oxygen-diffusion distance.
- ▶ **Coagulopathy:** ↑tissue factor triggers the extrinsic cascade; vWF and platelet aggregates plus NETs form **fibrin-rich microthrombi**. Anticoagulants (antithrombin, tissue factor pathway inhibitor, activated protein C) are depleted and fibrinolysis is impaired (↑PAI-1) → microvascular thrombosis; consumption of factors and platelets causes **DIC** and bleeding. The complement cascade is activated (C3a, C5a anaphylatoxins; **C5b-9 membrane attack complex**) amplifying injury.
- ▶ **Circulatory failure:** systemic **arteriolar vasodilation** (partly excess **nitric oxide**) lowers SVR; venodilation and capillary leak reduce venous return and preload; hypotension results. Up to half of patients develop **sepsis-induced cardiomyopathy** (↓LVEF, ↑end-diastolic volume index, RV impairment).
- ▶ **Cellular injury:** inadequate oxygen delivery plus direct injury from ROS/reactive nitrogen species and **mitochondrial/metabolic dysfunction** (cytopathic hypoxia) impair ATP generation and ion homeostasis even when oxygen delivery is restored → multiorgan injury. Anaerobic metabolism converts pyruvate to **lactate** (lactic acidosis), the biochemical hallmark.

Recognition and diagnostic criteria

- ▶ **Sepsis-3 (current):** sepsis = **life-threatening organ dysfunction from a dysregulated host response to infection**, operationalised as a rise of ≥ 2 in **SOFA score**. SOFA scores six systems — neurologic (GCS), cardiovascular (MAP/vasopressors), respiratory ($\text{PaO}_2/\text{FiO}_2$), hepatic (bilirubin), renal (creatinine), coagulation (platelets).
- ▶ **Septic shock:** vasopressor requirement to keep **MAP ≥ 65 mmHg** plus **lactate > 2 mmol/L** despite fluid resuscitation; mortality up to **40%**.
- ▶ **qSOFA** (rapid bedside screen): RR $\geq 22/\text{min}$, altered mentation (GCS < 15), SBP ≤ 100 mmHg — score ≥ 2 (with suspected infection) flags high mortality risk; more specific but less sensitive than SIRS.
- ▶ **Historical:** SIRS criteria (temp $< 36/ > 38$ °C, HR > 90 , RR > 20 or $\text{PaCO}_2 < 32$, WBC $< 4000/ > 12000$ or $> 10\%$ bands); Sepsis-1 (1992), Sepsis-2 (2003) preceded Sepsis-3.
- ▶ Initial workup: CBC with differential, basic metabolic panel, LFTs, **serum lactate**, coagulation panel, urinalysis; **cultures of blood and other sites before antibiotics**; targeted imaging (X-ray/CT/USG) for source. Exclude **sepsis mimics** (heart failure, mesenteric ischaemia, adrenal insufficiency, hypovolaemia) — ~25% of presumed sepsis are mimics.

Management of septic shock (Surviving Sepsis Campaign 2021)

- ▶ **Early antibiotics — most important survival lever:** immediate empiric **broad-spectrum antimicrobials within 1 h of shock recognition** (after cultures, but do not delay for them). Every

1-h delay adds an estimated 7–8% **mortality**. De-escalate on culture data; practise stewardship and short courses.

- Site-directed empiric choices: **ceftriaxone/cefotaxime** if *Pseudomonas* unlikely; **cefepime, piperacillin-tazobactam, or a carbapenem (meropenem/imipenem)** if *Pseudomonas* likely; add **vancomycin or linezolid** for MRSA risk; **echinocandin** if fungal risk (recent abdominal surgery, TPN, *Candida* colonisation).
- ▶ **Fluid resuscitation: balanced crystalloid (lactated Ringer's)** preferred over 0.9% saline; initial bolus ~30 mL/kg over 5–10 min. Albumin if large crystalloid volumes already given; **avoid hydroxyethyl/pentastarch** (kidney injury, death). Guide further fluids by **dynamic measures** (capillary refill time, passive leg raise, point-of-care ultrasound/IVC, SV variation) — *not* static CVP-targeted protocols.
- ▶ **Vasopressors: Norepinephrine is first-line** (α_1 vasoconstriction + β_1 inotropy/chronotropy) to target MAP ≥ 65 mmHg; add **vasopressin as second agent**, then **epinephrine third**. Place an arterial line for continuous BP. **Dopamine is not first-line** (arrhythmia; increased mortality in cardiogenic subgroup).
- ▶ **Corticosteroids: IV hydrocortisone 200 mg/day (50 mg q6h)** for ongoing vasopressor requirement.
- ▶ **Inotropy:** for sepsis-induced cardiomyopathy with persistent hypoperfusion after volume, **add dobutamine to norepinephrine or switch to epinephrine**; pulmonary artery catheter only for mixed septic + cardiogenic shock.
- ▶ **Source control:** drain abscesses, debride necrotising soft-tissue infection, decompress obstructed biliary/urinary tract, remove infected catheters — **as rapidly as possible**.
- ▶ **Organ support:** lung-protective ventilation (tidal volume 6–8 mL/kg ideal body weight, plateau pressure <30 cmH₂O, SpO₂ 90–96%; rescue with prone positioning, neuromuscular blockade, VV-ECMO); RRT for standard indications (refractory acidemia, hyperkalemia, uraemia, volume overload); transfuse PRBC for Hb <7 g/dL; insulin for glucose >180 mg/dL; stress-ulcer prophylaxis and early enteral nutrition (within 48 h) once shock is controlled.

Organ-specific complications and supportive targets

System	Frequency	Key management
Neurologic (encephalopathy)	~54%	Treat cause; correct metabolic/electrolyte derangements; limit neurotoxic sedatives (<i>cefepime, opioids, benzodiazepines</i>)
Cardiovascular (shock)	~25% (half with myocardial dysfunction)	Balanced crystalloid; norepinephrine → vasopressin →

System	Frequency	Key management
		epinephrine; hydrocortisone; dobutamine for low LVEF
Respiratory (ARDS)	~7%	SpO ₂ 90–96%; lung-protective ventilation; rescue therapies for refractory hypoxia
Renal (AKI)	up to ~67%	Maintain perfusion, avoid nephrotoxins; RRT/CRRT for standard indications
Hepatic (liver dysfunction)	~50% of septic shock	Avoid hypotension/hepatotoxins; USG if ↑bilirubin
Haematologic (DIC)	up to ~35% of septic shock	Cryoprecipitate (fibrinogen <150 mg/dL), platelets ($\leq 50 \times 10^9/L$ + bleeding), FFP for bleeding with prolonged PT/INR

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Oxygen-delivery / shock cascade flowchart:** Label — $DO_2 = CO \times CaO_2$; $CO = HR \times SV$; $SV \propto (Preload \times Contractility)/SVR$; $CaO_2 = (Hb \times 1.34 \times SaO_2) + (0.003 \times PaO_2)$; branch to the four shock types (Distributive / Cardiogenic / Obstructive / Hypovolemic); endpoint *anaerobic metabolism* → ↑lactate → cellular injury.
- ▶ **Septic-shock pathogenesis schematic:** Label — *Pathogen* → PAMPs/DAMPs → PRRs (TLR); Cytokines (IL-1 β , IL-6, TNF- α); Neutrophil + NETs; Endothelial activation → glycocalyx breakdown → capillary leak/oedema; Tissue factor → microthrombi → DIC; Complement C3a/C5a, C5b-9 (MAC); NO-mediated vasodilation → ↓SVR → hypotension; Mitochondrial dysfunction → tissue hypoxia.

Clinical / Diagnostic significance

- ▶ **Lactate** is central to diagnosis, risk stratification and monitoring; serial lactate (or capillary-refill-guided) resuscitation tracks response, though a major trial found capillary-refill-targeted resuscitation non-inferior to lactate-targeted for 28-day mortality.
- ▶ **Shock index** (HR/SBP; normal 0.5–0.7, abnormal >0.9) flags occult hypoperfusion and transfusion need.
- ▶ “**Windows**” of organ perfusion — CNS (confusion), kidney (oliguria <0.5 mL/kg/h), skin (mottling, prolonged capillary refill, cold clammy skin) — allow bedside recognition before labs return.
- ▶ POCUS/echocardiography differentiates shock type and detects sepsis-induced cardiomyopathy and mixed shock.

- ▶ Restrictive vs liberal fluid strategy and routine low-dose vasopressin-plus-norepinephrine showed no 90-day/28-day mortality difference — argues against rigid protocols.

High-yield exam pointers

- ▶ **Shock = supply–demand O₂ imbalance** → tissue hypoxia, reversible early, irreversible late.
- ▶ Four types by haemodynamics: **Distributive** (↓SVR, ↑CO) vs the three low-CO types (↑SVR); memorise the CVP/PCWP/CO/SVR table.
- ▶ **Septic shock = sepsis + vasopressor need for MAP ≥65 + lactate >2 despite fluids**; mortality up to 40%.
- ▶ Pathogenesis triad: **PAMPs/DAMPs–PRR inflammation** → **endothelial/glycocalyx injury & capillary leak** → **coagulopathy/microthrombi (DIC)**, plus NO-driven vasodilation and mitochondrial dysfunction.
- ▶ **Antibiotics within 1 h** of shock recognition — 7–8% added mortality per hour's delay.
- ▶ **Crystalloid (balanced) ~30 mL/kg**; guide further fluids by dynamic, not static (CVP), measures; avoid starches.
- ▶ Vasopressor ladder: **norepinephrine** → **vasopressin** → **epinephrine**; **hydrocortisone 200 mg/day** for refractory shock; **dobutamine/epinephrine** for sepsis-induced cardiomyopathy.
- ▶ Don't forget **source control and culture before antibiotics**.

Coverage note: All major specifics (hemodynamic profiles, Sepsis-3/qSOFA/SOFA criteria, drug doses, fluid volumes, complication frequencies) are sourced from these two chapters; the Sepsis-1 SIRS/Sepsis-2 historical criteria and shock-index cut-offs are also taken verbatim from Ch 314/315.

Definition of multidrug-resistant tuberculosis (MDR-TB) and molecular drug-susceptibility testing in its diagnosis

Asked in: Paper II 08 Apr 2026 — RGUHS MD General Medicine

Definition / Introduction — **Multidrug-resistant tuberculosis (MDR-TB)** is disease caused by *Mycobacterium tuberculosis* bacilli that are resistant at least to **isoniazid and rifampin**, the two most potent bactericidal first-line agents. Because rifampin resistance rarely occurs alone and is an excellent surrogate marker for MDR-TB, the WHO programmatically groups MDR-TB with rifampin-resistant

TB (MDR/RR-TB). **Molecular drug-susceptibility testing (mDST)** refers to nucleic-acid–based assays that detect *M. tuberculosis* and resistance-conferring mutations directly and rapidly (hours to days), and is now the WHO-recommended first-line approach to confirm both TB and drug resistance. An estimated 400,000 MDR/RR-TB cases occurred in 2023 (India accounting for ~27%), making rapid detection a priority.

Definitions: spectrum of drug-resistant TB (WHO 2021)

- **Drug-resistant TB** arises from spontaneous point mutations in the mycobacterial genome (rates 10^{-7} – 10^{-10} per drug) selected out by inadequate/monotherapy; it may be **primary** (infection with an already-resistant strain) or **acquired** (resistance developing during treatment).

Category	Definition
Mono-resistant TB	Resistance to one first-line drug only
Poly-resistant TB	Resistance to >1 first-line drug, but <i>not</i> both isoniazid + rifampin
Rifampin-resistant TB (RR-TB)	Resistance to rifampin (with or without resistance to other drugs); managed as MDR-TB
Multidrug-resistant TB (MDR-TB)	Resistance to at least isoniazid AND rifampin
Pre-XDR-TB	MDR/RR-TB that is also resistant to any fluoroquinolone
Extensively drug-resistant TB (XDR-TB)	MDR/RR-TB with resistance to any fluoroquinolone PLUS at least one other Group A drug (i.e., bedaquiline and/or linezolid)

- *Group A drugs* = levofloxacin/moxifloxacin, bedaquiline, linezolid — the backbone of modern oral MDR-TB regimens; resistance to these defines the most severe phenotypes.

Rationale for molecular DST — why it replaces phenotypic testing

- **Universal DST** to at least rifampin on every initial isolate is the WHO standard of care; **rifampin resistance is an excellent proxy for MDR-TB**, triggering expanded testing for isoniazid, fluoroquinolones and other second-line drugs.
- **Phenotypic (culture-based) DST is slow**: liquid (MGIT) DST needs ~1–2 weeks *after* growth (growth itself takes 1–3 weeks); solid-medium DST may take ≥8 weeks — too slow to guide initial therapy and to interrupt transmission of resistant strains.
- **Molecular DST is rapid and decentralisable**: detects resistance mutations directly from sputum in hours–days, needs minimal biosafety/training, and detects resistance even in smear-negative/paucibacillary specimens.
- **Placement by health-care level**: at the *peripheral/community* level — screening and referral; at the *district (secondary)* level — automated real-time NAAT (Xpert MTB/RIF, which also reports

rifampin resistance) replacing smear microscopy; at the *tertiary* level — molecular tests, rapid liquid culture and full DST. Truenat's portability extends molecular testing to peripheral microscopy centres.

Genotypic basis — resistance genes targeted by molecular DST

- ▶ Molecular assays interrogate the gene regions where resistance mutations cluster:

Drug	Principal resistance gene(s)	Approx. share of resistance
Rifampin	<i>rpoB</i> (β -subunit of RNA polymerase)	~95%
Isoniazid	<i>katG</i> (catalase-peroxidase)	50–95%
	<i>inhA</i> promoter (low-level)	up to 45%
Pyrazinamide	<i>pncA</i>	up to 98%
Ethambutol	<i>embB</i>	50–65%
Fluoroquinolones	<i>gyrA</i> / <i>gyrB</i> (DNA gyrase)	75–95%
Aminoglycosides	<i>rrs</i> (16S rRNA); <i>eis</i> promoter (C-12T)	up to 80%

- ▶ The ~95% concordance of *rpoB* mutations with rifampin resistance is the molecular basis for using rifampin resistance as the diagnostic gateway to MDR-TB.

Molecular tests used to diagnose MDR-TB

- ▶ **Xpert MTB/RIF assay** — fully automated, cartridge-based real-time **nucleic-acid amplification test (NAAT)** on the GeneXpert platform; simultaneously detects *M. tuberculosis* and rifampin resistance (*rpoB*) in <2 hours. WHO-recommended **first-line diagnostic test for all adults and children** with suspected TB, including PLWH and for CSF in suspected TB meningitis.
 - Pulmonary TB: overall sensitivity ~85% (98% in smear-positive, ~70% in smear-negative); specificity 98%.
 - For rifampin resistance vs phenotypic DST: sensitivity 96%, specificity 98%.
- ▶ **Xpert MTB/RIF Ultra** — same GeneXpert platform, greater sensitivity (~90% including “trace calls”); largest gains in smear-negative/culture-positive cases (+17%) and PLWH (+12%). Rifampin-resistance sensitivity 94%, specificity 99%.
- ▶ **Truenat MTB / MTB Plus** (chip-based, portable, battery-operated; usable at peripheral level) — sensitivities 73% and 80%; **Truenat MTB-Rif Dx** detects rifampin resistance (sensitivity 84%, specificity 97%).

- ▶ **Line probe assays (LPAs)** — DNA strip tests; after DNA extraction, PCR amplification of resistance-gene regions, then **labelled, probe-hybridised products detected by colorimetric development**.
 - *First-line LPA* — detects **isoniazid (katG, inhA) and rifampin (rpoB)** resistance in smear-positive specimens/culture isolates.
 - *Second-line LPA* — WHO-recommended initial test for **fluoroquinolone and second-line injectable** resistance in confirmed RR-/MDR-TB.
- ▶ **Whole-genome sequencing (WGS) / targeted next-generation sequencing (tNGS)** — comprehensive detection of resistance mutations; **tNGS is WHO-recommended** for comprehensive DST directly after diagnosis (still needs phenotypic confirmation for some new/repurposed drugs).
- ▶ **Other platforms** — high-throughput centralised assays (Abbott RealTime MTB & RIF/INH, FluoroType MTBDR, BD Max MDR-TB, cobas MTB-RIF/INH; sensitivity >91%, specificity 97–100%) and TB-LAMP (loop-mediated isothermal amplification — a replacement for smear microscopy but does **not** detect rifampin resistance).

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Diagnostic algorithm (flow chart):** *Presumptive TB* → Xpert MTB/RIF or Ultra (initial NAAT) → branch ① *RIF-sensitive* → standard first-line regimen; branch ② *RIF-resistant* → treat as MDR/RR-TB + send **first-line LPA (INH) and second-line LPA (fluoroquinolone/injectable)** + liquid culture + phenotypic DST → classify as **MDR / pre-XDR / XDR** → design appropriate regimen (e.g., BPaLM). Label boxes: *Sputum, NAAT, rpoB, katG/inhA, gyrA, MGIT culture, phenotypic DST*.
- ▶ **Resistance-gene map of *M. tuberculosis*:** bacillus with labelled gene–drug pairs — *rpoB*→rifampin, *katG/inhA*→isoniazid, *pncA*→pyrazinamide, *embB*→ethambutol, *gyrA/gyrB*→fluoroquinolones, *rrs/eis*→aminoglycosides.

Clinical / Diagnostic significance

- ▶ **Speed changes outcomes:** a same-day rifampin-resistance result lets clinicians start an effective MDR regimen immediately, averting amplification of resistance, treatment failure and ongoing transmission.
- ▶ **MDR-TB is suspected** in treatment failure (smear/culture still positive at ≥3 months), relapse after treatment interruption, contacts of known MDR cases, and patients from high-MDR settings — all warrant urgent molecular DST.
- ▶ A **positive Xpert/Ultra** in an appropriate setting justifies starting therapy; a **negative result does not exclude TB** — culture remains the gold standard and “trace calls” must be interpreted by context (treated as true-positive in PLWH, children and extrapulmonary specimens).

- ▶ mDST guides regimen choice: confirmed MDR/RR-TB (and pre-XDR) in patients ≥ 14 years is now treated with the 6-month all-oral **BPaLM** (bedaquiline–pretomanid–linezolid–moxifloxacin) regimen, with fluoroquinolone DST deciding whether moxifloxacin is retained.
- ▶ mDST does **not** replace phenotypic culture-based DST for monitoring emergence of additional resistance and for drugs not yet reliably covered by molecular tests; NAAT is **not** suitable for monitoring treatment response (detects non-viable bacilli).
- ▶ **Extrapulmonary MDR-TB**: Xpert/Ultra is the preferred initial test on CSF (suspected TB meningitis) and on selected non-respiratory specimens (lymph-node, pleural, synovial, gastric-lavage, fine-needle aspirates), simultaneously yielding the rifampin-resistance result that would otherwise be unobtainable from paucibacillary samples.
- ▶ **Pyrazinamide and second-line resistance** in MDR/RR-TB can be assessed by reverse-hybridisation LPA and by tNGS, refining whether a shorter all-oral regimen is feasible or a longer individualised regimen is required.

High-yield exam pointers

- ▶ MDR-TB = resistance to at least isoniazid + rifampin. RR-TB is managed as MDR-TB.
- ▶ Pre-XDR = MDR/RR + fluoroquinolone resistance; XDR = MDR/RR + fluoroquinolone + a Group A drug (bedaquiline/linezolid) — WHO 2021 definitions.
- ▶ Xpert MTB/RIF detects TB + rifampin resistance (*rpoB*) in <2 hours — WHO first-line initial test; RIF-resistance sensitivity 96%, specificity 98%.
- ▶ Xpert Ultra is more sensitive (especially smear-negative & PLWH); Truenat is portable/battery-operated for peripheral settings.
- ▶ *rpoB* = rifampin; *katG/inhA* = isoniazid; *gyrA/gyrB* = fluoroquinolones; *rrs* = aminoglycosides; *pncA* = pyrazinamide; *embB* = ethambutol.
- ▶ First-line LPA → INH + RIF; second-line LPA → fluoroquinolones + injectables; tNGS → comprehensive DST.
- ▶ Rifampin resistance is the proxy/gateway for MDR-TB; ~95% of RIF resistance is due to *rpoB* mutation.
- ▶ Molecular DST (hours–days) is far faster than phenotypic DST (weeks), enabling early effective therapy.

SOURCE & COVERAGE

- ▶ Harrison's Principles of Internal Medicine, 22e — "Tuberculosis" (definitions of MDR/RR/pre-XDR/XDR-TB, nucleic-acid amplification technology — Xpert MTB/RIF, Xpert Ultra, Truenat, line probe assays, WGS/tNGS, drug-susceptibility testing, resistance-gene targets) and "Antimycobacterial Agents" (*rpoB* / *gyrA*–*gyrB* resistance mechanisms).

- ▶ CDMT 2026 — “Pulmonary Disorders” (essential laboratory tests for *M. tuberculosis*: NAAT-TB and NAAT-R [resistance markers] performance, culture/phenotypic DST timing and characteristics).

Dengue fever with complications

Asked in: Paper II Dec 2023 — RGUHS MD General Medicine

Definition / Introduction — Dengue is an acute arboviral infection caused by any of four dengue viruses, DENV-1-4, transmitted predominantly by *Aedes aegypti* and, less efficiently, *Aedes albopictus*. Clinical disease ranges from asymptomatic infection or classical “break-bone fever” to **severe dengue**, formerly called dengue hemorrhagic fever/dengue shock syndrome. Complicated dengue is defined clinically by **plasma leakage causing shock or respiratory distress, severe bleeding, or severe organ dysfunction**.

Etiology, transmission and pathogenesis

- ▶ Dengue viruses are **flaviviruses** with four antigenically distinct serotypes; infection with one serotype gives durable homologous protection but not reliable long-term protection against the other serotypes.
- ▶ Transmission is mainly **human-mosquito-human**. The vector breeds close to human habitation in relatively fresh water in jars, vases, discarded containers, coconut husks, old tires and similar collections; biting is typically daytime.
- ▶ Rare non-vector routes include needlestick or mucocutaneous healthcare exposure, vertical transmission, blood products, bone marrow transplantation and solid-organ transplantation.
- ▶ Most primary infections are subclinical. Symptomatic patients develop a **febrile phase**, a possible **critical/plasma-leak phase** around defervescence, and a **recovery phase**.
- ▶ Severe disease is promoted by host and viral factors, especially **immune-mediated enhancement** during heterotypic reinfection. Severe dengue is associated with vascular permeability; Harrison notes a key role for **DENV NS1 protein** in the vascular-leak phenomenon.
- ▶ Risk is higher with secondary infection, some viral variants such as Southeast Asian DENV-2, serotype 2 disease in CDMT, diabetes/obesity, older age and comorbid cardiovascular, pulmonary, renal or cerebrovascular disease.

Clinical phases and warning signs

Phase	Usual timing and features	Exam emphasis
Febrile phase	Incubation is about 4-7 days in Harrison and usually 7-10 days in	May show facial flushing, conjunctival redness, pharyngeal

Phase	Usual timing and features	Exam emphasis
	CMDT. Abrupt high fever, chills, frontal headache, retro-orbital pain, severe myalgia/back pain, arthralgia, anorexia, nausea/vomiting and cutaneous hyperesthesia.	erythema, lymphadenopathy, hepatomegaly, transient macular rash, epistaxis or petechiae.
Critical phase	Often as fever declines, typically around days 3-5; only a subset enters this phase.	Look actively for plasma leak, hemoconcentration, falling platelets, narrow pulse pressure, restlessness, lethargy and shock.
Recovery phase	Reabsorption of extravascular fluid as leak resolves; BP improves and diuresis occurs.	Reduce fluids to avoid overload; patchy pruritic erythematous rash and desquamation may occur; fatigue/depression may persist.

- **Warning signs requiring admission/close observation:** severe abdominal pain, persistent vomiting, clinical fluid accumulation/serosal effusion, mucosal or GI bleeding, lethargy or restlessness, increasing liver size/hepatomegaly, rising hematocrit with thrombocytopenia, postural symptoms or narrowing pulse pressure.
- **Classical uncomplicated dengue** may show a saddle-back fever, trunk-to-extremity maculopapular rash near defervescence, scattered petechiae and a positive tourniquet test.
- **Tourniquet test:** 10 or more new petechiae in 1 square inch after 5 minutes of BP cuff inflation midway between systolic and diastolic pressure suggests microvascular fragility; it is more associated with severe dengue but is not by itself a marker of major bleeding.

Classification and complications

WHO-style category	Key clinical meaning	Typical action
Dengue without warning signs	Fever with dengue symptoms, no leak/bleeding/organ-risk features.	Outpatient care only if reliable hydration, follow-up and warning-sign education are assured.
Dengue with warning signs	Dengue plus warning signs suggesting impending critical phase.	Admit/observe; serial vitals, urine output, hematocrit, platelets and clinical fluid status.
Severe dengue	Presumptive or confirmed dengue plus severe plasma leakage causing shock/respiratory distress, severe bleeding, or severe organ dysfunction.	Emergency triage, monitored setting/ICU, judicious IV fluids, blood products if bleeding, organ support.

- ▶ **Vascular leak/shock:** intravascular volume depletion, hypoalbuminemia, pleural effusion, ascites, narrow pulse pressure, cyanosis, hypothermia, altered consciousness, metabolic acidosis and circulatory collapse. Shock usually lasts **2-3 days** if treated through the critical period.
- ▶ **Bleeding:** petechiae, ecchymoses, epistaxis, palatal/gingival bleeding, GI bleeding and severe hemorrhage; DIC may complicate shock and progressive organ impairment.
- ▶ **Organ dysfunction:** hepatitis and fulminant hepatitis, encephalitis or altered mental status/seizures, myocarditis/arrhythmias, acute kidney injury, ocular disease including iritis, retinal hemorrhage and maculopathy.
- ▶ **Other complications:** pneumonia, bone marrow failure, bacterial superinfection, orchitis, oophoritis, oral bleeding/gingivitis, phrenic neuropathy, Guillain-Barre syndrome, transverse myelitis, cerebral vasculitis, subdural hematoma and acute disseminated encephalomyelitis.
- ▶ **Pregnancy:** infection near term risks hemorrhage in mother and infant; severe dengue increases obstetric complications, cesarean delivery, fetal distress and maternal morbidity.

Investigations and diagnosis

- ▶ Diagnosis is clinical in an epidemic/endemic setting but should be **laboratory confirmed** because dengue mimics malaria, influenza, chikungunya, leptospirosis, scrub typhus, typhoid, rickettsial infections, meningococcemia, Zika, yellow fever and other viral hemorrhagic fevers.
- ▶ **Early illness, first 5 days:** dengue RT-PCR/nucleic acid amplification or **NS1 antigen** detection by ELISA/rapid test. Harrison emphasizes antigen detection and nucleic acid amplification early.
- ▶ **After febrile phase/recovery:** IgM ELISA, paired serology or seroconversion. Early, rapidly rising **IgG from about day 4** suggests secondary infection rather than primary infection.
- ▶ Interpret serology cautiously because flavivirus cross-reactivity occurs after infection with or vaccination for antigenically related viruses such as yellow fever, Zika and Japanese encephalitis.
- ▶ Baseline and serial tests: CBC with hematocrit and platelet count, AST/ALT, bilirubin if jaundice, albumin, electrolytes, urea/creatinine, glucose, PT/INR/aPTT and fibrinogen if bleeding/DIC is suspected, ABG/lactate in shock, urinalysis and pregnancy test where relevant.
- ▶ Bedside severity assessment: pulse pressure, postural BP, capillary refill, temperature, mental status, urine output, hepatomegaly and bleeding. Ultrasound or lateral decubitus CXR can detect pleural effusion/ascites before they are clinically obvious.

Management of dengue with complications

- ▶ There is **no proven specific antiviral therapy** for dengue. Chloroquine, statins and balapiravir have not shown clear benefit; management is supportive and time-critical.
- ▶ **Triage** every suspected case for warning signs and severe dengue. Admit patients with warning signs, comorbid illness, pregnancy, poor oral intake, bleeding, rising hematocrit, rapidly falling platelets or unreliable follow-up. Severe dengue needs monitored care/ICU.

- ▶ **Fever and pain:** use acetaminophen/paracetamol. Avoid aspirin and preferably avoid NSAIDs such as ibuprofen because of gastritis, platelet dysfunction and bleeding risk.
- ▶ **Fluids:** encourage oral fluids when stable; give early IV isotonic crystalloid when warning signs, hemoconcentration, poor intake or shock are present. Titrate to pulse pressure, BP, capillary refill, mental status, urine output, hematocrit trend, bleeding and signs of fluid overload.
- ▶ **Shock:** treat as plasma-leak hypovolemia. Restore intravascular volume promptly but avoid blind over-resuscitation. If shock persists after appropriate volume replacement, use blood products for hemorrhage and vasopressors for ongoing circulatory failure in monitored care.
- ▶ **Bleeding and thrombocytopenia:** platelet count alone does not predict clinically important bleeding. Consider platelet transfusion for active bleeding or severe thrombocytopenia $<10,000/\text{mcL}$; routine prophylactic platelet transfusion in non-bleeding dengue is not useful and may delay platelet recovery.
- ▶ **Recovery phase:** as vascular leak resolves, effusions are reabsorbed and diuresis begins. Reduce or stop IV fluids promptly to prevent pulmonary edema and respiratory distress.
- ▶ Provide organ-specific support: oxygen/ventilation for respiratory distress or ARDS, renal monitoring and dialysis if AKI is severe, correction of hypoglycemia/electrolytes/acidosis, management of encephalitis/seizures, and treatment of bacterial superinfection when clinically suspected.

Prevention and prognosis

- ▶ Prevention depends on **Aedes control**: remove stagnant water and discarded containers, cover water storage, use larvicidal/public-health measures, window screening, long sleeves, repellents and long-lasting insecticides. Emphasize early morning and late afternoon exposure risk.
- ▶ Screen blood transfusions for dengue in endemic settings where feasible; defer donation by acutely febrile or recently infected persons.
- ▶ **Vaccines:** Dengvaxia/CYD-TDV is a live attenuated tetravalent vaccine whose use is limited to persons with prior dengue infection because seronegative vaccinees have increased risk of severe dengue at first natural infection. TAK-003 has shown efficacy against symptomatic and hospitalized dengue in trials, with ongoing serotype-specific and policy considerations.
- ▶ Prognosis is excellent in uncomplicated dengue. Mortality in severe dengue falls sharply with early recognition, monitored fluids and bleeding control; Harrison notes case fatality can be as low as about 1% in experienced tropical centers, while CMDT cites about 2.5% of severe cases overall.
- ▶ Poor prognostic markers: shock, AKI in dengue shock syndrome, acute hepatitis/fulminant hepatitis, DIC, severe bleeding, persistent altered consciousness, metabolic acidosis, pregnancy near term, older age and major comorbid illness.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Natural history of dengue:** x-axis days 0-10; label febrile phase, defervescence, critical/plasma-leak phase, recovery phase, fever curve, platelet fall, hematocrit rise, shock window, fluid reabsorption/diuresis.
- ▶ **Severe dengue triad:** central “Severe dengue” box with three arms labelled plasma leakage -> shock/respiratory distress, severe bleeding -> GI/mucosal/DIC, severe organ dysfunction -> liver/CNS/heart/kidney/eye.

Clinical / Diagnostic significance

- ▶ Dengue is a must-consider diagnosis in acute fever with severe myalgia, retro-orbital pain, rash, leukopenia and thrombocytopenia after residence in or travel to an endemic area.
- ▶ The life-saving clinical point is **not the platelet count alone** but recognition of the critical phase: defervescence plus rising hematocrit, falling platelets, abdominal pain, vomiting, restlessness/lethargy, effusions or narrow pulse pressure.
- ▶ A falling hematocrit in an unstable patient suggests bleeding; a rising hematocrit with worsening perfusion suggests plasma leakage needing fluids.
- ▶ Differentiate from malaria, scrub typhus, leptospirosis and enteric fever in India; coinfection can occur, so a positive dengue test should not end evaluation if the clinical course is atypical.
- ▶ Avoid iatrogenic harm: NSAIDs/aspirin, unnecessary platelet transfusion and continued IV fluids during recovery can worsen outcomes.

High-yield exam pointers

- ▶ Write the **three severe dengue criteria:** severe plasma leakage, severe bleeding, severe organ dysfunction.
- ▶ Mention **warning signs at defervescence;** this is the usual time of deterioration.
- ▶ Pathogenesis keyword: **heterotypic secondary infection/antibody-dependent enhancement** plus **NS1-mediated vascular leak.**
- ▶ Investigations: **NS1/RT-PCR early, IgM/IgG later,** serial CBC hematocrit and platelets, LFT, albumin, renal function, coagulation profile, ultrasound/CXR for effusions.
- ▶ Management is **supportive, fluid-titrated and monitored;** no routine antiviral.
- ▶ Use **acetaminophen,** avoid aspirin/NSAIDs.
- ▶ Do **not** transfuse platelets just because the count is low; consider if bleeding or **<10,000/mcL.**
- ▶ In recovery, stop/reduce fluids because reabsorption of leaked fluid can cause pulmonary edema.
- ▶ Prevention answer must include **Aedes source reduction,** personal protection, blood safety and vaccine caveats.

SOURCE & COVERAGE

Harrison 22e — “Arthropod-Borne and Rodent-Borne Virus Infections”; CMDT 2026 — “Viral & Rickettsial Infections”; Critical Care — “Resuscitation From Circulatory Shock”.

Dengue fever

Asked in: Paper II Jul 2021 — RGUHS MD General Medicine

Definition / Introduction — Dengue is an acute, self-limiting yet potentially fatal *arthropod-borne flaviviral* illness caused by four antigenically distinct serotypes (DENV-1, -2, -3, -4; genus *Orthoflavivirus*, family *Flaviviridae*) transmitted chiefly by the day-biting *Aedes aegypti* (and *Ae. albopictus*) mosquito. It is the most prevalent arboviral disease of humans (~400 million infections/year, ~100 million clinically apparent), endemic in >100 countries, with Asia bearing ~70% of the global burden. The clinical spectrum ranges from asymptomatic infection and undifferentiated “**break-bone fever**” through a plasma-leakage **critical phase** to **severe dengue** (dengue haemorrhagic fever / dengue shock syndrome), the latter driven largely by **immune-mediated (antibody-dependent) enhancement** on secondary heterotypic infection.

Etiology, Vector and Epidemiology

- ▶ **Agent:** single-stranded positive-sense RNA orthoflavivirus, ~40–60 nm enveloped virion; four serotypes that cross-react serologically but confer only *transient* cross-protection. Lifelong immunity is serotype-specific — **infection with one serotype does NOT protect against the other three**.
- ▶ **Vector:** *Aedes aegypti* (principal) and *Ae. albopictus* (Asian tiger mosquito); anthropophilic, breed in fresh water in domestic containers (jars, tyres, coconut husks), **bite during daylight** (early morning, late afternoon).
- ▶ **Reservoir/cycle:** humans are the main amplifying host in the urban cycle; nonhuman primates maintain a sylvatic cycle.
- ▶ **Transmission:** principally human→mosquito→human; rarely needlestick/mucocutaneous, vertical (peripartum), and via blood transfusion or organ/marrow transplant.
- ▶ **Distribution:** year-round transmission between latitudes ~25°N and 25°S; spread driven by urbanisation, travel and climate. Along with malaria, dengue is one of the two commonest vector-borne diseases and the second commonest cause of febrile illness in returning travellers.

Pathogenesis — Antibody-Dependent Enhancement and Plasma Leakage

- ▶ **Primary infection** is usually subclinical or causes uncomplicated febrile dengue; it generates serotype-specific neutralising antibody (protective) plus *cross-reactive, non-neutralising* antibody whose protection wanes over weeks to months.
- ▶ **Antibody-dependent enhancement (ADE):** on **secondary infection with a different (heterotypic) serotype**, pre-existing non-neutralising antibody binds virus and, via Fc receptors, *enhances* uptake into mononuclear phagocytes → higher viral load and an amplified, dysregulated cytokine response → the central lesion of **increased vascular permeability and plasma leakage**.
- ▶ **NS1 (non-structural protein 1)** has a key, recently recognised role in driving the endothelial vascular-leak phenomenon of severe dengue.
- ▶ **Net effect:** capillary leak → intravascular volume depletion, haemoconcentration, hypoalbuminaemia, serosal effusions; with thrombocytopenia, coagulopathy and (in severe disease) DIC contributing to haemorrhage and shock.
- ▶ **Risk factors for progression to severe dengue:** enhancing non-neutralising antibody (secondary heterotypic infection — *the* major determinant), age (susceptibility falls markedly after 12 years), female sex, particular serotype sequences (DENV-1 then DENV-2 is especially severe), virulent Southeast-Asian DENV-2 variants; and per CMDT, suboptimally controlled type-2 diabetes, obesity, and comorbidity (cardiovascular/renal/pulmonary disease, older age).

Clinical Course and WHO Classification

After an **incubation of ~4–14 days** (typically 4–7 days), symptomatic illness evolves through **three phases**:

- ▶ **Febrile phase (days 1–~5):** abrupt high-grade fever, frontal headache, **retro-orbital pain**, severe myalgia/arthralgia (“break-bone fever”), facial flushing, transient macular rash, conjunctival injection, pharyngeal erythema, lymphadenopathy, hepatomegaly; a **positive tourniquet test** and petechiae may appear.
- ▶ **Critical / plasma-leakage phase (around defervescence, days 3–5, lasting 24–48 h):** the window for **plasma leakage** — pleural effusion, ascites, rising haematocrit with falling platelet count, hypoalbuminaemia, and, if a critical volume is lost, **shock**. Warning signs herald this phase.
- ▶ **Recovery phase:** reabsorption of extravascular fluid, haemodynamic stabilisation, diuresis; a confluent pruritic rash with islands of sparing may desquamate; prolonged fatigue/depression in convalescence.

Feature	WHO 1997 classification	WHO 2009 (revised) classification
Categories	Dengue fever (DF); Dengue haemorrhagic fever (DHF) graded I–IV; Dengue shock syndrome (DSS)	Dengue without warning signs; Dengue with warning signs; Severe dengue

Feature	WHO 1997 classification	WHO 2009 (revised) classification
DHF/severe defined by	Fever + thrombocytopenia + haemorrhage + plasma leakage (DHF); circulatory failure = DSS	Plasma leakage (shock / respiratory distress), severe bleeding, or severe organ involvement
DHF grades	I: fever + constitutional + positive tourniquet test only; II: grade I + spontaneous bleeding; III: circulatory failure (weak rapid pulse, narrow pulse pressure ≤ 20 mmHg, hypotension) = DSS; IV: profound shock, unrecordable BP/pulse = DSS	Stratifies management by warning signs (see below)

- ▶ **Warning signs (2009 WHO):** abdominal pain/tenderness, persistent vomiting, clinical fluid accumulation (ascites/pleural effusion), mucosal bleeding, lethargy/restlessness, tender hepatomegaly (>2 cm), and a rising haematocrit with rapid fall in platelet count.
- ▶ **Severe dengue (Harrison/2009 criteria):** definite/presumptive dengue **plus** (1) plasma leakage causing **shock or respiratory distress**, **or** (2) severe bleeding, **or** (3) severe organ dysfunction (e.g. transaminases markedly raised, impaired consciousness, myocarditis).
- ▶ **Organ involvement:** hepatitis, encephalitis/encephalopathy, myocarditis, acute kidney injury (AKI in shock syndrome carries high mortality), retinal haemorrhage/maculopathy.

Diagnosis and Investigations

- ▶ **Non-specific haematology:** leukopenia (with neutropenia), **thrombocytopenia**, and rising **haematocrit** (haemoconcentration = marker of plasma-leak severity); modestly elevated AST/ALT; normal ESR in most.
- ▶ **Phase-dependent virological/serological testing:**

Test	Useful window	Comment
NS1 antigen (ELISA / rapid test)	Days 1–~5 (febrile)	Early diagnosis; often combined with IgM at point of care
RT-PCR / viral isolation	First ~5 days	Confirms infection, allows serotyping
IgM ELISA	From ~day 4–5 onward	Indicates acute/recent infection
IgG ELISA / paired serology	Convalescence	Early, rapidly rising IgG (~day 4) suggests a secondary infection (primary = late, low-titre IgG)

- ▶ **Tourniquet (Hess) test:** ≥ 10 new petechiae per square inch on the forearm after BP-cuff inflation midway between systolic and diastolic for 5 min — a bedside index of capillary fragility; more often positive in severe dengue.
- ▶ **Imaging:** lateral-decubitus CXR / ultrasound detects pleural effusion and ascites before they are clinically obvious.
- ▶ **Caveat:** serologic **cross-reactivity** with other flaviviruses (Zika, yellow fever, Japanese encephalitis, prior vaccination) confounds IgG/IgM interpretation.
- ▶ **Differential diagnosis:** malaria, chikungunya (more chronic arthritis), Zika, leptospirosis, rickettsial/scrub typhus, typhoid, influenza, other viral haemorrhagic fevers.

Management

- ▶ **No specific antiviral exists** — care is **supportive**, hinging on meticulous fluid management and serial monitoring (vitals, urine output, **haematocrit**, platelets, albumin, AST/ALT).
- ▶ **Antipyretic/analgesic: acetaminophen (paracetamol); avoid aspirin and NSAIDs** (gastritis/bleeding risk, platelet effects).
- ▶ **Fluids:** judicious **isotonic crystalloid** titrated to clinical parameters; escalate to **colloid** and **blood products** in shock per WHO algorithmic protocols. In the recovery phase, anticipate **fluid reabsorption** and avoid overload/pulmonary oedema.
- ▶ **Severe dengue / DSS:** hospitalise, rapid triage, early IV fluids **before** overt shock; vasopressors and blood/component replacement for refractory shock or bleeding; manage AKI, hepatic and CNS complications.
- ▶ **Platelets:** counts do **not** reliably predict bleeding; **platelet transfusion only for severe thrombocytopenia** ($<10,000/\mu\text{L}$) or **active bleeding** — prophylactic transfusion gives no proven benefit and may delay count recovery.
- ▶ **Prognosis:** overall mortality of severe disease $\sim 2.5\%$ and falling with early recognition; at experienced tropical centres CFR may be as low as $\sim 1\%$. Thrombocytopenia, acute hepatitis and AKI in DSS predict poor outcome.

Prevention and Vaccines

- ▶ **Vector control** is the cornerstone: source reduction (eliminate breeding sites), screening, insecticides/repellents (especially early morning and late afternoon), and novel strategies (*Wolbachia*-infected or genetically modified *Aedes*). Screen blood donations in endemic areas.
- ▶ **CYD-TDV (Dengvaxia):** recombinant **live-attenuated tetravalent** vaccine on the **yellow-fever 17D backbone**; 0/6/12-month schedule; $\sim 56\%$ overall efficacy. **Increases risk of severe dengue in seronegative recipients** (“first serologic hit”) → WHO recommends use **only in the previously dengue-seropositive**, with pre-vaccination screening; indicated $\sim 9\text{--}45$ years; not for pregnant/immunosuppressed persons.

- ▶ **TAK-003 (Qdenga)**: live tetravalent, **two doses 3 months apart**; ~62% efficacy against symptomatic and ~83.6% against hospitalised dengue; protective against all four serotypes in seropositive children and DENV-1/-2 in seronegatives (weaker for DENV-3); approved in several European countries.
- ▶ **Newer candidates**: **Butantan-DV** (single-dose tetravalent — prevents DENV-1/-2) and **TV003/TV005** (single-dose) in late-phase evaluation.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Triphasic course of dengue (timeline graph)**. X-axis = days of illness (1–10); plot three overlapping curves and label: “**Febrile phase**”, “**Critical / plasma-leakage phase**”, “**Recovery phase**”; **Temperature** curve (high then defervescence at day ~3–5, optional “saddle-back” rise); **Platelet count** (falling, nadir in critical phase); **Haematocrit** (rising in critical phase, falling in recovery); mark the “**Warning-signs / leakage window**” at defervescence, and label complications — **shock, effusions, bleeding**.
- ▶ **Antibody-dependent enhancement (ADE) schematic**. Labels: **Primary DENV infection** → **serotype-specific neutralising antibody (protective)** vs **cross-reactive non-neutralising antibody (waning)**; **Secondary heterotypic DENV** → **antibody–virus complex** → **Fc-receptor uptake into macrophages** → **increased viral load + cytokine surge** → **NS1-mediated capillary leak** → **plasma leakage / DHF–DSS**.

Clinical / Diagnostic significance

- ▶ **Defervescence is the danger period**, not the end of illness — the critical plasma-leak phase begins as fever falls; serial haematocrit + platelet trends are the key bedside guide.
- ▶ A **rising haematocrit with falling platelets** is the earliest objective signal of significant plasma leakage and impending shock.
- ▶ **NS1 antigen** enables diagnosis in the first few febrile days (before antibodies appear); combine with IgM for higher yield.
- ▶ **Secondary heterotypic infection** is the principal driver of severe disease — a vital concept for hyperendemic regions and for the seronegative-vaccination hazard.
- ▶ Recognising **narrow pulse pressure (≤ 20 mmHg)** as early DSS allows fluid resuscitation before profound shock.
- ▶ Avoiding NSAIDs/aspirin and prophylactic platelet transfusion reflects evidence-based, harm-avoiding dengue care.

High-yield exam pointers

- ▶ Four serotypes DENV-1–4; immunity is **serotype-specific**; flavivirus; vector ***Aedes aegypti*, a day-biter**.
- ▶ Triphasic illness: **febrile** → **critical (plasma leak at defervescence)** → **recovery**.

- ▶ **WHO 2009:** dengue *without* warning signs / *with* warning signs / **severe dengue**; WHO 1997: DF, DHF grades I–IV, DSS.
- ▶ **Severe dengue** = dengue + plasma leakage (shock/respiratory distress) OR severe bleeding OR severe organ dysfunction.
- ▶ **Antibody-dependent enhancement on secondary heterotypic infection**; NS1 drives vascular leak.
- ▶ Labs: **leukopenia, thrombocytopenia, rising haematocrit**, raised transaminases; NS1 → RT-PCR → IgM → IgG; **early high IgG = secondary infection**.
- ▶ **Tourniquet test** = ≥ 10 petechiae/inch² after 5-min cuff.
- ▶ Treatment: **supportive + fluids + paracetamol**; **avoid NSAIDs/aspirin**; platelets only if $< 10,000/\mu\text{L}$ or bleeding.
- ▶ Vaccines: **Dengvaxia (CYD-TDV)** — seropositive only, risk in seronegatives; **Qdenga (TAK-003)** — two-dose tetravalent.

SOURCE & COVERAGE

- ▶ **Harrison's Principles of Internal Medicine, 22e** — “Arthropod-Borne and Rodent-Borne Virus Infections” (Flavivirids: Dengue and Severe Dengue; Viral Haemorrhagic Fever section) — pathogenesis, antibody-dependent enhancement, NS1, three-phase course, tourniquet-test definition, severe-dengue criteria, vaccines (CYD-TDV/Dengvaxia, TAK-003/Qdenga, Butantan-DV, TV003/TV005).
- ▶ **CMDT 2026** — “Viral & Rickettsial Infections: Dengue” — epidemiology, clinical findings, laboratory diagnosis (NS1/IgM/IgG/PCR), WHO 1997 vs 2009 classification, supportive management, platelet-transfusion threshold, prevention and vaccines.
- ▶ **Coverage note:** The explicit **DHF grading I–IV** table is the standard **WHO 1997** classification — universally accepted internal medicine but cited by name rather than tabulated verbatim in Harrison 22e (which adopts the 2009 scheme) / CMDT 2026; the consolidated **2009 warning-signs list** is standard WHO and partially enumerated in CMDT. Incubation period is given as ~4–7 days (Harrison) and 7–10 days (CMDT); both are within the accepted 4–14-day range.

Diagnosis and Laboratory Monitoring of HIV Infection

Asked in: Paper I Jul 2021 — RGUHS MD General Medicine

Definition / Introduction — Diagnosis of HIV infection rests on demonstrating either **antibodies to HIV and/or the p24 antigen** (serologic/screening tests) or **direct detection of the virus or its components** (nucleic acid/antigen tests). Laboratory monitoring then quantifies the **degree of immune**

damage (CD4+ T-cell count) and the **magnitude of viral replication** (plasma HIV RNA). Together these tools establish the diagnosis, stage the disease, time opportunistic-infection (OI) prophylaxis, and gauge the response to antiretroviral therapy (ART). The CDC recommends that HIV screening be offered as a routine part of health care.

The diagnostic window & basis of testing

- ▶ Antibodies to HIV generally appear in the circulation **3–12 weeks** after infection; with modern fourth-generation tests, antibody/antigen is detectable in ~99% within **6 weeks**, median ~2 weeks.
- ▶ The **window period** (interval from infection to detectability) has shortened progressively with assay generation: **22 days** with antibody testing → **16 days** with p24 antigen testing → **12 days** with nucleic acid testing (NAT).
- ▶ Standard screening detects **antibody and/or p24 antigen**; direct tests detect HIV RNA, proviral DNA, or p24 antigen.
- ▶ The screening enzyme immunoassay (ELISA/EIA) has sensitivity >99.5% but imperfect specificity; in low-risk populations (e.g., volunteer blood donors) as few as ~10% of EIA-positives are truly infected, so every reactive screen needs confirmation.

Screening & confirmatory tests — the CDC algorithm

- ▶ **Step 1 (initial/screening):** a fourth-generation HIV-1/2 antigen-antibody combination immunoassay — detects antibodies to HIV-1 and HIV-2 *plus* HIV-1 **p24 antigen** (closes much of the early window). Scored highly-reactive, non-reactive, or indeterminate.
- ▶ **Step 2 (confirmation/differentiation):** a reactive screen → **HIV-1/HIV-2 antibody differentiation immunoassay** (e.g., *Bio-Rad Geenius*), which both confirms and distinguishes HIV-1 from HIV-2.
- ▶ **Step 3 (NAT for discordant results):** if the differentiation assay is **negative or indeterminate** → **HIV-1 RNA (NAT)**. A **positive NAT with negative antibody** = **acute HIV-1 infection**; a negative NAT in this setting indicates a **false-positive** screen.
- ▶ The **Western blot** is **no longer used** for confirmation. A positive fourth-generation assay confirmed by a second HIV-1– or HIV-2–specific immunoassay *or* a plasma HIV RNA level is adequate for diagnosis.
- ▶ **Point-of-care/rapid tests** (blood or oral fluid) give results in 10–20 min, need minimal training, and have sensitivity/specificity >99% for chronic infection (lower in acute infection); a reactive rapid test must be confirmed by the standard algorithm. A home oral-swab test (*OraQuick*) is FDA-approved.

Test	What it detects	Role in algorithm
4th-gen Ag/Ab combination immunoassay	HIV-1 & HIV-2 antibody + HIV-1 p24 antigen	Initial screen (sensitivity >99.5%)
HIV-1/HIV-2 antibody differentiation immunoassay (Geenius)	Distinguishes HIV-1 vs HIV-2 antibody	Confirmation after reactive screen
HIV-1 RNA (NAT)	Plasma viral RNA	Resolves screen+ / differentiation- → acute HIV
Rapid antibody test (blood/oral fluid)	HIV-1/HIV-2 antibody	Field/POC screen; confirm if reactive

Direct detection of virus & its components

- ▶ **p24 antigen capture assay** — EIA detecting HIV core protein p24; ~30% of untreated patients have detectable free p24, rising to ~50% after weak-acid dissociation of antigen-antibody complexes (down to ~15 pg/mL). High early (pre-seroconversion) levels make it useful in suspected **acute HIV syndrome**; now incorporated into the 4th-generation screen.
- ▶ **Nucleic acid amplification tests (quantitative HIV RNA)** — provide both diagnosis (in misleading-serology settings) and prognosis/treatment monitoring:

Assay	Method	Lower reliable limit
RT-PCR	Reverse transcription + PCR amplification of HIV-1 RNA	20 copies/mL
bDNA (branched DNA)	Signal amplification of particle-associated RNA	50 copies/mL
NASBA	Isothermal amplification	80 copies/mL
TMA	Transcription-mediated amplification (T7 polymerase)	100 copies/mL

- ▶ **DNA PCR amplifies proviral DNA** from peripheral blood mononuclear cells (sensitive to 1 copy/10,000–100,000 cells) — valuable for **neonatal diagnosis** (maternal antibody crosses placenta, making serology unreliable) and in **hypogammaglobulinemia/advanced disease**.
- ▶ **“Gold standard” for diagnosis = a positive EIA together with a positive HIV RNA assay.** Because high sensitivity costs specificity, NAT should be used for diagnosis only when standard serology fails to give a definitive answer.

Special / difficult diagnostic situations

- ▶ **False-positive EIA** — anti-class II (HLA) antibodies (post-pregnancy, transfusion, transplant), autoantibodies (collagen-vascular/autoimmune disease), hepatic disease, recent **influenza vaccination**, acute viral infections, and prior HIV-vaccine receipt; confirm with a specific immunoassay or HIV RNA.

- ▶ **Acute (primary) HIV** — antibody may be absent; rely on **p24 antigen** and/or **HIV RNA** (RNA is typically very high). Caution: low-level viremia **<1000 copies/mL** with negative serology may be a false-positive RNA.
- ▶ **Recent vs established infection** — a “**detuned**” (less-sensitive) EIA scores positive only in established infection, helping date seroconversion for surveillance.
- ▶ **Reversion to negative EIA** can occur in patients treated very early; it does not mean cure.

Laboratory monitoring — CD4+ T-cell count

- ▶ The **CD4+ T-cell count** is the **best single indicator of immediate immunologic competence** and the basis for staging and OI prophylaxis.
- ▶ **Thresholds:** CD4 **<200/μL** → high risk of *Pneumocystis jirovecii* pneumonia → **start PCP prophylaxis**; CD4 **<50/μL** → risk of CMV, *Mycobacterium avium* complex (MAC), and *Toxoplasma* → **MAC primary prophylaxis** (unless ART is started immediately).
- ▶ **CDC staging (age ≥6 yr to adult):** Stage 1 = CD4 **≥500/μL** (≥26%); Stage 2 = **200–499/μL** (14–25%); Stage 3 (AIDS) = **<200/μL** (<14%) *or* an AIDS-defining OI. **CD4% of 15 ≈ CD4 count of 200/μL.**
- ▶ **Frequency:** at diagnosis, then **every 3–6 months** for the first 2 years; more often if declining. After ≥2 years on ART with HIV RNA persistently **<50 copies/mL** and CD4 **300–500/μL** → annually; if CD4 **>500/μL** monitoring is **optional**.
- ▶ **CD4 can mislead:** falsely high in **HTLV-1 co-infection**; use the **CD4 percentage** in hypersplenism, post-splenectomy, or marrow-suppressing therapy (e.g., IFN-α). Counts also fall transiently with intercurrent illness/vaccination and show diurnal/inter-laboratory variation — *trend matters more than a single value.*

Laboratory monitoring — HIV RNA, resistance & tropism

- ▶ **Plasma HIV RNA (viral load)** is the most accurate indicator of viral replication and the **response to ART**. Measure at diagnosis; after starting ART, monitor about **every 4 weeks** until a new steady state, then **every 3–6 months**.
- ▶ **Goal of effective ART:** HIV RNA falls to **<50 copies/mL within ~6 months**. Commercial assays reliably detect to ~20–50 copies/mL; avoid the term “undetectable” (virus is not zero). Never base decisions on a single value, as RNA fluctuates with immune activation, intercurrent infection, or immunization.
- ▶ **HIV drug-resistance testing** — **genotypic** (sequence vs known resistance profiles) or **phenotypic** (growth of patient virus across drug concentrations). Recommended **at initial diagnosis** and at **ART initiation**, and in **virologic failure**; requires HIV-1 RNA **>500–1000 copies/mL** for an accurate result.

- ▶ **Co-receptor tropism assay** (e.g., *Trofile*) before using the CCR5 antagonist **maraviroc**, which works only against **CCR5-tropic** virus (early disease tends CCR5-tropic, shifting to CXCR4 later).
- ▶ **Other markers** — hs-CRP, IL-6, D-dimer, and sCD14 correlate with all-cause mortality but are not used routinely.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **CDC diagnostic algorithm (flowchart)**: Box 1 “HIV-1/2 antigen/antibody combination immunoassay” → if **non-reactive** = “Negative (consider acute HIV → NAT if recent exposure)”; if **reactive** → Box 2 “HIV-1/HIV-2 antibody differentiation immunoassay” with three outputs — “HIV-1 antibodies +”, “HIV-2 antibodies +”, “**indeterminate/negative**”; the indeterminate/negative arm → Box 3 “HIV-1 NAT” → “NAT + = **acute HIV-1 infection**” / “NAT – = **HIV negative (false-positive screen)**”. Label arrows +/–.
- ▶ **CD4 vs opportunistic-disease graph**: Y-axis “**CD4 count (cells/μL)**” with marked lines at 500, 200, 50; plot disease onset bands — *herpes zoster* / *oral candidiasis* (~300–500), **PCP** / **Kaposi sarcoma** (≤200), **CMV retinitis** / **MAC** / **CNS lymphoma** / **cryptococcosis** (≤50). Title: *Relationship between CD4 count and opportunistic infections*.

Clinical / Diagnostic significance

- ▶ A **single reactive screen never diagnoses HIV** — the differentiation assay ($\pm$ NAT) is mandatory; this avoids labelling false-positives.
- ▶ The **fourth-generation Ag/Ab test + NAT** strategy diagnoses **acute HIV** that older antibody-only tests miss — critical for interrupting onward transmission.
- ▶ **CD4 count drives prophylaxis** (<200 → PCP; <50 → MAC/Toxo/CMV) and defines **AIDS** (Stage 3).
- ▶ **Viral load** confirms ART efficacy (target <50 copies/mL) and, with persistent suppression, supports **U=U** (untransmittable) and reduced monitoring frequency.
- ▶ **Resistance + tropism testing** individualises the regimen and is prerequisite for CCR5 antagonists.

High-yield exam pointers

- ▶ **Initial test** = 4th-generation HIV-1/2 antigen/antibody combination immunoassay (antibody + p24 antigen); EIA sensitivity >99.5%.
- ▶ **Confirmation** = HIV-1/HIV-2 antibody differentiation immunoassay (Genieus); Western blot is obsolete.
- ▶ **Discordant** (screen+, differentiation–) → HIV-1 NAT; NAT+ antibody– = acute HIV.

- ▶ **Window period:** antibody 22 d → p24 antigen 16 d → NAT 12 d.
- ▶ **Gold standard for diagnosis** = positive EIA + positive HIV RNA.
- ▶ CD4 <200/ μ L → PCP prophylaxis; <50/ μ L → MAC prophylaxis; CD4% 15 $\approx$ 200/ μ L.
- ▶ **CDC Stage 3 (AIDS):** CD4 <200/ μ L (or <14%) or an AIDS-defining illness.
- ▶ **Viral load** <50 copies/mL by 6 months = effective ART; monitor every 3–6 months; never act on a single value.
- ▶ **Resistance testing** needs HIV RNA >500–1000 copies/mL; tropism (Trofile) before maraviroc.
- ▶ **DNA PCR** for neonatal diagnosis (passive maternal antibody confounds serology).

SOURCE & COVERAGE

- ▶ **Harrison's Principles of Internal Medicine, 22e** — “Human Immunodeficiency Virus Disease: AIDS and Related Disorders” (diagnosis algorithm, window periods, p24 antigen and HIV RNA/DNA assays, CD4 and viral-load monitoring, resistance and tropism testing, CDC staging Tables 208-1/208-2/208-8).
- ▶ **CMDT 2026** — “HIV Infection & AIDS” (current fourth-generation Ag/Ab → differentiation → NAT algorithm, rapid/home tests, Table 36-2 commonly ordered tests, CD4-count interpretation and OI thresholds).

Coverage note: Both sources describe the U.S. CDC laboratory algorithm. The Indian NACO / WHO “three sequential rapid-test” (Strategy III) diagnostic algorithm used in resource-limited programmatic settings is standard practice but is not detailed in this corpus and has not been elaborated here.

Diagnosis and Management of Falciparum Malaria

Asked in: Paper II May 2019 — RGUHS MD General Medicine

Definition / Introduction — Malaria is a protozoan infection transmitted by the bite of an infected female *Anopheles* mosquito; *Plasmodium falciparum* is the species responsible for nearly all malaria deaths. It is distinguished from the other human plasmodia by its ability to invade red cells of **all ages** (producing very high parasitaemias) and by **cytoadherence and sequestration** of parasitised erythrocytes in vital organs, which underlies the life-threatening complications. Falciparum malaria must never be a clinical diagnosis alone — it requires parasitological confirmation — and severe disease is a medical emergency demanding immediate parenteral artesunate.

Pathophysiology relevant to diagnosis and severity

- ▶ After hepatic schizogony, merozoites invade RBCs and multiply 6- to 20-fold every 48 h; symptoms begin once densities reach $\sim$ 50/ μ L.

- ▶ *P. falciparum*–infected RBCs develop surface “knobs” expressing the variant adhesin **PfEMP1**, which mediates **cytoadherence** to endothelial receptors — **ICAM-1** and **endothelial protein C receptor (EPCR)** in the brain, **VAR2CSA/chondroitin sulfate A** in the placenta, and **CD36** in most other organs.
- ▶ **Rosetting** (binding to uninfected RBCs) and **agglutination** add to microvascular obstruction → tissue hypoxia and lactic acidosis.
- ▶ Because mature forms sequester, **only young ring forms circulate** in peripheral blood; peripheral parasitaemia therefore *underestimates* the true parasite burden — a key diagnostic caveat.

Clinical features and recognition of severe disease

- ▶ **Uncomplicated malaria:** non-specific prodrome (malaise, headache, fatigue, myalgia, abdominal discomfort) followed by fever; classic periodic paroxysms are *unusual* in falciparum. Few signs other than fever, mild anaemia, jaundice and splenomegaly. **Thrombocytopenia is usual** — a normal platelet count should question the diagnosis. There is no rash.
- ▶ Generalised **seizures** are specifically associated with falciparum malaria and may herald cerebral malaria.
- ▶ **Severe falciparum malaria** is defined by vital-organ dysfunction or parasitaemia >2% in a non-immune patient. Uncomplicated disease, promptly treated, has mortality <0.1%; once severe features appear, mortality rises steeply.

WHO criterion (severe falciparum malaria)	Threshold
Cerebral malaria (unarousable coma)	GCS <11, or Blantyre Coma Score <3; coma >30 min post-convulsion
Severe anaemia	Hb <5 g/dL (Hct <15%) with parasitaemia >10,000/μL
Acidosis	pH <7.25, HCO ₃ ⁻ <15 mmol/L, base deficit >8, or lactate ≥5 mmol/L
Hypoglycaemia	Plasma glucose <2.2 mmol/L (<40 mg/dL)
Acute kidney injury	Creatinine >265 μmol/L (>3 mg/dL)
Pulmonary oedema / ARDS	SpO ₂ <92% on air, RR >30, non-cardiogenic oedema
Shock	SBP <80 mmHg (adults) with impaired perfusion
Hyperparasitaemia	>5% non-immune (>10% any patient)
Bleeding/DIC, ≥2 convulsions/24 h, haemoglobinuria, jaundice (bilirubin >3 mg/dL with parasitaemia >100,000/μL), prostration	—

- ▶ **Poor-prognosis markers:** hyperlactataemia, acidotic (“respiratory distress”) breathing, deep coma, repeated convulsions, anuria, hypoglycaemia, >20% of parasites being pigment-containing

trophozoites/schizonts, or pigment in >5% of neutrophils. Concomitant bacteraemia (notably non-typhoidal *Salmonella*) complicates ~6% of children and adults with >20% parasitaemia.

Diagnosis

- ▶ **Demonstration of the parasite (gold standard):** thick and thin Giemsa-stained smears (Giemsa at pH 7.2; Field's, Wright's or Leishman's acceptable), examined immediately.
 - *Thick film* — unfixed, lyses RBCs and **concentrates parasites 40–100×**; high sensitivity (~0.001% parasitaemia); count asexual parasites per 200 WBC (assume WBC 8000/ μ L $\rightarrow$ parasites/ μ L = count $\times$ 40).
 - *Thin film* — methanol-fixed; allows **species identification** and quantification (parasitised RBC per 1000 RBC); in severe disease, assess proportion of mature forms and pigment-laden neutrophils.
 - Falciparum hallmarks: predominance of small **ring forms**, multiply-infected cells, appliqué/accolé forms, **banana-shaped gametocytes**, **Maurer's clefts**, and high parasite density.
 - A single negative smear does not exclude malaria — **repeat 12-hourly over 2–3 days** before excluding the diagnosis.
- ▶ **Rapid diagnostic tests (RDTs):** immunochromatographic detection of PfHRP2 (falciparum-specific), parasite LDH (pLDH) or aldolase.
 - Useful where reliable microscopy is unavailable; some carry a pan-malaria/vivax band to distinguish species.
 - Limitations: do **not quantify** parasitaemia; PfHRP2 **stays positive for weeks** after cure (a problem in high transmission, but an advantage when diagnosing severe malaria in a partly treated patient with negative film); false negatives from **pfhrp2/3 gene deletions** (notably the Horn of Africa).
- ▶ **PCR/molecular:** most sensitive for low-density and mixed infections and for speciation; used in reference labs — too sensitive for routine primary diagnosis in endemic areas. **Serology has no role** in acute illness.
- ▶ **Supportive laboratory findings:** normochromic normocytic anaemia, thrombocytopenia, normal/low WBC; in severe disease — metabolic acidosis, hypoglycaemia, hyponatraemia, elevated lactate, urea, creatinine, bilirubin and transaminases.

Treatment of uncomplicated falciparum malaria

- ▶ **WHO first-line = Artemisinin-based Combination Therapy (ACT)** — a fast-acting artemisinin derivative (artesunate/artemether/dihydroartemisinin) plus a slowly eliminated partner drug, given for **3 days**. Six WHO-recommended ACTs:

ACT regimen	Note
Artemether-lumefantrine (Coartem)	Most widely used; preferred in 1st-trimester pregnancy; take with fat/food (1.5/9 mg/kg bd × 3 days)
Artesunate-amodiaquine	First-line in much of Africa
Artesunate-mefloquine	SE Asia, South America
Dihydroartemisinin-piperaquine	Longest post-treatment prophylaxis (piperaquine t _{1/2} ~3 wk)
Artesunate-sulfadoxine-pyrimethamine	First-line in some countries
Artesunate-pyronaridine	Most recently approved

- ▶ Add a **single low dose of primaquine 0.25 mg base/kg** as a *gametocytocide* (to block transmission) in low-transmission/elimination settings — safe even in G6PD deficiency; **not** in pregnancy/infants.
- ▶ **Atovaquone-proguanil** (20/8 mg/kg/day × 3 days, with food) is an effective alternative for imported/traveller malaria.
- ▶ **Second-line / no ACT available:** oral **quinine 10 mg salt/kg tds × 7 days plus doxycycline** (3 mg/kg/day; avoid <8 yr and pregnancy) **or clindamycin** (10 mg/kg bd).
- ▶ Watch for vomiting within 1 h of an oral dose → repeat the dose; treat fever with paracetamol to reduce vomiting. Confirm parasite clearance with daily counts; failure to clear by day 7 → switch to a different ACT.

Treatment of severe falciparum malaria

- ▶ **IV artesunate is the drug of choice everywhere** — large RCTs showed mortality reduction of 35% in Asian adults/children (SEAQUAMAT) and 22.5% in African children (AQUAMAT) versus quinine. It is FDA-approved, simple, safe, needs no dose adjustment for hepatic/renal failure, and is given in pregnancy in all trimesters.
 - **Dose: 2.4 mg/kg IV at 0, 12 and 24 h, then once daily;** children <20 kg get **3 mg/kg per dose**. Continue parenteral therapy ≥24 h, then complete a **full 3-day oral ACT** once the patient can swallow (avoid mefloquine follow-on — post-malaria neurological syndrome).
 - **Pre-referral rectal artesunate** reduces mortality in rural children who cannot reach parenteral care.
- ▶ **Alternatives if artesunate unavailable:** IM **artemether** 3.2 mg/kg stat then 1.6 mg/kg/day; or **quinine dihydrochloride** 20 mg salt/kg loading over 4 h, then 10 mg salt/kg over 2–8 h every 8 h (rate-controlled infusion; risk of hypotension and hypoglycaemia; cardiac monitoring; reduce maintenance dose by 30–50% if renal failure persists >48 h — never the loading dose). In confirmed artemisinin-resistance areas, give **artesunate + quinine together**.

- ▶ **Supportive / intensive care** (severe malaria = ICU-level care):
 - **Fluids:** cautious — the line between under- and over-hydration is thin; **fluid boluses are dangerous** in severe malaria (unlike sepsis) and precipitate pulmonary oedema.
 - **Hypoglycaemia:** monitor glucose 4–6 hourly; treat with 20% dextrose 2 mL/kg over 10 min then 10% dextrose infusion; keep glucose >4 mmol/L.
 - **Seizures:** IV/rectal benzodiazepines; **levetiracetam** is the preferred anticonvulsant; avoid prophylactic high-dose phenobarbital (20 mg/kg) without ventilatory support (respiratory arrest).
 - **Anaemia:** transfuse if **Hct <20%** (threshold ~15% in high-transmission settings); fresh whole blood/packed cells slowly.
 - **AKI / severe acidosis:** early **haemofiltration or haemodialysis** (superior to peritoneal dialysis).
 - **Sepsis cover:** add broad-spectrum antibiotics (covering non-typhoidal *Salmonella*) in children and in adults with >20% parasitaemia or unexplained deterioration; take blood cultures.
 - **Exchange transfusion** is sometimes used for very high parasitaemia (>5–10%) but benefit is unproven.
 - **Ineffective/harmful adjuncts (do NOT use):** corticosteroids, mannitol, heparin, dextran, urea, desferrioxamine, anti-TNF- α , large fluid/albumin boluses.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Peripheral smear of P. falciparum (thin film): label — delicate ring/trophozoite, appliqué (accolé) form, double-chromatin ring, multiply-infected RBC, Maurer's clefts, banana-shaped (crescentic) gametocyte, pigment in neutrophil*.*
- ▶ **Pathogenesis of sequestration:** label — *infected RBC with knobs, PfEMP1 adhesin, endothelial receptors (ICAM-1/EPCR in brain, CD36, VAR2CSA in placenta), cytoadherence to venular endothelium, rosetting with uninfected RBCs, microvascular obstruction → coma/lactic acidosis.*

Clinical / Diagnostic significance

- ▶ **Speed saves lives:** start parenteral artesunate immediately in any patient with severe features; do not wait for full work-up.
- ▶ Cerebral malaria is a diffuse symmetrical encephalopathy (no focal signs, no meningism); retinal whitening and pale-centred haemorrhages on fundoscopy support the diagnosis. Death rates ~20% (adults) and ~15% (children) even with treatment.

- ▶ **Blackwater fever** — massive intravascular haemolysis with haemoglobinuria — and **delayed post-artesunate haemolysis** (1–3 weeks after clearing hyperparasitaemia, from synchronous loss of “pitted” once-parasitised cells) require monitoring of Hb after discharge.
- ▶ **Pregnancy**: falciparum causes placental sequestration, low birth weight and severe maternal disease (hypoglycaemia, pulmonary oedema) — treat with IV artesunate in all trimesters.
- ▶ **Resistance surveillance** uses molecular markers: **pfkelch13** (artemisinin), **pfcr1** (chloroquine), **pfmdr1** (mefloquine), **pfpm2** amplification (piperaquine).

High-yield exam pointers

- ▶ Falciparum invades RBCs of **all ages** → high parasitaemia; sequestration means **only rings** seen peripherally — count underestimates true burden.
- ▶ **Thick film** = most sensitive (concentrates 40–100×, detect & quantify); **thin film** = species ID; **Giemsa at pH 7.2** is the preferred stain.
- ▶ **RDTs** detect **PfHRP2 / pLDH / aldolase**; PfHRP2 stays positive weeks after cure; beware **pfhrp2/3 deletions** causing false negatives.
- ▶ Severe disease defined by WHO criteria — memorise coma (GCS <11/Blantyre <3), lactate ≥5, glucose <2.2 mmol/L, creatinine >3 mg/dL, Hb <5 g/dL, parasitaemia >5–10%.
- ▶ **IV artesunate 2.4 mg/kg at 0, 12, 24 h then daily** is first-line for severe malaria everywhere (SEAQUAMAT 35%, AQUAMAT 22.5% mortality reduction vs quinine).
- ▶ **Avoid fluid boluses** in severe malaria; manage hypoglycaemia, seizures (levetiracetam), AKI (early dialysis) and add antibiotics for possible bacteraemia.
- ▶ **ACT × 3 days** is first-line for uncomplicated falciparum; add **single-dose primaquine 0.25 mg/kg** as gametocytocide (safe in G6PD deficiency).
- ▶ A **normal platelet count** argues against falciparum malaria; malaria causes **no rash**.

SOURCE & COVERAGE

- ▶ **Harrison’s Principles of Internal Medicine, 22e** — “Malaria” (Ashley & White): pathophysiology, severe-malaria criteria (Tables 231-2/231-3), diagnostic methods (Table 231-5), treatment regimens (Tables 231-6/231-7), artesunate dosing and supportive care.
- ▶ **CMDT 2026** — “Protozoal & Helminthic Infections” (malaria section, Tables 40-2/40-3): current WHO ACT list, IV artesunate as FDA-approved standard of care, exchange-transfusion caveat, drug-specific notes.

Coverage note: The corpus covers this topic comprehensively; no significant gaps. Trial eponyms (SEAQUAMAT/AQUAMAT) are universally accepted designations for the artesunate-versus-quinine mortality data quoted verbatim from Harrison.

Diagnosis and treatment of Brucellosis

Asked in: Paper II Nov 2022 — RGUHS MD General Medicine

Definition / Introduction — Brucellosis is a bacterial **zoonosis** transmitted directly or indirectly to humans from infected animals, chiefly domesticated ruminants and swine. It is colloquially called **undulant fever** because of its remittent character. Although it usually presents as an acute febrile illness, its manifestations vary widely and definitive diagnostic signs are often absent; the clinical impression must therefore be confirmed by **bacteriologic and/or serologic tests**. The causative organisms are small, gram-negative, unencapsulated, nonsporulating **coccobacilli** of the genus *Brucella* that behave *in vivo* as **facultative intracellular** parasites of macrophages, explaining the chronicity, relapses and the need for prolonged combination therapy.

Aetiology & relevant microbiology

- *Brucella melitensis* — from **sheep, goats and camels**; the commonest cause of symptomatic human disease; tends to be **acute and aggressive**.
- *B. abortus* — from **cattle/buffalo**; often **insidious onset** and more likely to become chronic.
- *B. suis* — from **swine**; characteristically causes **focal abscesses**. *B. canis* — from **dogs**; generally milder but can cause serious disease such as endocarditis.
- Organisms grow aerobically on peptone-based medium at 37°C; growth of some types is improved by supplementary CO₂. They are killed by **boiling and pasteurisation** but resist freezing and drying — their resistance to drying renders them stable as an **aerosol**, facilitating airborne and laboratory transmission. They survive up to **2 months in soft cheeses** made from goat/sheep milk.
- **Routes:** ingestion (unpasteurised dairy, especially **soft cheeses**, milk, ice-cream), inhalation, and mucosal/percutaneous exposure. **Occupational risk:** farmers, shepherds, goatherds, veterinarians, abattoir and meat-plant workers, and **microbiology laboratory** staff. Accidental inoculation of **live vaccine strains** (*B. abortus* S19, RB51; *B. melitensis* Rev 1) can cause disease. *B. melitensis* and *B. suis* are recognised **bioterrorism** agents.

Clinical clues that prompt the diagnosis

- **Fever** is almost invariable, with profuse **night sweats**; untreated, it shows an **undulating** pattern persisting for weeks before an afebrile remission that may be followed by **relapse**. Constitutional features: apathy, fatigue, anorexia, weight loss, myalgia, headache, chills.
- **Musculoskeletal** symptoms/signs accompany the fever in about **half** of patients — a feature (along with the undulant pattern) that historically distinguished brucellosis from typhoid and malaria.
- Three recognisable patterns: (1) a **typhoid-like** febrile illness but less severe; (2) **fever with acute monoarthritis** of the hip or knee in a **young child**; (3) **long-lasting fever with low-back or hip pain in an older person** (especially men).

- ▶ A history of **travel to/residence in an endemic area**, unpasteurised milk-product consumption, animal contact, lab work, or **similar illness in the family** (documented in almost 50% of cases) is a strong pointer. Incubation period ranges from **1 week to several months**.
- ▶ **Focal involvement** (present in the majority): osteoarticular ~40% (sacroiliitis, spondylitis of **lumbar/low-thoracic** vertebrae, septic arthritis of knee/hip/shoulder/sternoclavicular joints); hepatosplenomegaly (~one-quarter); lymphadenopathy (10–20%); dry cough (~one-quarter); **epididymo-orchitis** (up to 10% of men); neurobrucellosis (depression, lethargy, **lymphocytic meningoencephalitis**); and **endocarditis** in ~1% (most often the **aortic valve**, the leading cause of brucellosis-related death).

Diagnostic approach

- ▶ **Non-specific labs**: routine biochemistry usually normal (hepatic enzymes/bilirubin may rise); peripheral leukocyte count **normal or low with relative lymphocytosis**; mild anaemia; thrombocytopenia and even DIC may occur; **ESR and CRP are often normal**. CSF/joint fluid shows **lymphocytosis with low glucose**; CSF **adenosine deaminase may be raised** and cannot distinguish from tubercular meningitis. Tissue biopsy may show **non-caseating granulomas without acid-fast bacilli**.
- ▶ **Culture (definitive)**: isolation from **blood, bone marrow, CSF, joint fluid or tissue** confirms the diagnosis; success in **50–70%** of cases. Automated systems (e.g., Bactec) usually flag positive **within 7 days**. The **laboratory must be alerted** — cultures need handling under containment for dangerous pathogens, and *Brucella* may be **misidentified** as *Agrobacterium*, *Ochrobactrum* or *Psychrobacter* (*Moraxella*) *phenylpyruvicus*. **MALDI-TOF MS** aids identification in well-resourced labs (note: *Ochrobactrum* is now reported as a *Brucella* subspecies, which can cause clinically important confusion).
- ▶ **Serology (often the only positive finding)**: IgM appears early, followed by IgG and IgA; all are active in **agglutination tests** (tube/plate/microagglutination — the mainstay). As agglutinins decline, antibody is still detected by **complement-fixation, Coombs antiglobulin and ELISA**. **Titre interpretation**: in endemic areas / occupational exposure, **1:320–1:640 or higher** is diagnostic; in **non-endemic** areas $\geq 1:160$ is significant; repeat at **2–4 weeks** to demonstrate a **rising titre**. **Rose Bengal test** is used for screening. **Cross-reactions** occur with *Yersinia enterocolitica* O:9, *E. coli* O157, *Francisella tularensis*, *Salmonella* group N, *Stenotrophomonas maltophilia* and *Vibrio cholerae*. **Rough strains* (*B. canis*, *B. ovis*) *give false-negative smooth-antigen serology*; *vaccine strain RB51 elicits no antibody** to smooth antigens.
- ▶ **PCR / NAAT**: more sensitive and quicker than culture and without the biohazard; targets include the **rrs-rrl (16S–23S) spacer, outer-membrane protein genes, IS711 and BCSP31**. False-negatives occur, and the significance of **prolonged post-treatment PCR positivity** is uncertain.

Brucellar spondylitis vs tuberculous spine (Table 174-1)

Feature	Brucellosis	Tuberculosis
Site	Lumbar and others	Dorsolumbar
Vertebrae	Multiple or contiguous	Contiguous
Diskitis	Late	Early
Vertebral body	Intact until late	Morphology lost early
Canal compression	Rare	Common
Osteophyte	Anterolateral (*parrot-beak*)	Unusual
Deformity	Wedging uncommon	Anterior wedge, gibbus
Psoas abscess	Rare	More likely

Tuberculosis is the single most important differential, since several antibrucella drugs (rifampin, aminoglycosides, fluoroquinolones) also treat TB — so TB must be excluded or a full antituberculous regimen used, to avoid masking TB or breeding resistance with rifampin monotherapy.

Treatment

- **Principles:** the aims are to **relieve current symptoms and prevent relapse**. Monotherapy (early streptomycin or tetracycline) caused frequent relapse, so **≥2 agents** are mandatory. Many drugs that look sensitive *in vitro* (e.g., β -lactams) are **therapeutically ineffective**, partly because of the **low intravacuolar pH**. **Acute non-focal disease (<1–2 months): 6 weeks** of **≥2 agents**; **complex/focal disease: ≥3 months**. **Adherence is critical** — poor adherence, not resistance, underlies almost all apparent failures (though rising TMP-SMX resistance is reported).

Setting	Regimen	Duration	Relapse
Gold standard, adult acute	Streptomycin 0.75–1 g IM daily + doxycycline 100 mg BD	Streptomycin 14–21 d; doxycycline 6 wk	5–10%
WHO / national alternative	Rifampin 600–900 mg/day + doxycycline 100 mg BD	6 weeks	~10% (trial); >20% non-trial*
Aminoglycoside substitute	Gentamicin 5–6 mg/kg/day in place of streptomycin (US/UK guidelines)	1–2 weeks	— (short courses fail)
Children / pregnant women (avoid tetracyclines)	High-dose TMP-SMX (2–3 standard tablets BD in adults, weight-based)	6 weeks	—

Setting	Regimen	Duration	Relapse
Complicated / poor adherence	Triple therapy: doxycycline + rifampin + initial aminoglycoside	≥3 months	lower
Neurobrucellosis	Ceftriaxone added to a standard regimen	3–6 months	—
Endocarditis	≥3 drugs — aminoglycoside + tetracycline + rifampin (many add ceftriaxone)	prolonged	—

\Rifampin lowers doxycycline levels and increases its clearance, partly explaining the higher non-trial relapse rate.*

- **Fluoroquinolones** show good *in vitro* activity and leukocyte penetration but **disappointing monotherapy** results; **ofloxacin or ciprofloxacin + rifampin for 6 weeks** is a possible alternative. A major meta-analysis and the *Ioannina Recommendations* did **not** endorse fluoroquinolones first-line (outside trials), though newer data are more supportive. **Triple-drug regimens** are superior in meta-analyses but are **not indicated for uncomplicated disease**.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- **Undulant (remittent) fever chart:** plot temperature (°C) on the y-axis against time (days/weeks) on the x-axis. Labels: “*Undulating/remittent fever spikes*,” “*Profuse night sweats*,” “*Afebrile remission*,” “*Relapse*,” and “*≈50% with musculoskeletal pain*.”
- **Brucellar spondylitis (lateral lumbar spine schematic):** Labels — “*Anterosuperior end-plate erosion (epiphysitis)*,” “*Anterolateral parrot-beak osteophyte*,” “*Vertebral body intact until late*,” “*Late diskitis*,” “*Whole-vertebra sclerosis on recovery*” (contrast with TB: gibbus, early disk/body destruction, psoas abscess).

Clinical / Diagnostic significance

- Suspect brucellosis in any PUO with **night sweats and back/joint pain** plus an **exposure history** (unpasteurised dairy, animal contact, abattoir/lab work) — in endemic areas it is the default diagnosis until excluded.
- **Always exclude tuberculosis** before/alongside therapy because of shared drugs and overlapping spinal disease; misclassification risks rifampin monotherapy-driven TB resistance.
- **Blood/bone-marrow culture + paired serology (rising titre) ± PCR** form the practical diagnostic triad; warn the lab to enable safe handling and correct identification.

- ▶ Combination therapy for ≥ 6 weeks with reinforced adherence prevents relapse; escalate to triple therapy / ≥ 3 months for spondylitis, neurobrucellosis and endocarditis, with ceftriaxone for CNS disease and valve-directed multidrug therapy for endocarditis.
- ▶ Pregnant women have increased fetal loss; teratogenicity is not described. There is no increased severity in HIV/immunosuppression.

High-yield exam pointers

- ▶ Undulant fever + night sweats + arthralgia/back pain; ~50% have musculoskeletal involvement.
- ▶ **B. melitensis* (goat/sheep) = commonest and most aggressive; *B. abortus* = insidious/chronic; *B. suis* = focal abscess; *B. canis** = milder but can cause endocarditis.
- ▶ Bone-marrow/blood culture is definitive (50–70%); Bactec positive ≤ 7 days; alert the lab (containment + misidentification risk).
- ▶ SAT titre: $\geq 1:160$ (non-endemic), 1:320–1:640 (endemic) is significant; confirm with rising titre. Beware *Yersinia* O:9 cross-reaction; rough strains/RB51 give false-negative smooth-antigen serology.
- ▶ Sacroiliitis/spondylitis is the classic focal lesion; differentiate from TB spine (parrot-beak osteophyte, body intact till late, rare canal compression/psoas abscess).
- ▶ Doxycycline + streptomycin (gentamicin) is the most effective (gold-standard) regimen; doxycycline + rifampin is the convenient WHO alternative with higher relapse.
- ▶ Children/pregnant $\rightarrow$ TMP-SMX-based (avoid tetracyclines/streptomycin).
- ▶ Neurobrucellosis $\rightarrow$ add ceftriaxone, 3–6 months; endocarditis $\rightarrow$ ≥ 3 drugs (aminoglycoside + tetracycline + rifampin).
- ▶ Relapse usually reflects poor adherence, not resistance.

SOURCE & COVERAGE

Harrison's Principles of Internal Medicine, 22e — Ch 174 "Brucellosis" (N.J. Beeching), including Table 174-1 (brucellar vs tuberculous spine). Coverage note: The provided chapter text ends mid-sentence within the endocarditis paragraph, so the full list of adjunctive endocarditis agents and valve surgery (universally accepted standard practice for *Brucella* endocarditis) is stated from standard internal-medicine teaching, not verbatim from the supplied excerpt. The excerpt contains no dedicated human-prevention/prognosis sections (only animal vaccination/control under epidemiology), so those angles are intentionally not expanded.

Pathophysiology and Management of Severe Sepsis

Asked in: Paper II May 2022 — RGUHS MD General Medicine

Definition / Introduction — Sepsis is an infectious syndrome causing considerable morbidity, mortality, and long-term sequelae among survivors. Under the historic Sepsis-1/Sepsis-2 framework, **severe sepsis** meant sepsis plus hypoperfusion or end-organ dysfunction (oliguria, acute mental-status change, or lactic acidosis), while **septic shock** was sepsis-induced hypotension persisting despite adequate volume resuscitation. The current **Sepsis-3 (2016)** consensus *eliminated the term “severe sepsis”* and redefined **sepsis** as *life-threatening organ dysfunction caused by a dysregulated host response to infection*, with **septic shock** as the subset showing profound circulatory, cellular, and metabolic abnormalities and markedly higher mortality. Thus, what was formerly called “severe sepsis” is, in present nomenclature, simply **sepsis**.

Evolving definitions — where “severe sepsis” fits

Consensus (year)	Sepsis criterion	“Severe sepsis”	Septic shock
Sepsis-1 (1992)	Suspected infection + ≥ 2 SIRS (temp <36 or $>38^{\circ}\text{C}$; HR >90 ; RR >20 or $\text{PaCO}_2 <32$; WBC <4000 or $>12,000/\mu\text{L}$ or $>10\%$ bands)	Sepsis + hypoperfusion / organ dysfunction (oliguria, altered mentation, lactic acidosis)	Sepsis-induced hypotension (SBP <90 or $\downarrow \geq 40$ from baseline) despite adequate volume resuscitation
Sepsis-2 (2003)	Expanded list of clinical & laboratory criteria beyond SIRS	Retained	As above
Sepsis-3 (2016)	Suspected/confirmed infection + $\uparrow\text{SOFA} \geq 2$ from baseline	Term abolished (folded into “sepsis”)	Vasopressor needed for MAP >65 mmHg and lactate >2 mmol/L despite fluid resuscitation

- Epidemiology: ~48.9 million sepsis cases occur globally each year with ~11 million deaths (1 in 5 of all global deaths; 85% in low/middle-income countries). Sepsis affects ~6% of hospitalised US adults, with ~15% overall mortality rising to **up to 40% in septic shock**.
- ~88% are community-onset; ~53% are culture-positive with a roughly even gram-positive/gram-negative split. Commonest primary sites: urinary tract (~49%), respiratory (~33%), intra-abdominal (~14%), skin/soft tissue (~10%). Key organisms: *S. aureus*, *Streptococcus*, *Enterococcus* (gram +) and *E. coli*, *Klebsiella*, *Pseudomonas* (gram –).

Pathophysiology — the dysregulated host response

The unifying mechanism is an **exuberant, dysregulated immune response** to infection causing systemic vasodilation, capillary leak, microvascular thrombosis, and impaired oxygen delivery/utilisation, culminating in multi-organ injury.

- **Triggers & recognition:** Pathogen components (**PAMPs** — e.g., LPS, cell-wall components, microbial nucleic acids) and host-derived **DAMPs** (histones, **HMGB1**, S100 proteins, oxidised

phospholipids, dsDNA, ATP) are sensed by **pattern-recognition receptors (PRRs)** — TLRs (10 in humans), C-type lectin receptors, RAGE, RIG-I, and NOD-like receptors.

- ▶ **Myeloid responses:** Activated **neutrophils** upregulate adhesion molecules (CD11b) and release **neutrophil extracellular traps (NETs)** — DNA webs studded with cathepsin-G, myeloperoxidase, and neutrophil elastase — which, with platelets and fibrin, form microthrombi. **Emergency granulopoiesis** (driven by IL-6, GM-CSF, G-CSF) releases immature neutrophils and predicts poor outcome. **Monocytes** (classical CD14⁺CD16⁻, intermediate, non-classical) differentiate into dendritic cells and **M1 (pro-inflammatory) macrophages** releasing IL-1 β , IL-6, and TNF- α .
- ▶ **Lymphoid responses & immunosuppression:** NK cells amplify inflammation (IFN- γ , granzyme) but also release IL-10. Progressive **lymphocyte apoptosis, exhaustion, and reduced proliferation**, plus myeloid-derived suppressor cells, produce a state of **sepsis-induced immunosuppression** predisposing survivors to secondary infection.
- ▶ **Endothelial activation:** PAMPs/DAMPs degrade the endothelial **glycocalyx** and upregulate **ICAMs and VCAM-1**, tissue factor, and PAI-1, while loss of **VE-cadherin** and tight junctions causes capillary leak $\rightarrow$ interstitial oedema, increased oxygen-diffusion distance, and hypoperfusion. Excess endothelial **nitric oxide (NO)** drives vasodilation.
- ▶ **Coagulopathy:** Endothelial/leukocyte **tissue factor** triggers the extrinsic cascade $\rightarrow$ thrombin $\rightarrow$ fibrin; vWF (Weibel-Palade bodies) aggregates platelets; all three complement pathways activate, releasing C3a/C5a anaphylatoxins and assembling the **membrane-attack complex (C5b-9)**. Natural anticoagulants (antithrombin, tissue-factor-pathway inhibitor, activated protein C) fall while antifibrinolytics (PAI, TAFI) rise, producing microvascular thrombosis; consumption of platelets/factors then causes bleeding (**DIC**).
- ▶ **Cellular injury:** Hypotension (vasodilation, myocardial depression, hypovolaemia), interstitial oedema, and microcirculatory thrombosis impair oxygen delivery; **ROS and reactive nitrogen species** (peroxynitrite) oxidise proteins/lipids and damage DNA. Even with adequate oxygen, **mitochondrial and metabolic dysfunction** disrupts ATP generation and ion homeostasis.

Clinical recognition, scoring & diagnosis

- ▶ Presentation is **non-specific** — fever, tachycardia, lethargy, myalgia — with or without localising features (cough, pyuria, abdominal pain) or signs of organ failure (oliguria, altered mentation). **There is no gold-standard diagnostic test.**
- ▶ **SOFA score** grades dysfunction in six systems: neurologic (GCS), cardiovascular (MAP / vasoactive agents), respiratory (PaO₂/FiO₂ or ventilation), hepatic (bilirubin), renal (creatinine), and coagulation (platelets). An increase of ≥ 2 operationalises Sepsis-3.
- ▶ **qSOFA** (RR ≥ 22 , GCS < 15 , SBP ≤ 100) ≥ 2 flags poor outcome — more specific but less sensitive than SIRS.

- ▶ Baseline workup: CBC with differential, basic metabolic panel, LFTs, **serum lactate**, coagulation panel, urinalysis, and **cultures of blood and suspected sites before antibiotics**, plus targeted imaging (x-ray/CT/ultrasound) to localise and enable **source control**.
- ▶ **Sepsis mimics** (~25% of suspected ICU cases): heart failure/cardiac arrest, non-infective COPD/pneumonitis, mesenteric ischaemia, inflammatory bowel disease, hypovolaemia, autonomic dysfunction, and adrenal insufficiency — mandating continuous re-evaluation.

Management — resuscitation per the 2021 Surviving Sepsis Campaign

Initial priorities: timely blood-pressure and organ support, antimicrobials, and source control; target ICU admission within 6 h for the critically ill.

- ▶ **Antibiotics:** In bacterial septic shock, every 1-h delay adds an estimated 7–8% **mortality** → give **empiric antibiotics within 1 h of shock recognition**. Without shock and with diagnostic uncertainty, a time-limited evaluation is acceptable, giving antibiotics by **3 h** if no alternative diagnosis emerges. Choice is guided by site, community vs health-care exposure, prior resistance, and host factors: third-generation cephalosporin (ceftriaxone/cefotaxime) if *Pseudomonas* unlikely; **cefepime, piperacillin-tazobactam, or a carbapenem** if *Pseudomonas* likely; **two** gram-negative agents if highly resistant organisms are a risk; add **vancomycin or linezolid** for MRSA risk. Add an **echinocandin** only for high fungal risk; **remdesivir/oseltamivir** for SARS-CoV-2/influenza. De-escalate and shorten courses with culture data.
- ▶ **Source control:** Drain/debride/decompress (intra-abdominal abscess, bowel perforation, pyelonephritis, cholangitis, necrotising soft-tissue infection) **as rapidly as possible**; remove infected indwelling catheters.
- ▶ **Fluids:** **Balanced crystalloid** (e.g., lactated Ringer's) is preferred over 0.9% saline (which risks hyperchloraemic acidosis); **avoid pentastarch/hydroxyethyl starch** (kidney injury, death). Give a bolus over 5–10 min at ~30 mL/kg (individualise in ESRD/systolic HF). Guide further fluids by **dynamic assessment** (capillary refill, passive-leg-raise, point-of-care ultrasound), *not* static CVP-based protocolised targets.
- ▶ **Vasopressors:** **Norepinephrine first-line** (MAP target ≥ 65 mmHg), add **vasopressin** second, **epinephrine** third. Place an arterial line for continuous monitoring.
- ▶ **Inotrope:** For myocardial dysfunction (sepsis-induced cardiomyopathy) with persistent hypoperfusion, add **dobutamine** to norepinephrine or use epinephrine alone.
- ▶ **Corticosteroids:** IV **hydrocortisone 200 mg/day** (50 mg q6h) if ongoing vasopressor requirement.

Organ-specific complications & targeted management

System (frequency)	Key findings	Management essentials
Neurologic (54% — encephalopathy)	Altered consciousness/cognition; seizure, stroke	Treat infection; correct metabolic/electrolyte derangement; limit neurotoxic drugs (e.g., cefepime), opiates, benzodiazepines; EEG/MRI/LP as indicated
Cardiovascular (25% shock; ½ with myocardial dysfunction)	Hypotension, skin mottling, prolonged capillary refill, oliguria	Balanced crystalloid ~30 mL/kg; norepinephrine → vasopressin → epinephrine; hydrocortisone 200 mg/d; dobutamine/PAC if mixed cardiogenic picture
Respiratory (7% — ARDS)	Tachypnoea, hypoxia; bilateral infiltrates, PaO ₂ /FiO ₂ <300	Target SpO ₂ 90–96% ; HFNC preferred over NIV; plateau pressure <30 cmH₂O , tidal volume 6–8 mL/kg IBW ; rescue: prone positioning, neuromuscular blockade, VV-ECMO
Renal (up to 67% — AKI)	Oliguria/anuria, ↑creatinine/BUN, acidaemia, hyperkalaemia	Maintain perfusion, avoid nephrotoxins; RRT for standard indications (refractory acidaemia, hyperkalaemia, uraemia, volume overload); CRRT preferred in shock; bicarbonate if pH ≤7.2
Hepatic/GI (50% liver dysfunction)	RUQ pain, jaundice, asterixis; ↑bilirubin/ALP	Treat infection, avoid hypotension/hepatotoxins; stress-ulcer prophylaxis for high-risk; enteral feeding within 48 h once shock controlled; insulin if glucose >180 mg/dL
Haematologic (35% septic shock — DIC)	Thrombocytopenia, ↑fibrin split products, ↓fibrinogen, prolonged PT/INR	Cryoprecipitate for fibrinogen <150 mg/dL; platelets if ≤50×10 ⁹ /L + bleeding; FFP for prolonged PT/INR + bleeding; PRBC for Hb <7.0 g/dL

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- **Sepsis pathogenesis schematic** (label clearly): *Pathogen* → PAMPs/DAMPs → PRR (TLR) on **monocyte/neutrophil**; *Tissue factor* on endothelium/leukocytes → *clotting cascade* → *thrombin* → *fibrin*; *NETs*; *platelet aggregates* + vWF; ↓*antithrombin*, ↑*PAI-1*; *complement C3a/C5a*, *MAC (C5b-9)*; *endothelial ICAMs/VCAM-1*, *glycocalyx degradation*, *loss of VE-*

System (frequency)	Key findings	Management essentials
	<i>cadherin</i> → <i>interstitial oedema</i>; <i>NO-mediated vasodilation</i>; <i>mitochondrial/metabolic dysfunction</i>; <i>M1 macrophage</i>; <i>lymphocyte exhaustion/apoptosis</i>. ► Sepsis-3 management algorithm: <i>Suspected infection</i> → <i>screen</i> ($\Delta\text{SOFA} \geq 2$ / $q\text{SOFA}$) → <i>cultures</i> + <i>lactate</i> → <i>empiric antibiotics</i> ≤ 1 h (shock) → <i>30 mL/kg balanced crystalloid</i> → <i>dynamic reassessment</i> (PLR/POCUS/capillary refill) → <i>norepinephrine</i> ($\text{MAP} \geq 65$) → <i>vasopressin</i> → <i>epinephrine</i> → <i>hydrocortisone 200 mg/d</i> → <i>source control</i> → <i>ICU</i> ≤ 6 h.	

Clinical / Diagnostic significance

- **Lactate** is both a diagnostic threshold for septic shock (>2 mmol/L) and a resuscitation marker; a randomised trial found capillary-refill-guided resuscitation was non-inferior to lactate-targeted resuscitation for 28-day mortality — relevant in resource-limited settings.
- **Sepsis-induced coagulopathy (SIC)** scoring (platelets, PT, SOFA) detects coagulopathy earlier and more sensitively than overt-DIC criteria.
- Machine-learning **phenotypes** (α , β , γ , δ) carry distinct mortality (2%, 5%, 15%, 32%) and may refine future trial design and prognostication.
- A restrictive-vs-liberal early-fluid trial and protocolised CVP/ScvO₂ targets showed **no mortality benefit**, underpinning the modern shift to individualised, dynamic resuscitation.

High-yield exam pointers

- Sepsis-3 abolished “severe sepsis”: today it is **sepsis** (organ dysfunction, $\Delta\text{SOFA} \geq 2$) and **septic shock** (vasopressor for $\text{MAP} > 65$ + lactate > 2 despite fluids).
- **Antibiotics within 1 h** of septic-shock recognition; ~7–8% **added mortality per hour** of delay.
- **Norepinephrine** → **vasopressin** → **epinephrine**; MAP target ≥ 65 mmHg.
- **Balanced crystalloid** ~30 mL/kg; avoid starch (HES); guide by dynamic measures, not CVP.
- **Hydrocortisone 200 mg/day** for vasopressor-dependent shock.
- **ARDS:** 6–8 mL/kg tidal volume, plateau < 30 cmH₂O, SpO₂ 90–96%; rescue with prone/NMB/VV-ECMO.
- **AKI:** RRT for **standard indications only**; bicarbonate if $\text{pH} \leq 7.2$; PRBC transfuse at **Hb** < 7 g/dL.
- Most frequent primary site = **urinary tract**; septic-shock mortality **up to 40%**.

SOURCE & COVERAGE

Harrison’s Principles of Internal Medicine, 22e — Ch 315 “Sepsis and Septic Shock” (Strich & Chertow). **Coverage note:** The exam phrasing “severe sepsis” reflects the older Sepsis-1/Sepsis-2 nomenclature; Harrison 22e follows **Sepsis-3 (2016)**, which eliminated the term — the answer therefore maps “severe sepsis” onto current “sepsis”/“septic shock” definitions. SIRS thresholds

and the original severe-sepsis/septic-shock criteria are quoted from the chapter's historical-definitions paragraph. All drug doses, vasopressor sequence, ventilation targets, transfusion triggers, and organ-specific frequencies are taken verbatim from the chapter text and Tables 315-1/315-2.

Discuss the neurologic disorders in Human Immunodeficiency Virus (HIV) disease

Asked in: Paper II Dec 2023 — RGUHS MD General Medicine

Definition / Introduction — Neurologic disease in HIV includes direct effects of HIV on the nervous system, opportunistic infections and neoplasms due to immunosuppression, immune reconstitution inflammatory syndromes, and treatment-related toxicities. Neurologic involvement may occur at any stage, from acute seroconversion meningitis to advanced AIDS with focal brain lesions, dementia, myelopathy, or peripheral neuropathy. The approach in an exam answer is to classify by **anatomic syndrome**, **CD4 count**, and **treatable emergency**.

Classification of neurologic disorders in HIV

- ▶ **Primary HIV-related disorders:**
 - **Acute HIV aseptic meningitis / meningoencephalitis** during seroconversion, with fever, headache, photophobia, lymphocytic CSF, and sometimes cranial neuropathies.
 - **HIV-associated neurocognitive disorder (HAND):** asymptomatic neurocognitive impairment, mild neurocognitive disorder, and **HIV-associated dementia**.
 - **Vacuolar myelopathy**, usually in advanced HIV, resembling subacute combined degeneration with spastic paraparesis and posterior-column signs.
 - **Peripheral neuropathies:** distal symmetric polyneuropathy, inflammatory demyelinating polyneuropathy, mononeuritis multiplex, radiculopathy, and autonomic neuropathy.
- ▶ **Opportunistic infections of CNS:**
 - **Toxoplasma encephalitis, cryptococcal meningitis, tuberculous meningitis, progressive multifocal leukoencephalopathy (PML), CMV encephalitis / polyradiculopathy, VZV vasculopathy, neurosyphilis, and bacterial or fungal abscesses.**
- ▶ **Neoplasms:**
 - **Primary CNS lymphoma**, systemic lymphoma with CNS spread, and rarely Kaposi-related or other metastatic disease.
- ▶ **Immune-mediated / ART-related:**

- **IRIS** unmasking or worsening cryptococcosis, tuberculosis, PML, or toxoplasmosis after ART initiation.
- Drug toxicities: zidovudine myopathy, older nucleoside analogue mitochondrial toxicity, efavirenz neuropsychiatric symptoms, and chemotherapy-related neuropathy.

Primary HIV-related neurologic syndromes

Syndrome	Typical setting	Key clinical features	Diagnosis	Management
Acute aseptic meningitis	Primary HIV infection	Fever, headache, meningism, photophobia, cranial nerve palsy; may accompany rash, pharyngitis, lymphadenopathy	CSF lymphocytic pleocytosis, raised protein, normal or mildly low glucose; exclude HSV, VZV, TB, cryptococcus	Supportive care; initiate ART as per HIV guidelines after evaluation
HAND / HIV-associated dementia	Chronic HIV; more severe with low CD4 and high viral load	Subcortical pattern: psychomotor slowing, impaired attention and executive function, apathy, gait difficulty, poor fine motor speed	Neuropsychological testing; MRI may show cerebral atrophy or white-matter signal change; exclude depression, drugs, OI, B12, thyroid disease	Effective ART with CNS-active regimen when possible; treat comorbidities and rehabilitation
Vacuolar myelopathy	Advanced AIDS	Slowly progressive spastic paraparesis, hyperreflexia, extensor plantars, sensory ataxia, urinary urgency; often with dementia or neuropathy	MRI spinal cord may be normal or show atrophy; B12, copper, HTLV-1, syphilis, compressive myelopathy must be excluded	ART; physiotherapy, antispasticity measures, bladder care

Syndrome	Typical setting	Key clinical features	Diagnosis	Management
Distal symmetric polyneuropathy	Common in advanced or treated HIV	Burning feet, numbness, allodynia, reduced ankle reflexes; length-dependent sensory loss	Clinical plus nerve conduction if uncertain; screen diabetes, B12 deficiency, alcohol, renal disease, drugs	ART optimization, remove neurotoxic drugs, pregabalin/gabapentin/duloxetine/TCA, foot care

- ▶ **HIV-associated dementia** is classically a **subcortical dementia**: slowed thinking, impaired concentration, apathy, personality change, gait imbalance, tremor, and later incontinence.
- ▶ It must not be diagnosed until **opportunistic infection, CNS lymphoma, metabolic encephalopathy, depression, substance use, and drug toxicity** have been excluded.
- ▶ **Vacuolar myelopathy** is the important spinal cord answer: corticospinal tract and posterior column dysfunction, often without a compressive lesion on imaging.
- ▶ **Peripheral neuropathy** is among the commonest neurologic complications of HIV; severe pain and loss of ankle reflexes are high-yield clinical clues.

Opportunistic infections: CD4-linked approach

Disorder	Usual immune setting	Clinical clues	Imaging / CSF clues	Treatment principle
Toxoplasma encephalitis	CD4 usually <100 cells/microL; Toxoplasma IgG positive	Headache, fever, confusion, seizures, focal deficits	Multiple ring-enhancing basal ganglia or corticomedullary lesions with edema; CSF PCR may help	Pyrimethamine + sulfadiazine + leucovorin or TMP-SMX; continue at least 6 weeks, then maintenance until immune recovery
Cryptococcal meningitis	CD4 often <100 cells/microL	Subacute headache, fever, vomiting, altered sensorium; meningism may be mild	High opening pressure; cryptococcal antigen positive; lymphocytic or paucicellular CSF	Amphotericin B plus flucytosine induction, then fluconazole consolidation and maintenance; repeated therapeutic LP for raised pressure

Disorder	Usual immune setting	Clinical clues	Imaging / CSF clues	Treatment principle
Tuberculous meningitis / tuberculoma	Any stage, common in advanced disease	Chronic fever, headache, basal meningitis, cranial neuropathy, stroke, hydrocephalus	Basal exudates, infarcts, hydrocephalus; CSF lymphocytes, high protein, low glucose; NAAT/culture	Standard anti-TB therapy with corticosteroids; manage hydrocephalus and ART timing carefully
PML (JC virus)	CD4 usually <200 cells/microL	Subacute focal deficits, visual field loss, aphasia, ataxia; usually no fever or mass effect	Non-enhancing or faintly enhancing white-matter lesions without marked edema; CSF JC virus PCR	No specific antiviral of proven value; restore immunity with ART; distinguish from PML-IRIS
CMV encephalitis / polyradiculopathy	CD4 usually <50 cells/microL	Delirium, ventriculoencephalitis, retinitis; cauda equina syndrome with flaccid weakness and urinary retention	CSF neutrophils may occur in polyradiculopathy; CMV PCR supportive	IV ganciclovir, often with foscarnet in severe disease; start or optimize ART

- ▶ **CNS toxoplasmosis** is the commonest cause of multiple ring-enhancing brain lesions in advanced AIDS; empirical treatment is reasonable when the clinical-radiologic picture is typical, but failure to improve should prompt biopsy to exclude lymphoma.
- ▶ **Cryptococcal meningitis** is a raised intracranial pressure disease: repeated lumbar puncture is therapeutic and lifesaving; corticosteroids are not routine unless another indication exists.
- ▶ **PML** gives progressive demyelinating focal neurologic deficits without a bulky enhancing mass; deterioration after ART may represent PML-IRIS.
- ▶ **CMV polyradiculopathy** is suggested by rapidly progressive flaccid paraparesis, saddle sensory loss, areflexia, and bladder dysfunction in very advanced HIV.

Focal brain lesion in HIV: differential diagnosis

- ▶ **Multiple ring-enhancing lesions:**
 - Most likely **toxoplasma encephalitis**, especially basal ganglia lesions with edema and positive Toxoplasma IgG.
 - Differentials: tuberculoma, fungal abscess, bacterial abscess, metastasis, and lymphoma.
- ▶ **Solitary enhancing mass:**
 - Consider **primary CNS lymphoma**, toxoplasmosis, tuberculoma, glioma, or abscess.

- CNS lymphoma often involves deep periventricular structures or corpus callosum and may show EBV DNA in CSF.
- ▶ **Non-enhancing white-matter lesions:**
 - Think of PML, HIV encephalopathy, demyelination, or small-vessel disease.
- ▶ **Meningitis picture:**
 - Cryptococcus, tuberculosis, syphilis, bacterial meningitis, viral meningitis, and primary HIV meningitis.
- ▶ **Myelopathy / radiculopathy:**
 - Vacuolar myelopathy, CMV polyradiculopathy, VZV radiculitis, lymphoma, epidural abscess, TB spine, B12 deficiency, and compressive cord disease.

Diagnostic approach

- ▶ Assess **stage of HIV**: duration, ART adherence, opportunistic infection prophylaxis, CD4 count, plasma HIV RNA, prior OI, and current ART drugs.
- ▶ Define the neurologic syndrome:
 - **Meningitis / encephalitis, focal brain lesion, dementia, myelopathy, neuropathy, myopathy, or stroke.**
- ▶ Urgent investigations:
 - **MRI brain with contrast** is preferred for focal deficits, seizures, altered sensorium, suspected PML, lymphoma, or toxoplasmosis.
 - **CT brain before LP** when raised intracranial pressure, focal deficit, papilledema, or mass lesion is suspected.
 - **CSF**: opening pressure, cells, protein, glucose; Gram stain/culture; cryptococcal antigen; AFB smear/culture/NAAT; VDRL; viral PCRs including HSV/VZV/CMV/JC virus as indicated; cytology/flow cytometry for lymphoma.
 - Blood tests: CD4 count, HIV RNA, complete blood count, electrolytes, renal/liver function, B12, thyroid tests, syphilis serology, hepatitis coinfection, and toxoplasma IgG.
- ▶ Neurophysiology:
 - Nerve conduction studies for neuropathy, demyelinating neuropathy, mononeuritis multiplex, or radiculopathy.
 - EMG and creatine kinase for suspected HIV or zidovudine-associated myopathy.
- ▶ Brain biopsy is reserved for:
 - Atypical lesions, negative serology, solitary mass, diagnostic uncertainty, or no clinical/radiologic response to appropriate empirical therapy.

Management principles

- ▶ **Stabilize first:** airway, breathing, circulation; treat seizures, raised intracranial pressure, sepsis, severe hyponatremia, and hypoglycemia promptly.
- ▶ **Start pathogen-specific therapy early** when a treatable OI is likely; do not wait for every test if toxoplasmosis, bacterial meningitis, HSV encephalitis, or TB meningitis is strongly suspected.
- ▶ **ART is central**, but timing must be individualized:
 - In most OIs, initiate ART after acute stabilization and early anti-infective therapy.
 - In **cryptococcal meningitis** and **TB meningitis**, very early ART can worsen intracranial inflammation; delayed initiation after induction therapy is often preferred.
- ▶ Prevent and treat **IRIS**:
 - Suspect IRIS when a patient worsens after ART despite microbiologic control or when occult infection becomes clinically apparent.
 - Continue ART in most cases, continue OI therapy, and use corticosteroids for severe inflammatory complications after excluding uncontrolled infection.
- ▶ Provide **secondary prophylaxis** until immune reconstitution:
 - Toxoplasmosis and cryptococcosis need maintenance therapy until sustained CD4 recovery on ART.
- ▶ Supportive care:
 - Rehabilitation for cognitive, gait, and focal deficits; neuropathic pain control; bladder and bowel care; nutrition; fall prevention; psychiatric assessment; adherence counselling.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Flowchart: neurologic syndrome in HIV** — labels: acute meningitis, focal brain lesion, diffuse encephalopathy/dementia, myelopathy, peripheral neuropathy; next labels: MRI brain, CSF with opening pressure, CD4 count, targeted PCR/antigen tests, empirical therapy.
- ▶ **CD4-linked CNS complications chart** — labels: CD4 <200: PML, TB, lymphoma; CD4 <100: toxoplasmosis, cryptococcus; CD4 <50: CMV encephalitis/polyradiculopathy; any CD4: acute HIV meningitis, neurosyphilis, stroke.

Clinical / Diagnostic significance

- ▶ Neurologic symptoms in HIV are often the first clue to **advanced immunosuppression** or ART failure.
- ▶ **Ring-enhancing lesion plus seizures or hemiparesis** in advanced HIV is toxoplasmosis until proved otherwise, but lymphoma must be considered if solitary, EBV-positive CSF, or nonresponsive.
- ▶ **Headache with high CSF opening pressure** in AIDS is a cryptococcal emergency; pressure control is as important as antifungal therapy.

- ▶ **Subacute focal deficits without fever or mass effect** point toward PML; treatment is immune restoration, not conventional antiviral therapy.
- ▶ **Rapid flaccid paraparesis with urinary retention** suggests CMV polyradiculopathy, whereas slowly progressive spastic paraparesis suggests vacuolar myelopathy.
- ▶ **Cognitive decline** may be HAND, but reversible mimics such as depression, drugs, metabolic disease, OI, and CNS lymphoma must be actively excluded.
- ▶ ART has reduced classic HIV dementia and many OIs, but has increased the importance of recognizing IRIS and chronic neurocognitive impairment.

High-yield exam pointers

- ▶ Classify HIV neurology as **direct HIV, opportunistic infection, neoplasm, immune-mediated/IRIS, and drug-related**.
- ▶ HAND is a **subcortical** cognitive-motor-behavioral syndrome; severe form is HIV-associated dementia.
- ▶ Vacuolar myelopathy causes **spastic paraparesis with posterior-column signs** in advanced AIDS.
- ▶ Toxoplasmosis: **multiple ring-enhancing basal ganglia lesions**; treat with pyrimethamine-sulfadiazine-leucovorin or TMP-SMX.
- ▶ Cryptococcal meningitis: **measure opening pressure** and repeat LPs for raised pressure.
- ▶ PML: JC virus, **non-enhancing white-matter demyelination**, no proven specific antiviral; optimize ART.
- ▶ CMV neurologic disease occurs at very low CD4 counts and may cause **ventriculoencephalitis or polyradiculopathy**.
- ▶ Primary CNS lymphoma is an AIDS-defining malignancy; think of it in a **solitary enhancing mass** or toxoplasma nonresponse.
- ▶ Always mention **CD4 count, HIV RNA, MRI with contrast, CSF studies, ART timing, and IRIS**.

CMDT 2026 — HIV infection/AIDS and opportunistic infection management.

Serological Tests in the Diagnosis of Infectious Diseases

Asked in: Paper I Dec 2023 — RGUHS MD General Medicine

Definition / Introduction — Serology is the laboratory detection and quantitation of pathogen-specific **antibodies** (or, by extension, microbial **antigens**) in serum and other body fluids, used to infer infection from the **host's immune response** rather than by isolating the organism. Harrison emphasises that serologic diagnosis is the *measurement of the host's response to pathogen exposure* and can typically be made **only in retrospect**, requiring paired **acute- and convalescent-phase serum samples**. It is the mainstay for organisms that are difficult or impossible to culture, but its sensitivity and specificity are variable and it is increasingly complemented (and replaced) by **antigen detection** and **nucleic-acid amplification tests (NAATs)**.

Basic principles & interpretive concepts

- ▶ **Antigen–antibody reaction** is the basis: a known antigen detects unknown antibody (or a known antibody detects unknown antigen) in the patient's specimen.
- ▶ **Indirect (antibody) detection vs direct (antigen) detection** — antibody tests reflect the *host response*; antigen tests detect *structural components of the pathogen* itself.
- ▶ **Antibody class**: IgM appears early and indicates **recent/acute** infection; IgG appears later, persists, and indicates **past exposure, convalescence or immunity**.
- ▶ **Seroconversion** — change from antibody-negative to antibody-positive; the **window period** is the interval after infection before antibody becomes detectable (a key cause of false-negatives, classically in HIV).
- ▶ **Diagnostic criterion**: a **fourfold (two-dilution) rise in titre** between acute and convalescent sera, or **seroconversion**, confirms recent infection; a single titre is harder to interpret.
- ▶ **Limitation flagged by Harrison**: for chronic infections, serology alone often **cannot distinguish active from latent infection** or identify repeat exposure, and sensitivity depends on the **organism** and the patient's immune status.

Classification of serological / immunodiagnostic techniques

Principle	Representative test(s)	Typical infectious-disease use
Agglutination	Widal, Weil–Felix, latex agglutination , cold agglutinins, heterophile (Paul–Bunnell/Monospot)	Enteric fever, rickettsioses, cryptococcal/CSF antigen , <i>Mycoplasma</i> , EBV mononucleosis
Precipitation / flocculation	VDRL, RPR (nontreponemal)	Syphilis screening
Complement fixation	CFT (historical Wassermann)	Older viral/fungal serology
Neutralization	ASO (anti-streptolysin O) titre	Recent streptococcal infection / rheumatic fever
Immunofluorescence	FTA-ABS, direct/indirect IFA	Treponemal confirmation, many viruses

Principle	Representative test(s)	Typical infectious-disease use
Enzyme immunoassay (ELISA/EIA)	Ag/Ab combo assays, capture (MAC) ELISA	HIV screen, hepatitis, dengue, many others
Immunoblot / Western blot	Confirmatory immunoblot	Historical HIV & Lyme confirmation
Chemiluminescence / lateral-flow rapid tests	Immunochromatographic strips	Point-of-care HIV, dengue NS1, malaria, cryptococcal LFA

(The taxonomy above is standard textbook microbiology — see Coverage note; the specific applications below are anchored in the provided chapters.)

Antibody-based serology in specific infections

- ▶ HIV — combined antigen/antibody (4th-generation) immunoassays detect both p24 antigen and anti-HIV antibody. Harrison's natural-history model (Fiebig staging) shows p24 antigenaemia appearing first in acute infection, transiently disappearing, then antibody rising at seroconversion, with viral load persisting — illustrating why early antibody-only testing missed acute disease and why molecular (PCR) viral-load testing transformed diagnosis and staging.
- ▶ Syphilis (*Treponema pallidum*) — notoriously difficult to stage by serology alone; requires two tiers: a nontreponemal test (Harrison cites RPR — rapid plasma reagin; also VDRL) for screening and activity, plus a treponemal test (fluorescent treponemal antibody, FTA-ABS; also TPHA/TP-PA) for confirmation. *CSF serology for *T. pallidum*** (CSF-VDRL) is highly useful in selected neurosyphilis patients.
- ▶ Lyme disease (*Borrelia burgdorferi*) — IgM and IgG antibody testing; Harrison gives IgM early-disease sensitivity ≈50% and specificity ≈80%, and notes IgG may reflect prior exposure rather than active disease in endemic regions — a classic example of serology's interpretive pitfalls (two-tier EIA → immunoblot).
- ▶ Tuberculosis (immunodiagnosis of host T-cell response) — tuberculin skin test (PPD) and interferon-γ release assays (IGRAs), which measure *cytokine release from T lymphocytes in response to M. tuberculosis-specific antigens. Both have limited sensitivity in immunodeficient hosts, and neither distinguishes latent from active infection — emphasising that serology is notoriously insensitive for TB*.
- ▶ Fungal CSF serology — antibody/antigen testing for *Coccidioides* is sensitive and useful in selected patients.

Antigen-detection assays (direct serodiagnosis)

- ▶ Viral structural antigens — hepatitis B surface antigen (HBsAg), HIV p24 antigen, SARS-CoV-2 spike protein.

- ▶ **Bacterial surface antigens / urinary antigen tests** — **Streptococcus pneumoniae* and **Legionella pneumophila* serogroup 1**.
- ▶ **Fungal antigens** — **Cryptococcus antigen* (CrAg; highly sensitive) and **Histoplasma**; less-specific cell-wall components: galactomannan (*Aspergillus*) and β -D-glucan (*Aspergillus** and other fungi).
- ▶ **CSF latex agglutination** — for ***Haemophilus influenzae* type b, group B *Streptococcus*, *S. pneumoniae*, and *Neisseria meningitidis*. **Harrison notes these are not recommended for screening (no more sensitive than Gram's stain) but help** presumptively identify organisms already seen on Gram's stain; **in contrast**, cryptococcal antigen** testing is highly sensitive and clinically useful.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **HIV serological markers in natural history (Fiebig-type curve)** — x-axis: Time (weeks → years); y-axis: Relative level; plot three curves labelled **p24 antigen**, **HIV antibody (Ab)**, **Viral load (VL)**; add a dashed **limit of detection** line; mark phases **Acute HIV → Chronic HIV → AIDS** and the **window period / seroconversion**.
- ▶ **Acute vs convalescent antibody response** — x-axis **time from onset**, y-axis **antibody titre**; two curves **IgM** (early, transient) and **IgG** (later, persistent); annotate the **fourfold rise in titre** between acute and convalescent samples as the diagnostic criterion.

Clinical / Diagnostic significance

- ▶ Serology is the **diagnostic approach of choice** when the organism is **unculturable or fastidious**, and for **epidemiological/seroprevalence surveys** and **immunity/vaccination status** (e.g., anti-HBs, rubella IgG).
- ▶ **Two-tier strategies** (sensitive screen → specific confirmatory) maximise accuracy — exemplified by **syphilis** (nontreponemal → treponemal) and **Lyme** (EIA → immunoblot).
- ▶ **IgM positivity supports acute infection**; **paired sera with a fourfold rise** give definitive evidence; **CSF antibody/antigen** localises CNS infection (neurosyphilis, cryptococcal, coccidioidal).
- ▶ **Pitfalls**: window-period false-negatives, **cross-reactivity** and false-positives (biological false-positive VDRL), inability to separate **active from latent/past** infection, and **reduced sensitivity in immunocompromised patients** — all argue for correlation with **clinical suspicion** and, increasingly, **NAAT/PCR**, which provide real-time diagnosis and can predict drug resistance.

High-yield exam pointers

- ▶ Serology = **host antibody response**; usually a **retrospective** diagnosis needing **acute + convalescent sera**; **fourfold titre rise** or **seroconversion** is confirmatory.
- ▶ **IgM = recent/acute**; **IgG = past/immunity**; beware the **window period**.

- ▶ Syphilis — nontreponemal RPR/VDRL + treponemal FTA-ABS/TPHA; biological false-positive VDRL is a classic trap.
- ▶ HIV — 4th-gen Ag/Ab combo (p24 + antibody); p24 antigen precedes antibody (narrows window).
- ▶ Lyme IgM early sensitivity ~50%, specificity ~80%; IgG may mean only past exposure.
- ▶ TB — PPD/IGRA test cell-mediated immunity, are insensitive in immunodeficiency, and cannot separate latent from active disease.
- ▶ Antigen tests: HBsAg, HIV p24, SARS-CoV-2 spike, pneumococcal/Legionella urinary antigen, cryptococcal antigen, galactomannan/ β -D-glucan.
- ▶ CSF latex agglutination (Hib, GBS, pneumococcus, meningococcus) is *not for screening* but aids Gram-stain-guided identification; CrAg is highly sensitive.
- ▶ Classic eponymous agglutination tests: Widal (enteric fever), Weil–Felix (rickettsia), Paul–Bunnell/Monospot (EBV), cold agglutinins (*Mycoplasma*), ASO (streptococcal).

SOURCE & COVERAGE

Harrison's Principles of Internal Medicine, 22e (2025) — Ch 126 “Microbial Genomics and Infectious Disease” (serologic vs antigen vs nucleic-acid diagnosis; HBsAg/HIV p24/SARS-CoV-2 spike; pneumococcal/Legionella urinary antigen; cryptococcal/histoplasma antigen; galactomannan/ β -glucan; HIV antibody–p24–viral-load seroconversion/Fiebig figure; syphilis RPR/FTA; Lyme IgM/IgG sensitivity-specificity; PPD/IGRA) and Ch 124 “Approach to the Patient with an Infectious Disease” (pathogen-specific serology/antigen/PCR testing; CSF latex agglutination for Hib, GBS, *S. pneumoniae*, *N. meningitidis*; cryptococcal antigen; CSF serology for *T. pallidum* and *Coccidioides*; high-titre antibody/IVIG).

Coverage note (spec gap = true): The provided chapters carry no dedicated “serology” section, so the technique-classification table (agglutination, precipitation/flocculation, complement fixation, neutralization, immunofluorescence, ELISA/EIA, Western blot, immunochromatography) and the eponymous tests Widal, Weil–Felix, Paul–Bunnell/Monospot, ASO, cold agglutinins, and dengue NS1/MAC-ELISA are supplied from universally accepted standard internal-medicine/microbiology knowledge, not directly from these two Harrison chapters. The disease-specific applications (HIV, syphilis, Lyme, TB, fungal/CSF antigen) and antigen-detection examples are faithfully grounded in the text above.

Ebola Virus Disease (Filovirid — Orthoebolavirus Infection)

Asked in: Paper II Jul 2020 — RGUHS MD General Medicine

Definition / Introduction — *Ebola virus (EBOV)* is an enveloped, non-segmented, negative-sense RNA virus of the family **Filoviridae**, genus *Orthoebolavirus*, and is the cause of **Ebola virus disease (EVD)** — the prototype of the filovirid viral haemorrhagic fevers (along with Marburg disease). EVD is a *World Health Organization Risk Group 4* zoonosis that begins as a non-specific influenza-like illness and rapidly evolves to gastrointestinal loss, coagulopathy, multi-organ dysfunction and shock, with a historically very high case-fatality rate. It is highly **infectious but not highly contagious**, spreading by direct contact with body fluids rather than by aerosol.

Etiology & Virology

- ▶ Family **Filoviridae** has nine official genera; only two contain human pathogens — *Orthoebolavirus* and *Orthomarburgvirus*. Collectively these cause **filovirid (filovirus) disease (FVD)**.
- ▶ **Ebola disease (EBOD)** is caused by four of the orthoebolaviruses; **Marburg disease (MARD)** by the two orthomarburgviruses (Marburg virus, Ravn virus).
- ▶ The virion is **pleomorphic and filamentous** (also torus-/”6”-shaped); width ≈91–98 nm, length <1 µm; enveloped, with a helical ribonucleoprotein capsid studded with **GP1,2 glycoprotein spikes**.
- ▶ Genome ≈19 kb, linear negative-sense RNA with **seven genes encoding seven structural proteins**: nucleoprotein (NP), polymerase cofactor (VP35), matrix protein (VP40), glycoprotein (GP1,2), transcriptional activator (VP30), ribonucleoprotein-associated protein (VP24) and the L protein (RNA-dependent RNA polymerase). Orthoebolaviruses *additionally* encode three non-structural proteins — *sGP*, *ssGP* and Δ -peptide.

Orthoebolavirus	Virus (abbrev.)	Pathogenicity in humans
<i>O. zairense</i>	Ebola virus (EBOV) — “Zaire”	Highly pathogenic; cause of the 2013–16 West Africa epidemic
<i>O. sudanense</i>	Sudan virus (SUDV)	Pathogenic; re-emerged Uganda/South Sudan 2022–23
<i>O. bundibugyoense</i>	Bundibugyo virus (BDBV)	Pathogenic
<i>O. taiense</i>	Taï Forest virus (TAFV)	Pathogenic (rare; only one human case)
<i>O. restonense</i>	Reston virus (RESTV)	Apparently non-pathogenic to humans
<i>O. bombaliense</i>	Bombali virus (BOMV)	Non-pathogenic (detected in bats)

Epidemiology & Transmission

- ▶ First recognised in **1976** in simultaneous outbreaks in *Zaire (now DR Congo)* and *South Sudan*; >20 outbreaks since, confined to equatorial **Western, Middle and Eastern Africa**.
- ▶ The **2013–2016 West Africa outbreak** (Guinea, Sierra Leone, Liberia, with exported cases) was the largest ever — **28,652 cases and 11,325 deaths** — and was the first to constitute a regional and global threat; CMDT cites an average case-fatality rate of **~60%**.
- ▶ **Reservoir:** the cave-dwelling **Egyptian rousette fruit bat* (*Rousettus aegyptiacus*) *is the proven reservoir for Marburg/Ravn viruses; fruit/insectivorous bats are the suspected (but unproven) reservoir for orthoebolaviruses**. Only ≈ 50 natural host-to-human spillover events have been recorded since 1967.
- ▶ **Spillover to humans:** contact with reservoir hosts or with infected/dead mammals — hunting or eating “bushmeat” (apes, monkeys, duikers, bush pigs).
- ▶ **Human-to-human spread:** direct person-to-person contact or exposure to **infected body fluids/tissues** (blood, vomitus, stool, sweat, semen, breast milk), parenteral inoculation (needlestick, needle reuse), and contact with corpses during **traditional burial/ritual washing**. *There is no natural aerosol or respiratory-droplet transmission.*
- ▶ Virus is **not transmissible before symptom onset**; infectivity rises with illness severity and viral load. Health-care workers and family caregivers bear the highest risk; nosocomial amplification drives outbreaks.

Pathogenesis

- ▶ Entry is via skin breaks or mucosa; **GP1,2 spikes** determine tropism by engaging the intracellular receptor NPC1 (Niemann-Pick C1 cholesterol transporter).
- ▶ **First targets are macrophages, monocytes and dendritic cells**. Structural proteins VP35, VP40 and VP24 **suppress innate immunity** (notably the type-I interferon pathway), permitting uncontrolled replication — serum titres exceed 10^6 PFU/mL with dissemination to almost all tissues (hepatocytes, adrenal cortex, fibroblasts, endothelium).
- ▶ **Immune dysregulation:** infected macrophages release a “cytokine storm”; dendritic cells fail to present antigen; massive **lymphoid (T-cell) apoptosis** in nodes, spleen and thymus causes the profound lymphopenia and predisposes to secondary bacterial/fungal infection.
- ▶ **Coagulopathy & endothelial dysfunction:** thrombocytopenia, raised tissue factor, consumption of clotting factors, raised D-dimer, falling protein C → features of **DIC**, fibrin deposition and microvascular thrombosis. Hepatocyte necrosis impairs clotting-factor synthesis.
- ▶ **Vascular leak:** cytokines, nitric oxide and direct endothelial infection raise vascular permeability → fluid redistribution, interstitial oedema, and **hypovolaemic/septic (distributive) shock**. *Massive external blood loss is actually uncommon* (though severe around childbirth).

Clinical Features & Disease Course

- ▶ **Incubation 2–25 days** (Harrison; CMDT 2–21 days), most often 7–10 days.

- ▶ Orthoebolavirus and orthomarburgvirus disease are clinically indistinguishable at the bedside.

Phase	Timing	Features
Prodrome (early)	Days 0–5	Abrupt fever, chills, severe headache, intense myalgia/arthralgia, asthenia, pharyngitis, cough; maculopapular rash
Peak / GI phase	≈Day 5–7 onward	Profuse nausea, vomiting, watery diarrhoea , abdominal pain → large volume/electrolyte loss; hypotension
Multi-organ / shock	Day 7–14	Hypovolaemic & septic shock , AKI, respiratory failure, encephalitis (confusion, agitation, seizures, coma), myocarditis/pericarditis, uveitis
Haemorrhagic	Late	Subconjunctival/conjunctival injection, petechiae, gingival bleeding, oozing from puncture sites; epistaxis, haematemesis, melena (overt bleeding in only ~1–5%)
Recovery / convalescence	Week 2–3+	Slow clearance of viraemia in survivors; prolonged sequelae

- ▶ **Typical laboratory findings:** early **leukopenia** (with left shift) then leukocytosis; **thrombocytopenia** (as low as 50,000/μL); **transaminitis** with **AST > ALT**, raised γ-GT; rising urea/creatinine with proteinuria; **electrolyte derangement** (hypo-/hyperkalaemia, hyponatraemia, hypocalcaemia); **hypoglycaemia**, hypoalbuminaemia; prolonged PT/PTT, raised D-dimer; raised CPK (rhabdomyolysis); markedly raised CRP.
- ▶ **Complications & sequelae:** secondary infection, persistent AKI, neuro-cognitive deficit, myocarditis, venous thrombosis; survivors report arthralgia/myalgia, fatigue, alopecia, **uveitis** and hearing loss, memory loss, and **post-EVD depression/anxiety/PTSD**.
- ▶ **Viral persistence in immune-privileged sites** — **semen** (up to ~9–12 months), CNS (recrudescent meningoencephalitis), eye (uveitis) and placenta — can cause **sexual transmission** and the rare re-ignition of outbreaks from survivors.

Diagnosis & Investigations

- ▶ EVD cannot be diagnosed clinically; an *exposure history* (bushmeat, bats, caves/mines, sick contacts, rural hospital clusters) plus compatible illness raises suspicion. Notify infectious-disease specialists and public-health authorities **immediately**.

- ▶ **Acute-phase blood/serum** is the preferred specimen (high virion titres).
- ▶ **Test of choice: reverse-transcription PCR (RT-PCR)** targeting filovirid genes; field-deployable platforms such as the **Cepheid GeneXpert** give rapid, standardised in-field results. RNA peaks $\approx$ day 7. A negative early sample (<3 days) should be repeated if symptoms persist.
- ▶ **Antigen-capture ELISA** and rapid antigen tests aid diagnosis (RDT sensitivity currently restricts use largely to post-mortem samples); **IgM/IgG capture ELISA** detect antibody in later disease and survivors.
- ▶ Virus isolation/electron microscopy require **maximum-containment (BSL-4)** facilities. Samples are inactivated (guanidinium for PCR, irradiation/heat for ELISA) and handled as extreme biohazards.
- ▶ **Key differentials:** *falciparum malaria* and *typhoid fever* (most important), plus enterohaemorrhagic *E. coli*, gram-negative/meningococcal sepsis, leptospirosis, rickettsioses, fulminant viral hepatitis, measles, **Lassa fever and yellow fever**; also snakebite, warfarin poisoning and other causes of coagulopathy.

Treatment & Prevention

- ▶ **Supportive care is the backbone:** aggressive IV fluid and **electrolyte repletion**, vasopressors, oxygen/ventilation, renal replacement, correction of hypoglycaemia, antipyretics/antiemetics/antidiarrhoeals, plus **empirical antimalarials and broad-spectrum antibiotics** in endemic settings. Intensive supportive care alone has cut mortality from 25–90% toward $<20\%$ in well-resourced units.
- ▶ **Specific therapeutics — anti-EBOV monoclonal antibodies** (validated by the PALM randomised controlled trial, DR Congo 2018–20):
 - **mAb114 — ansuvimab (Ebanga)** — single mAb.
 - **REGN-EB3 — atoltivimab/maftivimab/odesivimab (Inmazeb)** — triple-mAb cocktail.
 - Both are single IV infusions given as early as possible; the **2022 WHO guideline strongly recommends** either for PCR-confirmed Zaire EVD (including pregnant women, children and neonates ≤ 7 days of mothers with confirmed EVD), and conditionally **recommends against remdesivir and ZMapp**.
- ▶ **Vaccines:**
 - **rVSV-ZEBOV (Ervebo, Merck)** — live, single-dose recombinant vesicular stomatitis virus expressing EBOV GP; protective from **~ 10 days**; deployed as **reactive “ring” vaccination** of contacts-of-contacts and for pre-exposure protection of health workers (FDA/EMA approved 2019). *Preferred in outbreaks*.
 - **Ad26.ZEBOV (Zabdeno) + MVA-BN-Filo (Mvabea)** — heterologous **two-dose prime-boost** (~ 8 weeks apart); suited to peri-outbreak/pre-exposure use, not for rapid outbreak control.

- ▶ **Infection prevention & control:** isolation of cases, contact tracing, barrier nursing, PPE (gloves, gown, face shield/goggles; N95/N100 and powered respirators for aerosol-generating procedures), single-use equipment, and **safe burials**. Filovirions are enveloped and readily inactivated — **bleach 1:100 for surfaces, 1:10 for excreta/corpses**.
- ▶ **Survivor measures:** sexual abstinence or condom use for **≥12 months** (or until semen tests RNA-negative); vaccine/PEP for high-risk exposed health workers (e.g. needlestick).

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **EVD disease-course timeline** (Harrison Fig 216-6): x-axis *Days since onset* (−10 → +28); phases labelled **Incubation, Early phase, Peak phase, Recovery**. Stack the curves/bars — *non-specific prodrome* (fever, fatigue, myalgia, headache), *GI symptoms, rash, haemorrhage, shock, renal/respiratory/neurologic/cardiac dysfunction, uveitis*; overlay **viraemia (survivor vs non-survivor)**, **IgM, IgG**, and lab trends (↓WBC/↓PLT early, ↑AST/ALT, ↓glucose, ↑BUN/creatinine, coagulopathy ↑PT/PTT/D-dimer).
- ▶ **Filovirion structure:** label the **filamentous enveloped particle** with **GP1,2 surface spikes**, lipid envelope, **VP40 matrix**, helical **nucleocapsid (NP, VP35, VP30, VP24, L) wrapping the −ssRNA genome** (~19 kb).

Clinical / Diagnostic significance

- ▶ A **febrile traveller/contact returning from an Ebola-affected country** must be isolated, risk-assessed and tested by RT-PCR while excluding **malaria and typhoid** first — these are commoner and treatable.
- ▶ **AST > ALT**, marked thrombocytopenia, rising creatinine/BUN and high viral load are **adverse prognostic markers**; children <5 years, adults >40 years, pregnancy and immunosuppression carry the worst outcomes (maternal mortality ~86% in 2014–16).
- ▶ Early **fluid/electrolyte resuscitation plus a monoclonal antibody** is now standard of care and has transformed prognosis; the “70–90% mortality” figure is outdated.
- ▶ **Survivor surveillance** (semen testing, ophthalmology for uveitis, audiology, mental-health support) is essential to prevent relapse, sexual transmission and outbreak re-ignition.

High-yield exam pointers

- ▶ Family *Filoviridae*; genus *Orthoebolavirus*; **negative-sense ssRNA**, ~19 kb, **7 genes/7 structural proteins**; receptor NPC1.
- ▶ Four human-pathogenic ebolaviruses — **EBOV (Zaire, most lethal)**, **SUDV**, **BDBV**, **TAFV**; **Reston = non-pathogenic** to humans.
- ▶ **WHO Risk Group 4 / BSL-4**; highly infectious, not aerosol-contagious.
- ▶ Reservoir = **fruit bats (proven for Marburg = Rousettus aegyptiacus); spillover via bushmeat/primates**.

- ▶ Incubation 2–21 days; prodrome → GI loss → shock/MODS; overt haemorrhage in only ~1–5%.
- ▶ Diagnosis = RT-PCR (GeneXpert) on acute serum; AST > ALT, thrombocytopenia, leukopenia.
- ▶ Treatment = supportive care + mAb (Inmazeb / Ebanga) validated by the PALM trial; remdesivir/ZMapp not recommended.
- ▶ Vaccine = rVSV-ZEBOV (Ervebo), single-dose, ring vaccination; Zabdeno+Mvabea = 2-dose pre-exposure.
- ▶ Persistence in semen (~12 months), CNS, eye, placenta → late sexual transmission and outbreak re-ignition.
- ▶ IPC: isolation, contact tracing, PPE, safe burials, bleach 1:10 for corpses/excreta.

SOURCE & COVERAGE

- ▶ CDMT 2026 — "Viral & Rickettsial Infections: Viral Haemorrhagic Fevers — Ebola Viral Disease" (current case definition, clinical findings, WHO 2022 treatment guideline, Inmazeb/Ebanga, Ervebo and Zabdeno-Mvabea vaccines, prognosis, when-to-admit).

Extensively Drug-Resistant Tuberculosis (XDR-TB)

Asked in: Paper III Nov 2021 — RGUHS MD General Medicine

Definition / Introduction — Extensively drug-resistant TB (XDR-TB) is disease caused by *Mycobacterium tuberculosis* in which MDR-TB is compounded by additional resistance to any fluoroquinolone AND to at least one additional Group A drug (i.e., bedaquiline and/or linezolid). It sits at the apex of a graded spectrum of drug-resistant TB built on multidrug-resistant TB (MDR-TB) — bacilli resistant *at least to isoniazid and rifampin*, the two most potent first-line bactericidal agents. XDR-TB represents the most difficult-to-treat, costly and lethal form of TB, demanding all-oral, individualized, drug-susceptibility-testing (DST)–guided regimens delivered in specialized centres.

Spectrum & Definitions of Drug-Resistant TB

- ▶ Resistance is graded by the *number and class* of drugs lost; the updated (post-2021) hierarchy reflected in Harrison is summarised below.

Category	Resistance pattern (per Harrison 22e)
Mono-resistant TB	Resistance to a single first-line drug (e.g., isoniazid-resistant, rifampin-susceptible)

Category	Resistance pattern (per Harrison 22e)
RR-TB (rifampin-resistant)	Resistance to rifampin (with/without other drugs); monoresistance to R is rare and treated as MDR
MDR-TB	Resistance at least to isoniazid + rifampin
Pre-XDR-TB	MDR/RR-TB strain also resistant to any fluoroquinolone
XDR-TB	MDR/RR-TB + fluoroquinolone resistance + resistance to ≥ 1 additional Group A drug (bedaquiline and/or linezolid)

- ▶ **Primary resistance** = patient infected from the outset by a resistant strain; **acquired resistance** = develops in the infecting strain during inadequate treatment.
- ▶ Drug-resistant TB “almost invariably follows **monotherapy**” — failure to prescribe ≥ 2 effective drugs, poor adherence, malabsorption, or poor-quality drugs.

Molecular Basis & Mechanism of Resistance

- ▶ Resistance arises by **spontaneous chromosomal point mutations** occurring at low, predictable rates (10^{-7} – 10^{-10} per drug). There is *no plasmid-mediated* resistance and *no cross-resistance* between unrelated classes, so multi-class resistance is the *product* of individual probabilities — and is therefore generated almost solely by drug pressure on poorly-treated patients.

Drug	Key resistance gene(s) (frequency)
Rifampin	* <i>rpoB</i> * (95%)
Isoniazid	* <i>katG</i> (50–95%); <i>inhA</i> * promoter (up to 45%)
Pyrazinamide	* <i>pncA</i> * (up to 98%)
Ethambutol	* <i>embB</i> * (50–65%)
Fluoroquinolones	* <i>gyrA</i> – <i>gyrB</i> * (75–95%) — target DNA gyrase/topoisomerase IV
Aminoglycosides	* <i>rrs</i> (up to 80%); <i>eis</i> promoter C-12T* mutation
Bedaquiline	* <i>atpE</i> (ATP synthase subunit c); Rv0678/ <i>mmpR</i> , <i>pepQ</i> * (efflux — cross-resistance to clofazimine)
Linezolid	23S rRNA; ribosomal proteins *L3 (rplC), L4 (rplD)*

Epidemiology & Global Burden

- ▶ Of ~10.8 million incident TB cases in 2023, an estimated **400,000 MDR/RR-TB** cases occurred; only **189,000** were enrolled on treatment owing to limited DST capacity.

- ▶ >50% of all MDR/RR-TB occurs in: India (27%), Russian Federation (7.4%), Indonesia (7.4%), China (7.3%) and the Philippines (7.2%); the former Soviet states have the highest *proportion* of MDR among new cases (up to one-third).
- ▶ *The vast majority of XDR-TB cases remain undiagnosed* because reliable DST methods and laboratory capacity are lacking in low-income settings.

Diagnosis & Drug-Susceptibility Testing

- ▶ Culture remains the gold standard (liquid MGIT faster than solid Löwenstein-Jensen).
- ▶ Rapid molecular DST is mandatory before regimen design: nucleic-acid amplification Xpert MTB/RIF / Ultra detects *M. tuberculosis* + rifampin resistance (proxy for MDR); line-probe assays (LPAs) extend to isoniazid, fluoroquinolone and second-line resistance.
- ▶ For any RR/MDR diagnosis, DST for fluoroquinolones and (where possible) bedaquiline/linezolid is essential — these define the pre-XDR/XDR transition and dictate whether moxifloxacin can be retained.
- ▶ Continued monthly bacteriologic (culture) monitoring detects failure (persistent positivity or reversion after conversion) and emerging amplification of resistance.

WHO Classification of Anti-TB Drugs (for longer regimens)

- ▶ For complex MDR/XDR regimens, second-line drugs are ranked into three groups; regimens use all three Group A drugs + ≥1 Group B, adding Group C only to complete an effective combination.

Group	Drugs	Rule
A (use all three)	Levofloxacin/moxifloxacin · Bedaquiline · Linezolid	Ensures ≥4 likely-effective agents; ≥3 continue if bedaquiline stopped
B (add ≥1)	Clofazimine · Cycloserine / terizidone	At least one always included
C (complete regimen)	Delamanid · Pyrazinamide · Ethambutol · Imipenem-cilastatin/meropenem · Amikacin (or streptomycin) · Ethionamide/prothionamide · p-Aminosalicylic acid	Used when A/B cannot be

- ▶ Kanamycin and capreomycin are NO LONGER used (higher failure/relapse, toxicity); the injectables amikacin/streptomycin are reserved (≥18 yr, proven susceptibility, with audiometry).

Treatment of XDR-TB & Highly-Resistant Disease

- ▶ **Principle:** select agents *likely to be effective and tolerated*, build from the Group A/B/C hierarchy, give all-oral, fully-supervised therapy. **Levofloxacin/moxifloxacin, bedaquiline and linezolid should always be included** in longer regimens where active.
- ▶ **Pre-XDR-TB / MDR-RR (FQ retained or excluded):** the preferred regimen is the **6-month all-oral BPaLM** — Bedaquiline + Pretomanid + Linezolid 600 mg + Moxifloxacin (success rates ~90%). In **documented fluoroquinolone resistance, drop moxifloxacin → BPaL**. (*Excluded: pregnancy/breastfeeding, disseminated, CNS and osteoarticular TB, and prior >1-month exposure to these drugs.*)
- ▶ **XDR-TB:** because there is FQ + Group A drug resistance, the patient often does **not qualify for the standardized short regimens**; XDR-TB “follows the same principles” as a **longer (≥18–20-month) individualized regimen** (continued 15–17 months after culture conversion, ~6–7-month intensive phase), assembled from remaining effective Group A/B/C agents per DST.
- ▶ **Adjuncts:** aggressive management with early DST, strict DOT, monthly bacteriology and intensive patient support; **surgical resection (lobectomy/wedge)** for localized disease with adequate pulmonary reserve.
- ▶ **Key drug profile (the agents that define XDR):**

Drug	Class / mechanism	Dose	Major toxicity
Bedaquiline	Diarylquinoline — inhibits mycobacterial ATP synthase proton pump	400 mg/d × 2 wk, then 200 mg thrice-weekly	QT prolongation (black-box), hepatotoxicity, ↑ mortality signal; CYP3A4-metabolised
Linezolid	Oxazolidinone — binds 50S ribosome (protein synthesis)	600 mg once daily	Myelosuppression/pancytopenia, optic & peripheral neuropathy, lactic acidosis, serotonin syndrome (weak MAOI)
Pretomanid	Nitroimidazole prodrug (PA-824) — inhibits mycolic acid synthesis	200 mg daily	Hepatotoxicity
Moxifloxacin/levofloxacin	Fluoroquinolone — inhibits DNA gyrase	Standard	QT prolongation, GI/CNS
Clofazimine (Gp B)	Riminophenazine — reactive oxidants/membrane	—	Orange-brown skin discoloration, QT
Delamanid (Gp C)	Nitroimidazole — mycolic acid synthesis	100 mg twice daily	QT prolongation

Drug	Class / mechanism	Dose	Major toxicity
DIAGRAMS TO DRAW — IMAGE SUGGESTIONS ▶ Pyramid/ladder of drug-resistant TB (base → apex): <i>Drug-susceptible TB</i> → <i>Isoniazid mono-resistant</i> → <i>RR-TB</i> → <i>MDR-TB (H+R)</i> → <i>Pre-XDR-TB (+ fluoroquinolone)</i> → <i>XDR-TB (+ Group A drug: bedaquiline/linezolid)</i>. Label each tier with the defining resistance. ▶ Box diagram of WHO Group A/B/C drugs with three labelled boxes: Group A — Levofloxacin/Moxifloxacin, Bedaquiline, Linezolid; Group B — Clofazimine, Cycloserine/Terizidone; Group C — Delamanid, Pyrazinamide, Ethambutol, Carbapenem+clavulanate, Amikacin, Ethionamide/Prothionamide, PAS.			

Clinical / Diagnostic significance

- ▶ **Suspect resistance** in: previously treated TB, contacts of resistant cases, patients from high-MDR regions ($\geq 5\%$ incident MDR), and **failure of sputum-culture conversion at 2 months** — retest immediately and switch regimen.
- ▶ **DST drives everything**: FQ and bedaquiline/linezolid susceptibility distinguish pre-XDR from XDR and decide whether BPaLM, a shorter, or a longer regimen is used.
- ▶ **Cardiac safety**: multiple regimen drugs (bedaquiline, delamanid, clofazimine, fluoroquinolones) prolong QT — perform **baseline + serial ECG**; *withhold if QTc > 500 ms or history of ventricular arrhythmia*. Audiometry if amikacin used; haematology/visual monitoring on linezolid.
- ▶ **Active TB drug-safety monitoring (aDSM)**, informed consent, and HIV co-management (avoid efavirenz with bedaquiline; prefer dolutegravir-based ART) are integral.
- ▶ **Public-health imperative**: prompt diagnosis + effective regimen interrupts transmission of these strains and prevents *further* amplification of resistance.

High-yield exam pointers

- ▶ **XDR-TB** = MDR + fluoroquinolone resistance + resistance to ≥ 1 Group A drug (bedaquiline/linezolid). **Pre-XDR** = MDR + FQ resistance.
- ▶ **MDR** = resistant at least to isoniazid + rifampin. Monoresistant rifampin (RR) is managed as MDR.
- ▶ Resistance is by spontaneous point mutation; remember **rpoB (R)**, **katG/inhA (H)**, **pncA (Z)**, **embB (E)**, **gyrA/gyrB (FQ)**, **rrs (aminoglycoside)**, **atpE/Rv0678 (bedaquiline)**, **23S rRNA/rplC/rplD (linezolid)**.
- ▶ **Group A** (always all three): fluoroquinolone, bedaquiline, linezolid. **Group B**: clofazimine, cycloserine/terizidone.

- ▶ **BPaLM** = Bedaquiline + Pretomanid + Linezolid 600 mg + Moxifloxacin, 6 months, ~90% success — drop moxifloxacin (→ **BPaL**) if FQ-resistant.
- ▶ **Kanamycin and capreomycin are abandoned**; regimens are now **all-oral**.
- ▶ **Bedaquiline** inhibits ATP synthase, carries a **black-box QT/mortality warning**; **linezolid** causes **myelosuppression + neuropathy**.
- ▶ XDR/complex disease → **individualized longer regimen ≥18–20 months**, 15–17 months after culture conversion, with DOT, monthly cultures, aDSM ± surgery.

SOURCE & COVERAGE

Harrison's Principles of Internal Medicine, 22e (2025) — **Ch 183 "Tuberculosis"** (XDR/pre-XDR definitions, epidemiology, resistance genetics, WHO Group A/B/C Table 183-3, MDR/RR & BPaLM regimens) and **Ch 186 "Antimycobacterial Agents"** (BPaLM/BPaL trials, drug mechanisms, doses and toxicities). *Coverage note:* Harrison reflects the post-2021 WHO **revised XDR-TB definition** and does not give a single named "XDR-TB regimen" — XDR-TB is managed under the **longer individualized ≥18–20-month** regimen built from Group A/B/C drugs (Table 183-3), with the short BPaLM/BPaL regimens primarily validated for MDR/RR and pre-XDR disease. Fluoroquinolone mechanism (DNA gyrase) is standard textbook pharmacology consistent with the *gyrA/gyrB* resistance data in the chapter.

Extrapulmonary Tuberculosis

Asked in: Paper II Jul 2020 — RGUHS MD General Medicine

Definition / Introduction — Extrapulmonary tuberculosis (EPTB) is *Mycobacterium tuberculosis* infection of any organ system other than the lung parenchyma, resulting from lymphohaematogenous dissemination from a primary or post-primary focus, contiguous spread, or (for gut TB) ingestion. It accounts for **10–40%** of all TB cases depending on host immune status and bacterial strain; among people living with HIV (PLWH) up to **two-thirds** have extrapulmonary or combined disease. In descending order of frequency the sites involved are **lymph nodes > pleura > genitourinary tract > bones and joints > meninges > peritoneum > pericardium**, though virtually any organ may be affected. Most forms are **paucibacillary and essentially non-infectious**, making them diagnostically challenging and demanding tissue/fluid sampling for confirmation.

Pathogenesis and general features

- ▶ Tubercle bacilli disseminate via **lymphatics and the bloodstream** during the early bacillaemic phase of primary infection; dormant foci later reactivate when cell-mediated immunity (CMI) wanes (HIV, diabetes, anti-TNF-α therapy, chronic kidney disease, malnutrition, immunosuppression).

- ▶ EPTB is **more common in settings of high HIV prevalence** because failure of CMI permits widespread haematogenous seeding.
- ▶ Because lesions are paucibacillary, **smear and culture yields are lower** than in cavitary pulmonary disease, and **histology (caseating granuloma)** plus **nucleic-acid amplification** are pivotal.
- ▶ Constitutional (“B”) symptoms — low-grade fever, night sweats, anorexia, weight loss — are common but may be absent except in HIV co-infection.

Organ-specific clinical syndromes

Site (approx. share of EPTB)	Key clinical features	Best diagnostic approach
Lymph node (≈35%; >40% in US series)	Painless posterior-cervical/supraclavicular swelling = <i>scrofula</i> ; discrete nodes → matted mass → cold abscess/sinus draining caseum; systemic symptoms uncommon unless HIV	FNAC (yield up to 80%) or excision biopsy; granuloma ± AFB; culture positive in 70–80%; Xpert MTB/RIF on node biopsy near-100% (Ultra)
Pleura (≈20%)	Effusion from hypersensitivity to mycobacterial antigens (recent primary) or contiguous spread; fever, pleuritic pain, dyspnoea	Exudate, protein >50% of serum (≈4–6 g/dL), glucose normal–low, pH ≈7.3, WBC 500–6000/μL lymphocytic , rare mesothelial cells; ADA elevated (CMDT: >70 U/L ≈90% sens/spec); pleural biopsy granuloma/culture ≈80%; <i>pleural fluid Xpert NOT recommended (low sensitivity)</i>
Genitourinary (≈10–15%)	Cryptic/protean; dysuria, frequency, nocturia, haematuria, flank pain; female — tubes/endometrium → infertility; male — epididymis → tender mass/fistula	Sterile (culture-negative) pyuria in acidic urine ; 3 early-morning urine cultures positive in ≈90%; IVP/CT/MRI: calcification, ureteric stricture, hydronephrosis
Skeletal (≈10%)	Spine 40%, hip 13%, knee 10%; Pott’s disease = spondylitis of ≥2 adjacent vertebral bodies → disc involvement, kyphosis (gibbus) , paravertebral “cold” abscess (psoas)	CT/MRI; aspiration/bone biopsy (culture usually positive); synovial fluid/biopsy for peripheral joints
CNS — meningitis & tuberculoma (≈5%)	Subacute basal meningitis; weeks of fever/malaise → headache, cranial-nerve (esp. ocular) palsies, vasculitic infarcts, hydrocephalus, coma;	CSF: lymphocytic pleocytosis (≤1000/μL), high protein 1–8 g/L , low glucose ; Xpert/Ultra preferred initial test (~80%) ; culture gold standard (≈80%);

Site (approx. share of EPTB)	Key clinical features	Best diagnostic approach
	tuberculoma → seizures/focal signs	MRI: basal enhancement, hydrocephalus; tuberculoma = ring-enhancing lesion
Gastrointestinal (≈3.5%)	Ileocaecum most affected; pain, obstruction, mass, hematochezia; mimics Crohn disease; anal fistula → suspect rectal TB	Histology + culture of intraoperative/endoscopic specimens
Peritoneal	Nonspecific pain, fever, ascites; coexisting cirrhosis confounds	Exudative, high-protein, lymphocytic fluid; smear/culture low-yield; laparoscopic peritoneal biopsy often required
Pericardial	Subacute or acute with friction rub; effusion → tamponade; case-fatality up to 40%	Exudative, lymphocytic, often haemorrhagic fluid; smear rarely positive; culture ≈⅓; high ADA/lysozyme/IFN-γ; risk of constrictive pericarditis

Miliary (disseminated) TB

- ▶ Due to **massive haematogenous spread**; primary infection in children, recent infection or reactivation in adults.
- ▶ Lesions are **yellowish 1–2 mm granulomas resembling millet seeds** (hence “miliary”).
- ▶ Protean presentation: fever, night sweats, weight loss, weakness; **hepatosplenomegaly and lymphadenopathy**.
- ▶ **Choroidal tubercles are pathognomonic** (fundoscopy positive in up to 30%); meningismus in <10%.
- ▶ CXR: **miliary reticulonodular pattern** (early film may be normal, especially in PLWH).
- ▶ Haematology: anaemia, leukopenia/lymphopenia, leukaemoid reactions, occasionally pancytopenia or DIC; deranged LFTs with hepatic involvement.
- ▶ TST **negative in up to half** of cases (anergy); bronchoalveolar lavage, transbronchial / liver / bone-marrow biopsy give bacteriologic/granulomatous confirmation.
- ▶ Variants: **cryptic miliary TB** (elderly, chronic intermittent fever) and **non-reactive (septicaemic) miliary TB** (overwhelming, pancytopenic, rapidly fatal, nongranulomatous lesions).
- ▶ **Glucocorticoids have not proved beneficial** in miliary TB; untreated it is lethal but curable with timely therapy.

Diagnostic principles in EPTB

- ▶ **High index of suspicion** is the single most important factor — invasive sampling of the involved site is the rule.

- ▶ **Tissue/fluid > cytology:** caseating granuloma on histology, AFB smear, mycobacterial culture (MGIT liquid culture positive in 10 days–3 weeks; Löwenstein-Jensen 4–8 weeks), and **drug-susceptibility testing**.
- ▶ **Nucleic-acid amplification** (Xpert MTB/RIF / Ultra) is the preferred initial test on CSF and a recommended replacement test for selected non-respiratory specimens (FNA, pleural/other biopsy, gastric lavage); it also detects **rifampicin resistance**. Sensitivity varies by specimen — **lowest in pleural fluid (50%; 71% with Ultra), highest in synovial fluid (97%) and lymph-node biopsy (100% with Ultra)**.
- ▶ **Biomarkers:** elevated **adenosine deaminase (ADA)**, lysozyme and IFN- γ support TB in pleural, pericardial and peritoneal fluid.
- ▶ **Urine LF-LAM (lipoarabinomannan)** assay aids diagnosis in advanced HIV (CD4 $\leq$ 200/ μ L inpatients, $<$ 100/ μ L outpatients).
- ▶ **Imaging:** CT for intra-abdominal disease and Pott's spine; MRI for bone and intracranial TB.

Treatment

- ▶ **Most forms of EPTB are treated with the standard 6-month regimen** used for pulmonary TB: 2 months HRZE (intensive) + 4 months HR (continuation) = 2HRZE/4HR, daily throughout.
- ▶ Standard adult doses: Isoniazid 5 mg/kg (max 300 mg), Rifampin 10 mg/kg (max 600 mg), Pyrazinamide 25 mg/kg (max 2 g), Ethambutol 15 mg/kg.
- ▶ **TB meningitis:** ATS/CDC/IDSA recommend **extending the continuation phase to 7–10 months** (i.e. $\approx$ 9–12 months total). **Children with bone/joint TB, TB meningitis or miliary TB should receive up to 12 months** (2-month induction + 10-month consolidation).
- ▶ **Adjunctive glucocorticoids** improve survival/reduce disability in **TB meningitis** (dexamethasone or prednisolone tapered over 6–8 weeks, per WHO) and **may be used** in tuberculous pericarditis (note: the IMPI trial showed no overall benefit; ATS/CDC/IDSA do not advise routine use). Steroids are **not beneficial** in miliary or pleural TB.
- ▶ **Surgery** is adjunctive — drainage of large cold/psoas abscesses (paraparesis from spinal cord compression is an emergency), decortication for tuberculous empyema, relief of ureteric stricture/hydronephrosis, pericardiectomy for constriction, and resection in bowel obstruction/perforation.
- ▶ **HIV co-infection:** start ART early (within 2 weeks) — **but delay ART for 8 weeks in CNS TB** because of IRIS risk; use rifampicin-compatible ART (e.g. double-dose dolutegravir, or efavirenz; rifabutin as alternative).

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Descending-frequency chart of EPTB sites** — horizontal bars labelled: *Lymph node* $\approx 35\%$, *Pleura* $\approx 20\%$, *Genitourinary* $\approx 10\text{--}15\%$, *Bone/joint* $\approx 10\%$, *Meninges* $\approx 5\%$, *Gastrointestinal* $\approx 3.5\%$, *Peritoneum*, *Pericardium*.
- ▶ **Pott's disease (spinal TB) schematic** — label: *two adjacent vertebral bodies, destroyed intervertebral disc, anterior vertebral wedging/collapse, kyphotic angulation = gibbus, paravertebral "cold" abscess tracking to psoas/groin, spinal cord compression $\rightarrow$ paraplegia.*

Clinical / Diagnostic significance

- ▶ **Culture-negative sterile pyuria in acidic urine** is a classic clue to renal TB; 3 morning urine cultures clinch it.
- ▶ **Pleural fluid ADA / lymphocytic exudate with pleural biopsy** (not fluid Xpert) is the practical pathway to pleural TB; *choroidal tubercles* confirm miliary disease at the bedside.
- ▶ **Pott's disease** spares the disc early (unlike pyogenic osteomyelitis, which destroys the disc rapidly with sclerosis) — a key differentiating radiological point; paraparesis from a compressing abscess is a **medical emergency**.
- ▶ **Tuberculous meningitis** is uniformly fatal if untreated and leaves neurological sequelae in $\approx 25\%$ even when treated — early empirical therapy on a positive Xpert plus dexamethasone is mandatory.
- ▶ **Ileocaecal TB vs Crohn disease** is a recurring diagnostic dilemma; tissue for AFB/culture/granuloma and therapeutic response are decisive.
- ▶ EPTB diagnosis frequently mandates **invasive sampling** — FNAC/excision biopsy (node), needle pleural biopsy, D&C (endometrium), laparoscopy (peritoneum), pericardiocentesis/biopsy.

High-yield exam pointers

- ▶ EPTB = 10–40% of TB; **lymph node** is the commonest form (scrofula = cervical/supraclavicular nodes).
- ▶ **Pleural fluid**: lymphocytic exudate, ADA >70 U/L ($\approx 90\%$ sens/spec); **do NOT Xpert the fluid** — biopsy the pleura.
- ▶ **Renal TB**: sterile pyuria in acid urine; 3 morning urine cultures $\approx 90\%$ positive.
- ▶ **Pott's spine**: ≥ 2 adjacent vertebrae, disc spared early, **gibbus**, **psoas cold abscess**, paraplegia.
- ▶ **TB meningitis**: basal, cranial-nerve palsies, lymphocytic CSF (high protein, low glucose); **Xpert preferred**, culture gold standard; **add steroids**; extend therapy to 9–12 months.
- ▶ **Miliary TB**: millet-seed granulomas, **choroidal tubercles pathognomonic**, TST often negative; steroids not helpful.
- ▶ **Pericardial TB**: haemorrhagic lymphocytic effusion, high ADA, risk of constriction; tamponade is the acute danger.

- ▶ Standard treatment = 2HRZE/4HR for most EPTB; CNS/skeletal/miliary in children → up to 12 months.

SOURCE & COVERAGE

- ▶ Harrison's Principles of Internal Medicine, 22e — "Tuberculosis" (extrapulmonary forms, diagnosis, regimens, drug doses, special clinical situations).
- ▶ CMDT 2026 — "Pulmonary Disorders: Tuberculosis" (pleural fluid ADA, NAAT/Xpert diagnostics, imaging).

Gastrointestinal Tuberculosis

Asked in: Paper II Nov 2019 — RGUHS MD General Medicine

Definition / Introduction — Gastrointestinal (GI) tuberculosis (TB) is infection of the gut lumen, peritoneum, mesenteric lymph nodes and solid abdominal viscera by *Mycobacterium tuberculosis* (and, where bovine disease persists, *M. bovis*). It is the sixth commonest form of extrapulmonary TB and accounts for only ~3.5% of extrapulmonary cases in low-burden settings, but is common in India and other high-burden regions. The **terminal ileum and caecum** are the sites most often involved. Because it mimics Crohn disease, ileocaecal carcinoma, lymphoma and amoebiasis, it is a notorious "great imitator" requiring a high index of suspicion.

Epidemiology & Pathogenesis

- ▶ **Burden** — uncommon in the United States/Europe (mainly immigrants and patients with untreated AIDS); common in underdeveloped/high-prevalence countries including India.
- ▶ **Routes of seeding** (any may operate concurrently):
 - **Swallowing of infected sputum** with direct mucosal seeding (in active pulmonary TB).
 - **Haematogenous spread** from a pulmonary or miliary focus (explains peritoneal and solid-organ disease).
 - **Ingestion of milk** from cows with bovine TB (*M. bovis*) — relevant where pasteurisation is incomplete.
 - **Direct/contiguous spread and retrograde lymphatic spread** from ruptured mesenteric nodes and adjacent intra-abdominal organs (e.g., genital TB in women causing peritonitis).
- ▶ **Association with pulmonary TB** — coexistent **active pulmonary disease is present in <50%** of patients, so a normal chest radiograph does *not* exclude abdominal TB.
- ▶ **Ileocaecal predilection** is attributed to abundant lymphoid (Peyer patch) tissue, physiological stasis and increased contact time of bacilli with the mucosa at this site.

Pathology & morphological types

- ▶ The basic lesion is the **caseating epithelioid-cell granuloma**; in the gut these are characteristically **large, confluent, submucosal and few in number**, with surrounding lymphoid cuffs.
- ▶ Three classical macroscopic forms (standard surgical/pathological classification):
 - **Ulcerative** — multiple superficial, **transversely orientated (“girdle”) ulcers** of the antimesenteric border; the predominant pattern in florid disease and a cause of bleeding/perforation.
 - **Hypertrophic** — marked fibroblastic reaction with a thickened, mass-like bowel wall (especially ileocaecal), mimicking carcinoma and producing a palpable mass.
 - **Ultero-hypertrophic (stricturing)** — mixed pattern with ulceration plus fibrosis causing **strictures and obstruction**.
- ▶ Healing by fibrosis produces **short, concentric strictures**, a contracted caecum and a **patulous/incompetent ileocaecal valve**.

Clinical patterns & features

GI TB presents in four overlapping clinico-anatomical forms — luminal (intestinal), peritoneal, nodal and visceral.

- ▶ **Intestinal (luminal) TB** (commonest; ileocaecal):
 - Chronic **abdominal pain** (right iliac fossa pain at times mimicking appendicitis), **subacute/recurrent intestinal obstruction**, abdominal distension.
 - **Weight loss, low-grade fever, anorexia, night sweats**, diarrhoea or altered bowel habit.
 - A **palpable doughy mass** in the right iliac fossa (hypertrophic disease).
 - **Hematochezia/GI bleeding**, fistulae and, less often, free perforation.
 - With wall involvement, ulcers and fistulae **simulate Crohn disease** — the differential is “always difficult”; **anal fistulae should prompt evaluation for rectal TB**.
- ▶ **Tuberculous peritonitis** — follows rupture of caseous mesenteric nodes / spread from intra-abdominal organs (e.g., female genital TB) or haematogenous seeding. Three subtypes are recognised: **wet (ascitic)**, **dry/plastic (fibroadhesive)**, and **encysted (loculated)**. The classic triad is **nonspecific abdominal pain, fever and ascites**; “doughy abdomen” is described in the plastic form.
- ▶ **Nodal TB** — mesenteric/peripancreatic lymphadenopathy, often with central (caseous) necrosis on CT.
- ▶ **Visceral TB** — hepatic, splenic, pancreatic and peritoneal-fold involvement (uncommon).
- ▶ *Caveat*: coexisting **cirrhosis** greatly complicates recognition of tuberculous peritonitis, as both cause ascites.

Investigations / Diagnosis

- ▶ **Ascitic fluid (paracentesis) in peritonitis** — exudative fluid with **high protein**, **lymphocyte-predominant leucocytosis** (neutrophils occasionally early), and a **low serum–ascites albumin gradient (SAAG <1.1 g/dL)**. Direct smear and culture have **low yield**; culturing a large volume improves it. Elevated **adenosine deaminase (ADA)** supports the diagnosis (a value >~39 U/L is the commonly cited threshold).
- ▶ **Imaging** — **abdominal CT** shows thickening of the **caecum and ileocaecal valve**, mural thickening, **necrotic (“caseous”) mesenteric lymphadenopathy**, omental/peritoneal thickening and ascites; CT is also useful for other intra-abdominal/Pott disease.
- ▶ **Colonoscopy/ileoscopy with biopsy** — ulcerated mass, **ulcers with steep/undermined edges**, **transversely oriented ulcers**, **sessile inflammatory polyps**, **deformed patulous ileocaecal valve**, strictures, or pseudodiverticula, most often in the ileocaecal region; multiple deep biopsies from ulcer edges raise yield.
- ▶ **Histology/microbiology of biopsy or operative specimen** — diagnosis is confirmed by **caseating granuloma**, **acid-fast bacilli (AFB)** and/or **positive culture**. **PCR / nucleic-acid amplification on tissue** is now the most sensitive means of diagnosis.
- ▶ **Molecular tests** — **Xpert MTB/RIF** and **Xpert MTB/RIF Ultra** are the preferred initial tests on nonrespiratory specimens (FNA, biopsy, fluid); they confirm TB and detect **rifampin resistance** in <2 h.
- ▶ **Peritoneal biopsy (best obtained at laparoscopy)** is often required when fluid studies are nondiagnostic; laparoscopy permits direct visualisation and biopsy of peritoneum, liver and nodes.
- ▶ **Tuberculin skin test (PPD)** may be **negative**, especially with weight loss or AIDS, so a negative test does not exclude disease. Because surgery is needed in many obstructive/complicated cases, diagnosis is frequently established on **intra-operative histology and culture**.

Intestinal TB vs Crohn disease

Feature	Intestinal tuberculosis	Crohn disease
Ulcers	Transverse / circumferential (“girdle”)	Longitudinal, aphthous; cobblestoning
Distribution	Short segment, ileocaecal; patulous IC valve	Skip lesions; long segment; perianal disease
Granuloma	Caseating, large, confluent, submucosal, few	Non-caseating, small, discrete, numerous
AFB / culture / TB-PCR	May be positive	Negative
Strictures/fistulae	Short concentric strictures	Long strictures, multiple fistulae
Response to ATT	Mucosal healing on anti-TB therapy	No response to ATT

Note: misdiagnosing TB as Crohn (and giving steroids/anti-TNF) can cause fulminant dissemination — hence a **diagnostic anti-TB trial** is used when distinction is impossible.

Treatment / Management

- ▶ **First-line chemotherapy** is the same as for pulmonary TB: **2 months HRZE → 4 months HR** (2HRZE/4HR); this cures >90% of drug-susceptible cases. Many authorities extend the continuation phase to give a **total of 6–9 months** for extensive abdominal disease, but the corpus-supported standard is the **6-month regimen**.
- ▶ **Standard adult daily doses** (Harrison Table 183-2):
 - Isoniazid (H) 5 mg/kg, max 300 mg
 - Rifampin (R) 10 mg/kg, max 600 mg
 - Pyrazinamide (Z) 25 mg/kg, max 2 g
 - Ethambutol (E) 15 mg/kg
 - (paediatric doses are higher per kg, e.g., H 10 mg/kg).
- ▶ **Drug-resistant disease** — if rifampin resistance is detected (e.g., on Xpert), manage as MDR-TB with WHO Group A–C agents (bedaquiline, levofloxacin/moxifloxacin, linezolid, clofazimine, cycloserine, etc.).
- ▶ **Surgery** is reserved for complications — **obstruction unrelieved by medical therapy, perforation, massive haemorrhage, fistula or abscess**; stricturoplasty/limited resection is preferred over extensive resection. Anti-TB therapy must continue post-operatively.
- ▶ **Supportive care** — nutritional rehabilitation, correction of anaemia, and monitoring for hepatotoxicity (H/R/Z) and **ethambutol ocular toxicity**.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Labelled ileocaecal TB diagram:** terminal ileum, thickened/contracted caecum, incompetent (patulous) ileocaecal valve, transverse “girdle” ulcers, short fibrotic stricture, enlarged caseous mesenteric lymph nodes, and a hypertrophic ileocaecal mass.
- ▶ **Diagnostic algorithm box:** Suspected abdominal TB → CT abdomen + colonoscopy/ascitic tap → biopsy/fluid for histology (caseating granuloma), AFB, culture, Xpert MTB/RIF, TB-PCR → if nondiagnostic → laparoscopy + peritoneal biopsy → start 2HRZE/4HR.

Clinical / Diagnostic significance

- ▶ **Right-iliac-fossa mass + constitutional symptoms** in an endemic-area patient should trigger work-up for ileocaecal TB before labelling it appendicular mass or carcinoma.
- ▶ **Low-SAAG, high-protein, lymphocytic ascites with raised ADA** strongly suggests tuberculous peritonitis; laparoscopy is the most reliable confirmatory step.

- ▶ The **TB-vs-Crohn dilemma** has major therapeutic consequences — immunosuppression of misdiagnosed TB is dangerous; TB-PCR on biopsy and a therapeutic ATT trial resolve most cases.
- ▶ A **negative PPD and normal chest film do not exclude** the diagnosis (active pulmonary disease in <50%).

High-yield exam pointers

- ▶ Commonest GI site = **terminal ileum + caecum**; commonest extra-luminal form = **tuberculous peritonitis**.
- ▶ Three pathological types = **ulcerative, hypertrophic, ulcero-hypertrophic**; ulcers are **transverse**, valve becomes **patulous**.
- ▶ TB granuloma = **caseating, large, confluent, submucosal, few**; Crohn = **non-caseating, small, many**.
- ▶ **Xpert MTB/RIF/Ultra** = preferred rapid test (also gives rifampin resistance); **tissue TB-PCR** = most sensitive.
- ▶ Ascites: **exudate, high protein, lymphocytic, SAAG <1.1, raised ADA**; low smear/culture yield → **laparoscopic peritoneal biopsy**.
- ▶ Treatment = **2HRZE/4HR**, cures >90%; doses H 5 / R 10 / Z 25 mg/kg, E 15 mg/kg.
- ▶ Surgery only for **obstruction, perforation, bleeding, fistula** — continue ATT after.
- ▶ **Anal fistula** → think rectal TB; **bovine TB (M. bovis) via unpasteurised milk** is a recognised route.

SOURCE & COVERAGE

- ▶ **Harrison's Principles of Internal Medicine, 22e** — "Tuberculosis" (extrapulmonary section: *Gastrointestinal TB* and *Tuberculous peritonitis*; diagnosis — nucleic-acid amplification/Xpert MTB/RIF; Table 183-2 drug dosages; Table 183-4 regimens 2HRZE/4HR).
- ▶ **CMDT 2026** — "Gastrointestinal Disorders" (*Intestinal Tuberculosis*: ileocaecal predilection, CT/colonoscopy findings, PPD, biopsy/PCR diagnosis) and the ascites/SAAG and laparoscopy discussion for tuberculous peritonitis.
- ▶ **Coverage note**: The cited corpus (Harrison 22e + CMDT 2026) covers epidemiology, pathogenesis, ileocaecal disease, peritonitis, diagnostics and therapy directly. The three **morphological types** (ulcerative/hypertrophic/ulcero-hypertrophic), the wet/dry/encysted peritonitis subtypes, the detailed **TB-vs-Crohn histology/ulcer comparison**, and the **ADA cut-off (~39 U/L)** are presented as universally accepted standard textbook internal medicine/surgical pathology, used to organise (not contradict) the corpus, which states

only that intestinal TB “may simulate Crohn disease” and that ADA elevation supports a tuberculous aetiology.

Genital Ulcerations due to Infections

Asked in: Paper II Nov 2021 — RGUHS MD General Medicine

Definition / Introduction — Genital ulcer disease (GUD) is a syndrome of one or more breaks in the skin or mucosa of the genitalia, perineum or anus, most often sexually transmitted. It is clinically important because the same ulcers sharply **increase the risk of sexual acquisition and shedding of HIV**, and because the cause cannot be reliably named on inspection alone—syndromic, test-supported management is therefore standard. Five classic infectious causes dominate: **genital herpes (HSV)**, **primary syphilis**, **chancroid**, **lymphogranuloma venereum (LGV)** and **donovanosis (granuloma inguinale)**; today *genital herpes is by far the commonest cause worldwide*.

Aetiology and epidemiology

- ▶ **The five major infectious causes:** HSV-1/HSV-2 (genital herpes); *Treponema pallidum* (primary syphilis – the chancre); *Haemophilus ducreyi* (chancroid/soft sore); *Chlamydia trachomatis* serovars L1–L3 (LGV); *Klebsiella granulomatis* (donovanosis / granuloma inguinale).
- ▶ **Relative frequency:** In a 1996 study of genital ulcers in 10 U.S. cities with the highest rates of primary syphilis, PCR detected **HSV in 62%, T. pallidum in 13%, and H. ducreyi in 12–20%.* *With PCR testing, genital herpes is now the single commonest cause** of genital ulceration in both industrialised and most developing countries.
- ▶ In Asia and Africa, **chancroid** was once the commonest ulcer, followed by primary syphilis then herpes; control programmes, broad-spectrum antibiotic use and HIV-driven persistence of herpes have shifted the balance toward HSV.
- ▶ LGV had nearly disappeared from industrialised nations but is re-emerging as outbreaks of **proctitis in MSM**, frequently with concurrent **HIV and/or hepatitis C** infection.
- ▶ **Donovanosis** and LGV remain endemic causes of ulceration in some developing countries.

Clinical features — the five classic ulcers

- ▶ **Genital herpes (HSV)** — short incubation (2–7 days); a *vesicle* progresses to multiple small (1–2 mm), shallow, *painful/tender* ulcers on an erythematous base; tender, often bilateral inguinal nodes with the first episode; recurrences are common (more so with HSV-2). “Atypical” or trivial ulcers may be commoner than classic vesiculopustular lesions.
- ▶ **Primary syphilis (chancre)** — incubation 9–90 days (average ~2–6 weeks, rarely >6 weeks). A **single painless papule that erodes and becomes indurated** with a characteristic firm,

cartilaginous edge and base; usually solitary (multiple in a minority); base smooth, relatively non-vascular. Regional inguinal nodes are **firm, non-suppurative, painless and bilateral**, appearing within ~1 week. Heals spontaneously in 4–6 weeks (range 2–12 weeks). Sites: penis (heterosexual men); anal canal, rectum or mouth (MSM); cervix, vaginal wall, labia (women)—hence often unrecognised in women and MSM.

- ▶ **Chancroid (H. ducreyi) — incubation 1–14 days; begins as a pustule that breaks down into multiple, deep, excavated, very tender ulcers with undermined, ragged, irregular edges and a purulent base that bleeds easily**; tender, suppurative, loculated, usually unilateral inguinal nodes (bubo).
- ▶ **Lymphogranuloma venereum (C. trachomatis L1–L3) — a small, often painless, transient papulo-vesicular ulcer that is frequently not noticed; dominated instead by tender inguinal/femoral lymphadenopathy. The “sign-of-the-groove” (nodes above and below Poupart’s (inguinal) ligament) is suggestive but not specific. Anogenital LGV presents as severe proctitis/proctocolitis* that can mimic Crohn’s disease.*
- ▶ **Donovanosis / granuloma inguinale (K. granulomatis) — incubation 1–4 weeks (up to 6 months); elevated, beefy-red, velvety ulcer that bleeds readily; usually painless; true lymphadenopathy is absent but subcutaneous granulomas form pseudobuboes*.*

Comparison table (Harrison Table 141-7)

Feature	Syphilis (chancr e)	Genital herpes	Chancroid	LGV	Donovanosis
Organism	<i>T. pallidum</i>	HSV-1 / HSV-2	<i>H. ducreyi</i>	<i>C. trachomatis</i> L1–L3	<i>K. granulomatis</i>
Incubation	9–90 days	2–7 days	1–14 days	3 days–6 weeks	1–4 weeks (up to 6 mo)
Primary lesion	Papule	Vesicle	Pustule	Papule/pustule/vesicle	Papule
Number	Usually one	Multiple	Multiple, may coalesce	Usually one (often missed)	Variable
Edge / base	Sharply demarcated, indurated; smooth base	Erythematous, serous	Undermined, ragged; purulent, bleeds	Variable	Elevated, beefy-red, velvety; bleeds
Pain	Uncommon (painless)	Frequently tender	Very tender	Variable / mild	Uncommon

Feature	Syphilis (chancere)	Genital herpes	Chancroid	LGV	Donovanosis
Lymphadenopathy	Firm, non-tender, bilateral	Firm, tender, often bilateral (first episode)	Tender, suppurative, loculated, unilateral	Tender, may suppurate, unilateral	None; pseudobuboes

- ▶ **Memory aid:** *painful* ulcers = **herpes + chancroid**; *painless* ulcers = **syphilis + LGV + donovanosis**.

Non-classic and non-venereal causes (to exclude)

- ▶ Candidiasis and **traumatised genital warts**; genital involvement by widespread **dermatoses**.
- ▶ Cutaneous manifestations of **systemic disease** — e.g. genital mucosal ulceration in **Stevens-Johnson syndrome** or **Behçet's disease**.
- ▶ **Superinfection** of an originally STI lesion (e.g. MRSA complicating an HSV-2 ulcer).
- ▶ **Localised drug reactions** (e.g. topical paromomycin or boric acid preparations).
- ▶ A persistent ulcer must also raise suspicion of **carcinoma** and other non-venereal dermatoses.

Diagnostic approach

- ▶ ***Order a rapid serologic test for syphilis in every genital ulcer, and counsel and test all patients for HIV*** (and consider other STIs).
- ▶ **Syphilis:** dark-field microscopy, direct fluorescent antibody (DFA), or NAAT/PCR for *T. pallidum* from the lesion; serology = a **lipoidal (non-treponemal) test** (VDRL/RPR) plus a **treponemal test** (TPPA, EIA/CIA, FTA-ABS). Caveat: **~30% of chancres have an initially non-reactive serology** (both lipoidal and treponemal tests may be negative in very early primary syphilis)—so treat presumptively and repeat serology.
- ▶ **Herpes:** PCR/NAAT (most sensitive), culture, direct FA, or ELISA from the lesion; type-specific HSV-2 serology has limited value (may be falsely negative early/with HSV-1, and a positive result does not prove the current lesion is herpetic).
- ▶ **Chancroid:** culture (or PCR where available) for *H. ducreyi*—most useful when ulcers are painful and purulent with fluctuant nodes; **aspirate fluctuant nodes** for culture/PCR and Gram stain.
- ▶ **Persistent ulcer** (beyond the natural history—herpes 2–3 weeks, chancroid/syphilis up to ~6 weeks) that fails syndromic therapy → **biopsy** to exclude **donovanosis, carcinoma** and non-venereal causes.

Syndromic management (Harrison Table 141-8)

- ▶ **Principle:** after collecting all diagnostic specimens at the first visit, give **immediate syndrome-based treatment** without waiting for all results, because early therapy of HSV, syphilis and chancroid reduces morbidity and onward HIV transmission.
- ▶ **Herpes (confirmed/suspected):** oral **acyclovir, valacyclovir or famciclovir**.
- ▶ **Syphilis:** **benzathine penicillin G 2.4 million units IM single dose** (treat patient and recent—within ~3 months—seronegative partners). Penicillin G is the drug of choice for all stages; alternatives for non-pregnant penicillin-allergic patients are **doxycycline 100 mg PO BD** or **tetracycline 500 mg PO QID** for 2 weeks.
- ▶ **Chancroid (confirmed/suspected):** **ciprofloxacin 500 mg PO single dose, or ceftriaxone 250 mg IM single dose, or azithromycin 1 g PO single dose**.
- ▶ **LGV (e.g. proctitis):** **doxycycline 100 mg PO BD for 21 days** (alternative: azithromycin 1 g once weekly × 3 weeks).
- ▶ **Partner management, HIV testing/counselling and STI screening** are integral.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Diagram 1 — “Five classic genital ulcers” comparison chart:** five labelled boxes/columns — *Syphilis (chancre)*, *Herpes*, *Chancroid*, *LGV*, *Donovanosis* — each labelled with **Organism, Incubation, Painful/Painless, Edge (indurated / undermined / beefy-red), Lymphadenopathy (non-tender bilateral / tender bilateral / suppurative unilateral bubo / sign-of-the-groove / pseudobuboes)**.
- ▶ **Diagram 2 — Syndromic algorithm for a genital ulcer:** boxes labelled *Genital ulcer* → *take history + examine* → *collect specimens (dark-field/PCR for *T. pallidum*, PCR/culture for HSV ± *H. ducreyi*) + RPR/VDRL + offer HIV test* → *vesicles/painful = treat herpes; painless indurated = treat syphilis (benzathine penicillin 2.4 MU IM); painful purulent + bubo = treat chancroid* → *review; persistent ulcer* → *biopsy (exclude donovanosis/carcinoma)*.

Clinical / Diagnostic significance

- ▶ GUD is a powerful **co-factor for HIV transmission and acquisition**—ulcer control is an HIV-prevention strategy.
- ▶ **Jarisch-Herxheimer reaction** can follow the first dose of penicillin in syphilis: self-limited fever, chills, myalgia, headache, tachycardia and increased respiratory rate from lipoproteins released by dying treponemes; occurs in ~50% of primary and ~90% of secondary cases—warn the patient (and pregnant women, in whom it may cause mild contractions).
- ▶ **Post-treatment serologic follow-up** of syphilis: monitor quantitative VDRL/RPR for a **fourfold (two-dilution) decline**; review primary/secondary syphilis at 6 and 12 months (more often if HIV-co-infected).

- ▶ LGV rectal biopsy shows crypt abscesses, granulomas and giant cells—**mimicking Crohn's disease**; recognition matters because LGV is curable with doxycycline.
- ▶ Recognise non-infectious ulcers (**Behçet's, Stevens-Johnson, fixed drug eruption, malignancy**) to avoid missing serious systemic disease.

High-yield exam pointers

- ▶ **Painful ulcers** → herpes + chancroid; **painless ulcers** → syphilis + LGV + donovanosis.
- ▶ **Genital herpes is now the commonest cause of GUD** worldwide (HSV 62%, *T. pallidum* 13%, *H. ducreyi* 12–20% in the classic 10-city study).
- ▶ **Chancre** = single, painless, indurated, *cartilaginous* ulcer with firm, non-tender, **bilateral** inguinal nodes; **~30% have non-reactive serology** initially.
- ▶ **Chancroid** = multiple, deep, painful ulcers with **undermined ragged edges** + tender **suppurative unilateral bubo**.
- ▶ **LGV** = inconspicuous ulcer + tender adenopathy with the “**sign-of-the-groove**”; re-emerging as proctitis in MSM; Rx **doxycycline 21 days**.
- ▶ **Donovanosis** = **beefy-red, velvety, bleeding ulcer, pseudobuboes**, diagnosed on **biopsy** (Donovan bodies).
- ▶ **Always do syphilis serology and offer HIV testing in every genital ulcer.**
- ▶ Syphilis Rx = **benzathine penicillin 2.4 MU IM single dose**; chancroid Rx = single-dose **azithromycin / ceftriaxone / ciprofloxacin**.
- ▶ **Biopsy any ulcer persisting beyond its natural history** (to exclude donovanosis and carcinoma).

SOURCE & COVERAGE

Harrison's Principles of Internal Medicine, 22e — Ch 141 “Sexually Transmitted Infections: Overview and Clinical Approach” (Tables 141-7 clinical features and 141-8 initial management of genital/perianal ulcer) and Ch 187 “Syphilis” (primary chancre, serology, treatment, Jarisch-Herxheimer reaction). *Coverage note:* detailed clinical descriptions of chancroid, LGV and donovanosis are summarised within Ch 141; their dedicated chapters (Ch 162 chancroid, Ch 178 donovanosis, Ch 197 HSV) were not provided, so organism-level detail (e.g. LGV serovars L1–L3, Donovan bodies) is given from universally accepted standard internal-medicine teaching consistent with the provided text.

Immune Reconstitution Inflammatory Syndrome (IRIS)

Asked in: Paper II Sep 2025 — RGUHS MD General Medicine

Definition / Introduction — Immune reconstitution inflammatory syndrome (IRIS) is a *paradoxical clinical deterioration* that follows the recovery of pathogen-specific immunity, most classically after initiation of effective antiretroviral therapy (ART) in a person with advanced HIV disease. It represents a dysregulated, exaggerated inflammatory response — directed against the antigens of a treated, partially treated, or previously undiagnosed opportunistic infection (or, less often, a tumour or autoimmune antigen) — that emerges precisely *because* immune function is restored. It is therefore not a treatment failure but a sign of immune recovery, and is a diagnosis of exclusion.

Pathogenesis / Immunology

- ▶ Triggered by the rapid restoration of antigen-specific (predominantly CD4+ T-cell) immunity as plasma HIV-RNA falls and CD4 counts rise after ART.
- ▶ The underlying mechanism resembles a **type IV (delayed/cell-mediated) hypersensitivity reaction** — a vigorous immune response mounted against the antigens of organisms present in the tissues.
- ▶ Antigenic stimulus is provided both by *viable* organisms and by **antigens released as bacilli/fungi are killed** during effective antimicrobial chemotherapy; the recovering immune system suddenly “sees” this antigen load and reacts intensely.
- ▶ Characterised by a surge of pro-inflammatory cytokines — **IL-6, TNF- α , IFN- γ , IL-12p40, IL-10 and IFN- γ -inducible protein-10 (IP-10)** — whose suppression underlies the benefit of glucocorticoids.
- ▶ The term **immune reconstitution disease (IRD)** is sometimes used to separate IRIS due to *opportunistic infections/tumours* from IRIS related to *autoimmune* disease; IRD is especially common with underlying untreated mycobacterial or fungal infection.

Classification (two clinical forms)

Feature	Paradoxical IRIS	Unmasking IRIS
Underlying condition	Known, already-diagnosed (often partially treated) opportunistic infection / neoplasm	Previously undiagnosed , subclinical infection
What ART does	Causes worsening/flare of the existing, treated condition	“Unmasks” a latent infection that becomes clinically apparent
Typical example	Worsening lymphadenitis or new pulmonary infiltrates in a treated TB patient	New active TB or cryptococcal disease appearing after ART start
Inflammatory component	Prominent	Prominent, may mimic acute primary infection

- ▶ Beyond infections, ART may also **exacerbate pre-existing autoimmune conditions or trigger new ones** (e.g. *Graves’ disease*, sarcoidosis).

Epidemiology & risk factors

- ▶ Some form of IRIS occurs in **10–30%** of patients after starting ART (varies with setting); TB-associated IRIS occurs in **~10%** of HIV-infected TB patients.
- ▶ **Strongest risk factor:** starting ART at a very low **CD4+ count** (<50 cells/ μ L) together with a *precipitous drop in HIV-RNA*.
- ▶ The **earlier** ART is begun after starting treatment of the opportunistic infection, and the **lower the baseline CD4 count**, the **greater the risk** of IRIS.
- ▶ Disseminated / **extrapulmonary** disease and **advanced immunosuppression** increase risk.
- ▶ IRIS is largely confined to ART-treated HIV patients but analogous syndromes occur in **transplant recipients** (after reduction of immunosuppression), in **neutropenia recovery**, post-partum, and occasionally even in non-immunocompromised hosts (e.g. cryptococcosis).
- ▶ **Timing of onset:** anywhere from **2 weeks to 2 years** after ART; for TB-IRIS typically **1–3 months** after ART initiation.

Clinical spectrum (organism-specific manifestations)

Pathogen / condition	Characteristic IRIS presentation
Mycobacterium tuberculosis	Fever, enlarging lymphadenopathy, worsening pulmonary infiltrates, new pleural effusion; <i>CNS-TB → serious neurological deterioration, can be fatal</i>
Mycobacterium avium complex	Focal, often suppurative lymphadenitis or granulomatous masses
Cryptococcus neoformans	Recurrent meningitis-like picture, fever, headache, lymphadenopathy, raised ICP; hard to distinguish from relapse
CMV retinitis	Immune-recovery vitritis/uveitis
JC virus (PML)	Atypical/worsening course of progressive multifocal leukoencephalopathy
Kaposi sarcoma	Flare/worsening of lesions shortly after ART start
Hepatitis B/C	Flare of hepatitis (immune-mediated hepatic injury)
Autoimmune	<i>Graves' disease</i> , sarcoidosis, new autoimmune phenomena

- ▶ General manifestations from Harrison: localized lymphadenitis, prolonged fever, pulmonary infiltrates, hepatitis, raised intracranial pressure, uveitis, sarcoidosis and Graves' disease. The course can be protracted and severe cases may be **fatal**.

Diagnosis

- ▶ **There is no confirmatory diagnostic test** — IRIS is a **clinical diagnosis of exclusion** resting on case definitions that combine clinical and laboratory data.
- ▶ Essential first step: **exclude the alternatives** —
 - *failure of the antimicrobial therapy* (e.g. drug-resistant or inadequately treated TB),
 - *a new/second opportunistic infection*,
 - *drug toxicity or hypersensitivity*, and
 - *non-adherence / poor drug levels*.
- ▶ Supportive features: temporal link to ART, documented **fall in HIV-RNA and rise in CD4**, and an inflammatory (rather than purely infective) clinical picture.
- ▶ For cryptococcosis, a tissue biopsy may be required to distinguish inadequately treated infection from IRIS.

Management & timing of ART (prevention)

- ▶ **General principle:** *continue ART* wherever possible — IRIS reflects desirable immune recovery; stopping ART is reserved for life-threatening situations.
- ▶ **Mild–moderate paradoxical reactions:** symptomatic/supportive management; these do not worsen TB-treatment outcomes.
- ▶ **Severe reactions:** **glucocorticoids** to blunt inflammation while specific antimicrobial therapy continues. For severe TB-IRIS, **prednisolone for 4 weeks** (*1.5 mg/kg/day for 2 weeks, then half that dose for the remaining 2 weeks* — the Meintjes regimen) reduces hospitalisation and therapeutic procedures and hastens symptom relief, mediated by suppression of IL-6, IL-10, IL-12p40, TNF- α , IFN- γ and IP-10.
- ▶ **Optimising the timing of ART** is the key preventive strategy:

Co-infection	Recommended ART timing	Rationale
TB meningitis	Do NOT start ART within the first 8 weeks of anti-TB therapy	CNS-TB IRIS can cause fatal neurological deterioration
Cryptococcal meningitis	Start ART 4–6 weeks after starting antifungal therapy	Early ART increases IRIS and mortality
Cryptococcal antigenaemia (no active disease)	Pre-emptive fluconazole; start ART 2 weeks after antifungal therapy	Treat occult infection before immune recovery

- ▶ **Prophylactic dexamethasone is NOT recommended** in HIV-associated cryptococcosis — it is associated with **reduced fungal clearance and increased mortality**.
- ▶ Screen high-risk patients (CD4 <100–200/ μ L) with **serum cryptococcal antigen (CRAg)** before ART to detect occult infection and avert unmasking IRIS.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Timeline / mechanism schematic:** horizontal time-axis labelled “ART started”. Two crossing curves — one falling “HIV-RNA / viral load”, one rising “CD4+ T-cell count”. Mark the inflammatory peak (“IRIS: 2 weeks–2 years; TB-IRIS 1–3 months”) at the crossover. Side boxes labelled: *Antigen load (live organisms + dead-organism antigens) → Restored CD4 / Type IV hypersensitivity response → Cytokine surge (IL-6, TNF- α , IFN- γ , IP-10) → Tissue inflammation.*
- ▶ **Two-arm classification box:** central node “IRIS” branching to “Paradoxical (known, treated infection worsens)” and “Unmasking (previously undiagnosed infection appears)”, each with one example (TB lymphadenitis flare; new cryptococcal meningitis).

Clinical / Diagnostic significance

- ▶ Anticipate IRIS in any patient who deteriorates *after* starting ART, particularly with baseline CD4 <50/ μ L — recognising it avoids the dangerous reflex of stopping life-saving ART or escalating (unnecessary) second-line antimicrobials.
- ▶ Mandates a careful **work-up to exclude treatment failure and new OIs** before attributing deterioration to IRIS.
- ▶ Drives the **sequencing of therapy**: treat the opportunistic infection first, then introduce ART after an appropriate interval (immediately–2 weeks for most OIs if CD4 very low, but **defer 8 weeks in TB meningitis** and **4–6 weeks in cryptococcal meningitis**).
- ▶ Justifies **CRAg screening** and pre-emptive antifungal therapy in advanced HIV to prevent unmasking cryptococcal IRIS.
- ▶ Glucocorticoids are a double-edged tool — beneficial in severe paradoxical reactions but harmful as *prophylaxis* in cryptococcosis.

High-yield exam pointers

- ▶ IRIS = paradoxical worsening after ART due to *restored immunity*; **not** drug or treatment failure.
- ▶ Two forms: **paradoxical** (known infection flares) vs **unmasking** (latent infection revealed).
- ▶ Highest risk: CD4 <50/ μ L + steep fall in viral load; commonest with **TB and cryptococcosis**.
- ▶ Onset **2 weeks–2 years** post-ART (TB-IRIS **1–3 months**); incidence **10–30%** overall, **~10%** in HIV-TB.
- ▶ Mechanism = **type IV hypersensitivity-like** reaction; cytokines IL-6, TNF- α , IFN- γ , IP-10.
- ▶ **Diagnosis of exclusion** — rule out treatment failure, new OI, drug toxicity.
- ▶ Management = **continue ART** + supportive care; **glucocorticoids only for severe disease** (TB-IRIS: prednisolone 1.5 mg/kg/day $\times$ 2 wk, then half $\times$ 2 wk).

- ▶ Timing rules: TB meningitis → no ART in first 8 weeks; cryptococcal meningitis → ART at 4–6 weeks; prophylactic dexamethasone contraindicated in cryptococcosis.
- ▶ Other faces: CMV immune-recovery uveitis/vitreitis, MAC suppurative lymphadenitis, KS flare, hepatitis B/C flare, Graves' disease.

SOURCE & COVERAGE

- ▶ **Harrison's Principles of Internal Medicine, 22e** — “Human Immunodeficiency Virus Disease: AIDS and Related Disorders” (IRIS section + Table 208-12, Characteristics of IRIS); “Tuberculosis” (TB-IRIS, ART timing in TB meningitis, prednisolone regimen, cytokine profile); “Cryptococcosis” (cryptococcal IRIS, ART timing 4–6 weeks, dexamethasone caution, CRAg screening).
- ▶ **CMDT 2026** — “HIV Infection & AIDS” (Inflammatory Reactions / IRIS — diagnosis of exclusion, conservative management, corticosteroids for severe reactions, CMV/MAC/KS examples).

Immunization for travel in adults

Asked in: Paper II Nov 2021 — RGUHS MD General Medicine

Definition / Introduction — Travel immunization is the pre-travel administration of vaccines to protect the international traveller against infections encountered en route or at the destination, and to satisfy entry/exit regulations of host countries. About 30% of travellers report a travel-related illness, and vaccine-preventable infections (influenza/COVID-19 most common, then typhoid and hepatitis A) are an important, preventable subset. Because several vaccines are given as a **series** and all take roughly a week to induce protective immunity, travellers should ideally be referred to a travel clinic **at least 4–6 weeks before departure**, though even last-minute consultation provides benefit.

Framework: the pretravel consultation and the three vaccine categories

- ▶ The pretravel consultation has four pillars: (1) **trip risk assessment** (itinerary + traveller), (2) **immunizations**, (3) **prevention of arthropod-borne infection (malaria/vector)**, and (4) **prevention of gastrointestinal illness** — with shared decision-making on whether to travel.
- ▶ Travel vaccines are traditionally grouped into three (overlapping) categories:
 - **Routine** — those on the national child/adult schedule (e.g., MMR, Tdap, influenza, hepatitis B); travellers must simply be *up to date*, since these infections occur worldwide.
 - **Recommended** — not on the routine schedule but advised because of *anticipated risk* from the specific itinerary (e.g., typhoid, hepatitis A, Japanese encephalitis, rabies).

- **Required** — *mandated* by international regulation or by a specific country for entry/exit; proof is documented on the **International Certificate of Vaccination or Prophylaxis (ICVP, the “yellow card”)**. The prototype is **yellow fever**; cholera and meningococcal (Hajj/Umrah) requirements also exist.
- A traveller without proof or a documented **medical waiver** for a required vaccine may face entry barriers, vaccination on arrival, quarantine or other penalties.

Vaccines to consider for most destinations

Vaccine	Primary series in unvaccinated adults	Booster	Key travel point
Hepatitis A (Havrix, Vaqta)	2 doses 6–12 mo (Havrix) / 6–18 mo (Vaqta) apart	Not required after series	One of the commonest VPIs in travellers; a single dose protects healthy young adults before travel; consider Ig 0.1 mL/kg if >40 y or immunocompromised
Hepatitis B (recombinant; Heplisav-B)	3 doses 0,1,6 mo; Heplisav-B 2 doses 0,1 mo	Not after routine series	Important for long-term travellers, HCWs, sexual exposure; Twinrix accelerated schedule (days 0,7,21–30) if departing soon
Influenza + COVID-19	Per current seasonal recommendation	Seasonal	<i>Most common</i> VPIs in travel; give influenza even if local season has peaked (year-round risk in tropics)
Measles–mumps–rubella (MMR)	2 doses ≥28 days apart	None	Resurgent worldwide; ensure 2-dose evidence of immunity; immune if born before 1957 ; only MMR available for adults
Tetanus–diphtheria–pertussis (Td/Tdap)	Age-appropriate per schedule	Td q10y	Early tetanus booster (<10 y) for high-injury trips; diphtheria booster within 5 y if outbreak destination
Varicella	2 doses	—	Evidence of immunity needed; immune if born in US before 1980 or prior disease/zoster

Vaccine	Primary series in unvaccinated adults	Booster	Key travel point
Poliomyelitis (IPV)	3 doses if never vaccinated	Single lifetime adult booster	One IPV booster before travel to countries with wild-type or circulating vaccine-derived poliovirus in prior 12 months

Destination- or activity-specific travel vaccines

Vaccine	Schedule / type	Indication / pearl
Yellow fever (live attenuated)	1 dose; valid for life, from day 10	Sub-Saharan Africa & tropical S. America; <i>required</i> — see below
Typhoid	Vi capsular polysaccharide (injectable, 1 dose, booster 2 y) or oral live attenuated (4 doses 48 h apart, booster 5 y)	Highest risk South Asia; oral vaccine contraindicated if immunocompromised ; <i>no protection against paratyphoid</i>
Japanese encephalitis (IXIARO, inactivated Vero-cell)	2 doses, days 0 and 7–28	Risk <1 per million travellers but ↑ in long-term/rural/evening exposure in Asia & W. Pacific
Rabies (HDCV/PCECV, pre-exposure)	2 doses days 0 and 7 (revised 2022)	Endemic on all continents except Antarctica; 3rd dose (21 d–3 y) or titre check if >3-y risk; PrEP still needs urgent post-exposure boosters
Meningococcal ACWY (conjugate)	1 dose	African “meningitis belt” in dry season (Dec–June); required for Hajj/Umrah within preceding 3 y; conjugate preferred over polysaccharide
Cholera (Vaxchora, live oral)	1 oral dose	Efficacy ~90% at 10 days, 80% at 3 months; for outbreak areas/HCWs who cannot maintain hygiene
Tick-borne encephalitis (inactivated)	3 doses; 2 doses adequate for short-term travel	Forested Europe/Asia; <i>Ixodes</i> tick; also via unpasteurised dairy
Chikungunya (live, 2023)	1 dose, age ≥18 y	For increased-exposure travellers; contraindicated if immunocompromised
Dengue	No FDA-approved vaccine for travellers	Dengvaxia only for seropositive endemic residents; Qdenga (EU, age ≥4) may be considered

Yellow fever — the prototype “required” vaccine

- ▶ **Live attenuated vaccine**, available **only at state-authorized yellow-fever clinics**, recorded on the ICVP; valid for entry from **day 10** after administration and for the **lifetime** of the vaccinee — the 10-yearly booster requirement was **removed from the WHO International Health Regulations in 2016**.
- ▶ **Booster after 10 years is still advised** for: women pregnant during primary immunization, persons with HIV at the time of vaccination, post-HSCT recipients, and those at especially high risk (epidemics, prolonged stay, peak season).
- ▶ Requirement triggers: arrival from an endemic country within 10 days, or a transit stop ≥ 12 h in an endemic country.
- ▶ **Contraindications:** severe immunosuppression (immunosuppressive therapy, primary immunodeficiency, symptomatic HIV or $CD4 < 200/\mu L$), malignancy, thymus disorders, severe egg allergy. **Precautions:** age ≥ 60 y, pregnancy, breastfeeding, asymptomatic HIV with $CD4$ 200–499/ μL .
- ▶ **Adverse events:** mild fever/myalgia/lymphadenopathy/rash; rare serious events include anaphylaxis, neurologic disease (GBS, meningitis, encephalitis) and **yellow fever vaccine-associated viscerotropic disease (YEL-AVD)** (~ 0.3 per 100,000 doses, higher in the elderly/immunosuppressed).

Co-administration, special populations and general principles

- ▶ All routine travel vaccines may be given on the same day. Exceptions: **oral typhoid must be given ≥ 8 h after oral cholera**; and **live-virus vaccines** (yellow fever, MMR, live-attenuated influenza, varicella) should be given on the **same day or spaced ≥ 28 days apart** (otherwise repeat the second dose after ≥ 28 days).
- ▶ **Pregnancy:** live-virus vaccines (MMR, varicella, and yellow fever as a precaution) are generally **contraindicated**; inactivated vaccines (Tdap each pregnancy at 27–36 weeks, inactivated influenza, hepatitis B) are safe and recommended.
- ▶ **Immunocompromised:** avoid live vaccines (yellow fever, oral typhoid, live chikungunya, MMR, varicella) when severely immunosuppressed; risk of vaccine-virus dissemination. A true **contraindication** is anaphylaxis to the vaccine or a component; a precaution is moderate/severe acute illness.
- ▶ **Malaria is NOT vaccine-preventable in travellers** — prevention rests on **mosquito-bite avoidance** (DEET 20–50%, permethrin-treated clothing, insecticide-treated nets) plus **chemoprophylaxis** (atovaquone-proguanil, chloroquine/hydroxychloroquine, doxycycline, mefloquine, primaquine, tafenoquine — tailored to species and resistance) and early recognition of fever.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Pretravel consultation flow box** with four labelled arms: *Risk assessment (Itinerary + Traveller) → Immunizations (Routine / Recommended / Required–ICVP) → Vector/Malaria prevention → GI-illness prevention.*
- ▶ **Yellow fever endemicity map (schematic)**: outline of *Africa* and *South America* shaded for **sub-Saharan Africa** and **tropical South America**, labelled “Yellow fever endemic / vaccine recommended”; annotate *ICVP valid from day 10, lifelong.*

Clinical / Diagnostic significance

- ▶ A focused **itinerary + traveller history** (destinations, season, rural vs urban, duration, accommodation, activities, pregnancy, immune status, drug interactions) drives vaccine selection and chemoprophylaxis choice.
- ▶ **Documentation matters medico-legally**: the ICVP/“yellow card” is the legal proof for required vaccines; medical waivers must be issued by authorised clinics.
- ▶ **Returning febrile traveller**: always consider **malaria** (leading cause of life-threatening infection in travellers) and typhoid/dengue; urge early evaluation — a key counselling point at the pretravel visit.
- ▶ Counsel on **rabies wound care** (immediate soap-and-water/povidone-iodine washing, urgent assessment for PEP = rabies immune globulin + vaccine series) and on **travellers’ diarrhoea** food/water precautions.

High-yield exam pointers

- ▶ Three categories: **Routine, Recommended, Required** — required = ICVP-documented (yellow fever prototype).
- ▶ Refer **4–6 weeks before travel**; vaccines need ~1 week for immunity.
- ▶ **Yellow fever**: single dose = lifelong protection; 10-yearly booster dropped by WHO (2016); YEL-AVD ~0.3/100,000.
- ▶ **Meningococcal ACWY required for Hajj/Umrah** within preceding 3 years; meningitis belt epidemics Dec–June.
- ▶ **Oral typhoid and oral cholera are live** → contraindicated in immunocompromised; give oral typhoid ≥8 h after oral cholera.
- ▶ **Live-virus vaccines**: same day or ≥28 days apart; contraindicated in pregnancy and severe immunosuppression.
- ▶ **Rabies pre-exposure**: 2 doses (days 0, 7) since 2022; still requires post-exposure boosters.
- ▶ Immunity benchmarks: **measles** — **born before 1957**; **varicella** — **US-born before 1980**.

- ▶ **Malaria has no traveller vaccine** — bite avoidance (DEET 20–50%, permethrin, nets) + chemoprophylaxis.

SOURCE & COVERAGE

Harrison's Principles of Internal Medicine, 22e — Ch 130 "Health Recommendations for International Travel" (primary; Tables 130-1 and 130-3, Fig. 130-1) and Ch 129 "Immunization Principles and Vaccine Use" (general contraindications/precautions, pregnancy and immunocompromised principles). Coverage note: Harrison gives vaccine *types and schedules* but not granular antigen content/dosage in mL; chemoprophylaxis regimen specifics are deferred to Ch 231 (Malaria) and are summarised here only at the level stated in Ch 130. US-centric immunity criteria (birth-year cut-offs) are quoted verbatim from the text and should be adapted to local epidemiology.

Infections due to HACEK

Asked in: Paper II Jul 2021 — RGUHS MD General Medicine

Definition / Introduction — HACEK is an acronym for a group of *fastidious, slow-growing, capnophilic* (CO₂-requiring) *gram-negative bacilli/coccobacilli* that are normal commensals of the **oral cavity and upper respiratory tract**. The members are *Haemophilus* species (classically *H. aphrophilus*, now reclassified), *Aggregatibacter* species (formerly *Actinobacillus actinomycetemcomitans* and *Haemophilus aphrophilus*), *Cardiobacterium hominis*, *Eikenella corrodens*, and *Kingella kingae*. Their clinical importance lies chiefly in being the principal **gram-negative cause of subacute infective endocarditis (IE)** on native and prosthetic valves; they also produce a spectrum of localised oral, skeletal, and abscess-forming infections. They account for ~0.8–6% of all IE (CMDT: <5%).

Microbiology and taxonomy of the HACEK group

- ▶ Common biology: fastidious, **slow-growing**, gram-negative; require an atmosphere **enriched with CO₂ (capnophilic)**; **do not grow on MacConkey/enteric media**; normal flora of the mouth.
- ▶ Taxonomy has been revised — the modern names differ from the original acronym:

Letter	Modern genus/species	Former name	Key disease niche
H	<i>Haemophilus parainfluenzae</i> (commonest <i>Haemophilus</i> in HACEK IE)	—	Subacute IE, polymicrobial abscess

Letter	Modern genus/species	Former name	Key disease niche
A	<i>Aggregatibacter actinomycetemcomitans</i> , <i>A. aphrophilus</i> , <i>A. paraphrophilus</i>	<i>Actinobacillus</i> ; <i>Haemophilus aphrophilus</i>	Commonest cause of HACEK IE; brain abscess; periodontitis
C	<i>Cardiobacterium hominis</i> (and <i>C. valvarum</i>)	—	Aortic-valve subacute IE
E	<i>Eikenella corrodens</i>	—	Human-bite/clenched-fist wounds; least common HACEK IE
K	<i>Kingella kingae</i>	—	Paediatric septic arthritis/osteomyelitis ; IE in older children/adults

- ▶ **HACEK bacteraemia is strongly predictive of underlying IE** (overall positive predictive value ~60%), but the association is organism-dependent: IE found in **62–100%** of *A. actinomycetemcomitans*, **17–55%** of *H. parainfluenzae*, **~50%** of *C. hominis*, but only **0–6%** of *Eikenella* bacteraemias.

Pathogenesis and routes of entry

- ▶ Reside as commensals in the **gingival crevice/oropharynx**; gain bloodstream access after **dental procedures, periodontal disease, or nasopharyngeal infection** — hence the typical history of recent dental work in a patient with valvular disease.
- ▶ *Eikenella corrodens* is inoculated through **human bites / clenched-fist** (“fight-bite”) injuries.
- ▶ *Kingella kingae* invasion is preceded by **upper respiratory tract infection or stomatitis** in ~80%; oropharyngeal colonisation peaks (≈5–10%) in the **first 3 years of life** and is higher in **daycare attenders**, explaining its age-restricted invasive disease (6 months–4 years) and reported child-to-child **outbreaks**.

HACEK infective endocarditis — clinical profile

- ▶ Predisposition: nearly always **pre-existing valvular disease or a prosthetic valve**; *Aggregatibacter* is linked to **prosthetic-valve endocarditis (PVE)** more than *Haemophilus*.
- ▶ Course is usually **subacute/indolent** (especially *Aggregatibacter* and *Cardiobacterium* — patients ill for weeks–months before diagnosis); *K. kingae* IE may be **more aggressive**.
- ▶ Compared with non-HACEK IE, HACEK IE occurs in **younger patients** and shows **more embolic, vascular and immunologic phenomena**.

- ▶ **Large vegetations** and **systemic embolism** are characteristic: major emboli in **28–71%** of series; echocardiographic vegetations seen in **up to 85%**.
- ▶ Valve localisation: *Aggregatibacter* and *Haemophilus* → **mitral**; *Cardiobacterium* → **aortic**.
- ▶ Complications: **congestive heart failure** (19–50% with *Haemophilus*), septic emboli (including **CNS emboli**), **mycotic aneurysms**, immune-complex glomerulonephritis, vasculitis, and renal failure.

Diagnosis

- ▶ **Alert the microbiology laboratory** when HACEK IE is suspected.
- ▶ Most clinically significant cultures turn **positive within the first week** using modern automated systems (BACTEC); studies have **not** shown that *prolonged incubation* improves recovery (CMDT: HACEK now usually grows within the standard 5-day incubation).
- ▶ Inoculating fluids (e.g., synovial fluid for *K. kingae*) into **aerobic blood-culture bottles** enhances recovery.
- ▶ **Molecular/rapid tools**: broad-range **16S rRNA gene PCR** (blood/valve tissue) and **MALDI-TOF mass spectrometry** on colonies improve speed and accuracy; **real-time PCR** is increasingly recovering *K. kingae* from culture-negative cases.
- ▶ HACEK organisms are listed among the “**typical**” IE **pathogens** that fulfil the **microbiologic major criterion** of the modified Duke / 2023 Duke-ISCVID criteria.
- ▶ Because of **slow growth**, **β-lactamase production may be missed** on susceptibility testing; Etest improves accuracy. Resistance is most common in *Haemophilus* and *Aggregatibacter*; in recent studies **ceftriaxone and levofloxacin were active against all isolates**.

Treatment of HACEK infections

Organism / setting	Preferred therapy	Alternatives / notes
HACEK IE (all five genera)	Ceftriaxone 2 g IV once daily	Favourable outcome in 80–90% ; NVE 4 weeks, PVE 6 weeks
β-lactam-intolerant	Levofloxacin 750 mg/day (data limited)	Fluoroquinolones not for patients <18 years
Alternative β-lactam	Ampicillin/sulbactam (3 g ampicillin q6h)	Amp/sulbactam resistance described in <i>Haemophilus</i> & <i>Aggregatibacter</i>
If β-lactamase excluded & susceptible	Penicillin 16–18 MU q4h or ampicillin 2 g q4h	Susceptibility hard to confirm due to slow growth

- ▶ **Surgery is usually NOT required** — unlike PVE from other gram-negative bacilli, HACEK IE is often cured by antibiotics alone.

- ▶ *Eikenella corrodens* is **resistant to clindamycin, metronidazole, and aminoglycosides** — relevant in bite-wound polymicrobial cover.
- ▶ **Prognosis is excellent**, significantly better than non-HACEK IE; 1-year mortality is lower than that of viridans-streptococcal IE.
- ▶ **Prophylaxis** (high-risk cardiac lesions before dental manipulation): **amoxicillin 2 g PO 1 h before**; if penicillin-allergic — cephalexin 2 g, azithromycin/clarithromycin 500 mg, or doxycycline 100 mg PO. This is directly relevant because HACEK organisms originate from the oral flora.

Organism-specific pearls (beyond endocarditis)

- ▶ ***Haemophilus parainfluenzae** — *commonest Haemophilus in HACEK IE; also pneumonia, meningitis, and brain/dental/pelvic/liver abscess; septicaemia often polymicrobial**.
- ▶ ***Aggregatibacter** — *commonest HACEK IE; A. actinomycetemcomitans co-isolated with Actinomyces israelii in soft-tissue abscesses; A. aphrophilus is an important cause of brain abscess** (10% of brain abscesses in one series) and bone/joint infection.
- ▶ ***Cardiobacterium hominis** ($\pm$ C. valvarum) — *aortic vegetations; presents with long-standing infection, embolisation, mycotic aneurysms**, immune-complex glomerulonephritis, vasculitis, arthritis.
- ▶ ***Eikenella corrodens** — *eponymous “corroding”/pitting of agar; human-bite wounds, head-and-neck and visceral abscesses, osteomyelitis, IUD-associated gynaecologic infection; usually part of mixed** infection.
- ▶ ***Kingella kingae** — *has surpassed S. aureus as the leading cause of septic arthritis and osteomyelitis in young children; bacteraemia can present with a petechial rash mimicking meningococcaemia**; adult/older-child IE is aggressive (arterial emboli, CVA, tricuspid insufficiency, cardiovascular collapse).

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Labelled heart with HACEK endocarditis**: draw a left heart in long-axis; label **mitral valve vegetation** (*Aggregatibacter*/*Haemophilus*), **aortic valve vegetation** (*Cardiobacterium*), **large friable vegetation** $\rightarrow$ **systemic/CNS embolus, mycotic aneurysm, and immune-complex glomerulonephritis** as peripheral consequences.
- ▶ **Flow box of HACEK pathway**: *Oral/upper-respiratory commensal $\rightarrow$ dental procedure / periodontitis / bite $\rightarrow$ transient bacteraemia $\rightarrow$ adherence to damaged or prosthetic valve $\rightarrow$ subacute vegetation $\rightarrow$ embolic + immunologic complications.* Label each arrow.

Clinical / Diagnostic significance

- ▶ Consider HACEK in any culture-negative or “fastidious-organism” subacute IE, particularly with poor dentition, recent dental work, prosthetic valve, large vegetations, or prominent embolic phenomena.
- ▶ Maintain the blood-culture incubation and **flag the lab**; add 16S rRNA PCR / MALDI-TOF when conventional cultures are negative.
- ▶ Differentiate from other culture-negative IE causes — *Coxiella burnetii*, *Bartonella*, *Tropheryma whippelii*, *Brucella*, nutritionally-variant streptococci (*Granulicatella*/*Abiotrophia*/*Gemella*) — which need **serology/special media**, not just longer incubation.
- ▶ A positive HACEK blood culture (especially *Aggregatibacter*, *Cardiobacterium*) should **prompt echocardiography** given the high predictive value for IE.

High-yield exam pointers

- ▶ HACEK = Haemophilus, Aggregatibacter (was *Actinobacillus*), *Cardiobacterium hominis*, *Eikenella corrodens*, *Kingella kingae* — fastidious, CO₂-requiring, oral commensals.
- ▶ **Commonest gram-negative cause of subacute IE**; ~0.8–6% of all IE.
- ▶ **Aggregatibacter** = commonest HACEK IE and commonest in PVE; **Cardiobacterium** → aortic, **Aggregatibacter**/*Haemophilus* → mitral.
- ▶ HACEK bacteraemia PPV for IE ≈ 60%; highest with *A. actinomycetemcomitans*, lowest with *Eikenella*.
- ▶ **Large vegetations + frequent emboli** (28–71%); younger patients; vegetations on echo up to 85%.
- ▶ First-line therapy = ceftriaxone 2 g/day; NVE 4 weeks, PVE 6 weeks; often cured medically without surgery; excellent prognosis.
- ▶ *Eikenella* resists clindamycin, metronidazole, aminoglycosides; think of it in clenched-fist bite wounds.
- ▶ *Kingella kingae* = top cause of paediatric septic arthritis/osteomyelitis; inoculate joint fluid into blood-culture bottles; petechial rash mimics meningococcaemia.
- ▶ HACEK qualifies as a “typical” organism (major criterion) in the modified Duke / Duke-ISCVID criteria.

SOURCE & COVERAGE

- ▶ **Harrison’s Principles of Internal Medicine, 22e** — “Infections Due to the HACEK Group and Miscellaneous Gram-Negative Bacteria” (Tamar F. Barlam) and “Infective Endocarditis” (etiology, modified Duke/Duke-ISCVID criteria, HACEK treatment regimens, antibiotic prophylaxis).

- **CMDT 2026** — “Bacterial & Chlamydial Infections” (Infective Endocarditis: HACEK organisms; culture-negative endocarditis) for current management and the classic acronym expansion.

Infective Endocarditis

Asked in: Paper II Jul 2021 — RGUHS MD General Medicine

Definition / Introduction — Infective endocarditis (IE) is microbial infection of the endocardial surface of the heart, most often the valves, whose prototypic lesion is the **vegetation** — a mass of platelets, fibrin, microorganisms and scant inflammatory cells. Infection may also involve the low-pressure side of a ventricular septal defect, mural endocardium damaged by aberrant jets or foreign bodies, or intracardiac devices; the analogous process on arteriovenous/arterio-arterial shunts (patent ductus, coarctation) is termed **infective endarteritis**. In developed countries the incidence is **~15 cases per 100,000 population/year** and is rising, with predisposition shifting from chronic rheumatic heart disease (still dominant in developing countries) towards injection drug use, degenerative valve disease and intracardiac devices.

Classification

IE is classified by temporal course, site, cause, or predisposing risk factor:

- **By tempo:** *Acute IE* — hectically febrile, rapidly destroys cardiac structures, seeds distant sites, fatal in weeks if untreated (β -haemolytic streptococci, *S. aureus*, pneumococci). *Subacute IE* — indolent, slowly progressive, rarely metastasises (viridans streptococci, enterococci, CoNS, HACEK).
- **By valve type:** Native-valve endocarditis (NVE), prosthetic-valve endocarditis (PVE — 16–30% of cases), transcatheter aortic valve replacement (TAVR)-PVE, and cardiovascular implantable electronic device IE (CIED-IE).
- **By setting:** Community-acquired, **health care-associated** (25–35% of NVE), IE in people who inject drugs (PWID).
- **PVE timing:** *Early* (<2 months post-surgery — nosocomial: *S. aureus*, CoNS, gram-negative bacilli, diphtheroids, fungi); *late* (>12 months — microbiology like community NVE). Risk is highest in the first year, higher for bioprosthetic than mechanical valves.

Etiology (microbiology)

- **Staphylococcus aureus** — now the **most common** overall cause; predominates in health care-associated IE (~52%) and PWID (often methicillin-resistant).

- ▶ **Viridans streptococci** (oral portal) — classic subacute NVE; *Streptococcus gallolyticus* (formerly *S. bovis*) arises from the gut and signals **colonic polyps/tumours**.
- ▶ **Enterococci** (genitourinary portal), **coagulase-negative staphylococci** (chief cause of PVE; usually methicillin-resistant), and the **HACEK** group — *Haemophilus*, *Aggregatibacter*, *Cardiobacterium hominis*, *Eikenella corrodens*, *Kingella kingae* (upper-respiratory portal).
- ▶ **Culture-negative IE (5–15%)**: one-third to one-half due to prior antibiotics; remainder due to fastidious organisms — *Coxiella burnetii* (Q fever, predilection for prosthetic valves), *Bartonella* spp., *Tropheryma whippelii*, and nutritionally variant *Granulicatella*, *Abiotrophia*, *Gemella*. *Mycobacterium chimaera* has caused a global PVE outbreak from contaminated heater-cooler units.
- ▶ Mimics of culture-negative IE: atrial myxoma, marantic (non-bacterial thrombotic) endocarditis, antiphospholipid antibody syndrome.

Pathogenesis

- ▶ Intact endothelium resists most bacteria. **Endothelial injury** (high-velocity jets, low-pressure side of a lesion) → deposition of a platelet–fibrin thrombus = **nonbacterial thrombotic endocarditis (NBTE)**, the nidus for bacterial attachment during transient bacteraemia.
- ▶ Cardiac lesions prone to NBTE: mitral regurgitation, aortic stenosis, aortic regurgitation, VSD, complex congenital disease. NBTE also arises from hypercoagulable states (marantic endocarditis in malignancy; bland vegetations in SLE/antiphospholipid syndrome).
- ▶ Organisms adhere via **MSCRAMMs** (microbial surface components recognising adhesive matrix molecules) — fibronectin-binding proteins, clumping factor (*S. aureus*), FimA/glucans (streptococci). *S. aureus* can invade even **intact** endothelium via von Willebrand factor and fibronectin-binding proteins.
- ▶ Organisms deep in the vegetation are **metabolically inactive (nongrowing)** and relatively resistant to antibiotics — the rationale for prolonged, bactericidal, parenteral therapy.

Clinical features

Feature	Frequency
Fever	80–90%
Heart murmur	80–85%
New/worsened regurgitant murmur	20–50%
Arterial emboli	20–50%
Splenomegaly	15–50%
Neurologic manifestations	20–40%
Peripheral stigmata (Osler, Janeway, splinter, Roth)	2–15%

Feature	Frequency
Anaemia	70–90%
Elevated CRP	>90%

- ▶ **Cardiac:** new regurgitant murmur (valve/chordal destruction); congestive heart failure in 30–40% (chief surgical indication); paravalvular abscess (commonest with aortic valve) burrowing into the septum → **heart block**; coronary embolism (2%).
- ▶ **Peripheral stigmata:** ***Osler nodes** (*painful, immunologic, finger/toe pulps*), **Janeway lesions** (*painless, septic-embolic, palms/soles*), **Roth spots** (*retinal exudates*), *splinter/subungual haemorrhages, petechiae (palate, conjunctiva), clubbing**.
- ▶ **Embolic/metastatic:** stroke or encephalopathy (15–35%); renal/splenic infarcts; mycotic aneurysm; spondylodiscitis. *S. aureus*, vegetations >10 mm, and mitral anterior-leaflet involvement independently raise embolic risk; embolic rate falls sharply after effective therapy.
- ▶ **Immune-mediated:** diffuse hypocomplementaemic glomerulonephritis (immune-complex), positive rheumatoid factor, microscopic haematuria.
- ▶ **PWID:** 35–60% have isolated **tricuspid IE** — fever with faint/absent murmur, septic pulmonary emboli causing cough, pleuritic pain, nodular infiltrates.

Diagnosis — 2023 Duke-ISCVID criteria

Definite IE = 2 major or 1 major + 3 minor or 5 minor (clinical), or pathologic confirmation in a vegetation/abscess. **Possible IE** = 1 major + 1 minor or 3 minor.

Major criteria	Minor criteria
Positive blood cultures: typical IE organism in ≥2 sets (e.g. <i>S. aureus</i> , <i>S. lugdunensis</i> , <i>E. faecalis</i> , all streptococci except <i>S. pneumoniae</i> / <i>S. pyogenes</i> , <i>Granulicatella</i> / <i>Abiotrophia</i> / <i>Gemella</i> , HACEK); atypical organism in ≥3 sets	Predisposition (prior IE, IV drug use, prosthetic/repared valve, congenital disease, CIED, >mild regurgitation/stenosis, HCM)
Positive lab test: PCR for <i>Coxiella</i> / <i>Bartonella</i> / <i>T. whipplei</i> ; <i>C. burnetii</i> phase I IgG ≥1:800; <i>Bartonella</i> IgG ≥1:800	Fever >38.0°C
Imaging: echocardiography or cardiac CT showing vegetation, perforation, abscess, pseudoaneurysm, fistula, new dehiscence, or new regurgitation	Vascular phenomena (arterial/septic pulmonary emboli, mycotic aneurysm, intracranial/conjunctival haemorrhage, Janeway lesions)
FDG-PET/CT abnormal uptake on a prosthetic valve/graft/lead	Immunologic phenomena (glomerulonephritis, Osler nodes, Roth spots, rheumatoid factor)
Direct evidence at heart surgery	Microbiologic evidence not meeting major criteria

- ▶ **Blood cultures (gold standard):** three two-bottle sets (10 mL/bottle) from separate venipunctures before antibiotics; in stable suspected subacute IE, withhold empirical therapy to allow uncontaminated cultures.
- ▶ **Echocardiography:** TTE misses vegetations <2 mm and is inadequate in ~20%; TEE detects vegetations in >90% — a negative TEE with high suspicion warrants repeat in 7–10 days. CTA is superior for pseudoaneurysm/abscess; FDG-PET/CT boosts sensitivity for PVE/TAVR-PVE, CIED and graft infection — CTA and PET findings now count as **major** criteria.
- ▶ Routine TEE is recommended in *S. aureus* bacteraemia because of the high prevalence of underlying IE (8–14%).

Management

Principles: all bacteria in the avascular, metabolically dormant vegetation must be killed → **prolonged, parenteral, bactericidal** therapy; duration is timed from the first negative blood culture. Manage with infectious-disease consultation, especially for *S. aureus*.

Organism	Representative regimen
Penicillin-susceptible streptococci (MIC ≤0.12)	Penicillin G or ceftriaxone 2 g/day × 4 wk (vancomycin if allergic)
Enterococci	Ampicillin + ceftriaxone, or ampicillin/penicillin + gentamicin × 4–6 wk
MSSA, native valve	Nafcillin/oxacillin/flucloxacillin (or cefazolin) × 4–6 wk; gentamicin not recommended
MRSA, native valve	Vancomycin or daptomycin (8–10 mg/kg/day) × 4–6 wk
Staphylococcal PVE	Vancomycin/antistaphylococcal penicillin + rifampin + gentamicin × 6–8 wk
HACEK	Ceftriaxone 2 g/day × 4 wk
<i>Coxiella burnetii</i>	Doxycycline + hydroxychloroquine ≥18 mo (24 mo if prosthetic)

- ▶ **Empirical:** acute IE → vancomycin + gentamicin/cefepime (covers MRSA, gram-negatives); subacute NVE → vancomycin + ceftriaxone.
- ▶ **Right-sided uncomplicated MSSA IE** may respond to a 2-week course; left-sided staphylococcal IE needs ≥6 weeks.
- ▶ **Rifampin** is essential in staphylococcal PVE (kills biofilm-embedded organisms) but is added only after bacteraemia clears, to avoid resistance.
- ▶ **CIED-IE:** antibiotics are **adjunctive to complete device removal** (percutaneous lead extraction preferred).

- ▶ **Anticoagulation:** neither anticoagulant nor antiplatelet therapy prevents emboli and both risk haemorrhagic transformation; reserve for independent indications (mechanical valve, AF) and reverse after acute stroke/haemorrhage.

Surgical indications (Table 133-6): moderate–severe CHF from valve dysfunction (commonest); paravalvular extension (abscess, fistula, heart block); persistent bacteraemia despite 7–10 days of therapy; lack of effective therapy (fungal, *Brucella*, multidrug-resistant gram-negatives); unstable dehiscence prosthesis; large (>10 mm) hypermobile vegetation with prior embolus and valve dysfunction; very large (>30 mm) vegetation. Surgery for NVE confers a survival benefit of ~27–55%, greatest with the most pressing indications.

Prevention

- ▶ Antibiotic prophylaxis is limited to **highest-risk lesions** (Table 133-9): prosthetic valves/material, prior IE, unrepaired cyanotic congenital disease (or repair with residual defect/within 6 months), LVAD/transplant valvulopathy — and **only** before procedures that manipulate gingiva/periapical tissue or perforate oral mucosa.
- ▶ **Regimen:** amoxicillin 2 g PO 1 h before procedure (ampicillin/cefazolin/ceftriaxone IV if NPO; doxycycline/azithromycin if penicillin-allergic). The AHA now **advises against clindamycin** (*C. difficile* risk). Good dental hygiene matters more than prophylaxis.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Valve vegetation:** cross-section of a valve leaflet — label *vegetation* (platelets + fibrin + microorganisms), *endothelial injury site*, *underlying NBTE*, *regurgitant jet*, *paravalvular abscess*, *embolus shedding into bloodstream*.
- ▶ **Peripheral stigmata figure:** label *Osler nodes* (painful, finger pulps), *Janeway lesions* (painless, palms/soles), *splinter/subungual haemorrhages*, *Roth spots* (retina), *petechiae* (conjunctiva/palate), *clubbing*, *splenomegaly*.

Clinical / Diagnostic significance

- ▶ A new or changing regurgitant murmur with fever, or fever plus an IE-associated organism on blood culture, mandates echocardiography and the Duke-ISCVID work-up.
- ▶ *S. aureus* bacteraemia without an obvious focus is presumptive IE/CIED-IE until echocardiography proves otherwise.
- ▶ *S. gallolyticus* IE warrants **colonoscopy** to exclude colonic neoplasia.
- ▶ Persistent fever beyond 7 days on appropriate therapy demands a search for paravalvular/extracardiac abscess or embolic complication.
- ▶ Overall survival in developed countries is 80–85%; worse with prosthetic valves, *S. aureus*/resistant pathogens, neurologic complications and early PVE (40–50% mortality).

High-yield exam pointers

- ▶ **Vegetation** = platelets + fibrin + microorganisms + scant inflammatory cells; deep organisms are dormant → need prolonged bactericidal therapy.
- ▶ *****S. aureus* is now the commonest cause**** of IE overall; viridans streptococci classically cause subacute NVE.
- ▶ **HACEK** = *Haemophilus*, *Aggregatibacter*, *Cardiobacterium hominis*, *Eikenella corrodens*, *Kingella kingae*.
- ▶ **Osler nodes** = painful (immune); **Janeway lesions** = painless (septic emboli); **Roth spots** = retinal.
- ▶ Diagnosis by **2023 Duke-ISCVID criteria**: definite = 2 major / 1 major + 3 minor / 5 minor; CTA and FDG-PET/CT now count as major.
- ▶ TEE sensitivity >90% (vs TTE ~55–65%); repeat in 7–10 days if negative but suspicion high.
- ▶ PWID → **tricuspid** valve, *S. aureus* (often MRSA), septic pulmonary emboli.
- ▶ Staphylococcal PVE triple therapy includes **rifampin** (biofilm) + gentamicin.
- ▶ Prophylaxis only for high-risk lesions before dental/oral-mucosal procedures: **amoxicillin 2 g**; clindamycin no longer advised.
- ▶ Commonest surgical indication = **refractory heart failure** from valve dysfunction.

Lepra Reactions

Asked in: Paper II May 2022 · Paper IV Nov 2020 (2×) — RGUHS MD General Medicine

Definition / Introduction — *Lepra (leprosy) reactions* are acute, immunologically mediated inflammatory episodes that interrupt the otherwise chronic, stable course of leprosy and may occur **before, during, or after** multidrug therapy (MDT). They are *medical emergencies* because they cause acute neuritis and nerve-function impairment; if not diagnosed and treated early they lead to permanent deformity, disability, and blindness. Two principal types are recognised — **Type 1 reaction** (T1R / **reversal reaction**), a delayed (cell-mediated) hypersensitivity event, and **Type 2 reaction** (T2R /

erythema nodosum leprosum, ENL), an immune-complex-mediated event — with *Lucio's phenomenon* as a third, distinct reactional state.

Overview & immunological basis

- ▶ Reactions reflect a sudden shift in the host immune response to *Mycobacterium leprae* antigens along the Ridley–Jopling spectrum (TT–BT–BB–BL–LL).
- ▶ Immunologic resistance is strongest at the tuberculoid (TT) pole and weakest at the lepromatous (LL) pole; the **unstable borderline groups (BT, BB, BL)** are most prone to reactions.
- ▶ Reactions can occur in untreated patients but are commonest after starting MDT; new reactions and nerve damage may appear **up to 3 years after completion** of therapy.
- ▶ The two types differ fundamentally in immunopathology — T1R = **Type IV (delayed) hypersensitivity** with upgrading cell-mediated immunity (CMI); T2R = **Type III (immune-complex) hypersensitivity / Arthus phenomenon**.

Type 1 Lepra Reaction (T1R / Reversal Reaction)

- ▶ A **delayed hypersensitivity reaction** associated with a *sudden alteration of CMI status* and a shift in the patient's position on the leprosy spectrum.
- ▶ Histologically marked by infiltration of lesions by **activated CD4+ T lymphocytes (especially T helper cells)**.
- ▶ Termed a “**reversal reaction**” because of the *upgrading* of CMI status; usually seen in the **borderline** portion of the spectrum (BT especially susceptible).
- ▶ **Skin**: existing lesions undergo *acute swelling and redness* (erythema and oedema of pre-existing patches/plaques), which may ulcerate.
- ▶ **Nerves**: painful, tender nerve trunks (*neuritis*) with consequent nerve damage and disfigurement; in severe T1R, **nerve abscesses** may form.
- ▶ “**Silent neuritis**” (“quiet nerve paralysis”): progressive sensory and/or motor impairment of hands, feet, and face *without* the usual inflammatory signs — easily missed, hence routine nerve assessment is essential.
- ▶ Less common features: arthralgia/arthritis; rarely fever, malaise, tenosynovitis, and oedema of the feet and hands.

Type 2 Lepra Reaction (T2R / Erythema Nodosum Leprosum)

- ▶ An **immune-complex-mediated syndrome** (antigen–antibody reaction involving complement) causing inflammation of skin, nerves, and other organs with systemic malaise — a **Type III hypersensitivity reaction (Coombs & Gell) / Arthus phenomenon**.
- ▶ Occurs in the **multibacillary (BL and LL)** end of the spectrum, mostly during MDT but also in untreated patients.

- ▶ **Skin:** crops of evanescent, *pink-to-red, tender, warm* maculopapular/papular/nodular or plaque lesions on the **outer aspects of thighs, legs, and face**; lesions blanch with light finger pressure and last a few days, changing colour pink/red → bluish/brownish (24–48 h) → dark over a week.
- ▶ Severe forms become vesicular, pustular, bullous, or necrotic and ulcerate — **erythema nodosum necroticans**.
- ▶ **Systemic / multi-organ involvement:** fever and constitutional symptoms, lymph-node enlargement, myositis, arthritis, synovitis, rhinitis, epistaxis, laryngitis, iridocyclitis and glaucoma, painful dactylitis, acute epididymo-orchitis, nephritis and renal failure, hepatosplenomegaly, anaemia, and — at a late stage — **amyloidosis**.
- ▶ **Severe T2R** includes swollen, painful, tender nerve trunks with sensory and motor deficits (i.e. it too causes neuritis).

Lucio's Phenomenon

- ▶ A distinct reactional state seen in **diffuse leprosy of Lucio and Latapí** (*"lepra bonita"*), occurring chiefly in Mexico and Central America; may be a variant of erythema nodosum necroticans.
- ▶ Pathology: **marked vasculitis with thrombosis** of superficial and deep dermal vessels → cutaneous haemorrhage and infarction.
- ▶ Lesions: slightly indurated, bluish-red, ill-defined, painful, rarely palpable plaques with an erythematous halo, usually on one limb; irregular/triangular shape, becoming purplish centrally with a *central haemorrhagic infarct* ± blister and an easily detached **necrotic eschar**, leaving an irregular ulcer that heals with a superficial scar.
- ▶ Patients remain **afebrile** throughout.

Comparison: Type 1 vs Type 2 reactions

Feature	Type 1 (Reversal)	Type 2 (ENL)
Immunology	Type IV / delayed (cell-mediated) hypersensitivity	Type III / immune-complex (Arthus)
Mechanism	Upgrading of CMI; CD4+ T-cell infiltration	Antigen–antibody complexes + complement
Spectrum affected	Borderline (BT, BB, BL)	Multibacillary (BL, LL)
Skin lesions	Acute erythema & swelling of <i>existing</i> lesions	<i>New</i> crops of tender erythematous nodules
Systemic upset	Usually mild	Prominent — fever, malaise, multi-organ
Neuritis	Common and often severe	Occurs, mainly in severe T2R
Drug of choice	Oral prednisolone (glucocorticoid)	Thalidomide / high-dose prednisolone

Treatment of lepra reactions

- ▶ **General:** identify and treat early; assess nerve function; reassure regarding non-contagiousness; continue MDT through the reaction.
- ▶ **Type 1 reaction:** oral short-acting **glucocorticoids** are the treatment of choice — **prednisolone 1 mg/kg/day once daily (max 60–80 mg)**; WHO programmes commonly use an initial dose of **40 mg**, tapered slowly by **5 mg every 2 weeks over ~20 weeks** (better outcomes and lower relapse than the older 12-week regimen). Review every 2 weeks with nerve assessment; reactions often flare again as the dose falls to <10–20 mg.
- ▶ **Type 2 reaction (ENL):**
 - *Mild, first episode (localised nodules):* aspirin and **pentoxifylline**.
 - *Rapid control:* **thalidomide** is the most effective drug (rapidly suppresses skin signs, neuritis, and iritis); **100–200 mg once or twice daily**, tapered and stopped after 1–2 weeks in acute first episodes; maintenance **50 mg/day** for severe recurrent ENL. *Strictly contraindicated in pregnancy* (teratogenic) — use only in women of child-bearing age after counselling, a negative pregnancy test, and strict contraception.
 - *Where thalidomide is restricted:* **high-dose oral prednisolone**, quickly tapered over 2–3 weeks to zero or a low maintenance dose; ENL is usually transient (resolving in ~2 weeks).
 - *Recurrent ENL:* **high-dose clofazimine** — 300 mg/day for 1 month → 200 mg/day for 1 month → 100 mg/day maintenance (maximal effect takes several weeks; GI side-effects and skin discolouration with prolonged use).
- ▶ **Silent neuropathy / neuritis without skin signs:** managed as for T1R — **high-dose prednisolone** is the drug of choice; nerve-decompression surgery is of unproven benefit (no RCT evidence).
- ▶ **Nerve-recovery prognosis:** good if steroids are started soon after onset of nerve-function impairment; some recovery possible up to 6 months, but impairment persisting >6 months rarely benefits from steroids.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Ridley–Jopling spectrum bar** (left = TT, right = LL): label *TT – BT – BB – BL – LL*; mark a bracket over BT–BB–BL as “Type 1 (reversal) reaction zone” and a bracket over BL–LL as “Type 2 (ENL) reaction zone”; annotate “high CMI / paucibacillary” at the TT end and “low CMI / multibacillary” at the LL end.
- ▶ **Comparison schematic of skin lesions:** (a) T1R — *existing* plaque becoming red and swollen; (b) T2R — *new* crop of tender erythematous nodules on the leg. Labels: “Type IV hypersensitivity (T1R)”, “Type III / immune complex (T2R)”, “neuritis – tender thickened nerve”.

Clinical / Diagnostic significance

- ▶ Reactions are the *leading cause of nerve damage and disability* in leprosy; recognition prevents permanent deformity and blindness.
- ▶ **Neuritis** (tender, thickened nerve trunks with sensory/motor loss) is the key emergency component of both reactions — palpate the **greater auricular, ulnar, radial, radial cutaneous, median, lateral popliteal, posterior tibial, sural, and superficial peroneal nerves** at every visit.
- ▶ Eye involvement in T2R (iridocyclitis, glaucoma) is sight-threatening and demands urgent treatment.
- ▶ Differentiate ENL nodules from the lesions of T1R, cellulitis, and vasculitis; necrotic ulcerating lesions raise the possibility of erythema nodosum necroticans or Lucio's phenomenon.
- ▶ Monitor for steroid- and thalidomide-related toxicity; counsel rigorously on thalidomide teratogenicity.

High-yield exam pointers

- ▶ **T1R = reversal reaction = Type IV (delayed/CMI) hypersensitivity**, borderline spectrum, *upgrading* CMI, CD4+ T-cell infiltration.
- ▶ **T2R = ENL = Type III (immune-complex/Arthus) hypersensitivity**, BL/LL spectrum, *new* tender nodules + systemic features.
- ▶ T1R inflames *pre-existing* lesions; ENL produces *new* crops of nodules.
- ▶ **Prednisolone 1 mg/kg/day** is first-line for T1R; **thalidomide 100–200 mg/day** is the most effective drug for ENL (teratogenic — pregnancy contraindicated).
- ▶ **Silent neuritis** = progressive nerve impairment without inflammatory signs — treat as T1R with steroids.
- ▶ **Lucio's phenomenon** = vasculitis/thrombosis with cutaneous infarction in diffuse (Lucio–Latapí) leprosy; patient afebrile.
- ▶ Reactions can occur **before, during, or after** MDT, up to **3 years** after completing treatment — MDT is continued during a reaction.
- ▶ Erythema nodosum necroticans = necrotic/ulcerating severe ENL; late ENL complication = **amyloidosis**.

SOURCE & COVERAGE

Harrison's Principles of Internal Medicine, 22e (2025) — Ch 184 "Leprosy" (sections: *Leprosy Reactions; Treatment of Leprosy Reactions; Treatment and Prognosis of Nerve Function Impairment; Ridley–Jopling Classification*). Coverage note: the chapter fully supports both reaction types, Lucio's phenomenon, and management; the explicit "Type IV" and "multibacillary BL/LL" labels for T1R/T2R respectively are standard textbook immunology consistent with the chapter's description (delayed CMI for T1R; immune-complex/Type III for T2R).

Leptospirosis

Asked in: Paper II Nov 2019 — RGUHS MD General Medicine

Definition / Introduction — Leptospirosis is a globally important **zoonotic** spirochaetal infection caused by pathogenic *Leptospira* species, transmitted to humans chiefly through contact with water, soil or animal tissue contaminated by the urine of infected reservoir hosts (especially rats). It produces a wide clinical spectrum from asymptomatic/anicteric febrile illness to fulminant multi-organ disease; the classic severe form — the triad of **jaundice, acute kidney injury and haemorrhage** — is termed **Weil's syndrome**. Severe pulmonary haemorrhage is an increasingly recognised, highly lethal presentation. An estimated ~1 million severe cases occur annually with a mean case-fatality of nearly 10%.

Aetiologic agent & microbiology

- ▶ *Leptospira* are spirochaetes of order **Spirochaetales**, family **Leptospiraceae**. Traditional dichotomy: pathogenic *L. interrogans* (sensu lato) and free-living *L. biflexa* (sensu lato).
- ▶ Modern phylogenetic (core-genome) analysis defines **64 species** — **17 pathogenic**, **21 intermediate**, **26 non-pathogenic (saprophytic)**.
- ▶ For clinical/epidemiologic purposes, **serologic** classification is used: pathogenic leptospires are divided into **>260 serovars** arranged in **26 serogroups** by antigenic (LPS) composition.
- ▶ Morphology: coiled, thin, highly motile organisms with **hooked ends** and **two periplasmic (axial) flagella**; **6–20 µm long**, **~0.1 µm diameter**. Stain poorly — visualised by **dark-field microscopy** and **silver impregnation** of tissue.
- ▶ Fastidious: require special media and **weeks to months** to grow in culture. Double-membrane cell wall rich in lipoproteins; **LPS has relatively low endotoxic potency**, yet protective humoral immunity is **serovar-specific anti-LPS antibody**.

Epidemiology & transmission

- ▶ Worldwide distribution; greatest in **tropics/subtropics** (warm, humid climate, poor sanitation favour survival). Most cases in **men**, peaking in **summer–autumn** (temperate) and the **rainy/monsoon season** (tropics).
- ▶ **Reservoir**: almost all mammals; **rodents** — **especially rats** — **are the most important**. Leptospires colonise the host renal tubule symbiotically and are shed in urine for years.
- ▶ Characteristic **serovar–host associations**: *Icterohaemorrhagiae* and *Copenhageni* — rats; *Grippityphosa* — voles; *Hardjo* — cattle; *Canicola* — dogs; *Pomona* — pigs.
- ▶ **Transmission**: direct contact with infected animal urine/blood/tissue, or (more commonly) environmental exposure — **water is the key vehicle** (leptospires survive months in moist conditions). Outbreaks follow **floods**, recreational freshwater activity (triathlons, rafting, mud-runs), and sporting events.

- ▶ **High-risk occupations:** veterinarians, agricultural/rice-field workers, sewage and abattoir workers, fishing-industry workers; also urban slum/unhoused populations exposed to rat urine. Also a recognised **traveller's disease**.

Pathogenesis

- ▶ **Portal of entry:** cuts, abraded skin, or mucous membranes (conjunctival, oral).
- ▶ **Leptospiraemic phase:** highly motile organisms proliferate, cross tissue barriers and **disseminate haematogenously to all organs**, evading complement-mediated killing and phagocytosis. An exaggerated **pro-inflammatory** response correlates with mortality.
- ▶ **Immune phase:** appearance of antibody coincides with clearance from blood, but organisms persist in **kidney, liver, lung, heart and brain**; leptospires are then shed in **urine**.
- ▶ **Kidney:** acute tubular damage + **interstitial nephritis** → interstitial oedema and acute tubular necrosis; dysregulated tubular transporters cause impaired Na⁺ absorption, **K⁺ wasting and polyuria** (non-oliguric hypokalaemic renal failure).
- ▶ **Liver:** focal hepatocellular necrosis (widespread necrosis unusual), inflammation, disruption of intercellular junctions and **bile-canalicular plugging/leakage** → jaundice with relatively preserved synthetic function.
- ▶ **Haemorrhage:** widespread petechiae/haemorrhages; **thrombocytopenia** (platelet consumption), consumptive coagulopathy/DIC, and **endothelial-cell activation** (raised soluble E-selectin, von Willebrand factor) increasing vascular permeability — histology shows endothelial swelling **without overt vasculitis or necrosis**.

Clinical features — biphasic course

- ▶ **Incubation:** usually 1–2 weeks (range 2–30 days). Disease is classically **biphasic**: an acute leptospiraemic phase (fever 3–10 days, organism culturable/PCR-positive in blood) followed by an immune phase (antibodies appear, leptospires shed in urine). Severe disease may be monophasic and fulminant.

Feature	Mild (anicteric) leptospirosis	Severe (icteric) leptospirosis — Weil's syndrome
Frequency	~99% of infections; often unrecognised	~1% of infections
Onset	Abrupt flu-like illness	May be indistinguishable initially, then rapidly progressive
Hallmarks	Fever, chills, intense frontal/retro-orbital headache (dengue-like), conjunctival suffusion, myalgia of	Triad — jaundice + acute kidney injury + haemorrhage; pulmonary haemorrhage; hypotension/shock

Feature	Mild (anicteric) leptospirosis	Severe (icteric) leptospirosis — Weil's syndrome
	calves/back/abdomen, nausea/vomiting	
CNS	Aseptic meningitis (commoner in children); usually benign	Altered sensorium, leptospiral meningitis
Course/mortality	Self-limited over 7–10 (4–30) days; low mortality	Case-fatality 5–40% (CMDT); multi-organ failure

- ▶ **Conjunctival suffusion** (redness without exudate) and severe **calf myalgia** are characteristic clues.
- ▶ **Pulmonary haemorrhage** (cough, chest pain, respiratory distress, haemoptysis ± jaundice) is a major, often lethal presentation and may not be apparent until intubation.
- ▶ **Jaundice** occurs in 5–10%; can be deep/orange-tinged but rarely reflects fulminant hepatic necrosis; tender hepatomegaly.
- ▶ **AKI** common — oliguric or non-oliguric; **hypokalaemia, hyponatraemia, and urinary magnesium loss** (uniquely associated with leptospiral nephropathy). Dialysis can be life-saving; renal recovery is the rule in survivors.
- ▶ **Other:** myocarditis with non-specific ST–T changes/arrhythmias (poor prognostic sign), pancreatitis (raised amylase), rhabdomyolysis (raised CK), and late **autoimmune uveitis** (chronic sequela).
- ▶ **Poor prognostic factors:** age >40 years, altered mental status, acute renal failure, respiratory insufficiency, hypotension, and arrhythmias.

Investigations & diagnosis

- ▶ **Supportive non-specific findings:** leukocytosis with left shift, raised CRP/procalcitonin/ESR; **thrombocytopenia** (platelets $\leq 100 \times 10^9/L$) correlating with bleeding and renal failure; raised bilirubin with only **moderate** aminotransferase/ALP rise; **elevated serum CK** (helps distinguish from viral hepatitis, where CK is normal); coagulation markers of DIC in pulmonary haemorrhage ($\uparrow$ PT/PTT/D-dimer, $\downarrow$ fibrinogen).
- ▶ **Non-oliguric hypokalaemic renal insufficiency** is characteristic of early disease; urine shows leukocytes, erythrocytes, casts, mild proteinuria.
- ▶ **CSF (if meningitic):** pleocytosis (few to >1000 cells/ μL), early polymorphonuclear then lymphocytic predominance; protein normal/mildly raised, glucose normal.
- ▶ **Definitive diagnosis** — isolation of the organism, positive PCR, seroconversion, or a rising titre:

- **Microscopic agglutination test (MAT)** — reference standard (live antigen panel); a single titre of 1:200–1:800 with strong clinical evidence, or preferably a ≥ 4 -fold rise between acute and convalescent sera. Identifies presumptive serogroup.
 - **ELISA** — broadly reacting antigen; plus commercial **rapid lateral-flow/agglutination** tests for resource-limited settings.
 - Antibodies usually undetectable until the **second week**; serology is insensitive in the first ~5 days.
 - **PCR (real-time)** — confirms diagnosis during the **first 5 days** of illness, detecting leptospiral DNA in blood, urine, CSF and aqueous humour — its key advantage over serology.
- **Imaging:** chest radiograph shows **patchy bilateral alveolar infiltrates** (alveolar haemorrhage, lower-lobe predominant), pleural-based densities, or ARDS-pattern ground-glass.

Differential diagnosis

- **Febrile/myalgic phase:** influenza, SARS-CoV-2, **dengue**, **chikungunya**, malaria, **typhoid**, scrub typhus/rickettsioses, viral hepatitis, acute HIV.
- **Haemorrhagic/renal presentation:** dengue haemorrhagic fever, **hantavirus** (HFRS/HCPs), yellow fever, and other viral haemorrhagic fevers. Co-infection (e.g. with dengue/rickettsiae) occurs — test for these when leptospirosis is suspected.

Treatment

- **General principle:** start antibiotics **early** (especially in severe disease, as soon as the diagnosis is *considered*) — benefit diminishes once organ damage is established. Leptospire are susceptible to β -lactams, cephalosporins, aminoglycosides and macrolides, but **not** to vancomycin, rifampicin, metronidazole or chloramphenicol. Resistance has not been reported.

Indication	Regimen (7 days)
Mild	Doxycycline 100 mg PO bid or Amoxicillin 500 mg PO tid or Ampicillin 500 mg PO tid (azithromycin 500 mg OD $\times 3$ days an alternative; doxycycline/azithromycin preferred where rickettsioses co-endemic)
Moderate/severe	Penicillin G 1.5 million units IV/IM q6h or Ceftriaxone 2 g/day IV or Cefotaxime 1 g IV q6h or Doxycycline 200 mg IV load then 100 mg IV q12h
Chemoprophylaxis	Doxycycline 200 mg PO once weekly or Azithromycin 250 mg PO once/twice weekly

- Randomised trials show **no significant difference** between penicillin, ceftriaxone, cefotaxime and doxycycline for severe disease (a 2024 meta-analysis found no clear survival benefit for any single antibiotic).

- ▶ **Supportive care is essential and can be life-saving:** aggressive fluid/electrolyte resuscitation in non-oliguric renal dysfunction; **early haemodialysis/peritoneal dialysis** for oliguric renal failure (reduces mortality, usually needed only briefly); **lung-protective low-tidal-volume ventilation** for pulmonary haemorrhage/ARDS. Evidence for **glucocorticoids** and **desmopressin** in pulmonary involvement is contradictory.
- ▶ A **Jarisch–Herxheimer reaction** may occur within hours of starting therapy.

Prevention

- ▶ Avoid exposure to contaminated water/soil and animal urine/tissue; use protective **footwear, eyewear and clothing**; targeted **rodent control**.
- ▶ **Pre-/post-exposure doxycycline** for well-defined short-term exposure (e.g. monsoon flooding) — efficacy disputed; a 2024 meta-analysis did not show reduced infection or mortality.
- ▶ **Vaccines:** animal (veterinary) bacterin vaccines must match local serovars; human bacterin vaccines (Japan, China, Cuba, France) give short-term serovar-specific immunity with significant side effects and limited availability.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Biphasic natural history (timeline):** x-axis weeks 1–4 then months–years. Mark **Incubation period (2–30 days)** → **Acute/leptospiroemic phase (fever; Leptospira in blood & CSF)* → *Immune/convalescent phase (antibody rise; Leptospira in urine; uveitis, interstitial nephritis)*. Overlay curves for **leptospiroemia**, **antibody titre (MAT)**, and **specimen windows for blood culture/PCR (early) vs urine PCR/culture and serology (late)**. Labels: Leptospiroemia, Leptospiruria & immunity, Fever, Antibody titre*.
- ▶ **Weil's syndrome triad (Venn/triangle):** three overlapping circles labelled **Jaundice (liver)**, **Acute kidney injury (kidney)**, **Haemorrhage (pulmonary/GI/skin)** with central label **Weil's syndrome**.

Clinical / Diagnostic significance

- ▶ Suspect leptospirosis in any **febrile illness with myalgia, conjunctival suffusion and an exposure history** (flood/freshwater/occupational/animal contact), particularly post-monsoon in endemic India.
- ▶ The combination of **jaundice + AKI + thrombocytopenia/haemorrhage** with only modestly raised transaminases but **high CK** strongly favours leptospirosis over viral hepatitis.
- ▶ **Non-oliguric hypokalaemic AKI** and **urinary magnesium loss** are near-pathognomonic renal clues.
- ▶ Use **PCR in the first 5 days** and **paired MAT serology** thereafter — do not withhold empirical antibiotics awaiting serology.

High-yield exam pointers

- ▶ Cause: *Leptospira interrogans* (sensu lato); >260 serovars in 26 serogroups; hooked-ended motile spirochaete seen on **dark-field**.
- ▶ Main reservoir = **rats**; serovar *Icterohaemorrhagiae/Copenhageni* causes severe disease; **water-borne**, monsoon/flood-associated.
- ▶ **Weil's syndrome** = jaundice + AKI + haemorrhage; **pulmonary haemorrhage** is a leading cause of death.
- ▶ **Conjunctival suffusion** + **calf myalgia** = classic bedside clues; headache is **frontal/retro-orbital** (dengue-like).
- ▶ Diagnosis: **MAT** (≥ 4 -fold rise / titre 1:200–1:800) is reference; **PCR** best in first 5 days; antibodies appear in **week 2**.
- ▶ Renal hallmark: **non-oliguric hypokalaemic** renal insufficiency; **CK elevated** (normal in viral hepatitis).
- ▶ Treatment: **IV penicillin / ceftriaxone / cefotaxime** (severe) or **oral doxycycline/amoxicillin/azithromycin** (mild) $\times 7$ days; early **dialysis** and **lung-protective ventilation** are life-saving.
- ▶ Prophylaxis: **doxycycline 200 mg weekly** for short-term high-risk exposure (efficacy disputed). Watch for **Jarisch–Herxheimer** reaction.

SOURCE & COVERAGE

- ▶ Harrison's Principles of Internal Medicine, 22e — "Leptospirosis" (Goeijenbier & Wagenaar) — aetiology, pathogenesis, clinical syndromes, diagnosis, Table 189-1 treatment/chemoprophylaxis.

Mechanisms of Antibiotic Drug Resistance

Asked in: Paper I Jul 2021 — RGUHS MD General Medicine

Definition / Introduction — *Resistance* is the reduction in or loss of an antibacterial agent's effect on a bacterium, and the bacterial properties or alterations that produce this reduced activity are termed *resistance mechanisms*. It is quantified in the laboratory by the **minimal inhibitory concentration (MIC)** — the lowest drug concentration that inhibits growth under standardised conditions — which, compared against regulatory **breakpoints**, classifies an isolate as susceptible, intermediate, or resistant. Resistance may be **intrinsic** (a natural property of the species) or **acquired** (via mutation or gene

transfer), and bacteria frequently carry combinations of mechanisms conferring **multidrug resistance (MDR)**.

Genetic basis — how resistance arises and spreads

- ▶ **Chromosomal mutation** — spontaneous point mutations during DNA replication, selected under antibiotic pressure (e.g. *rpoB* for rifampin, *gyrA/parC* for quinolones, ribosomal mutations).
- ▶ **Acquisition of new genes by horizontal transfer** — usually on self-replicating **plasmids** or other mobile elements (**transposons**, gene cassettes) carrying one or several resistance genes, so a single plasmid can confer multidrug resistance.
- ▶ **Transformation** — uptake of fragments of environmental DNA from related species and direct recombination into the chromosome; important in *Streptococcus pneumoniae* and *Neisseria gonorrhoeae* (generates **mosaic PBP** genes).
- ▶ **Origin and selection** — many resistance genes originated in antibiotic-**producer** organisms (self-protection) and were later mobilised onto plasmids; antimicrobial exposure in humans, animals and the environment then **selects** resistant strains. Initial fitness costs are often offset over time by **compensatory mutations**, allowing resistant strains to persist even without ongoing drug pressure.

The three broad mechanistic categories

All resistance mechanisms fall into three groups (Harrison, Table 150-1; Fig. 150-1):

Category	Strategy	Representative examples
1. Altered / bypassed target	Modify or substitute the drug's binding site so binding falls	Altered PBPs (MRSA <i>mecA</i> /PBP2a, mosaic PBPs); d-Ala-d-Lac in VRE; <i>gyrA/parC</i> mutations; <i>rpoB</i> ; ribosomal methylation; bypass DHFR/DHPS
2. Altered access to target	Reduce uptake (porin loss) or increase active efflux	Loss of OprD/porins (carbapenems); MexXY, broad-spectrum multidrug efflux pumps
3. Drug inactivation / modification	Enzymatically destroy or chemically modify the drug	β -lactamases (ESBL, AmpC, carbapenemases); aminoglycoside-modifying transferases; chloramphenicol acetyltransferase

Mechanism by drug class

- ▶ **β -Lactams (penicillins, cephalosporins, monobactams, carbapenems):** Three routes — (a) β -lactamase degradation of the β -lactam ring (commonest in gram-negatives, concentrated in the

periplasmic space); (b) **altered PBP targets**; (c) **reduced porin diffusion**. β -Lactamase classes: *plasmid* enzymes inactivating penicillins/early cephalosporins; **extended-spectrum β -lactamases (ESBLs)** that also degrade ceftriaxone, cefotaxime, ceftazidime, aztreonam (some also cefepime); **AmpC** (chromosomal in *Enterobacter*; inducible/derepressed, degrades most cephalosporins except cefoxitin/cefepime); and **carbapenemases** that destroy nearly all β -lactams — *Klebsiella pneumoniae* carbapenemase (KPC), **New Delhi metallo- β -lactamase (NDM)**, originally Indian subcontinent), and **OXA-48**. PBP-mediated resistance: **mosaic PBPs** (penicillin-resistant pneumococcus, gonococcus, meningococcus) and **PBP2a** encoded by *mec* in MRSA (a bypass transpeptidase of low affinity; only **ceftaroline** binds PBP2a). β -Lactamase **inhibitors** — clavulanate, sulbactam, tazobactam, avibactam, vaborbactam, relebactam, durlobactam — restore activity; only *avibactam*, *vaborbactam*, *relebactam* inhibit AmpC and KPC-type carbapenemases (but **not** metallo-enzymes such as NDM).

- ▶ **Glycopeptides (vancomycin, teicoplanin)**: Acquisition of **van** gene cassettes in enterococci (VRE) replaces the terminal d-Ala-d-Ala of the peptidoglycan stem peptide with d-Ala-d-Lac, which vancomycin binds with **1000-fold lower affinity**; *van* genes are transposon/plasmid-borne and have rarely transferred to *S. aureus* (true VRSA). **VISA** (intermediate resistance) arises instead from stepwise chromosomal mutations producing a thickened, poorly cross-linked cell wall that traps vancomycin at decoy d-Ala-d-Ala termini away from the synthesis site.
- ▶ **Aminoglycosides (gentamicin, tobramycin, amikacin, plazomicin)**: Mainly plasmid-encoded **aminoglycoside-modifying enzymes** adding acetyl, adenylyl or phosphate groups (amikacin/plazomicin spared by most); **16S rRNA methylases** confer resistance to *all* aminoglycosides including plazomicin; ribosomal-protein mutation (streptomycin); MexXY **efflux** in *Pseudomonas*.
- ▶ **Tetracyclines & glycylcyclines**: Plasmid-mediated **active efflux** and **ribosomal protection proteins** (*TetM/TetO*). Newer agents (tigecycline, eravacycline, omadacycline) evade common mechanisms but can be lost to broad-spectrum efflux overexpression.
- ▶ **Macrolides/lincosamides/streptogramins (MLS)**: Acquired **Erm methylases** modify the 23S rRNA binding site (the **MLSB** phenotype, inducible or constitutive); plus **efflux** pumps and, for streptogramins/chloramphenicol, drug-modifying enzymes. 23S rRNA mutational resistance is commoner in organisms with few rRNA gene copies (mycobacteria, *H. pylori*, *Treponema*).
- ▶ **Oxazolidinones (linezolid, tedizolid)**: 23S rRNA mutations (more in enterococci) and the plasmid **Cfr methylase** (cross-resistance with chloramphenicol/lefamulin).
- ▶ **Quinolones**: Chromosomal **target mutations** in DNA gyrase and topoisomerase IV; **efflux** overexpression; and acquired plasmid genes — *qnr* (target protection), *aac(6')-Ib-cr* (modifies ciprofloxacin/norfloxacin), and efflux determinants — that also enrich for higher-level resistance and link to multidrug-resistance plasmids.

- ▶ **Rifamycins (rifampin, rifabutin, rifapentine):** A **single mutation in the β subunit of RNA polymerase (rpoB) gives high-level resistance — hence rifamycins are always used in combination**.
- ▶ **Sulfonamides & trimethoprim:** Plasmid-acquired **resistant DHPS** and **resistant DHFR** that *bypass* inhibition of the native enzymes; resistance to co-trimoxazole needs both.
- ▶ **Polymyxins (colistin, polymyxin B):** Mutations reducing the **negative charge of LPS**, and the transferable plasmid **mcr-1** (and variants) encoding a phosphoethanolamine transferase that masks the LPS target.
- ▶ **Daptomycin / metronidazole / nitrofurantoin:** Daptomycin — multigene mutations altering membrane charge; metronidazole — loss of activating nitroreductase / *nim* genes; nitrofurantoin — stepwise loss of nitroreductase activity.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **“Gram-negative bacterium showing antibiotic targets and resistance mechanisms”** (after Harrison Fig. 150-1). Draw the cell with **outer membrane + porin, periplasmic space, inner membrane, ribosome, DNA, and a resistance plasmid**. Label: *Loss of porins* → carbapenem resistance; *β -lactamases in periplasmic space*; *Overexpressed transmembrane efflux pump* (β -lactams, quinolones, aminoglycosides, tetracyclines, chloramphenicol); *Altered iron-uptake pathway (cefiderocol)*; *Bypass targets — trimethoprim (DHFR), sulfonamides (DHPS)*; *Antibiotic-modifying enzymes (aminoglycosides, ciprofloxacin)*; *Ribosomal mutation/methylation (tetracyclines, oxazolidinones, aminoglycosides)*; *Target mutations (DNA gyrase, topoisomerase IV)*; *LPS modification (polymyxins)*.
- ▶ **Simple flow box:** *Three categories of resistance — (1) Altered/bypassed target* → (2) *Reduced uptake / increased efflux* → (3) *Drug inactivation* — each with one example arrow.

Clinical / Diagnostic significance

- ▶ **Laboratory detection:** MIC by broth/agar microdilution, disk diffusion, or **E-test** (gradient strip) interpreted against breakpoints; phenotypic tests for ESBL, AmpC and carbapenemase; molecular detection of *mecA*, *vanA/B*, KPC/NDM/OXA, *mcr*.
- ▶ **Empiric vs definitive therapy:** Because prevalence varies by geography and institution, empirical choice should follow the **local antibiogram**; therapy must then be **de-escalated** to the *narrowest-spectrum* agent for the *shortest effective duration* once susceptibilities return.
- ▶ **Apparent treatment failure** despite “susceptible” report — consider undrained pus/foreign body, poor drug penetration (CNS, intracellular sites), superinfection, emergence of resistance on therapy, polymicrobial infection, impaired host defences, or non-infective causes (drug fever).

- ▶ **Salvage agents for MDR gram-negatives:** ceftazidime-avibactam, meropenem-vaborbactam, imipenem-relebactam, **cefiderocol** (siderophore cephalosporin taken up via iron transport, stable to many β -lactamases including carbapenemases), and polymyxins.
- ▶ **Combination therapy** is used for synergy and to *prevent emergence of resistance* (classically rifampin, antitubercular regimens), not merely for broad coverage.

High-yield exam pointers

- ▶ Three mechanistic categories: **target alteration/bypass**, **reduced access (porin loss/efflux)**, **drug inactivation**.
- ▶ **MRSA** = **mecA** $\rightarrow$ **PBP2a** (bypass transpeptidase); **ceftaroline** is the anti-MRSA β -lactam.
- ▶ **VRE** = **van genes** $\rightarrow$ **d-Ala-d-Lac** (1000 $\times$ lower vancomycin affinity); **VISA** = **thickened cell wall**, not van.
- ▶ **ESBL** spares carbapenems; **carbapenemases** = **KPC, NDM, OXA-48**; avibactam/vaborbactam/relebactam cover KPC but **not** NDM (metallo-).
- ▶ **Rifampin resistance = single rpoB mutation** $\rightarrow$ never use as monotherapy.
- ▶ **Quinolone resistance** = gyrA/parC mutations + efflux + plasmid *qnr* / *aac(6')-Ib-cr*.
- ▶ **Colistin resistance** = **plasmid mcr-1** (phosphoethanolamine transferase on LPS).
- ▶ **16S rRNA methylase** defeats *all* aminoglycosides, including plazomicin.
- ▶ CDC 2019: **>2.8 million** resistant infections, **~35,900 deaths/year**; **urgent threats** — CRE, carbapenem-resistant *Acinetobacter*, drug-resistant *N. gonorrhoeae*, *C. difficile*, *Candida auris*. Countered by the **five core actions** and a **One Health** approach.

SOURCE & COVERAGE

Melioidosis

Asked in: Paper II Nov 2020 — RGUHS MD General Medicine

Definition / Introduction — Melioidosis (*Whitmore's disease*) is a potentially fatal infection caused by *Burkholderia pseudomallei*, a gram-negative, facultative intracellular saprophyte of soil and surface

water in the tropics. It is geographically restricted chiefly to **Southeast Asia and northern Australia**, with sporadic cases from India, China and other tropical zones. Among the pseudomonads, *B. pseudomallei* is one of the most virulent species: host compromise is **not** a prerequisite for disease, the clinical spectrum runs from asymptomatic infection to fulminant septicaemia, and the organism's capacity for intracellular survival permits prolonged **latency and late reactivation** (the so-called “*Vietnamese time-bomb*”).

Etiology & microbiology

- ▶ **Organism:** *Burkholderia pseudomallei* — a non-lactose-fermenting, oxidase-positive, motile gram-negative bacillus of the genus *Burkholderia* (formerly *Pseudomonas*).
- ▶ A **facultative intracellular** pathogen that replicates within polymorphonuclear leukocytes (PMNs) and macrophages; survival is aided by a **polysaccharide capsule**.
- ▶ A close relative, *B. mallei*, causes **glanders** (an equine zoonosis) — covered in the same chapter and a frequent comparison point (see below).
- ▶ **Environmental reservoir:** soil and water; the organism is a *primary pathogen* (unlike opportunistic *P. aeruginosa* and *Stenotrophomonas*). Humans are **never colonised without being infected**.
- ▶ A recognised **potential agent of biological warfare**, which has stimulated interest in vaccine development; it is handled as a high-consequence select agent and has caused point-source outbreaks (e.g. contaminated *aromatherapy spray*).

Epidemiology & risk factors

- ▶ **Endemic zones:** Southeast Asia (notably Thailand) and tropical northern Australia; occasional cases in India and China. Should be suspected in **returning travellers and military personnel** from endemic regions — symptoms may appear only later because of latency.
- ▶ **Routes of acquisition** — three principal portals:
 - *Percutaneous inoculation* through skin abrasions (the commonest route; rice-paddy and soil exposure).
 - *Inhalation* of contaminated aerosols/dust (associated with severe pneumonic and septicaemic disease, e.g. during monsoon/heavy rains).
 - *Ingestion* of contaminated water.
- ▶ **Person-to-person transmission is rare.**
- ▶ **Predisposing host factors** (present in many, though not all, patients): **diabetes mellitus** (the single most important association), **chronic renal failure**, **alcohol abuse**, and other chronic illness.
- ▶ A significant cause of **fatal community-acquired pneumonia and septicaemia** in endemic areas, with reported mortality as high as **44% (Thailand)**.

Pathogenesis

- ▶ After inoculation/inhalation, *B. pseudomallei* is taken up by phagocytes but **survives intracellularly**, escaping killing within PMNs and macrophages.
- ▶ The **polysaccharide capsule** and a functional **type III secretion system** (which mediates intracellular survival and cell-to-cell spread) are key virulence determinants.
- ▶ Intracellular persistence underlies the characteristic **latency** and ability to relapse months to years after primary exposure.
- ▶ Infection provokes a **florid inflammatory/granulomatous (abscess-forming) response**; haematogenous dissemination, most often in debilitated hosts, seeds multiple deep organs and produces the highly lethal septicaemic forms.

Clinical manifestations

B. pseudomallei causes a **wide spectrum**, from asymptomatic infection to multifocal abscesses, pneumonia and disseminated septic disease. The major recognised forms:

Clinical form	Key features
Acute pulmonary (commonest diagnosed form)	Ranges from mild illness with upper-lobe infiltrates on chest film to severe necrotizing pneumonia ; high fever, cough
Chronic pulmonary	<i>Mimics pulmonary tuberculosis</i> — chronic cough, fever, haemoptysis, night sweats , cavitary lung disease
Cutaneous / localised	Skin ulceration with associated lymphangitis and regional lymphadenopathy
Septicaemic / disseminated	Spread from lung or skin (esp. in debilitated patients) → bacteraemia with multi-organ abscesses (liver, spleen, prostate, kidney) and septic shock; high mortality
Neurological (CNS) melioidosis	Endemic in South Asia and Australia; encephalomyelitis / brain abscess / meningitis
Latent / reactivation	Quiescent infection reactivating later, often when host defences fall

Diagnosis / investigations

- ▶ **Definitive diagnosis is by culture**, which is the gold standard — *B. pseudomallei* isolated from blood, sputum, pus/abscess aspirate, urine or wound swab confirms the disease (isolation from any site is diagnostic, as humans are not colonised).
- ▶ The organism is a non-fermenting, **oxidase-positive** gram-negative rod; on Gram stain it classically shows **bipolar (“safety-pin”) staining**, and it grows well on selective Ashdown’s agar (wrinkled colonies). [*microbiology details: standard, see Coverage note*]

- ▶ **Imaging** to map deep abscesses: chest radiograph (upper-lobe infiltrates / cavitation), and ultrasound or CT of liver, spleen, prostate and kidneys to detect visceral abscesses; MRI for suspected CNS disease.
- ▶ Screen for and assess **underlying diabetes and renal impairment**, which modify prognosis and management.
- ▶ **Differential diagnosis**: pulmonary tuberculosis (the chronic cavitary form is a classic mimic), other causes of community-acquired pneumonia, and disseminated pyogenic abscesses.

Treatment

Treatment is prolonged and deliberately divided into **two sequential phases** — an IV *intensive* (*eradication-initiation*) phase to control sepsis, followed by a long oral *eradication* phase to clear intracellular organisms and **prevent relapse**.

Phase	Regimen (Harrison, Table 170-2)	Duration
Intensive (IV)	Ceftazidime 2 g IV q6h <i>or</i> meropenem 1 g IV q8h <i>or</i> imipenem 500 mg IV q6h	≥2 weeks; 4–8 weeks (Australian guidelines) for severe infection, osteomyelitis and CNS disease
Eradication (oral)	Trimethoprim-sulfamethoxazole (TMP-SMX) 1600/320 mg PO q12h	≥3 months (12 weeks)

- ▶ The intensive IV phase must be **lengthened** for deep-seated disease (severe sepsis, osteomyelitis, neurological melioidosis), and large abscesses require **drainage** alongside antibiotics.
- ▶ The prolonged oral eradication course is essential because intracellular persistence causes **relapse** if treatment is curtailed.
- ▶ *B. pseudomallei* is **intrinsically resistant** to many agents (e.g. aminoglycosides, many early penicillins/cephalosporins) — empirical “sepsis” regimens that omit ceftazidime/carbapenems may fail; susceptibility is to advanced penicillins, ceftazidime and carbapenems.
- ▶ **Glanders (B. mallei)** is treated with the same drugs for the same duration as melioidosis (and is additionally susceptible to the macrolides azithromycin and clarithromycin).

Melioidosis vs glanders (companion comparison)

Feature	Melioidosis (<i>B. pseudomallei</i>)	Glanders (<i>B. mallei</i>)
Reservoir	Environmental — soil & water	Not environmental ; persists only in equine hosts
Acquisition	Inoculation / inhalation / ingestion	Contact with infected horses; respiratory secretions highly infectious; at-risk = horse

Feature	Melioidosis (<i>B. pseudomallei</i>)	Glanders (<i>B. mallei</i>)
		handlers, equine butchers, veterinarians
Distribution	SE Asia, N Australia, India, China	Africa, Asia, South America (eradicated from Europe/N America)
Capsule	Major virulence factor	Critical virulence determinant
Treatment	Ceftazidime/carbapenem → TMP-SMX	Same as melioidosis (+ azithromycin/clarithromycin susceptible)

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Pathogenesis / portals-of-entry schematic:** a central soil-and-water reservoir with three arrows to a human — labels: *Percutaneous inoculation, Inhalation, Ingestion* → *B. pseudomallei* (facultative intracellular) → uptake & survival in macrophage/PMN (capsule, Type III secretion system) → branching to *Localised skin ulcer + lymphangitis, Acute/chronic pneumonia, Haematogenous dissemination* → *multi-organ abscesses (liver, spleen, prostate, kidney) + septicaemia*, and a dashed loop labelled *Latency / relapse*.
- ▶ **Two-phase treatment timeline bar:** Label segment 1 *Intensive IV phase — ceftazidime / meropenem (≥2 wks; 4–8 wks if severe/osteomyelitis/CNS)*; Label segment 2 *Oral eradication phase — TMP-SMX ≥3 months (prevents relapse)*.

Clinical / Diagnostic significance

- ▶ Consider melioidosis in any febrile patient from an endemic area — especially a diabetic — presenting with community-acquired pneumonia, sepsis, or multifocal abscesses; it is a **great mimic of tuberculosis** and of pyogenic abscess disease.
- ▶ **Isolation of the organism from any clinical specimen is diagnostic** — alert the microbiology laboratory, both for biosafety (select agent) and because the organism may be misidentified by automated systems.
- ▶ Therapeutic success hinges on choosing the **right drug class** (ceftazidime/carbapenem, not aminoglycosides) and **completing the long eradication course** — incomplete therapy leads to relapse.
- ▶ Search systematically for **occult visceral abscesses** (prostate, liver, spleen) and treat underlying **diabetes/renal disease**, as these influence outcome.

High-yield exam pointers

- ▶ **Melioidosis = Whitmore's disease**, caused by *Burkholderia pseudomallei*, a **facultative intracellular gram-negative saprophyte of soil and water**.

- ▶ **Endemic in SE Asia (esp. Thailand) and northern Australia**; sporadic in India/China — suspect in returning travellers/soldiers.
- ▶ **Diabetes mellitus** is the dominant predisposing factor; renal failure and alcohol abuse also predispose; *host compromise is not essential*.
- ▶ Three portals: **inoculation, inhalation, ingestion**; person-to-person spread is rare.
- ▶ **Acute pulmonary disease** is the commonest form; **chronic cavitary pneumonia** mimics TB; septicaemic disease carries mortality up to 44%.
- ▶ Virulence: **polysaccharide capsule + type III secretion system** → intracellular survival, **latency and relapse**.
- ▶ **Diagnosis = culture (gold standard)**; isolation from any site is significant.
- ▶ **Treatment = two phases**: intensive IV **ceftazidime/meropenem** ≥2 wks → oral **TMP-SMX** ≥3 months; drain abscesses; *intrinsically resistant to aminoglycosides*.
- ▶ Closely related **B. mallei** → **glanders** (equine zoonosis); both are **potential bioterrorism (select) agents**.

SOURCE & COVERAGE

- ▶ **Harrison's Principles of Internal Medicine, 22e** — “Infections Due to *Pseudomonas*, *Burkholderia*, and *Stenotrophomonas* Species” (*Burkholderia pseudomallei*/melioidosis and *B. mallei*/glanders sections, incl. Table 170-2 antibiotic regimens); “Acute Meningitis” (CNS melioidosis as a regional cause); and the genomic-epidemiology chapter (point-source *B. pseudomallei* aromatherapy-spray outbreak).
- ▶ **CMDT 2026** — antimicrobial-spectrum/treatment tables listing *B. pseudomallei* (melioidosis) and *B. mallei* (glanders).
- ▶ **Coverage note**: Harrison covers the etiology, epidemiology, pathogenesis, clinical spectrum and staged treatment of melioidosis well, but does not detail laboratory morphology. The **bipolar “safety-pin” Gram appearance**, growth on **Ashdown's selective agar**, the eponym **Whitmore's disease**, and the **“Vietnamese time-bomb”** latency nickname are universally accepted standard microbiology/clinical facts added for completeness and are not verbatim from the cited chapters.

Multidrug-Resistant Tuberculosis (MDR-TB)

Asked in: Paper II May 2022 — RGUHS MD General Medicine

Definition / Introduction — Multidrug-resistant tuberculosis (MDR-TB) is disease caused by a strain of *Mycobacterium tuberculosis* resistant *at least* to **isoniazid (H)** and **rifampin (R)** — the two most efficacious first-line bactericidal drugs. It represents one end of a spectrum that ranges from rifampin-

resistant (RR) through pre-XDR to extensively drug-resistant (XDR) TB. Because the two most potent drugs are lost and co-resistance to other first-line agents (e.g., ethambutol) is common, MDR-TB requires longer, more toxic, costlier and individualised regimens. Drug resistance almost invariably follows effective **monotherapy** (provider error, poor adherence, malabsorption, or poor-quality/crushed drugs).

Definitions & resistance spectrum

Category	Resistance pattern (Harrison 22e)
RR-TB	Resistant to rifampin ($\pm$ other drugs); rifampin resistance is an excellent <i>proxy</i> for MDR-TB
MDR-TB	Resistant at least to isoniazid AND rifampin
Pre-XDR-TB	MDR/RR-TB strain <i>additionally</i> resistant to any fluoroquinolone
XDR-TB	MDR-TB + resistance to any fluoroquinolone AND at least one additional Group A drug (i.e., bedaquiline or linezolid)

- ▶ **Primary resistance** = patient infected from the outset by a resistant strain; **acquired resistance** = develops in the infecting strain during inadequate treatment.
- ▶ *Mono-resistance to rifampin is rare and is managed as MDR-TB.*

Epidemiology & risk factors

- ▶ Of an estimated **10.8 million** new TB cases in 2023, **~400,000** were RR/MDR-TB — **3.2% of new** and **16% of previously treated** cases. Only ~189,000 were enrolled on treatment, reflecting limited culture/DST capacity.
- ▶ Geography: **>50% of all MDR/RR-TB occurs in India (27%), Russian Federation (7.4%), Indonesia (7.4%), China (7.3%) and the Philippines (7.2%)**; the former Soviet states have the highest *proportion* among new cases (up to one-third).
- ▶ **Risk factors:** presenting from an area where $\geq 5\%$ of incident cases are MDR, **prior TB treatment**, treatment default/failure/relapse, and contact with a known MDR case.
- ▶ The **vast majority of XDR-TB remains undiagnosed** because reliable DST and laboratory capacity are lacking in low-income settings.

Molecular basis of drug resistance

Resistance is due to **spontaneous chromosomal mutations** (no plasmid transfer); knowing the target genes underpins rapid molecular DST.

Drug	Gene(s)	Encoded target / note
Isoniazid	<i>katG</i> , <i>inhA</i> (also <i>kasA</i> , <i>ndh</i>)	Catalase-peroxidase; enoyl-ACP (keto-enoyl) reductase
Rifampin	<i>rpoB</i>	β -subunit of RNA polymerase (core region; mostly missense)
Pyrazinamide	<i>pncA</i>	Pyrazinamidase (activates prodrug); mutated in 72–98%
Ethambutol	<i>embB</i> (codon 306 in 50–70%)	Arabinosyltransferase
Fluoroquinolones	<i>gyrA</i> , <i>gyrB</i>	DNA gyrase
Bedaquiline	<i>atpE</i> ; <i>Rv0678/mmpR</i> , <i>pepQ</i>	ATP synthase subunit c; efflux-pump repressor → <i>cross-resistance with clofazimine</i>
Linezolid	23S rRNA, <i>rplC</i> (L3), <i>rplD</i> (L4)	50S ribosomal subunit

Diagnosis — rapid drug-susceptibility testing (DST)

- ▶ Universal DST is the WHO standard of care: every initial isolate should be tested at least to rifampin (proxy for MDR); expanded testing to isoniazid, fluoroquinolones and key second-line drugs is mandatory once RR-TB is found.
- ▶ Rapid molecular tests (preferred first test):
 - Xpert MTB/RIF & Xpert MTB/RIF Ultra — detect *M. tuberculosis* and *rpoB* (rifampin resistance) simultaneously.
 - Truenat MTB-Rif Dx — portable, battery-operated; rifampin resistance sensitivity ~84%, specificity ~97%.
 - Line probe assays (LPAs) — DNA-strip tests detecting *rpoB*, *katG*, *inhA*; second-line LPAs are the recommended initial test for fluoroquinolone / injectable resistance in confirmed RR/MDR-TB.
- ▶ Phenotypic culture-based DST (MGIT liquid ~3 weeks; solid Löwenstein-Jensen ≥8 weeks) is still needed for drugs/mutations not covered by molecular tests and to monitor emerging resistance.
- ▶ Whole-genome sequencing (WGS) and targeted next-generation sequencing (tNGS) give comprehensive resistance profiles; tNGS can be run directly on sputum.

WHO drug grouping (for longer regimens) & treatment regimens

WHO priority grouping (Table 183-3):

Group	Drugs	Rule
A (use all three)	Levofloxacin/moxifloxacin; bedaquiline; linezolid	All three included; ≥ 3 retained if bedaquiline stopped
B (≥ 1 included)	Clofazimine; cycloserine/terizidone	Add a 2nd if a Group A drug cannot be used
C (complete the regimen)	Ethambutol, delamanid, pyrazinamide, imipenem- cilastatin/meropenem, amikacin (or streptomycin), ethionamide/prothionamide, PAS	Used when A/B insufficient

- **Kanamycin and capreomycin are NO LONGER recommended** (worse failure/relapse); injectables are now largely avoided. All-oral regimens are preferred.

Recommended all-oral regimens (2022–2024 WHO):

Regimen	Composition & duration	Use
BPaLM (<i>preferred</i>)	Bedaquiline + Pa pretomanid + Linezolid 600 mg + Moxifloxacin $\times 6$ months	MDR/RR or pre-XDR, age ≥ 14 y, any HIV status; <i>drop Mfx if documented fluoroquinolone resistance</i> (= BPaL)
BDLLfxCfz	Bedaquiline + delamanid + linezolid 600 + levofloxacin + clofazimine $\times 6$ months	Non-inferior alternative; usable in children, adolescents, pregnant/breast-feeding women
9-month all-oral	BLMZ, or BLLfxCfzZ, or BDLLfxZ	No fluoroquinolone resistance & no prior exposure to B/D/L
Longer individualised	≥ 3 Group A + ≥ 1 Group B (add C as needed); ≥ 18 –20 months (15–17 months after culture conversion)	Complex patterns including XDR-TB

- **BPaLM** achieves treatment success $\sim 90\%$ (TB-PRACTECAL, Nix-TB, ZeNix). It is **avoided in disseminated, CNS and osteoarticular TB and in pregnancy/breast-feeding** (incomplete pretomanid safety data).
- Landmark trials: **STREAM stage-1** (9-month “Bangladesh” regimen), **Nix-TB/ZeNix** (BPaL, linezolid dose-finding), **TB-PRACTECAL** (24-week BPaLM non-inferior with fewer serious adverse events), **endTB** and **BEAT-TB**.
- **Surgery** (lobectomy/wedge resection) may be added for localised disease with adequate pulmonary reserve.

Monitoring, key drug toxicities & special situations

- ▶ **QT-prolonging drugs** — bedaquiline, delamanid, clofazimine, fluoroquinolones: baseline + serial ECG; do **not** use if QTc >500 ms or history of ventricular arrhythmia.
- ▶ **Bedaquiline**: 400 mg/day × 2 weeks then 200 mg thrice-weekly; FDA **black-box warning** (QT prolongation; excess mortality 11.4% vs 2.5% in one trial); CYP3A4-metabolised — rifampin/efavirenz lower its levels.
- ▶ **Linezolid**: 600 mg once daily; optic & peripheral neuropathy, **myelosuppression/pancytopenia**, lactic acidosis, serotonin syndrome (weak MAO inhibitor).
- ▶ **Clofazimine**: reversible orange-brown skin/secretion discoloration; very long t_{1/2} (~70 days). **Cycloserine**: seizures, psychosis, depression. **Amikacin** (if used): serial **audiometry**.
- ▶ **HIV co-infection**: integrase inhibitor **dolutegravir/raltegravir at double dose** (not bictegravir/cabotegravir/elvitegravir) or efavirenz; advanced immunosuppression (CD4 <100/μL) raises failure/relapse risk.
- ▶ **Programmatic essentials**: DOT/patient support, informed consent, monthly bacteriologic monitoring, active drug-safety monitoring, infection-control measures.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Concentric/Venn classification of drug resistance**: outermost ring “RR-TB (rifampin-R)” → inner “MDR-TB (H + R resistant)” → “Pre-XDR (MDR + any fluoroquinolone-R)” → core “XDR (+ bedaquiline or linezolid-R)”. Label each with its defining drug(s).
- ▶ **Diagnostic-to-treatment algorithm**: *Sputum* → Xpert MTB/RIF Ultra → *Rifampin resistance detected (RR-TB)* → **second-line LPA / phenotypic DST (fluoroquinolone)** → branch to “BP_aLM (6 mo)”, “9-month all-oral”, or “Longer ≥18-mo individualised (XDR)”. Labels: *Group A / B / C drugs, DST, culture conversion*.

Clinical / Diagnostic significance

- ▶ A single **rifampin-resistance** result on Xpert should trigger a full second-line DST and an MDR regimen — never treat presumptively as drug-susceptible.
- ▶ Empirical MDR therapy is justified in a high-likelihood patient (failure/default, MDR contact) while confirmatory DST is awaited.
- ▶ Avoid repeated empirical **fluoroquinolone** courses for “community-acquired pneumonia” — they delay TB diagnosis and **breed fluoroquinolone resistance**.
- ▶ Prevention of resistance = ≥2 quality-assured bactericidal drugs to which the strain is susceptible, **fixed-dose combinations**, supervised therapy, and completion of the full course.

High-yield exam pointers

- ▶ MDR = resistant to at least H + R; XDR adds fluoroquinolone + bedaquiline/linezolid resistance.

- ▶ Rifampin resistance (*rpoB*) is the molecular proxy for MDR — basis of Xpert MTB/RIF.
- ▶ Isoniazid resistance: *katG* / *inhA*; pyrazinamide: *pncA*; ethambutol: **embB306**; fluoroquinolone: *gyrA*; bedaquiline: *atpE* / **Rv0678** (cross-resistant to clofazimine).
- ▶ Group A = levofloxacin/moxifloxacin, bedaquiline, linezolid (memorise — most heavily weighted).
- ▶ BPaLM × 6 months is now the preferred MDR/RR regimen (age ≥14 y); BPaL if fluoroquinolone-resistant.
- ▶ Kanamycin and capreomycin are no longer recommended.
- ▶ Mandatory ECG monitoring for QT-prolonging anti-TB drugs; linezolid → cytopenias & neuropathy; bedaquiline → black-box QT/mortality warning.
- ▶ India carries 27% of the world's MDR/RR-TB burden.

SOURCE & COVERAGE

Harrison 22e — Ch 183 “Tuberculosis” (epidemiology, definitions, diagnosis/DST, WHO drug groups & regimens, monitoring) + Ch 186 “Antimycobacterial Agents” (drug mechanisms, resistance genes, doses, MDR definition, BPaLM/trials). Coverage note: All specifics (definitions, gene names, regimen compositions, doses, QT cut-off, epidemiology) are drawn from these two chapters; RNTCP/NTEP (India)–specific programmatic nomenclature is not in Harrison and is therefore not quoted.

Neurocysticercosis

Asked in: Paper II Nov 2020 — RGUHS MD General Medicine

Definition / Introduction — Neurocysticercosis (NCC) is the term for involvement of the **brain, spinal cord, or cerebrospinal fluid (CSF)** by the **larval (cysticercus) stage of the pork tapeworm Taenia solium**. It follows ingestion of *T. solium* eggs, in which humans act as the intermediate (dead-end) host. NCC is the single most important cause of acquired epilepsy in the developing world and in immigrants from endemic regions, and is highly prevalent in India, Latin America, sub-Saharan Africa, China and Southeast Asia*. Globally an estimated 20 million people carry cysticerci, ~400,000 develop neurological symptoms and ~50,000 die each year.

Aetiology, life cycle and pathogenesis

- ▶ ***T. solium* causes two distinct human infections* — taeniasis (*adult tapeworm in the gut, acquired by eating undercooked pork containing cysticerci*) and cysticercosis (*tissue larval infection, acquired by ingesting eggs*). Humans are the only definitive host; the pig is the usual intermediate host*.

- ▶ **Route to cysticercosis** — faecal–oral ingestion of eggs from a **human tapeworm carrier**. Eggs are sticky and found under the carrier’s fingernails; **autoinfection** can occur (carrier ingests own ova). Hence cysticercosis can occur even in people who never eat pork, including vegetarians, if exposed to a carrier’s faeces.
- ▶ **Pathogenesis** — Ingested eggs release **oncospheres** that penetrate the intestinal wall and disseminate haematogenously to tissues, preferentially the **CNS, skeletal muscle, subcutaneous tissue and eye**. The oncosphere matures into a fluid-filled **cysticercus** (single invaginated scolex) over ~60–90 days.
- ▶ ***Worm morphology (helps distinguish from *T. saginata*)** — *scolex bears an armed rostellum with two rows of hooklets plus four suckers; mature tapeworm up to 3 m with up to 1000 proglottids; each gravid proglottid has 8–12 uterine branches (vs 15–30 in *T. saginata**) and releases ~50,000 immediately-infective eggs.*
- ▶ **Symptom generation** — clinical effects depend on **location, number, size and viability** of cysts and, critically, on the **host inflammatory response** to a degenerating cyst. A live (vesicular) cyst evades immunity and may stay silent; symptoms typically arise when the larva **degenerates** and provokes oedema and gliosis.

Classification and clinical manifestations

NCC is classified by **anatomical location and parasite viability** (Harrison Fig. 242-1), which dictates presentation and treatment.

Location / form	Key features	Typical clinical picture
Parenchymal (viable cyst)	Round cyst 5–20 mm, often with visible scolex	Seizures (commonest); usually benign course
Single enhancing lesion	Solitary degenerating cyst with ring/disc enhancement + perilesional oedema	New-onset focal seizures (classic <i>Indian</i> presentation — solitary cysticercus granuloma)
Parenchymal calcification	Old, dead, calcified larva	Recurrent seizures, especially if perilesional oedema/enhancement
Intraventricular	Thin-walled cyst, fluid isodense to CSF	Obstructive hydrocephalus , raised ICP, <i>Bruns’ syndrome</i>
Subarachnoid / basal (racemose)	Grape-like proliferating cysts up to 6 cm, no scolex	Chronic meningitis, arachnoiditis , vasculitis/strokes, communicating hydrocephalus — most aggressive form
Spinal / ocular	Cord or subretinal/vitreous cysts	Progressive myelopathy; visual loss

- ▶ **Seizures** are the most frequent manifestation — focal, focal with secondary generalisation, or generalised — driven by inflammation of parenchyma surrounding the cyst.
- ▶ **Headache** accompanies virtually all CNS forms.
- ▶ **Hydrocephalus** results from CSF-flow obstruction by ventricular cysts and/or inflammation, or from **communicating hydrocephalus due to arachnoiditis**; raised-ICP features include headache, vomiting, dizziness, ataxia, papilloedema and visual loss.
- ▶ ***Bruns' syndrome** — *intermittent acute hydrocephalus precipitated by head movement/position change, the mobile ventricular cyst acting as a ball valve**.
- ▶ **Racemose cysticercosis** — proliferating clusters of cysts at the base of the brain → altered consciousness and death if untreated.
- ▶ **Extra-neural disease** — muscle (asymptomatic **cigar-shaped calcifications**), painless **subcutaneous nodules**, and ocular disease (subretinal/vitreous cyst, or ptosis from extra-ocular muscle involvement).

Diagnosis — imaging, serology, CSF and Del Brutto criteria

- ▶ **Neuroimaging is the primary diagnostic tool.** A cystic lesion containing an eccentric **mural scolex** (“dot-in-hole” appearance) is pathognomonic. Parenchymal cysts are 5–20 mm and round; subarachnoid cysts may reach 6 cm and be lobulated.
- ▶ **CT vs MRI** — CT is superior for calcified lesions; MRI is superior for small cysts, the scolex, enhancement, and ventricular/subarachnoid cysts (best seen on FIESTA / 3D-CISS sequences). Performing both is ideal.
- ▶ **Serology** — the enzyme-linked immunoelectrotransfer blot (EITB) using *lentil-lectin-purified glycoprotein* antigens is >99% sensitive and specific in patients with **multiple** cysts; sensitivity falls with **single lesions or calcifications** (may be seronegative). **Serum is more sensitive than CSF.** Crude-antigen ELISAs have high false-positive/negative rates and **should be avoided.** Antigen-detection (monoclonal antibody) and real-time PCR aid diagnosis/follow-up of extraparenchymal disease.
- ▶ **CSF** — lymphocytic, neutrophilic or **eosinophilic pleocytosis**; raised protein; glucose usually normal **but may be markedly reduced** (mimics tuberculous/fungal meningitis in basal disease).
- ▶ **Revised Del Brutto diagnostic criteria (2017)** — diagnosis is graded *definitive* or *probable* by combining the following, after excluding mimics:

Tier	Criteria
Absolute	Histology of parasite; subretinal cysticercus on funduscopy; conclusive scolex-in-cyst on neuroimaging

Tier	Criteria
Neuroimaging — major	Cystic lesions without scolex; typical enhancing lesions; multilobulated subarachnoid cysts; typical parenchymal calcifications
Neuroimaging — confirmative	Resolution of cysts after cysticidal drugs; migration of ventricular cyst on serial imaging
Neuroimaging — minor	Obstructive hydrocephalus or abnormal basal-leptomeningeal enhancement
Clinical/exposure — major	Positive EITB antibody or cysticercal antigen; cysticercosis outside CNS; household <i>T. solium</i> contact
Clinical/exposure — minor	Symptoms suggestive of NCC; residence in/origin from an endemic area

- ****Indian validated criteria — in a patient from an endemic area with a single enhancing lesion, seizures, a normal examination and no systemic disease, a round lesion 5–20 mm without midline shift* is almost always NCC (the solitary cysticercus granuloma*).**

Management

Principle: treat the **complications first** (seizures, raised ICP, hydrocephalus); **antiparasitic therapy is never an emergency** and must never be started while ICP is elevated or before ocular disease is excluded.

Problem	Approach
Seizures	Antiseizure drugs; taper after 6 months in single-lesion disease if imaging normalises and seizure-free; after 2 years in multilesional disease if lesions resolve without calcification. Calcified lesions = higher recurrence risk.
Viable parenchymal cysts	Albendazole 15 mg/kg/day for 8–28 days (CMDT: 10–15 mg/kg/day; may escalate to 30 mg/kg/day). For >2 cysts, add praziquantel 50 mg/kg/day (combination superior).
Subarachnoid / giant cysts	Prolonged or combination antiparasitics plus prolonged glucocorticoids for arachnoiditis/vasculitis; shunt if hydrocephalus.
Anti-inflammatory cover	High-dose glucocorticoids during all antiparasitic therapy — dexamethasone 0.1–0.4 mg/kg/day or prednisone 60 mg/day. Methotrexate / TNF inhibitors as steroid-sparing agents for prolonged courses.
Hydrocephalus / intraventricular cyst	Reduce ICP first; neuroendoscopic/surgical cyst removal (lateral & 3rd ventricle endoscopically; 4th

Problem	Approach
	ventricle by posterior microdissection). Avoid antiparasitics before surgery (they make cysts friable). VP shunt if removal impossible; antiparasitics + steroids reduce shunt failure.
Diffuse cerebral oedema (cysticercotic encephalitis)	Glucocorticoids are the mainstay; antiparasitic drugs are contraindicated.
Ocular / spinal	Drug-induced inflammation may cause irreversible damage; intraocular disease → surgery ; spinal disease → combined medical + surgical.

- ▶ **Drug interaction pearl** — corticosteroids **lower** praziquantel levels but **raise** albendazole levels, favouring albendazole when steroids are co-administered.
- ▶ **Taeniasis (gut carrier)** — single-dose **praziquantel 10 mg/kg** (or niclosamide 2 g); praziquantel may rarely trigger CNS inflammation if cryptic cysticercosis coexists.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Label the T. solium life cycle (cause of taeniasis vs cysticercosis):* Human definitive host → gravid proglottids/eggs in faeces → Pig (intermediate host) ingests eggs → oncosphere → cysticercus in pig muscle → undercooked pork eaten by human → adult tapeworm (taeniasis); *AND the cysticercosis loop:* Human ingests eggs (faecal–oral/autoinfection) → oncosphere → cysticercus in CNS/muscle/eye → neurocysticercosis. *Mark the scolex with hooklets** on the larva.
- ▶ **Axial MRI/CT cartoon labelling:** *vesicular cyst with eccentric scolex (“dot-in-hole”), ring-enhancing single lesion with perilesional oedema, intraventricular cyst causing hydrocephalus, and a parenchymal calcified nodule.*

Clinical / Diagnostic significance

- ▶ **Leading infective cause of adult-onset focal epilepsy** in endemic India — any young adult from an endemic area with new focal seizures and a normal exam should have neuroimaging for a solitary cysticercus granuloma.
- ▶ **Basal/subarachnoid NCC with low-glucose, lymphocytic CSF closely mimics tuberculous meningitis** — a crucial differential in Indian practice; EITB serology and characteristic imaging help separate them.
- ▶ **Calcified NCC** is the commonest imaging finding in endemic regions and a marker of remote infection; perilesional oedema around a calcification can cause **recurrent seizures**.
- ▶ **Public-health link** — household screening of a tapeworm carrier (the egg source) prevents new cases; control needs mass chemotherapy of humans and pigs, meat inspection, sanitation, and the **pig vaccine licensed in India**.

High-yield exam pointers

- ▶ NCC = larval *T. solium* in CNS; acquired by ingesting **eggs** (faecal–oral), *not* by eating pork — even vegetarians can get it.
- ▶ **Seizure = commonest manifestation**; NCC = top cause of acquired epilepsy in the developing world.
- ▶ “Dot-in-hole” scolex sign is diagnostic; CT best for calcification, MRI best for scolex/cysts (FIESTA/3D-CISS).
- ▶ EITB (immunoblot) >99% sensitive/specific for multiple cysts; single/calcified lesions may be seronegative; serum > CSF.
- ▶ **Del Brutto 2017 criteria** = absolute + neuroimaging (major/confirmative/minor) + clinical/exposure (major/minor).
- ▶ ***Bruns’ syndrome*** = positional intermittent obstructive hydrocephalus from a mobile ventricular ball-valve cyst.
- ▶ Always give glucocorticoids with antiparasitics; never give antiparasitics with raised ICP or in cysticercotic encephalitis.
- ▶ Albendazole is first-line; add praziquantel for >2 viable cysts; manage seizures/hydrocephalus before killing the parasite.

SOURCE & COVERAGE

- ▶ Harrison’s Principles of Internal Medicine, 22e — “Cestode Infections” (Taeniasis solium & Cysticercosis; Revised Diagnostic Criteria Table 242-1; Fig. 242-1) and “Seizures and Epilepsy” (NCC as a cause of acquired epilepsy).
- ▶ CMDT 2026 — “Protozoal & Helminthic Infections” (Cysticercosis: epidemiology, racemose form, treatment regimens, steroid–antiparasitic interaction).
- ▶ *Coverage note*: The corpus is solid on aetiology, the Del Brutto criteria, imaging and management. It classifies NCC by **location and viability** (parenchymal/intraventricular/subarachnoid/calcified) rather than by the named four-stage radiological evolution (*vesicular* → *colloidal-vesicular* → *granular-nodular* → *nodular-calcified*); that staging is universally accepted standard neurology and is reflected here in descriptive terms faithful to the source.

Nipah Virus Infection

Asked in: Paper II Sep 2025 — RGUHS MD General Medicine

Definition / Introduction — *Nipah virus* (NiV) is a highly virulent, enveloped negative-sense RNA virus of the family **Paramyxoviridae**, genus **Henipavirus** (alongside *Hendra virus*), first recognised in

humans in 1998–99. It is a bat-borne zoonosis that causes a severe **acute encephalitis with prominent respiratory involvement** and a very high case-fatality rate ($\approx 67\text{--}92\%$). It is a classic *emerging infectious disease* — the Malaysian emergence in 1998 was driven by deforestation and intensive pig farming — and is a recurrent public-health threat in South and Southeast Asia (Malaysia, Singapore, Bangladesh, India). It must be handled at **biosafety level 4 (BSL-4)** and is a *WHO R&D Blueprint priority pathogen* for which there is no licensed human vaccine or proven specific therapy.

Etiology and Virology

- ▶ **Family Paramyxoviridae, genus Henipavirus**; the two prototype species are Nipah virus and Hendra virus — the most lethal members of the family. Named after Sungai Nipah* village, Malaysia, the site of the index outbreak.
- ▶ **Enveloped, non-segmented, negative-sense single-stranded RNA virus**; pleomorphic.
- ▶ Two key surface glycoproteins: **G (attachment) glycoprotein** and **F (fusion) glycoprotein**. The G protein binds host cell-surface receptors **ephrin-B2 and ephrin-B3**, which are highly expressed on **neurons and vascular endothelium** — explaining the dual neuro-vascular tropism.
- ▶ F-protein-mediated cell–cell fusion produces multinucleated **syncytia**, a hallmark cytopathic effect.
- ▶ Unusually **broad host range** (bats, pigs, horses, humans) and the ability to infect both CNS and respiratory epithelium underlie its severity.

Epidemiology and Transmission

- ▶ **Natural reservoir**: fruit bats of the genus *Pteropus* (flying foxes), which are persistently infected but asymptomatic.
- ▶ **Geography**: cases concentrated in **Malaysia, Singapore, Bangladesh and India**; a distinct *Malaysian strain* and a more virulent, more transmissible *Bangladesh/India strain* are recognised.
- ▶ **Transmission routes (well documented)**: *pig-to-human*, *cow-to-human*, *human-to-human*, and **nosocomial** spread. Consumption of **raw date-palm sap** contaminated by bat saliva/excreta is the principal vehicle in Bangladesh/India; close contact with respiratory secretions of cases (and caregiving) drives person-to-person and hospital clusters.

Outbreak setting	Vehicle / amplifier	Key features
Malaysia 1998–99 / Singapore	Intermediate amplifying host = pigs; abattoir workers	First recognition; linked to deforestation + intensive pig farming (Harrison); predominantly encephalitis
Bangladesh (e.g., 2010–14 cluster: 14 cases, 8 fatal)	Raw date-palm sap; person-to-person	Higher CFR, more human-to-human and nosocomial transmission

Outbreak setting	Vehicle / amplifier	Key features
India (West Bengal, Kerala)	Date-palm sap / bat contact; hospital clusters	Recurrent seasonal outbreaks; high mortality

- Incubation period is typically 4–14 days (occasionally longer).
- High case-fatality rate (67–92%) — far exceeding most arboviral encephalitides.

Pathogenesis

- After mucosal/respiratory entry, the virus targets **endothelial cells and neurons** via ephrin-B2/B3 receptors.
- Produces a **systemic vasculitis** with endothelial syncytia, vasculitis-induced thrombosis, ischaemia and microinfarction — most marked in the **CNS** (and also lung, heart, kidney).
- Combined **direct neuronal infection** plus **vasculitic microinfarcts** generates the characteristic disseminated, multifocal encephalitic picture.
- Respiratory tract infection produces an **acute respiratory distress syndrome (ARDS)**-like illness and facilitates aerosol/droplet person-to-person spread.

Clinical Features

- Spectrum ranges from **asymptomatic/mild** infection to **fulminant encephalitis** and ARDS; the dominant syndrome is **acute febrile encephalitis**.

Phase / syndrome	Manifestations
Prodrome	Fever, headache, myalgia, vomiting, sore throat — non-specific
Acute encephalitis	Altered sensorium, encephalopathy , cranial nerve palsies , dystonia , segmental myoclonus, areflexia, hypotonia, seizures; brain-stem signs carry a grave prognosis
Respiratory	Cough, atypical pneumonia, ARDS — a key distinguishing feature from arboviral encephalitides; aids transmission
Autonomic/vascular	Tachycardia, hypertension, features of disseminated vasculitis
Late / relapsing	Relapsing or late-onset encephalitis weeks–months after recovery (≈ 3.4 – 7.5%), due to recrudescence of latent CNS infection

- **Neurologic sequelae** (cranial nerve palsies, persistent encephalopathy, dystonia, cognitive/behavioural deficits) persist in ≈ 15 – 32% of survivors.

Diagnosis

- ▶ **Strong epidemiological clues are essential:** travel/residence in an endemic area, **date-palm sap** ingestion, contact with sick pigs/bats, or contact with a known case; consider NiV in any **cluster of severe encephalitis with respiratory features** in South/Southeast Asia.
- ▶ **Laboratory confirmation (CMDT):**
 - ELISA — IgM/IgG antibody detection in **serum and CSF**.
 - RT-PCR — viral RNA in **urine and respiratory secretions** (note: **not reliably detected in blood**); CSF and throat/nasal swabs are also used.
 - **Virus isolation / immunohistochemistry** on tissue — performed only under BSL-4 containment.
- ▶ **CSF:** features of viral encephalitis (mild–moderate pleocytosis, raised protein, normal glucose).
- ▶ **Neuroimaging:** MRI typically shows **multiple small (2–7 mm) disseminated subcortical and deep white-matter T2/FLAIR hyperintensities** corresponding to microinfarcts (a relatively characteristic pattern).
- ▶ **Differential diagnosis** (per Harrison): Japanese encephalitis, herpes simplex and other viral encephalitides, cerebral malaria, leptospirosis, scrub typhus, bacterial meningoencephalitis — empirical **acyclovir** and antibacterials should cover treatable mimics until NiV is confirmed.

Management and Prevention

- ▶ **No proven specific antiviral therapy; care is largely supportive** — ICU-level management of encephalitis (seizure control, raised intracranial pressure, SIADH) and of respiratory failure/ARDS (oxygen, mechanical ventilation).
- ▶ **Ribavirin** was used in the Malaysian outbreak with a *possible* reduction in mortality, but benefit is unproven; **remdesivir** and the experimental human monoclonal antibody **m102.4** (targets the G-glycoprotein ephrin-binding site) are investigational/compassionate-use agents.
- ▶ **Infection prevention and control (critical):** strict **contact + droplet (and airborne for aerosol-generating procedures)** precautions, isolation of cases, PPE for caregivers, safe handling/burial practices, and BSL-4 handling of specimens — nosocomial amplification is a recurring feature of outbreaks.
- ▶ **Public-health prevention:** avoid raw date-palm sap (cover collection pots/use bamboo skirts), avoid contact with sick pigs/bats and bat-bitten fruit, surveillance of *Pteropus* populations, and rapid outbreak containment with contact tracing and quarantine.
- ▶ **No licensed human vaccine** (a recombinant Hendra-G subunit equine vaccine exists for horses; human candidates are in trials).

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Nipah virus transmission cycle (label):** *Pteropus* fruit-bat reservoir → contamination of **date-palm sap and fruit** (Bangladesh/India route) and infection of **pigs (amplifying host)**

(Malaysia route) → **human** infection → **human-to-human / nosocomial** spread; annotate **ephrin-B2/B3 receptor** tropism for **neurons + endothelium**.

- ▶ **Virion structure (label):** envelope, G (attachment) glycoprotein, F (fusion) glycoprotein, helical nucleocapsid with **negative-sense ssRNA**, matrix protein.

Clinical / Diagnostic significance

- ▶ NiV is the **most lethal paramyxovirus** and a model **One-Health emerging zoonosis** — its emergence illustrates how **ecological disruption** (deforestation, intensive farming, **sap harvesting**) precipitates spillover.
- ▶ Suspect NiV in **clustered, rapidly progressive encephalitis with respiratory illness** in endemic regions; early suspicion enables containment and prevents nosocomial catastrophe.
- ▶ Diagnostic pearl: **PCR is positive in urine/respiratory secretions but not blood**; paired serum + CSF ELISA confirms the diagnosis.
- ▶ Survivors require **neurological follow-up** for late/relapsing encephalitis and persistent deficits.

High-yield exam pointers

- ▶ **Family Paramyxoviridae, genus Henipavirus**; sister virus = **Hendra**; named after *Sungai Nipah*, Malaysia (1998).
- ▶ **Reservoir* = *Pteropus fruit bats*; *pigs* = *amplifying host* (Malaysia); *raw date-palm sap** (Bangladesh/India).
- ▶ Receptors **ephrin-B2/B3** → **neuro-vascular tropism**; pathology = **endothelial syncytia + vasculitis** → **microinfarcts**.
- ▶ Syndrome = **acute encephalitis + respiratory illness**; signs include **cranial nerve palsies, segmental myoclonus, dystonia, brain-stem involvement**.
- ▶ **CFR 67–92%**; neurologic sequelae **15–32%**; relapsing/late encephalitis **3.4–7.5%**.
- ▶ **Dx:** ELISA (serum + CSF) and RT-PCR (**urine/respiratory secretions, NOT blood**); MRI = multiple small disseminated lesions; handle at **BSL-4**.
- ▶ **Rx:** supportive ICU care; ribavirin/remdesivir/**m102.4 mAb** investigational; **no licensed human vaccine**.
- ▶ **Prevention:** droplet/contact isolation, avoid raw sap & sick animals; a **WHO priority/Blueprint pathogen** with pandemic potential.

SOURCE & COVERAGE

- ▶ **Harrison's Principles of Internal Medicine, 22e** — “Emerging and Re-Emerging Infectious Diseases” (Nipah as an emerging zoonosis; Malaysia 1998 emergence linked to deforestation + intensive pig farming; Hendra/Nipah listed); “Acute Meningitis and

Encephalitis” chapter (Nipah, a Paramyxoviridae, as a cause of Southeast-Asian encephalitis outbreaks); “Arthropod-Borne and Rodent-Borne Virus Infections” (Nipah in the encephalitis differential).

- ▶ **CMDT 2026** — “Viral & Rickettsial Infections” (Nipah under paramyxoviruses): first described 1999; geography; fruit-bat reservoir; Bangladesh date-palm-sap cluster (14 cases, 8 fatal); pig-/cow-/human-/nosocomial transmission; CFR 67–92%; neurologic sequelae 15–32%; relapses 3.4–7.5%; ELISA (serum/CSF) and PCR (urine/respiratory secretions, not blood) diagnosis.
- ▶ **Coverage note:** The corpus covers Nipah only briefly — Harrison treats it as an emerging-disease/encephalitis example and CMDT provides the main clinical paragraph; there is **no dedicated Nipah chapter**. Standard, universally-accepted virology and management details not explicitly in the corpus but added for completeness and accuracy: genus *Henipavirus* and ephrin-B2/B3 receptors; G/F glycoproteins and syncytia; *Pteropus* genus; incubation 4–14 days; MRI microinfarct pattern; ribavirin/remdesivir/m102.4 and the absence of a licensed human vaccine; BSL-4 and WHO-priority-pathogen status; and Indian (West Bengal, Kerala) outbreaks.

Preventive strategies for antibiotic resistance in multidisciplinary intensive care units

Asked in: Paper I Sep 2025 — RGUHS MD General Medicine

Definition / Introduction — *Antimicrobial resistance (AMR)* is the reduction or loss of an antibacterial agent’s activity, arising from spontaneous chromosomal **mutation** or **horizontal acquisition** of resistance genes (plasmids, transposons, transformation). The multidisciplinary ICU is the hospital’s *epicentre of resistance* because it concentrates the three drivers of resistance simultaneously — intense **antibiotic selection pressure**, a dense reservoir of **colonised/infected hosts** (high colonisation pressure), and abundant opportunities for **cross-transmission** via invasive devices and the hands of staff. Prevention is therefore not a single measure but a coordinated, institution-wide programme resting on **two complementary pillars** — **antimicrobial stewardship** (rational prescribing) and **infection prevention and control** (interrupting transmission) — backed by surveillance and a *One Health* perspective. The CDC estimates >2.8 million resistant infections and 35,900 deaths annually in the United States, underscoring the stakes.

Why the ICU breeds resistance (the rationale to target)

- ▶ **Selection pressure:** broad-spectrum empirical regimens, prolonged courses and unnecessary antibiotics select resistant strains and “bystander” organisms; prior antibiotic exposure, prior

resistant infection and prior hospitalisation each raise the odds of harbouring a resistant pathogen.

- ▶ **Colonisation pressure:** the proportion of patients on a ward who are colonised is itself a risk factor for spread; antibiotic-altered microbiota become readily colonised by **multidrug-resistant organisms (MDROs)**, which then act as silent reservoirs.
- ▶ **Cross-transmission:** transmitted on hands, shared equipment (stethoscopes, glucometers, ultrasound, BP cuffs), contaminated environment, plumbing and water.
- ▶ **Devices and breached barriers:** central lines, urinary catheters, endotracheal tubes and surgical wounds are portals of entry — catheter-associated bloodstream infection alone *triples* in-hospital mortality risk, and ventilator-associated pneumonia (VAP) occurs in up to 10% of ventilated patients.
- ▶ **The MDRO targets:** CDC *urgent* threats — carbapenem-resistant *Acinetobacter*, *Candida auris*, *Clostridioides difficile*, **carbapenem-resistant Enterobacterales (CRE)** and drug-resistant *N. gonorrhoeae*; *serious* threats include ESBL-producing Enterobacterales, VRE, MDR *Pseudomonas aeruginosa*, MRSA and drug-resistant *S. pneumoniae*. Key enzymes: **ESBLs**, **AmpC**, and carbapenemases **KPC**, **NDM** (originally Indian subcontinent) and **OXA-48**; plasmid-borne colistin resistance via *mcr-1*.

Pillar 1 — Antimicrobial stewardship (ASP)

*Stewardship promotes the appropriate drug, dose, route and duration, with four goals: (1) improve patient care, (2) preserve antibiotics by curbing resistance, (3) reduce adverse effects (e.g. *C. difficile*), and (4) control cost.* Mandated/supported by **CDC** core elements, **The Joint Commission** Medication Management Standards, CMS Conditions of Participation and the 2015 **National Action Plan for Combating Antibiotic-Resistant Bacteria**.

- ▶ **Multidisciplinary team:** infectious-disease physician + clinical pharmacist with ID training (core dyad), plus clinical microbiologist, infection-prevention practitioner, hospital epidemiologist and information-systems specialist.

Strategy	What it involves
Prospective audit + feedback	ID physician/pharmacist reviews broad-spectrum orders (carbapenems) or costly agents (daptomycin, ceftazidime-avibactam) and recommends alternatives
Formulary restriction	Limited set of agents on formulary to curb indiscriminate use
Preauthorisation	Approval required before using restricted agents — via CPOE criteria or ID consultation

Strategy	What it involves
De-escalation / streamlining	Narrow therapy once culture & susceptibility known; stop the “anti-pseudomonal/anti-MRSA” drug if not recovered
Dose optimisation (PK/PD)	Use pharmacokinetic-pharmacodynamic targets (e.g. extended β -lactam infusions, AUC/MIC)
IV-to-oral conversion	Switch when patient stable and gut absorbing
Antibiotic time-out / shortest duration	Reassess at 48–72 h; use the shortest effective course (shorter courses select less resistance)
Diagnostic stewardship	Avoid culturing asymptomatic bacteriuria; restrict unnecessary tests to prevent inappropriate treatment
Guidelines, indication documentation, education	Local pathways, documenting indication, ongoing prescriber education

- The “Four Moments of Antibiotic Decision-Making” (a practical bedside frame): (1) *Does this patient have an infection that needs antibiotics?* (2) *Have appropriate cultures been taken before starting?* (3) *After a few days — can antibiotics be stopped, narrowed, or switched IV-to-oral?* (4) *What duration is truly necessary?*
- **ICU/VAP-specific algorithm (6 steps):** (1) start broad-spectrum empirically to cover MDR GNB/MRSA; (2) **stop** if infection becomes unlikely; (3) **narrow** once the organism is identified; (4) **optimise** by PK/PD; (5) **switch to monotherapy on days 3–5**; (6) **shorten duration** (a short, fixed course e.g. ~7–8 days for most VAP). Quantitative lower-respiratory cultures (BAL $\geq 10^4$ CFU/mL or tracheal aspirate $\geq 10^5$ CFU/mL) with a de-escalation algorithm increase antibiotic-free days without harming outcome.
- **Rapid diagnostics & biomarkers:** rapid molecular detection of organisms/resistance (multiplex PCR, MALDI-TOF) shortens time to appropriate therapy and to de-escalation; **procalcitonin-guided** cessation reduces antibiotic exposure in the ICU (*PRORATA* trial) and is a recognised adjunct.

Pillar 2 — Infection prevention and control (interrupt transmission)

- **Hand hygiene** before/after every patient contact — alcohol-based hand rub, but **soap-and-water (mechanical removal)** for *C. difficile* and norovirus (spores/non-enveloped virus resist alcohol).
- **Standard precautions** for all patients + **transmission-based precautions:** **contact** (gown + gloves) for MDROs and *C. difficile*; **droplet** and **airborne** (N95 + negative-pressure room, ≥ 12 air changes/h) as indicated.
- **Daily 2% chlorhexidine gluconate bathing** of ICU patients with central lines — standard of care to prevent bloodstream infection.

- ▶ **Environmental cleaning** of high-touch surfaces and shared equipment; **sporicidal (bleach)** cleaning and adjunctive **UV-C** for tenacious pathogens; dedicated disinfectants and screening of transfers for *C. auris*; **water-safety/management plans** (*Legionella*, NTM, MDR gram-negatives in drains).
- ▶ **Device-care bundles** (the single highest-yield ICU intervention) — see table — plus the cardinal rule: *insert devices only when essential and review the need for each device daily*.

Bundle	Key evidence-based elements
CLABSI	Hand hygiene; maximal sterile barrier ; chlorhexidine-alcohol skin prep; ultrasound-guided insertion; prefer subclavian (femoral most infection-prone); all-inclusive kit + checklist; scrub-the-hub; disinfectant caps; chlorhexidine-impregnated dressings; daily chlorhexidine baths; daily review of line need
VAP	Avoid intubation (HFNO/NIV); head-of-bed 30–45° ; daily oral care/tooth-brushing; aseptic respiratory-equipment care (no tap-water rinsing); minimise sedation , early mobilisation, early enteral feeding, daily extubation-readiness (spontaneous breathing trials)
CAUTI	Catheterise only when strictly necessary; aseptic insertion + closed drainage; minimise manipulation; daily review of need ; alternatives — bladder scan, condom/intermittent catheter
SSI	Treat infection pre-op; prophylaxis within 1 h before incision and stop after closure ; clip (not shave) hair; chlorhexidine-alcohol antisepsis; nasal mupirocin decolonisation in <i>S. aureus</i> carriers for high-risk surgery

- ▶ **Active surveillance & cohorting**: screen high-risk transfers/long-term-care admissions for MDROs/*C. auris*, isolate pending results, cohort staff and patients during outbreaks; reduce colonisation pressure.
- ▶ **C. difficile control**: because antibiotic exposure is the chief cause, *stewardship is the first-line preventive measure* — restricting **fluoroquinolones and clindamycin** reduces incidence; add contact isolation, soap-and-water hand hygiene and bleach disinfection.
- ▶ **Selective digestive/oropharyngeal decontamination (SDD/SOD)**: may reduce HAP and mortality, but routine use is *limited by concern over selecting resistance* and remains context-dependent.

Institutional, surveillance and One Health measures

- ▶ **Surveillance & tracking:** laboratory-based + automated electronic surveillance; mandatory reporting (e.g. NHSN), expressed as **standardised infection ratios**; produce a periodic **antibiogram** to guide empirical therapy to *local* susceptibility data.
- ▶ **Outbreak response:** molecular typing — **whole-genome sequencing** (gold standard) — to confirm clonality and trace plasmid-borne resistance genes; case definition, case-finding, control measures, communication.
- ▶ **Regional/interfacility communication** of MDRO status on transfer; **CDC five core actions** — (1) infection prevention & control, (2) tracking & data, (3) antibiotic use & access (stewardship), (4) vaccines/therapeutics/diagnostics, (5) environment & sanitation via the **One Health** approach (agriculture, animal antibiotic use, environmental reservoirs).

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **“Two-pillar prevention framework”:** a central box *Preventing AMR in the ICU* feeding two columns — **Antimicrobial Stewardship** (label: audit-and-feedback, formulary restriction, preauthorisation, de-escalation, PK/PD dosing, IV-to-oral, antibiotic time-out, shortest duration, diagnostic stewardship) and **Infection Prevention & Control** (label: hand hygiene, contact/droplet/airborne precautions, CLABSI/VAP/CAUTI/SSI bundles, chlorhexidine bathing, environmental + water safety, active surveillance/isolation) — both resting on a base bar labelled *Surveillance • Antibiogram • Outbreak investigation (WGS) • One Health*.
- ▶ **“Chain of transmission interrupted”:** Reservoir (colonised patient/environment/device) → Hands of HCW / shared equipment → Susceptible patient; mark the break-points — *hand hygiene, contact precautions, environmental cleaning, device removal*.

Clinical / Diagnostic significance

- ▶ **Empirical-to-targeted transition:** appropriate early empirical cover saves lives in septic ICU patients, but must be paired with mandatory cultures *before* antibiotics and prompt **de-escalation** once susceptibilities return — this is where resistance is actually contained.
- ▶ **Local data drive choice:** the institutional antibiogram and individual risk factors (prior antibiotics, prior MDRO, length of stay) determine the empirical regimen; rapid diagnostics shorten the window of unnecessary broad-spectrum exposure.
- ▶ **Bundle compliance is auditable:** process measures (hand-hygiene compliance, line-insertion checklist adherence) and outcome measures (CLABSI/VAP/CAUTI rates, hospital-onset *C. difficile*) feed quality improvement and reimbursement.
- ▶ **Stewardship pays clinically:** demonstrated reductions in *C. difficile*, improved susceptibility patterns and lower cost without worse outcomes.

High-yield exam pointers

- ▶ AMR prevention in the ICU = **two pillars**: *Antimicrobial Stewardship + Infection Prevention & Control*, on a base of *surveillance/One Health*.
- ▶ **Three core ASP strategies**: prospective audit + feedback, formulary restriction, preauthorisation.
- ▶ **Four Moments of Antibiotic Decision-Making**; ASP goals = better care, less resistance, fewer adverse effects, lower cost.
- ▶ **VAP 6-step strategy**: start broad → stop if unlikely → narrow → PK/PD optimise → **monotherapy** day 3–5 → **shorten duration**.
- ▶ **Shorter courses select less resistance**; de-escalate on cultures; consider **procalcitonin-guided** stop (*PRORATA*).
- ▶ **Device bundles** + “insert only if essential, review daily”; **daily 2% chlorhexidine** baths prevent CLABSI; HOB 30–45° for VAP.
- ▶ **Hand hygiene** is the single most effective IPC measure — but **soap-and-water** for *C. difficile*/norovirus; **contact precautions** for MDROs.
- ▶ **Stewardship is first-line prevention of *C. difficile*** — restrict **fluoroquinolones + clindamycin**.
- ▶ CDC **urgent** threats: CR-*Acinetobacter*, *C. auris*, *C. difficile*, CRE, drug-resistant gonorrhoea; carbapenemases KPC/NDM/OXA-48.
- ▶ CDC **five core actions** + **One Health**; outbreak typing by **whole-genome sequencing**.

SOURCE & COVERAGE

- ▶ **Harrison’s Principles of Internal Medicine, 22e** — “Bacterial Resistance to Antimicrobial Agents” (mechanisms, CDC threats table & five core actions, One Health); “Treatment and Prophylaxis of Bacterial Infections” (antimicrobial stewardship strategies, ASP team, prophylaxis); “Infections Acquired in Health Care Facilities” (device bundles, transmission-based precautions, chlorhexidine bathing, surveillance, *C. difficile*/*C. auris*).
- ▶ **CMDT 2026** — “Common Problems in Infectious Diseases & Antimicrobial Therapy” (antimicrobial stewardship, *Four Moments of Antibiotic Decision-Making*, selective digestive decontamination).
- ▶ **Murray & Nadel’s Textbook of Respiratory Medicine** — “Ventilator-Associated Pneumonia” (ICU 6-step antimicrobial management, quantitative-culture de-escalation, PK/PD, monotherapy on days 3–5, duration, procalcitonin/PRORATA, rapid diagnostics).
- ▶ *Coverage note*: the corpus covers stewardship and infection control fully; explicit ICU-specific stewardship detail is consolidated chiefly from the Murray VAP chapter (the general texts treat it more briefly, as the spec anticipated). Procalcitonin/PRORATA and short fixed VAP courses are standard, source-supported ICU practice.

Progressive Multifocal Leucoencephalopathy

Asked in: Paper II Nov 2021 — RGUHS MD General Medicine

Definition / Introduction — Progressive multifocal leucoencephalopathy (PML) is a subacute, usually fatal **demyelinating disease of the central nervous system** caused by lytic reactivation of the **JC virus** (a human polyomavirus) in profoundly immunosuppressed patients. It is the **only known clinical manifestation of JC virus infection** and characteristically produces *multifocal, non-enhancing* white-matter lesions that coalesce over time. In Harrison's it is described chiefly as a **late opportunistic infection of AIDS** (seen in ~1–4% of AIDS patients) and, in the multiple sclerosis chapter, as the **principal serious risk of natalizumab** and certain other disease-modifying therapies (DMTs).

Etiology & Pathogenesis

- ▶ **Causative agent:** JC virus, a ubiquitous **human polyomavirus** (double-stranded DNA, non-enveloped). The eponym derives from the initials of the index patient (*John Cunningham*).
- ▶ **High background seroprevalence:** ~80% of the **general adult population** have antibodies to JC virus, indicating prior (usually childhood, asymptomatic) infection. The virus then remains **latent** (kidney/lymphoid tissue).
- ▶ **Restricted replication in health:** <10% of **healthy adults** show any evidence of ongoing viral replication — disease requires a permissive immunosuppressed state.
- ▶ **Reactivation:** Loss of immune surveillance permits viral reactivation, haematogenous spread to the CNS, and **lytic infection of oligodendrocytes**, producing demyelination.
- ▶ **Pathology:** Lesions begin as **small foci of demyelination in subcortical white matter** that progressively **coalesce**. The **cerebral hemispheres, cerebellum, and brainstem** may all be involved.
- ▶ **Why immunomodulators raise risk:** Natalizumab blocks the **$\alpha 4 \beta 1$ integrin (adhesion molecule)**, *preventing lymphocytes from binding endothelial cells and entering the CNS* — the resulting loss of intrathecal immune surveillance permits unchecked JC virus replication, the mechanistic basis of its PML risk.

Predisposing immunosuppressed states (who gets PML)

Setting	Key points (per source)
Advanced HIV/AIDS	A late manifestation of AIDS ; occurs in ~1–4% of AIDS patients; one of the few opportunistic infections that continues to occur despite widespread ART
Natalizumab (Tysabri) for MS	Anti- $\alpha 4 \beta 1$ integrin MAb; major risk is PML (~0.4%); give only if serum JC virus antibodies are absent (~50% of patients); repeat JCV antibody testing every 6 months on treatment

Setting	Key points (per source)
Dimethyl/diroximel fumarate for MS	Rare PML cases, associated with persistent lymphopenia
Cladribine (Mavenclad) for MS	Lymphocytotoxic; infection risk including PML
Other (standard)	Haematological malignancy, transplant/chemotherapy, other potent immunosuppression — <i>see Coverage note</i>

Clinical features

- ▶ **Tempo:** Subacute, protracted course with **multifocal neurologic deficits**, *with or without* changes in mental status.
- ▶ **Focal signs:** Hemiparesis, **visual field defects** (hemianopia), **ataxia**, **aphasia**, and **sensory deficits** — reflecting the multifocal white-matter involvement.
- ▶ **Seizures:** Occur in ~20% of patients.
- ▶ **Notable negatives:** Headache, fever, nausea and vomiting are rarely seen — their presence should prompt a search for an alternative diagnosis (e.g., toxoplasmosis, lymphoma).
- ▶ **Course:** Relentless progression; cognitive and focal deficits accumulate.

Investigations & Diagnosis

- ▶ **MRI brain (key investigation):**
 - Multiple, NON-enhancing white-matter lesions that may coalesce.
 - Predilection for the occipital and parietal lobes.
 - T2-weighted: signal hyperintensity; T1-weighted: diminished (low) signal.
 - Absence of mass effect and absence of enhancement help distinguish PML from enhancing/space-occupying lesions.
- ▶ **CSF JC virus DNA (PCR):** Diagnostic sensitivity ~76%, specificity close to 100% — a positive CSF JCV PCR in the right clinical/MRI context is effectively confirmatory.
- ▶ **Brain biopsy:** Reserved for atypical cases (definitive demonstration of demyelination with oligodendroglial inclusions) — *standard practice; see Coverage note*.
- ▶ **CD4 count / HIV viral load** in PML complicating HIV, as these carry prognostic weight (below).

Differential diagnosis (HIV CNS lesions)

Feature	PML	CNS toxoplasmosis	Primary CNS lymphoma
Enhancement	Non-enhancing	Ring-enhancing (eccentric <i>target sign</i>)	Enhancing (often homogeneous)

Feature	PML	CNS toxoplasmosis	Primary CNS lymphoma
Number/site	Multifocal, white matter , occipito-parietal	Multiple, deep + grey–white junction/basal ganglia	Single or few, periventricular
Mass effect	Minimal/absent	Present (oedema)	Present
Confirmatory test	CSF JCV DNA PCR	Response to anti-toxoplasma Rx; serology	CSF EBV DNA; biopsy

Treatment & Prognosis

- ▶ No specific antiviral therapy exists for PML; agents such as **cidofovir** have failed to show clear benefit.
- ▶ Cornerstone = restore immunity / remove the trigger:
 - In HIV: initiate/optimize ART to reconstitute CD4 immunity.
 - In drug-induced PML: **stop the offending DMT** (and, for natalizumab, consider plasma exchange to accelerate drug clearance — *standard; see Coverage note*).
- ▶ Immune reconstitution inflammatory syndrome (IRIS): Paradoxical worsening of PML can follow ART initiation as an immune-reconstitution phenomenon — a key management caveat.
- ▶ Prognosis (HIV-associated):
 - Pre-ART era: most patients died **within 3–6 months** of symptom onset.
 - With ART: dramatically improved — **median survival ~2 years**, and survival >15 years has been reported; however, **only ~50%** of HIV-PML patients show neurologic improvement.
 - Favourable predictors: **baseline CD4+ count >100/μL** and ability to maintain HIV viral load <500 copies/mL. Baseline HIV-1 viral load itself has **no independent predictive value**.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Axial T2/FLAIR MRI brain schematic (PML lesions).** Labels to mark: *Asymmetric subcortical white-matter hyperintensity; Parieto-occipital predilection; Coalescing demyelinating foci; Involves subcortical U-fibres; NON-enhancing on post-contrast T1; T1-hypointense / T2-hyperintense; No/minimal mass effect; Grey matter relatively spared.*
- ▶ **Pathogenesis flow diagram.** Boxes/arrows: *Latent JC virus (kidney/lymphoid tissue) → Severe immunosuppression (HIV with low CD4 / natalizumab / fumarate / cladribine) → Viral reactivation → Haematogenous spread to CNS → Lytic infection of oligodendrocytes → Multifocal demyelination → Progressive multifocal neurological deficits.*

Clinical / Diagnostic significance

- ▶ **AIDS-defining illness:** PML is an AIDS-defining opportunistic infection; its appearance signals **advanced immunosuppression** and warrants ART optimisation.
- ▶ **Pharmacovigilance for DMTs:** **JC virus antibody stratification** is mandatory before and during **natalizumab** therapy — JCV-seronegative patients are preferred candidates; rising JCV index, prior immunosuppressant use, and longer treatment duration raise risk.
- ▶ **“Non-enhancing white-matter lesions + focal deficits + immunosuppression”** is the classic triad that should trigger CSF JCV PCR.
- ▶ **Watch for IRIS** when starting ART in a patient with (or at risk of) PML — neurologic worsening may be inflammatory rather than progressive infection.
- ▶ **MRI + CSF JCV DNA PCR** can often avoid the need for brain biopsy.

High-yield exam pointers

- ▶ **JC virus = human polyomavirus;** PML is its **ONLY clinical manifestation**; ~80% adults are seropositive.
- ▶ **Occurs in ~1–4% of AIDS patients;** a late AIDS manifestation; persists despite ART.
- ▶ **MRI:** multiple **NON-enhancing** white-matter lesions, **occipito-parietal**, **T2-hyperintense / T1-hypointense**.
- ▶ **CSF JC virus DNA PCR:** sensitivity ~76%, specificity ~100%.
- ▶ ~20% have seizures; headache/fever/vomiting are **rare** (suggest another diagnosis).
- ▶ **No specific therapy;** **cidofovir ineffective** — treat by **immune reconstitution (ART) / stopping the culprit DMT**.
- ▶ **Natalizumab PML risk ~0.4%** — give only if **JCV antibody negative**; retest q6 months.
- ▶ **Prognosis:** pre-ART death in **3–6 months**; with ART median survival ~2 years; better if **CD4 >100/μL** and **VL <500 copies/mL**.
- ▶ **ART can cause paradoxical worsening = PML-IRIS.**

SOURCE & COVERAGE

Harrison’s Principles of Internal Medicine, 22e (2025) — **Ch 208 “Human Immunodeficiency Virus Disease: AIDS and Related Disorders”** (JC virus/PML epidemiology, clinical features, MRI, CSF JCV PCR, ART/prognosis, IRIS) and **Ch 455 “Multiple Sclerosis”** (Table 455-6: natalizumab/fumarate/cladribine PML risk and JCV antibody stratification). **Coverage note (spec.gap = true):** Harrison 22e has **no dedicated PML chapter**; content is distributed across the HIV chapter (which cross-refers to Ch 142 on polyomaviruses, *not supplied here*) and the MS-therapeutics chapter. Items added as **universally accepted standard internal medicine but NOT explicitly stated in the two supplied chapters** are flagged in-text: the *John Cunningham* eponym expansion; **oligodendrocyte** as the lytically infected target cell; **brain biopsy** as the definitive test;

plasma exchange to clear natalizumab; and non-HIV immunosuppressed settings (haematologic malignancy, transplant/chemotherapy). The differential-diagnosis comparison draws on toxoplasmosis (eccentric target sign, ring enhancement) and CNS lymphoma descriptions within Ch 208.

Pyrexia of Unknown Origin (PUO / Fever of Unknown Origin)

Asked in: Paper I Sep 2025 — RGUHS MD General Medicine

Definition / Introduction — Pyrexia of unknown origin (PUO), more often termed *fever of unknown origin* (FUO), denotes a **prolonged febrile illness that defies diagnosis despite intensive, structured evaluation**. The term should be reserved for such illnesses — most fevers either resolve spontaneously or declare a cause once distinguishing features appear. FUO is not a single disease but a final common presentation of an atypical manifestation of a common disorder far more often than a rare exotic disease. The diagnostic challenge lies in disciplined pursuit of *potentially diagnostic clues* rather than indiscriminate testing.

Diagnostic criteria — classic vs current definition

- ▶ The original Petersdorf and Beeson (1961) definition: illness of ≥ 3 weeks' duration, fever $\geq 38.3^{\circ}\text{C}$ ($\geq 101^{\circ}\text{F}$) on two occasions, with diagnosis uncertain despite 1 week of inpatient evaluation.
- ▶ Harrison's **current (modern) definition** retains time/temperature thresholds but mandates a standardised minimum workup and excludes the immunocompromised:

Criterion	Requirement
Temperature	Fever $\geq 38.3^{\circ}\text{C}$ ($\geq 101^{\circ}\text{F}$) on at least two occasions
Duration	Illness of at least 3 weeks
Host	No known immunocompromised state
Investigation	Diagnosis uncertain after thorough history, examination and the obligatory investigations (see below)

- ▶ **Inflammation of unknown origin (IUO)** — identical to FUO *except the temperature criterion*: persistently raised CRP/ESR for ≥ 3 weeks in an immunocompetent patient with a **normal body temperature** and no explanation despite the same obligatory workup. IUO and FUO share the **same causes and the same workup**.
- ▶ For perspective, normal mean oral temperature is $\sim 36.6^{\circ}\text{C}$; *fever* is a pyrogen-driven upward shift of the hypothalamic set point (mediated by pyrogenic cytokines IL-1, IL-6, TNF), distinct

from hyperthermia (uncontrolled heat gain, set point unchanged, unresponsive to antipyretics).

Hyperpyrexia = fever $>41.5^{\circ}\text{C}$.

Classification — categories of FUO

The classic Durack–Street four-category scheme separates the immunocompetent “classic” patient from special hosts, each with a distinct differential and threshold (durations per CMDT 2026):

Category	Defining features
Classic FUO	≥ 3 weeks, fever $\geq 38.3^{\circ}\text{C}$, immunocompetent, undiagnosed after the obligatory workup
Hospital-associated (nosocomial) FUO	Fever in a hospitalised patient from a process not present/incubating on admission ; cultures negative; undiagnosed despite appropriate evaluation (≥ 3 days, including ≥ 2 days culture incubation)
Neutropenic FUO	Fever with <500 neutrophils/ μL ; cultures negative; undiagnosed after 3 days — <i>fungal and occult bacterial infection</i> dominate
HIV-associated FUO	Confirmed HIV, febrile ≥ 4 weeks as outpatient or ≥ 3 days as inpatient; undiagnosed after 3 days (≥ 2 days incubation) — <i>mycobacterial/opportunistic infection</i> dominate

- Special scenarios with unique differentials: FUO in solid-organ transplant recipients (CMV, fungi, nocardiosis, *P. jirovecii*, mycobacteria) and FUO in the returning traveller (malaria, enteric fever, leishmaniasis, rickettsioses).

Etiology — broad categories

The five working categories (CMDT) and their geographic skew (Harrison):

Category	Key examples
Infections	Extrapulmonary/miliary tuberculosis, infective/culture-negative endocarditis, occult abscess (hepatic, splenic, subphrenic, pelvic, renal), diverticulitis, vertebral osteomyelitis/spondylodiscitis; brucellosis, Q fever (<i>Coxiella burnetii</i>), Whipple disease (<i>Tropheryma whippelii</i>), EBV/CMV, malaria, leishmaniasis, HIV seroconversion
Noninfectious inflammatory diseases (NIIDs)	Adult-onset Still's disease, large-vessel vasculitis / giant cell arteritis, polymyalgia rheumatica, SLE, polyarteritis nodosa, cryoglobulinemia, sarcoidosis; autoinflammatory syndromes (familial Mediterranean fever, VEXAS, Schnitzler's)

Category	Key examples
Malignancy	Malignant lymphoma (most common neoplastic cause), leukaemia, renal cell carcinoma, hepatic tumours, atrial myxoma, Castleman disease
Miscellaneous	Drug fever, factitious/fraudulent fever, granulomatous hepatitis, subacute thyroiditis, recurrent pulmonary emboli, alcoholic hepatitis
Undiagnosed	~Half of cases (higher in Western cohorts — “the FVO paradox”); most resolve spontaneously

- **Geography matters:** infection (esp. **tuberculosis** — up to half of infective FVO) predominates in Asia/Middle-East; **NIIDs predominate in Western cohorts** (up to one-third). In adults >65 years, multisystem immune diseases (GCA, PMR, sarcoid, RA) cause 25–30%.
- **Eponym pearls:** *VEXAS* — somatic UBA1 variants, elderly males, vacuoles in myeloid precursors. *Schnitzler’s* — urticaria + bone pain + monoclonal gammopathy. *Marantic (nonbacterial thrombotic) endocarditis* — paraneoplastic. Common **drug-fever** culprits: allopurinol, carbamazepine, lamotrigine, phenytoin, sulfasalazine, furosemide, sulfonamides, minocycline, vancomycin, β -lactams, isoniazid; fever subsides **within ~72 h** of stopping the drug.

Diagnostic approach — obligatory workup and PDC-driven strategy

- **Obligatory minimum investigations** (define the patient as true FVO): ESR and CRP; full blood count with differential and platelets; haemoglobin, electrolytes, creatinine, total protein, ALP, ALT, AST, LDH, creatine kinase, ferritin; ANA and rheumatoid factor; serum protein electrophoresis; urinalysis; **blood cultures (n = 3)**; urine culture; **chest radiograph**; **abdominal ultrasonography**; and TST or IGRA. (CMDT additionally lists HIV antibody/antigen and TSH.)
- **Hunt for Potentially Diagnostic Clues (PDCs)** — all localising signs, symptoms and abnormalities pointing to a diagnosis — through *repeated* history and examination. History: fever pattern/duration, drugs, travel (remote and recent), animal/occupational exposures, sexual and family history, country of origin. Examination: eyes/**fundoscopy**, lymph nodes, **temporal arteries**, liver, spleen, skin and mucosae, surgical scars.
- **Stop confounders early:** discontinue **antibiotics and glucocorticoids** before further testing (they mask cultures and shrink nodes); withdraw all drugs/supplements to exclude **drug fever**; exclude **factitious fever** (self-induced) and **fraudulent fever** (manipulated thermometer) by simultaneous multi-site temperature measurement and by noting **pulse–temperature dissociation**.
- **Targeted, PDC-guided testing only:** “screening” serologies/febrile agglutinins are low-yield and discouraged without a clue. Hold blood cultures long enough for fastidious HACEK organisms; use special media when *Legionella*, *Bartonella*, *Histoplasma* or nutritionally-variant streptococci are suspected. Headache → CSF examination (HSV-2, *Cryptococcus*, *M. tuberculosis*). For

suspected **miliary TB**, **liver biopsy** for acid-fast smear, culture and PCR has the highest yield.

Cryoglobulins are a useful low-cost screen.

- ▶ **Yield of invasive tests:** bone-marrow biopsy 15–25% (higher in HIV); liver biopsy 10–15% — pursue any abnormal finding aggressively (rash → skin biopsy; node → excision biopsy + culture).

Imaging — role of 18F-FDG-PET/CT

- ▶ **18F-FDG-PET/CT is the pivotal functional imaging test** when PDC-guided tests are unrevealing. FDG accumulates in high-glycolysis tissue — **malignant cells and activated leukocytes** — so it images infection, sterile inflammation **and** malignancy (an advantage in FUO, where all three are possible). It localises the metabolic focus to direct biopsy/culture.
- ▶ **Diagnostic yield ~50%** (Harrison meta-analyses); CMDT cites yields of **84–98%** for underlying cause. Perform it **during active inflammation** (raised CRP/ESR or while febrile) for best yield; **postpone glucocorticoids** until after the scan (they rapidly quench FDG uptake in vasculitis and lymphoma).
- ▶ **Alternatives** when PET/CT is unavailable: **67Ga-citrate scintigraphy** (yield ~21–54%) or **111In-/99mTc-labelled leukocyte scintigraphy** (~8–31%); whole-body MRI is a promising emerging option.
- ▶ **Giant cell arteritis** is found in up to 17% of elderly FUO patients; PET/CT detects large-vessel involvement, but **temporal artery biopsy is still recommended in patients ≥55 years** (small-calibre temporal vessels and high cerebral FDG can confound PET).

Treatment, prognosis and the role of therapeutic trials

- ▶ **Treat the established cause** — empirical therapy is generally *avoided*; it can mask infection/lymphoma and abolish culture yield. **Empirical therapy is justified only when the patient is haemodynamically unstable, septic, neutropenic or deteriorating**, or with strong suspicion of TB or sight-threatening GCA.
- ▶ **Therapeutic trials** (used selectively): antituberculous therapy (reassess at **6 weeks** — no response argues against TB); NSAIDs (often dramatic in Still's disease); **colchicine** (prevents FMF and recurrent pericarditis attacks); glucocorticoids (impressive in **GCA/PMR**, but only after lymphoma/infection excluded); **IL-1 inhibition with anakinra** (recombinant IL-1Ra blocking IL-1 α and IL-1 β) for autoinflammatory FUO with serositis, high ferritin and high CRP.
- ▶ **Prognosis is favourable** in undiagnosed FUO: fever resolves spontaneously in ~75% of undiagnosed patients; long-term mortality is $\leq 8\%$. A **normal PET/CT predicts spontaneous resolution**. A **second opinion at an FUO expert centre** yields a diagnosis in over half of previously unexplained cases.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Diagnostic algorithm for FUO** (flow chart): *Fever* $\geq 38.3^{\circ}\text{C}$ + *illness* ≥ 3 weeks + *immunocompetent* → **History + examination + obligatory investigations** → *Stop antibiotics/glucocorticoids; exclude thermometer manipulation and drug fever* → branch: **PDCs present** → guided tests → diagnosis; **PDCs absent/misleading** → cryoglobulins + fundoscopy → **^{18}F -FDG-PET/CT** → *Abnormal* → confirm by biopsy/culture; *Normal* → repeat history/examination, PDC-driven invasive testing → *Stable* → follow up for new PDCs / NSAID vs *Deteriorating* → further tests / therapeutic trial.
- ▶ **Etiologic pie/box with labels**: **Infections, Noninfectious inflammatory diseases (NIIDs), Malignancy, Miscellaneous, Undiagnosed** — annotated with the geographic contrast (TB-rich Asia vs NIID-rich West).

Clinical / Diagnostic significance

- ▶ The single highest-value manoeuvre is the **repeated, meticulous history and examination** to extract PDCs — FUO is usually an atypical presentation of a *common* disease.
- ▶ **Tuberculosis (especially miliary/extrapulmonary)** is the most important treatable infectious cause in India and the tropics; a negative TST/IGRA does **not** exclude it.
- ▶ **Giant cell arteritis** must be actively sought in any elderly FUO with raised ESR/CRP, headache or visual symptoms — it is treatable and sight-threatening.
- ▶ Always re-examine for **endocarditis (including culture-negative/HACEK), occult abscess, lymphoma and drug fever** — the four “must-not-miss” recurring culprits.
- ▶ Discontinuing antibiotics/steroids and timing PET/CT to active inflammation materially change diagnostic yield.

High-yield exam pointers

- ▶ **Petersdorf–Beeson 1961**: ≥ 3 weeks, fever $\geq 38.3^{\circ}\text{C}$ (101°F) $\times 2$, undiagnosed after **1 week inpatient** evaluation.
- ▶ Modern definition adds a **mandatory minimum workup** and excludes the **immunocompromised**; IUO = FUO with a *normal temperature*.
- ▶ **Four categories**: classic, nosocomial, neutropenic ($<500/\mu\text{L}$), HIV-associated (4 wks OP / 3 days IP).
- ▶ Five etiologic classes: **infection, malignancy, NIID/autoimmune, miscellaneous, undiagnosed** (~50%).
- ▶ **Lymphoma** = commonest malignant cause; **TB/endocarditis** = commonest infective causes; **GCA/Still's/SLE/sarcoid** lead the NIIDs.
- ▶ **^{18}F -FDG-PET/CT** is the key functional scan; do it during active inflammation; hold steroids until after.

- ▶ **Drug fever** resolves within ~72 h of stopping the culprit; suspect with eosinophilia/DRESS.
- ▶ **Empirical therapy is the exception** (instability, neutropenia, suspected TB, GCA with visual loss); most undiagnosed FUO resolves spontaneously, mortality ≤8%.

SOURCE & COVERAGE

- ▶ **Harrison's Principles of Internal Medicine, 22e** — “Fever of Unknown Origin”; and “Fever” (definition, fever vs hyperthermia, pyrogenic cytokines).
- ▶ **CMDT 2026** — “Common Problems in Infectious Diseases & Antimicrobial Therapy: Fever of Unknown Origin” (categories, age/duration considerations, laboratory/imaging/biopsy yields, current management).
- ▶ *Coverage note:* The spec lists no dedicated subspecialty textbook for this topic; the Durack–Street four-category framework is named per standard internal-medicine teaching (Harrison 22e details the classic/IUO definitions and the structured PET/CT-based approach; CMDT 2026 supplies the explicit nosocomial/neutropenic/HIV thresholds). All numbers, eponyms and criteria were verified against these chapters.

Rationale, pre-requisites and contraindications to short course MDR TB regimen. Name the drugs and the duration of use

Asked in: Paper II May 2025 — RGUHS MD General Medicine

Definition / Introduction — Multidrug-resistant tuberculosis (MDR-TB) is disease caused by a strain of *M. tuberculosis* resistant at least to **isoniazid and rifampin**, the two most potent first-line bactericidal drugs; rifampin-resistant TB (RR-TB) is treated identically. A **short-course MDR-TB regimen** is an all-oral course of **6–9 months** that has now replaced the older 18–24-month, injectable-containing regimens. The flagship is the **6-month BPaLM regimen** (bedaquiline, pretomanid, linezolid, moxifloxacin), recommended by WHO since 2022 and incorporated into the 2024 guidance for MDR/RR-TB.

Resistance categories that frame the regimen choice

Term	Resistance pattern
RR-TB	Resistance to rifampin (managed as MDR)
MDR-TB	Resistance to isoniazid + rifampin
Pre-XDR-TB	MDR/RR-TB plus resistance to any fluoroquinolone

Term	Resistance pattern
XDR-TB	MDR-TB + fluoroquinolone resistance + resistance to ≥1 other Group A drug (bedaquiline or linezolid)

- ▶ India alone carries ~27% of the global MDR/RR-TB burden; resistance arises by spontaneous point mutations (*rpoB* → rifampin in 95%; *katG/inhA* → isoniazid; *gyrA/gyrB* → fluoroquinolones), and almost always follows effective **monotherapy** or poor adherence.

Rationale for a short-course, all-oral regimen

- ▶ **Traditional regimens were unacceptable:** ≥18–24 months, dominated by toxic injectable agents (kanamycin, capreomycin, amikacin) causing **ototoxicity and nephrotoxicity**, with poor tolerability, high default rates and cure in only ~50–60%.
- ▶ **Evidence base for shortening:** a 2018 individual-patient meta-analysis of >12,000 patients linked **better outcomes to linezolid, bedaquiline, clofazimine, carbapenems and later-generation fluoroquinolones**, and **worse outcomes to kanamycin and capreomycin** — which were therefore dropped.
- ▶ **Landmark trials:** the STREAM-1 trial validated a 9–12-month shorter (“Bangladesh”) regimen (~90% success); Nix-TB and ZeNix established **BPaL** (bedaquiline–pretomanid–linezolid, ~89% favourable outcomes) for highly resistant TB and showed **linezolid 600 mg** caused far fewer adverse events than 1200 mg; TB-PRACTECAL proved the 24-week **BPaLM** regimen **non-inferior** with **fewer serious adverse events** than the 9–20-month standard of care; **BEAT-Tuberculosis** validated **BDLLfxCfz**.
- ▶ **Programmatic advantages:** all-oral therapy removes painful injections, **lowers pill burden**, improves adherence and completion, shortens the period of infectiousness (interrupting transmission), is more **cost-effective**, and reduces amplification of further resistance.

Name the drugs and the duration of use

WHO/Harrison now endorse **four approaches** to MDR/RR-TB; all-oral regimens are preferred, and the choice depends on disease severity, drug-resistance pattern and prior treatment.

Regimen	Component drugs	Duration
BPaLM (preferred)	Bedaquiline + Pa (pretomanid) + Linezolid 600 mg + Moxifloxacin	6 months (drop moxifloxacin → BPaL if fluoroquinolone resistance documented)
BDLLfxCfz	Bedaquiline + Delamanid + Linezolid 600 mg + Levofloxacin + Clofazimine	6 months (Lfx or Cfz may be omitted per FQ-DST; usable in children & pregnancy)
9-month all-oral	BLMZ, or BLLfxCfzZ, or BDLLfxZ	9 months (when FQ-susceptible, no prior 2nd-line exposure)

Regimen	Component drugs	Duration
Longer individualised	Group A (Lfx/Mfx, bedaquiline, linezolid) + ≥1 Group B (clofazimine, cycloserine/terizidone) ± Group C	≥18–20 months (XDR-TB / complex resistance)

Component drug detail (BPALM):

- ▶ **Bedaquiline** — diarylquinoline; inhibits mycobacterial ATP synthase; dose **400 mg once daily** ×2 weeks, then **200 mg thrice weekly** for ~6 months; CYP3A4-metabolised, very long $t_{1/2}$ (>14 days); carries an FDA **black-box warning** (QT prolongation, mortality signal).
- ▶ **Pretomanid** — nitroimidazole **prodrug** inhibiting mycolic-acid synthesis; **200 mg once daily**; main risk **hepatotoxicity**.
- ▶ **Linezolid** — oxazolidinone binding the 50S ribosome; **600 mg once daily** (better tolerated than 1200 mg); toxicities — **myelosuppression, optic and peripheral neuropathy, lactic acidosis, serotonin syndrome** (weak MAOI).
- ▶ **Moxifloxacin** — fluoroquinolone inhibiting DNA gyrase/topoisomerase IV; **400 mg once daily** in BPALM; QT prolongation.
- ▶ (BDLLfxCfz adds **delamanid 100 mg twice daily** and **clofazimine** — a riminophenazine causing reversible **orange–brown skin/fluid discolouration**, $t_{1/2}$ ~70 days.)

Pre-requisites before starting a short-course regimen

- ▶ **Confirmed RR/MDR-TB** by rapid molecular DST (e.g., Xpert MTB/RIF) — rifampin resistance at minimum.
- ▶ **Baseline fluoroquinolone DST** — mandatory; decides whether moxifloxacin/levofloxacin is retained (it directs BPALM vs BPAL, and BDLLfxCfz composition).
- ▶ **No prior exposure (or <1 month)** to the regimen's novel drugs (bedaquiline, pretomanid, linezolid for BPALM; bedaquiline, delamanid, linezolid for BDLLfxCfz) — unless susceptibility is confirmed.
- ▶ **Eligible age & disease form**: BPALM for patients ≥14 years, all forms **except** disseminated, CNS and osteoarticular TB (BDLLfxCfz extends to children and pregnant/breastfeeding women).
- ▶ **Baseline cardiac assessment**: ECG/QTc and serum electrolytes (K^+ , Mg^{2+} , Ca^{2+}) — patients on QT-prolonging drugs (bedaquiline, delamanid, clofazimine, fluoroquinolones) need on-treatment ECG monitoring.
- ▶ **Baseline organ-function screen**: LFTs (hepatotoxic drugs), **full blood count** (linezolid marrow suppression), **visual acuity & colour vision** (linezolid optic neuritis), renal function, **HIV test** and **pregnancy test**.
- ▶ **Informed consent** and enrolment in active TB drug-safety monitoring (aDSM).

- ▶ **Adherence support** — directly observed therapy (DOT) or **video-observed therapy (VOT)**, social/nutritional support, plus pyridoxine where neuropathy risk is high.

Contraindications and cautions

- ▶ **Pregnancy and breastfeeding** — a contraindication to BPaLM (pretomanid safety data incomplete); use BDLLfxCfz or a bedaquiline-based 9-month/longer regimen instead (avoid thioamides, bedaquiline and delamanid where data are lacking in pregnancy).
- ▶ **Disseminated, CNS (meningeal) and osteoarticular TB** — excluded from BPaLM; require longer, individualised therapy.
- ▶ **QTc >500 ms or a history of ventricular arrhythmia** — do **not** give the QT-prolonging agents (bedaquiline, delamanid, clofazimine, fluoroquinolones).
- ▶ **Significant prior exposure (>1 month)** to, or documented resistance to, the regimen's core drugs.
- ▶ **Age <14 years** for BPaLM (choose a child-appropriate regimen).
- ▶ **Severe drug intolerance/allergy** to a core agent, and clinically significant **drug–drug interactions** (e.g., strong CYP3A4 inducers lowering bedaquiline, serotonergic drugs with linezolid).
- ▶ Injectable agents **kanamycin and capreomycin must not be used**; amikacin is reserved (≥ 18 years, with audiometry) only when oral options fail.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Resistance ladder (vertical steps)**: label RR-TB (*rifampin-R*) → MDR-TB (*isoniazid + rifampin-R*) → Pre-XDR (MDR + *fluoroquinolone-R*) → XDR (MDR + FQ-R + *bedaquiline/linezolid-R*).
- ▶ **BPaLM 6-month timeline (horizontal bar)**: labels — *Baseline (Day 0): DST + FQ-DST, ECG/QTc, LFT, CBC, vision, HIV, pregnancy test*; four parallel drug bars — *Bedaquiline 400 mg OD ×2 wk → 200 mg thrice-weekly, Pretomanid 200 mg OD, Linezolid 600 mg OD, Moxifloxacin 400 mg OD (omit if FQ-resistant → BPaL)*; bracket 26 weeks (*extend if culture-positive at month 4*); footer *Monthly monitoring: sputum culture, ECG, CBC, vision & neuro review*.

Clinical / Diagnostic significance

- ▶ **Universal upfront DST**, especially for rifampin and fluoroquinolones, is the single most important determinant of regimen selection and prevents inadvertent under-treatment.
- ▶ **Sputum culture (liquid)** is the standard for monitoring; Xpert MTB/RIF and serial chest X-rays are **not** suitable for response monitoring (they detect non-viable bacilli / lag behind).
- ▶ **QTc surveillance** during treatment is essential because several agents are additively cardiotoxic; correct hypokalaemia/hypomagnesaemia.

- ▶ Linezolid demands monthly FBC, vision and neurological review; dose reduction or interruption mitigates marrow suppression and optic/peripheral neuropathy.
- ▶ Persistent culture positivity at month 4 (or extensive cavitation) flags slow responders who may need **regimen extension or re-evaluation for amplified resistance** and surgery in localised disease.

High-yield exam pointers

- ▶ MDR-TB = resistance to at least isoniazid + rifampin; XDR = MDR + fluoroquinolone + a second Group A drug (bedaquiline/linezolid).
- ▶ BPaLM = Bedaquiline + Pretomanid + Linezolid (600 mg) + Moxifloxacin for 6 months — the preferred short-course regimen; becomes BPaL if fluoroquinolone-resistant.
- ▶ Bedaquiline 400 mg OD ×2 wk then 200 mg thrice-weekly; linezolid 600 mg OD; pretomanid 200 mg OD; moxifloxacin 400 mg OD.
- ▶ **Pre-requisites:** confirmed RR/MDR-TB, baseline FQ-DST, no prior drug exposure, age ≥14, baseline ECG/LFT/CBC/vision, informed consent, aDSM.
- ▶ **Contraindications:** pregnancy/breastfeeding (BPaLM), CNS/osteoarticular/disseminated TB, QTc >500 ms, prior exposure/resistance, age <14.
- ▶ **All-oral and injectable-free** — kanamycin/capreomycin abandoned for worse outcomes and toxicity.
- ▶ **Group A** = levofloxacin/moxifloxacin, bedaquiline, linezolid (always in longer regimens); **Group B** = clofazimine, cycloserine/terizidone.
- ▶ Treatment success with short-course all-oral regimens approaches ~**89–90%** (Nix-TB/ZeNix/TB-PRACTECAL).

SOURCE & COVERAGE

- ▶ **Harrison's Principles of Internal Medicine, 22e** — “Tuberculosis” (drug-resistant TB definitions, the four WHO approaches, BPaLM/BDLLfxCfz/9-month regimens, Group A/B/C drugs, pre-requisites, contraindications and monitoring) and “Antimycobacterial Agents” (drug mechanisms, doses, adverse effects; STREAM-1, Nix-TB, ZeNix, TB-PRACTECAL trial detail).
- ▶ **CMDT 2026** — “Pulmonary Disorders” (current management of drug-resistant TB; isoniazid- and pyrazinamide-mono-resistant regimens; bedaquiline–pretomanid–linezolid reference).

Coverage note: The corpus fully supports the regimens, drugs, doses, pre-requisites and contraindications above. The specific WHO operational rule that BPaLM may be **extended from 26 to 39 weeks** in patients still culture-positive at month 4 is standard WHO programmatic

guidance and is stated here as such, as the precise extension figure is not given verbatim in the chapters read.

Rhino-Orbital-Cerebral Mucormycosis

Asked in: Paper II Nov 2022 — RGUHS MD General Medicine

Definition / Introduction — Mucormycosis is a group of life-threatening, highly angioinvasive and relentlessly progressive infections caused by fungi of the order **Mucorales** (subphylum *Mucoromycotina*). The **rhino-orbital-cerebral (ROCM)** form is the most common presentation worldwide and classically affects patients with **uncontrolled diabetes mellitus, especially diabetic ketoacidosis (DKA)**. It begins in the paranasal sinuses and spreads contiguously/haematogenously to the orbit and brain, producing the characteristic black necrotic eschar and cavernous-sinus thrombosis. Mortality remains high; outcome depends on early polyene therapy, aggressive surgical debridement and rapid reversal of the predisposing state.

Etiology and Predisposing Factors

- ▶ The Mucorales comprise **seven families** that cause human disease. ***Rhizopus oryzae and R. delemar** (family *Mucoraceae*) are by far the most common causes. *Apophysomyces elegans* is an important agent in India, and *Mucor irregularis** in China.
- ▶ Mucormycosis incidence is **higher in India than most other countries even before the COVID-19 pandemic**; during the pandemic it occurred commonly as a co-infection in hospitalised COVID-19 patients, driven by high-dose corticosteroids combined with the high background prevalence of diabetes.

Family	Representative genera/species
Mucoraceae	<i>Rhizopus oryzae</i> , <i>R. delemar</i> , <i>R. microsporus</i> , <i>Rhizomucor</i> , <i>Mucor</i> , <i>Actinomucor</i>
Lichtheimiaceae	<i>Lichtheimia</i> (formerly <i>Mycocladius</i> / <i>Absidia</i>)
Cunninghamellaceae	<i>Cunninghamella</i>
Saksenaceae	<i>Saksenaea</i> , <i>Apophysomyces</i>
Mortierellaceae, Thamnidaceae, Syncephalastraceae	<i>Mortierella</i> , <i>Cokeromyces</i> , <i>Syncephalastrum</i>

- ▶ **Key predisposing factors:** uncontrolled diabetes mellitus / DKA (→ ROCM specifically); defects in phagocytic function (**neutropenia**, high-dose **corticosteroids**); **elevated free iron** (e.g., deferoxamine therapy in iron-overloaded dialysis patients); solid-organ or **haematopoietic stem-cell transplant (HSCT)**; haematological malignancy.

- ▶ Patients on **itraconazole** or **voriconazole** prophylaxis may be at increased risk; breakthrough disease is also reported with **posaconazole**, **isavuconazole** or **echinocandin** prophylaxis.
- ▶ *Important caveat:* the **majority of diabetics presenting with mucormycosis are NOT acidotic**, and many have **no prior diagnosis of diabetes** — presentation may be the first recognition of **hyperglycaemia** (often unmasked by recent glucocorticoids).

Pathogenesis — the Iron / GRP78 / CotH Axis

- ▶ The Mucorales are ubiquitous environmental fungi; infection follows inhalation of spores into the sinuses in a susceptible host.
- ▶ **Free iron is the central virulence determinant.** In DKA, acidosis causes **dissociation of iron from sequestering proteins**, enhancing fungal survival and virulence. The ketoacid β -**hydroxybutyrate** upregulates host and fungal receptors mediating adherence and tissue penetration.
- ▶ **Deferoxamine** acts as a fungal **xenosiderophore** — it chelates iron for the host but delivers it directly to the Mucorales, historically causing rapidly fatal disseminated disease.
- ▶ Even without acidosis, **hyperglycaemia** promotes infection by ≥ 4 mechanisms: (1) **hyperglycation of iron-sequestering proteins** (disrupts iron sequestration); (2) **upregulation of GRP78**, a mammalian receptor that binds Mucorales and enables tissue penetration; (3) poorly characterised **defects in phagocyte function**; (4) enhanced expression of **CotH**, a Mucorales-specific invasin that mediates host-cell invasion by binding GRP78.
- ▶ The hallmark is **angioinvasion** $\rightarrow$ **vascular thrombosis** $\rightarrow$ **tissue infarction and necrosis**, which also impairs antifungal drug delivery to the infected site.

Clinical Features and Stage-wise Progression of ROCM

- ▶ Patients with **diabetes/DKA** typically develop the **rhino-orbital-cerebral form** and only rarely pulmonary or disseminated disease.
- ▶ **Early symptoms are non-specific:** eye or facial pain, **facial numbness**, followed by **conjunctival suffusion**, periocular swelling and **blurry vision**.
- ▶ Periorbital skin takes on a **dusky, subacute appearance** — in contrast to the acute, bright-red periocular changes of **bacterial orbital cellulitis**.
- ▶ **Fever may be absent in up to half** of cases; the WBC count is usually elevated as long as marrow function is intact.
- ▶ **Sino-orbital spread:** untreated infection spreads from the **ethmoid sinus** $\rightarrow$ **orbit**, causing compromise of extraocular-muscle function, **proptosis** and **chemosis**.
- ▶ **Intracranial / cavernous-sinus spread:** from the orbit the fungus extends contiguously or haematogenously to the **frontal lobe**, and via venous drainage to the **cavernous sinus**. **Contralateral eye involvement with bilateral proptosis, chemosis, vision loss and ophthalmoplegia is ominous and suggests cavernous-sinus thrombosis.**

- ▶ **Local tissue evolution:** infected tissue may look **normal** initially (hence “blind” biopsy of normal-appearing sinus is warranted when suspicion is high) → **erythematous** (± oedema) → **violaceous** → **black necrotic eschar**. Extension into the mouth produces painful necrotic ulceration of the **hard palate** — a *late* finding indicating extensive, well-established disease.
- ▶ *Note:* progression is **variable, not always fulminant** — death may occur in days, or progression may take months, depending on host immunity, inoculum and species virulence.

Diagnosis

- ▶ **A high index of suspicion is essential** — autopsy series show **up to half of cases are diagnosed only post-mortem**.
- ▶ **Definitive diagnosis:** positive culture from a **sterile site** (needle aspirate, tissue biopsy, pleural fluid) or histopathological evidence of **invasive disease**. Biopsy with histopathology is the most sensitive and specific modality.
- ▶ **Characteristic histology:** broad/wide ($\geq 6\text{--}30\ \mu\text{m}$), thick-walled, **ribbon-like, aseptate** (pauciseptate) hyphae that **branch at right angles** ($\approx 90^\circ$). Best stained with PAS or H&E; methenamine silver may not stain optimally.

Feature	Mucorales	Aspergillus / Fusarium / Scedosporium
Septation	Aseptate / pauciseptate	Septate
Hyphal width	Broad, ribbon-like ($6\text{--}30\ \mu\text{m}$)	Thin
Branching angle	Wide, $\sim 90^\circ$ (right angle)	Acute ($\sim 45^\circ$)

- ▶ **Culture caveats:** positive in **<50%** of cases — long filamentous hyphae are killed by tissue **homogenisation**, so alert the lab and place **minced tissue sections** (not homogenate) on media; incubate at both **room temperature and 37°C** . Mucorales are not fastidious and grow within **48–96 h**. Species identification requires culture (not histology).
- ▶ **Imaging:** sinusitis on CT/MRI is often **indistinguishable from bacterial sinusitis**, and bony erosion into the orbit is **rarely seen on CT even when clinically present**. MRI is **more sensitive** ($\sim 80\%$) for orbital and CNS disease. Imaging routinely **underestimates** extent — high-risk patients should undergo **endoscopy and/or surgical exploration with biopsy**.
- ▶ **PCR of Mucorales-specific targets** is useful but **not FDA-approved**. Because therapy must often start empirically, **begin a lipid polyene as soon as suspicion is reasonable** while confirmation is awaited.

Differential Diagnosis

- ▶ **Other invasive moulds:** aspergillosis, scedosporiosis, fusariosis, dematiaceous (brown-pigmented) fungi — distinguishing them matters because **polyenes treat Mucorales whereas**

expanded-spectrum triazoles treat most septate moulds, and voriconazole actually exacerbates mucormycosis.

- ▶ **Entomophthoromycoses** (*Basidiobolus*, *Conidiobolus*) — histologically similar but distinguished by culture; also treated with polyenes, so urgent differentiation is unnecessary.
- ▶ **Bacterial orbital cellulitis / cavernous-sinus thrombosis** (most commonly *Staphylococcus aureus*, also streptococci and gram-negatives).
- ▶ ***Klebsiella rhinoscleromatis*** (indolent facial rhinoscleroma).
- ▶ ***Tolosa-Hunt syndrome** — *painful ophthalmoplegia, ptosis, headache and cavernous-sinus inflammation; lack of progression** helps distinguish it from mucormycosis.

Treatment

- ▶ **Four pillars of management:** (1) **early initiation** of antifungal therapy; (2) **surgical debridement** of all necrotic tissue when feasible; (3) **rapid reversal of predisposing factors**; (4) **treat the underlying malignancy without waiting** to finish antifungals.
- ▶ **Surgery:** because thrombosis/necrosis impairs drug penetration, **debridement is an independent predictor of favourable outcome**; intra-operative frozen sections help delineate infected margins. Use a *moderated* approach — debride to the extent it is safe.
- ▶ **Reverse the host defect:** correct **hyperglycaemia and acidosis** (sodium bicarbonate improved survival in DKA mice), **taper corticosteroids**, and **avoid iron** — use a **conservative RBC-transfusion policy** (haemolysis liberates free iron).

Line	Drug	Dose	Notes
First-line	Liposomal AmB (LAmB)	5–10 mg/kg/day	Preferred for brain disease — best CNS penetration; consider 7.5–10 mg/kg/day for CNS, but no benefit above 10 mg/kg/day (autoinduction lowers levels)
First-line	AmB lipid complex (ABLC)	5 mg/kg/day	Less nephrotoxic than deoxycholate; possibly less effective than LAmB for CNS
First-line	AmB deoxycholate	1.0–1.5 mg/kg/day	Cheap, FDA-approved, but highly toxic and poor CNS penetration
Second-line / salvage	Isavuconazole	200 mg (372 mg isavuconazonium sulfate) load q8h ×6, then once daily	FDA-approved; rational empirical choice when septate-mould vs Mucorales is unresolved

Line	Drug	Dose	Notes
Second-line / salvage	Posaconazole	200 mg four times daily	Salvage only; lower blood levels than isavuconazole
Combination	Echinocandin + lipid polyene	Standard echinocandin doses	Synergy in murine disease; retrospective benefit in ROCM. Do NOT escalate echinocandin ≥ 3 mg/kg/day (paradoxical loss of benefit)

- ▶ **Primary therapy must be a polyene** except perhaps in mild, surgically excised, isolated suprafacial cutaneous disease in an immunocompetent host.
- ▶ **Deferasirox** is fungicidal *in vitro* and synergistic with LAmB in DKA mice; however human trial evidence is limited (see Coverage note).

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Coronal section of face/skull showing ROCM spread** — Labels: *ethmoid/maxillary sinus (primary focus), nasal turbinate with black eschar, orbit with proptosis & chemosis, extraocular muscles, optic nerve, cavernous sinus (thrombosis), internal carotid artery, frontal lobe extension, hard-palate necrotic ulcer.*
- ▶ **Histopathology of Mucorales** — Labels: *broad ribbon-like aseptate hypha (6–30 μ m), right-angle (90°) branching, thrombosed blood vessel with intravascular hyphae (angioinvasion), surrounding tissue infarction.*

Clinical / Diagnostic significance

- ▶ In any **diabetic with sinusitis + facial/orbital pain, numbness, or proptosis**, suspect ROCM and act emergently — delay is lethal.
- ▶ **Hyperglycaemia with new sinusitis and possible orbital extension** warrants suspicion even with no known history of diabetes.
- ▶ **Bilateral proptosis/ophthalmoplegia** = **cavernous-sinus thrombosis**, a neurosurgical/ophthalmic emergency.
- ▶ Diagnostic workup: **urgent ENT endoscopy + biopsy/KOH + histopathology + fungal culture, MRI brain/orbit/sinuses**, glycaemic and acid-base assessment.
- ▶ **Never give voriconazole** if mucormycosis is in the differential — it worsens disease.
- ▶ Management is **multidisciplinary** (Internal medicine/Endocrine, ENT, Ophthalmology, Neurosurgery, Microbiology) with combined medical + surgical therapy.

High-yield exam pointers

- ▶ **ROCM** = most common form worldwide; diabetes/DKA is the classic host; India has disproportionately high incidence (further amplified by COVID-19 + steroids).
- ▶ ***Rhizopus oryzae/R. delemar** = *commonest agents; aseptate, broad, ribbon-like hyphae, right-angle branching*.*
- ▶ Central mechanism = **free iron + GRP78/CotH-mediated angioinvasion**; **deferoxamine** is a risk factor (xenosiderophore).
- ▶ Hallmark sign = **black necrotic eschar** (nasal/palatal); periorbital skin is **dusky**, not bright-red.
- ▶ **MRI > CT** for orbital/CNS extent; **culture positive in <50%** — alert lab, do not homogenise tissue; **PCR not FDA-approved**.
- ▶ **First-line** = **liposomal amphotericin B 5–10 mg/kg/day + early surgical debridement + control of diabetes/acidosis/iron**.
- ▶ **Isavuconazole and posaconazole** are second-line/salvage; **avoid voriconazole**.
- ▶ Disseminated disease mortality **>90%**; mucormycosis-related **necrotising fasciitis ~80%**.

SOURCE & COVERAGE

Harrison's Principles of Internal Medicine, 22e (2025) — **Ch 224 “Mucormycosis”** (Spellberg & Ibrahim), incl. Tables 224-1 (taxonomy) and 224-2 (antifungal options) and Fig. 224-1 (histopathology).

Coverage note: The provided chapter text is **truncated at the start of the adjunctive-deferasirox phase-2 trial sentence**, so the final human trial outcome (the *DEFEAT-Mucor*-type result showing no benefit/possible harm of adjunctive deferasirox) and any concluding outcome/mortality figures for ROCM specifically were not in the supplied text and are therefore stated only as far as the text supports. **Hyperbaric oxygen** as adjunctive therapy is *not* mentioned in the provided text and has been deliberately omitted to avoid fabrication.

Strongyloides Hyperinfection Syndrome

Asked in: Paper II May 2025 — RGUHS MD General Medicine

Definition / Introduction — *Strongyloides stercoralis* is a soil-transmitted intestinal nematode that is **unique among helminths** (along with *Capillaria*) in its ability to complete its entire life cycle and replicate within the human host through **autoinfection**, allowing infection to persist silently for decades. **Hyperinfection syndrome** is the dangerous acceleration of this autoinfection cycle, with massive multiplication of filariform larvae within the normal migratory route (gut → lungs), triggered by impaired cell-mediated immunity. When larvae spread beyond this route to organs such as the CNS, liver, kidney, skin and peritoneum, the condition is termed **disseminated strongyloidiasis**. It carries a

very high mortality (approaching 100% untreated, ~25% even when treated) and is most often unmasked by glucocorticoid therapy.

Life cycle & pathophysiology (basis of hyperinfection)

- **Acquisition:** filariform larvae in faecally-contaminated soil penetrate skin/mucosa → bloodstream → lungs → ascend bronchial tree → swallowed → mature into adult worms embedded in proximal small-bowel mucosa.
- The minute (1–2 mm) **parthenogenetic adult females** produce eggs that hatch in the mucosa into **rhabditiform larvae** (~250 µm, short buccal cavity).
- **Autoinfection:** some rhabditiform larvae transform *within the bowel* into invasive **filariform larvae** (~450 µm) that penetrate the colonic wall or perianal skin and re-enter the circulation — perpetuating internal reinfection without fresh exogenous exposure.
- This autoinfection cycle is normally **restrained by intact cell-mediated (Th2) immunity and eosinophils**. When this restraint fails, larval numbers amplify exponentially → **hyperinfection**, and disrupted gut mucosa allows **translocation of enteric gram-negative bacteria** → bacteraemia/sepsis.

Risk factors / Predisposing conditions

Category	Specific predisposing factors
Drugs (greatest risk)	High-dose / prolonged corticosteroids (the single most important trigger); other immunosuppressants — calcineurin inhibitors, chemotherapy, biologics
Viral / retroviral	HTLV-1 infection (classic, strong association — shifts immunity away from protective Th2); AIDS/HIV
Haematological / malignancy	Haematologic malignancies (lymphoma, leukaemia); cytotoxic chemotherapy
Transplantation	Solid-organ and haematopoietic stem-cell transplantation (donor-derived transmission described)
Host / nutritional	Malnutrition, alcohol use disorder, diabetes, chronic debilitating illness, hypogammaglobulinaemia
Epidemiological exposure	Residence in / travel to Southeast Asia, sub-Saharan Africa, Brazil , endemic SE United States; immigrants, refugees, military personnel — <i>even decades earlier</i> (latent autoinfection)

- ▶ **Exam pearl:** Strongyloides hyperinfection is the classic helminth disease **precipitated by steroids** — eosinophilia is *not* protective once steroids blunt the immune response, and (importantly) eosinophilia is often **suppressed by the very steroids** that precipitate the syndrome.

Clinical presentation

Uncomplicated (chronic) strongyloidiasis — often asymptomatic or:

- ▶ **Cutaneous:** recurrent **urticaria** (often buttocks); **larva currens** — a *pathognomonic*, pruritic, raised, serpiginous track that advances rapidly (up to **10 cm/h**).
- ▶ **GI:** mid-epigastric pain mimicking peptic ulcer (aggravated by food), nausea, watery diarrhoea, bloating, occult GI bleeding, weight loss.
- ▶ **Eosinophilia** that fluctuates over time; pulmonary symptoms rare.

Hyperinfection / disseminated disease — overwhelming, multi-system and often fulminant:

System	Manifestations
Gastrointestinal	Severe colitis/enteritis, malabsorption, paralytic ileus, intestinal obstruction , perforation, massive GI haemorrhage
Pulmonary	Pneumonitis, cough, wheeze, haemoptysis , diffuse infiltrates/ARDS, respiratory failure; larvae/eggs in sputum
Bloodstream	Recurrent gram-negative bacteraemia / polymicrobial sepsis from enteric flora translocation — a frequent presenting feature
CNS	Gram-negative (E. coli/enteric) meningitis , brain abscess; larvae may be seen in CSF
Skin	Widespread purpuric/petechial eruption, “thumbprint” periumbilical purpura from migrating larvae
Other	Hepatic, renal, peritoneal involvement; progression to shock and death

- ▶ **Red flag combination:** an immunosuppressed (especially steroid-treated) patient with **recurrent gram-negative sepsis or enteric meningitis + unexplained ileus/abdominal signs + pulmonary infiltrates**, particularly with a remote tropical exposure, is hyperinfection until proven otherwise.

Diagnosis / Investigations

- ▶ **Stool microscopy** — demonstrates motile **rhabditiform larvae** (not eggs); short buccal cavity distinguishes them from hookworm larvae. *Single stool sensitivity is low (~30%; detects only ~one-third of uncomplicated cases)* → request **serial (3–7) samples**.

- ▶ **Concentration / culture techniques** — agar-plate culture and Baermann concentration markedly raise sensitivity.
- ▶ **Duodenal sampling** — aspiration or biopsy of duodenojejunal contents (string test) when stools repeatedly negative.
- ▶ **Serology (ELISA)** — sensitive (~90% sensitivity/specificity, CDC assay) for *uncomplicated/chronic* infection; cross-reacts with other helminths. **Indicated to screen before immunosuppression / transplantation**, especially with eosinophilia or endemic exposure.
- ▶ **PCR / molecular assays** — increasing sensitivity and species specificity.
- ▶ **In hyperinfection:** larval burden is huge, so a **single stool exam is usually positive**; filariform larvae are readily found in **stool, sputum, BAL fluid, CSF and surgical drainage fluid** — i.e. sample the migration sites.
- ▶ **Supportive:** eosinophilia + mild anaemia in chronic disease; **eosinophilia is frequently ABSENT in hyperinfection (poor prognostic sign)**; hypoproteinaemia, deranged LFTs, and diffuse pulmonary infiltrates on imaging; blood cultures growing **enteric gram-negative organisms**.

Treatment

- ▶ **Drug of choice** — Ivermectin, more effective than albendazole:
 - *Uncomplicated:* ivermectin 200 µg/kg/day orally for 1–2 days.
 - *Alternative:* albendazole 400 mg orally twice daily for 3 days (less effective).
- ▶ **Hyperinfection / disseminated disease:**
 - Prolonged ivermectin continued daily until at least 14 days after stool/sputum become and remain larva-negative.
 - In immunocompromised hosts, **repeat the ivermectin course ~2 weeks after the initial treatment**; with ongoing immunosuppression, **regular suppressive dosing (e.g. monthly ivermectin)** may be needed.
 - When oral route impossible (ileus): ivermectin has been given **per rectum** or **parenterally** (veterinary preparation under single-patient expanded-access protocols).
- ▶ **Adjuncts:** broad-spectrum antibiotics for concurrent gram-negative sepsis/meningitis; supportive care for ARDS, ileus, fluid/electrolyte derangement; **taper/withdraw glucocorticoids and other immunosuppression** wherever feasible.
- ▶ **Even asymptomatic infection must be treated** because of the lifelong risk of fatal hyperinfection — eradication is the goal (monitor falling eosinophil count and antibody titre as response markers).

Prevention / screening (high-yield):

- ▶ Screen all at-risk patients (serology ± stool) **BEFORE** starting corticosteroids, chemotherapy, biologics, or transplantation, especially with any history — even remote — of residence in an endemic area.
- ▶ **Presumptive ivermectin treatment** is warranted in seropositive (or strongly exposed) patients even when stool examination is negative.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Diagram 1 — Life cycle of Strongyloides stercoralis** (labels):* filariform larva penetrates skin → bloodstream → lungs / alveoli → ascends trachea, swallowed → adult female in small-bowel mucosa (parthenogenesis) → eggs hatch → rhabditiform larva (~250 µm); *branch the three fates — (a) Direct/Indirect free-living cycle in soil, (b) Autoinfection (rhabditiform → filariform → perianal skin/colonic wall → recirculate), and (c) Hyperinfection/Dissemination (with immunosuppression → massive filariform larvae → lungs, CNS, liver, kidney, skin + gram-negative sepsis*).*
- ▶ **Diagram 2 — “Autoinfection → Hyperinfection → Dissemination” arrow ladder,** annotated with the immune trigger (**steroids / HTLV-1 / impaired CMI**) at the step where control is lost.

Clinical / Diagnostic significance

- ▶ Classic “**steroid-unmasked**” parasitosis — always exclude/treat Strongyloides before immunosuppressing a patient from an endemic area.
- ▶ **Recurrent enteric gram-negative bacteraemia or E. coli meningitis** in an immunosuppressed host should prompt a search for Strongyloides as the conduit.
- ▶ **Eosinophilia is paradoxically a good sign** (intact immunity); its absence in a deteriorating immunosuppressed patient is ominous.
- ▶ Untreated dissemination is **near-uniformly fatal** — early empirical ivermectin saves lives when suspicion is high.

High-yield exam pointers

- ▶ **Autoinfection** makes Strongyloides the helminth that can persist **for decades** and the only common one to cause **fatal hyperinfection**.
- ▶ **Greatest single risk factor = corticosteroids**; strongest infective co-factor = HTLV-1.
- ▶ **Larva currens** (10 cm/h serpiginous track) is *pathognomonic*; **periumbilical “thumbprint” purpura** suggests dissemination.
- ▶ Stool ova-and-parasite finds **larvae, not eggs**; **single stool ~30% sensitive** → do serial stools + agar-plate culture; serology (ELISA ~90%) for screening.
- ▶ **Hyperinfection:** larvae in sputum/BAL/CSF; **single stool usually positive**; eosinophilia often absent.

- ▶ Ivermectin 200 µg/kg/day is drug of choice; in dissemination continue ≥ 2 weeks after larvae clear and repeat course in the immunosuppressed.
- ▶ Screen + treat before immunosuppression / transplant; treat even asymptomatic carriers.
- ▶ Mortality: ~100% untreated, ~25% treated — outcome hinges on early recognition.

SOURCE & COVERAGE

- ▶ **Harrison's Principles of Internal Medicine, 22e** — “Intestinal Nematode Infections” (Strongyloidiasis section: life cycle, autoinfection/hyperinfection/dissemination, larva currens, HTLV-1 and glucocorticoid risk, diagnosis, ivermectin treatment).
- ▶ **CMDT 2026** — “Protozoal & Helminthic Infections” (Strongyloidiasis: risk factors, mortality figures ~100%/25%, ELISA sensitivity, screening before immunosuppression, ivermectin regimens for hyperinfection).

Coverage note: The corpus has no dedicated infectious-disease subspecialty textbook in the spec (specialty_books empty); depth is therefore drawn from Harrison 22e + CMDT 2026, which together cover the topic comprehensively. The “thumbprint periumbilical purpura” sign is universally-accepted standard ID teaching included for completeness though not verbatim in the two cited chapters.

Role of CD4 Count in the Management of HIV Infection

Asked in: Paper II May 2019 — RGUHS MD General Medicine

Definition / Introduction — The CD4+ T lymphocyte is the principal target cell of HIV and the central pivot of immune competence; the **absolute CD4 count** (cells/µL) is therefore the single most widely used marker for *staging, prognosis* and *guiding opportunistic-infection (OI) prophylaxis* in HIV. HIV preferentially infects and depletes CD4+ helper T cells (gp120 binds the 55-kDa CD4 molecule plus a co-receptor, CCR5 or CXCR4), so the count is a direct readout of the degree of immunodeficiency. It is complementary to, not a substitute for, the **plasma HIV RNA (viral load)** — the count measures *immune damage already done*, the viral load measures *active replication and treatment response*.

CD4 cell biology — what the count actually measures

- ▶ CD4 is a glycoprotein on **helper (Th) T lymphocytes**, also on monocytes/macrophages and dendritic cells; it is the primary HIV receptor.
- ▶ In an untreated patient the count falls at an **average of ~50 cells/µL per year**; when it crosses **<200/µL** the immunodeficiency is severe enough to expose the patient to OIs and AIDS-defining neoplasms.

- ▶ The count thus serves four management roles: (1) **stage** the disease, (2) **risk-stratify** for specific OIs, (3) decide **start/stop of OI prophylaxis**, and (4) **monitor immune reconstitution** on antiretroviral therapy (ART).

CD4-based CDC staging and the AIDS-defining threshold

The CDC (MMWR 2014) classifies HIV by CD4 count (count takes precedence; percentage used only if count missing) for persons aged ≥ 6 years:

Stage	CD4 count (cells/ μ L)	CD4 percentage
Stage 1	≥ 500	$\geq 26\%$
Stage 2	200–499	14–25%
Stage 3 (AIDS)	< 200	$< 14\%$

- ▶ A diagnosis of AIDS is made in any person ≥ 6 years with HIV and a CD4 $< 200/\mu$ L (Stage 3) or a CD4 percentage $< 14\%$, or who develops an AIDS-defining (stage-3) opportunistic illness regardless of count.
- ▶ The 200/ μ L cut-off is evidence-based: cohort studies show AIDS develops within ~ 3 years in $> 80\%$ of untreated persons whose counts fall below this level.

CD4 count and the spectrum of opportunistic disease

The CD4 count predicts *which* complications are likely, allowing a focused differential at any given count:

Approx. CD4 (cells/ μ L)	Characteristic complications
> 500	Acute retroviral syndrome, persistent generalised lymphadenopathy; later — herpes zoster, vaginal candidiasis, oral hairy leukoplakia, Kaposi sarcoma
200–500	Bacterial pneumonia, pulmonary TB, mucocutaneous candidiasis, ITP
< 200	** <i>Pneumocystis jirovecii</i> pneumonia (PCP), toxoplasmosis, cryptococcosis, coccidioidomycosis, cryptosporidiosis**
< 50	* <i>Disseminated Mycobacterium avium complex (MAC), CMV retinitis, CNS lymphoma, disseminated histoplasmosis*</i>

- ▶ This graded relationship (Harrison Fig. 208-32; CMDT Fig. 36-1) is the basis for using the count to anticipate, prevent and empirically treat OIs.

CD4 thresholds for opportunistic-infection prophylaxis (start / stop)

Decisions on prophylaxis are based on CD4 count, recent viral load and prior OI history (NIH/CDC/IDSA guidelines):

Pathogen	Start primary prophylaxis	First-choice agent	Stop (immune reconstitution)
P. jirovecii (PCP)	CD4 <200/ μ L, CD4 <14%, oropharyngeal candidiasis, or prior PCP	TMP-SMX 1 DS tab daily	CD4 >200/ μ L for $\geq$ 3 months on ART
Toxoplasma gondii	Toxoplasma IgG-positive and CD4 <100/ μ L	TMP-SMX 1 DS tab daily	CD4 >200/ μ L + HIV RNA suppressed $\geq$ 3 months
M. avium complex	CD4 <50/ μ L <i>only if ART not initiated</i> (rarely needed now)	Azithromycin 1200 mg weekly	Once on fully suppressive ART
<i>Cryptococcus</i> / <i>CMV</i>	Secondary (post-disease) prophylaxis only	Fluconazole / valganciclovir	CD4 >100/ μ L for $\geq$ 6 months + suppression
<i>Histoplasma</i> (endemic)	Prior disease or CD4 <150/ μ L with high risk	Itraconazole 200 mg	CD4 >150/ μ L $\geq$ 6 months on ART

- ▶ **Key teaching point:** a single TMP-SMX DS tablet covers **both PCP and toxoplasmosis**, so the practical rule is — start co-trimoxazole when CD4 <200/ μ L and continue until immune reconstitution.
- ▶ Prophylaxis is *safely discontinued* once ART raises the CD4 above the starting threshold (and viral load is suppressed) — prophylaxis decisions are dynamic, driven by the **trend** of the CD4.

Role of CD4 in initiating and monitoring ART

- ▶ **When to start ART:** Current DHHS guidance recommends **ART for everyone with HIV, as soon as possible after diagnosis, regardless of CD4 count or viral load — the count no longer gates whether to treat, but still informs timing and urgency**.
- ▶ **Urgency by CD4:** With **advanced disease** (CD4 <50/ μ L) ART should be started as soon as possible. When an OI is diagnosed concurrently and CD4 $\geq$ 50/ μ L, a 2–4 week delay may be considered (treating the OI first) to reduce the severity of immune reconstitution inflammatory syndrome (IRIS) — relevant especially to TB and cryptococcal meningitis.
- ▶ **Expected response to ART:** a rapid $\geq$ 1-log (10-fold) fall in HIV RNA within 1–2 months, suppression to <50 copies/mL by ~6 months, and a CD4 rise of ~100–150 cells/ μ L over the same period.
- ▶ **Monitoring frequency** (CMDT Table 36-5): CD4 every 3–6 months; this can be reduced to **every 12 months** once viral load is suppressed on ART for 2 years with CD4 >300/ μ L, and routine CD4 monitoring becomes **optional/unnecessary** once CD4 is consistently >350–500/ μ L with sustained virologic suppression. Thereafter **viral load** is the chief monitoring tool.

- ▶ **IRIS** (Table 208-12): paradoxical worsening or unmasking of an OI weeks–months after starting ART; most common when ART is begun at $\text{CD4} < 50/\mu\text{L}$ with a precipitous drop in viral load, classically with TB.

Limitations and pitfalls of CD4 interpretation

- ▶ Subject to **diurnal variation**, transient depression with intercurrent illness or recent vaccination, and **inter-/intra-laboratory variability** — therefore the **trend matters more than a single value**.
- ▶ The **CD4 percentage** is more stable; $<14\% \approx \text{CD4} < 200/\mu\text{L}$, and a percentage of $\sim 15\% \approx 200$ cells/ μL .
- ▶ After **splenectomy** the absolute count is unreliable (artefactual lymphocytosis) — use the **CD4 percentage**.
- ▶ The CD4 count says nothing about viral replication; **viral load is the more accurate marker of activity and ART response**, providing prognostic information independent of the count.
- ▶ Patients immunised when CD4 was $<100/\mu\text{L}$ should be **re-immunised** once the count recovers to $>200/\mu\text{L}$ for an adequate response; live vaccines are avoided at $\text{CD4} < 200/\mu\text{L}$.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ “**CD4 staircase**” — **CD4 count vs opportunistic disease**: Draw a vertical CD4 axis (cells/ μL) marked at 500, 200, 50. Place labelled boxes at each level — >500 : herpes zoster, oral hairy leukoplakia, vaginal candidiasis, Kaposi sarcoma; <200 : PCP, toxoplasmosis, cryptococcosis, coccidioidomycosis, cryptosporidiosis; <50 : disseminated MAC, CMV retinitis, CNS lymphoma, histoplasmosis. Add a dashed line at 200 = “**AIDS / start PCP prophylaxis**.”
- ▶ **Natural-history curve**: time on X-axis; plot **falling CD4** against **rising/plateauing HIV RNA**, labels — *acute retroviral syndrome*, *clinical latency* (~ 10 yrs, *decline* $\sim 50/\mu\text{L}/\text{yr}$), *symptomatic/AIDS* ($<200/\mu\text{L}$).

Clinical / Diagnostic significance

- ▶ Establishes **stage and prognosis**, and identifies the patient who has progressed to **AIDS** even when asymptomatic.
- ▶ Directs **OI prophylaxis** (start and stop) and shapes the **empirical differential** when a person with HIV presents acutely (e.g., headache + $\text{CD4} < 100 \rightarrow$ think cryptococcal meningitis/CNS toxoplasmosis).
- ▶ Confirms **immune reconstitution** on ART (rising CD4) and flags risk of **IRIS** when baseline CD4 is very low.
- ▶ A baseline CD4 is part of the initial work-up alongside HIV RNA, genotypic resistance testing, CBC/chemistry, hepatitis and toxoplasma serology, and TB screening.

High-yield exam pointers

- ▶ AIDS = CD4 <200/ μ L (or <14%) OR an AIDS-defining illness in a person with HIV.
- ▶ CDC stages: 1 $\geq$ 500, 2 = 200–499, 3 <200 cells/ μ L.
- ▶ Untreated CD4 declines ~50 cells/ μ L per year; median time to AIDS ~10 years.
- ▶ PCP prophylaxis at <200, toxoplasmosis (IgG+) at <100, MAC at <50 (only if ART deferred) — TMP-SMX covers PCP *and* toxoplasma.
- ▶ Stop PCP prophylaxis when CD4 >200/ μ L for $\geq$ 3 months on ART.
- ▶ ART is for everyone regardless of CD4 — CD4 now guides *timing/urgency*, not eligibility; start ASAP if CD4 <50.
- ▶ Expect a CD4 rise of ~100–150/ μ L in the first months of effective ART.
- ▶ IRIS is most frequent when ART starts at CD4 <50/ μ L, classically with TB/cryptococcus.
- ▶ Use CD4 **percentage** ($\approx$ 15% = 200/ μ L) when the absolute count is unreliable (post-splenectomy, acute illness).
- ▶ **Trend > single value**; viral load, not CD4, is the marker of treatment response.

Scrub typhus

Asked in: Paper II Jul 2021 — RGUHS MD General Medicine

Definition / Introduction — Scrub typhus is an acute, mite-borne, febrile zoonosis caused by *Orientia tsutsugamushi*, an obligately intracellular gram-negative bacterium of the family **Rickettsiaceae**. It is transmitted to humans by the bite of larval **trombiculid mites (chiggers)** and is characterised pathologically by **endothelial-cell infection with increased vascular permeability (vasculitis)**. The classic clinical triad is an **eschar** at the chigger-bite site, **regional/generalised lymphadenopathy**, and a transient **maculopapular rash**, on a background of high fever. It is endemic across the “**tsutsugamushi triangle**” of Asia-Pacific (including India), is a leading cause of **acute undifferentiated febrile illness and fever of unknown origin**, and is highly responsive to **doxycycline**.

Etiology, vector and epidemiology

- **Organism:** *Orientia tsutsugamushi* (genus *Orientia*, family Rickettsiaceae). It differs substantially from *Rickettsia* species both **genetically** and in **cell-wall composition** — notably it **lacks lipopolysaccharide (LPS)** and has no peptidoglycan, hence its separation into a distinct genus. Related species *O. chuto* (south-western Asia) and *Candidatus O. chiloensis* (Chile) are emerging.
- **Vector & reservoir:** larval **trombiculid mites = chiggers** (*Leptotrombidium deliense* and others). The chigger is the **only stage that feeds on a host**; the mite is both vector and reservoir, the organism being maintained by **transovarial transmission**. Infected chiggers cluster in areas of **heavy scrub vegetation during the wet season**.
- **Antigenic diversity:** *O. tsutsugamushi* shows **remarkable antigenic diversity** (classically the *Karp*, *Gilliam* and *Kato* serotypes). Immunity to the **homologous strain wanes over 1–3 years**, and cross-protective immunity against heterologous strains may be lost in as little as **1 month** — hence reinfection is common (in some areas >3% of the population is infected/reinfected each month).
- **Geography:** endemic and **re-emerging** in eastern and southern Asia, northern Australia and islands of the western Pacific and Indian Oceans — the “**tsutsugamushi triangle**”. A major cause of acute febrile illness in **India and China**; more common in rural areas but increasingly urban, and now recognised in travellers.
- **Other transmission:** vertical (transplacental), **transfusion**, and **occupational/laboratory** exposures are documented.

Feature	Scrub typhus
Organism	<i>Orientia tsutsugamushi</i> (lacks LPS)
Vector	Larval trombiculid mite (chigger), e.g. <i>Leptotrombidium deliense</i>
Incubation period	6–21 days (≈1–3 weeks)
Pathognomonic sign	Eschar (tache noire) ± regional lymphadenopathy
Rash	Macular/maculopapular, trunk, day 4–8, fleeting
Drug of choice	Doxycycline (alt: azithromycin, chloramphenicol)
Untreated mortality	~6% (classic) up to 10–30% in severe series

Pathogenesis

- Chigger bite **inoculates organisms into the dermis**; *O. tsutsugamushi* spreads **lymphohaematogenously** and infects **vascular endothelial cells** (and macrophages).
- The central lesion is a **disseminated vasculitis / vasculitic perivasculitis** with **increased vascular permeability**, producing oedema, hypovolaemia, microvascular leak and multi-organ ischaemia — the same final common pathway shared by all rickettsioses.

- ▶ At the bite site, local vasculitis and necrosis produce the **eschar** (a black, crusted, painless ulcer with an erythematous halo); the draining nodes enlarge first (**regional lymphadenopathy**), reflecting initial lymphogenous spread.
- ▶ Severe disease reflects widespread endothelial injury → **interstitial pneumonitis/ARDS**, **myocarditis**, **meningoencephalitis**, **hepatitis**, **AKI** and, late, **haemophagocytosis**.

Clinical features

- ▶ **Onset**: after a 6–21-day (1–3 week) incubation, abrupt **high fever**, **severe headache**, **myalgia**, **malaise**, **chills**, **backache**, **cough** and **gastrointestinal symptoms** (nausea, vomiting, diarrhoea in nearly two-thirds — corresponding to mucosal erosions/haemorrhage).
- ▶ **Eschar (most useful sign)**: a papule at the bite site that ulcerates into a **black, painless, crusted eschar (tache noire)**, typically in moist/covered intertriginous skin. It is **highly suggestive but not always present** — recognised in only ~19% in a South Korean series, and in <50% of **returning travellers**; absence does not exclude the diagnosis.
- ▶ **Lymphadenopathy**: tender **regional** node enlargement near the eschar, sometimes becoming **generalised** — a helpful clue.
- ▶ **Rash**: **macular** → **maculopapular**, mainly on the **trunk**, appearing around **day 4–8**; it may be fleeting or absent (rash in <40%), peaking ~day 8 and occasionally lasting up to 21 days.
- ▶ **Relative bradycardia** (pulse–temperature dissociation) is characteristic.
- ▶ **Complications**: **pneumonitis/ARDS**, **myocarditis**, **meningoencephalitis** or **aseptic meningitis**, **acute kidney injury**, **hepatitis** and **haemophagocytic lymphohistiocytosis (HLH)**; ARDS or haemophagocytosis tends to develop in the **second–third week**. Infection confers **prolonged immunity against homologous strains** but only transient immunity against heterologous strains.

Investigations / Diagnosis

- ▶ **Supportive laboratory findings** (shared rickettsial signature): **thrombocytopenia**, **normal or low WBC count**, **elevated hepatic aminotransferases**, **hyperbilirubinaemia**, **raised creatinine**, **hyponatraemia**, **raised CRP**, and **hypoalbuminaemia**.
- ▶ **Serology (reference standard)**: **indirect immunofluorescence assay (IFA)** and **indirect immunoperoxidase assay** are the **gold standard** but are expensive and of limited availability; a fourfold rise in paired acute/convalescent titres is confirmatory. **ELISA** detecting *Orientia*-specific antibodies and **rapid lateral-flow chromatographic tests** are widely used point-of-care options.
- ▶ **PCR (most sensitive)**: amplification of *Orientia* genes is **most sensitive from the eschar** (eschar crust/swab), and can also be done on blood/buffy coat; best performed **before doxycycline** is started.
- ▶ **Culture**: possible from early blood but requires a **BSL-3 laboratory**; rarely used. **Combined ELISA + PCR** is recommended where available.

- ▶ ***Weil-Felix test** (*Proteus OX-K agglutination*) is the classic cheap field test for scrub typhus but is insensitive and non-specific*, and is now largely superseded by IFA/ELISA/PCR.

Differential diagnosis

- ▶ The major mimics of acute undifferentiated tropical fever: **dengue, malaria, leptospirosis, enteric (typhoid) fever, Q fever, viral haemorrhagic fevers, other rickettsioses, and meningitis**. Co-infection (e.g. with malaria) can occur.
- ▶ Discriminators favouring scrub typhus: **an eschar, lymphadenopathy, relative bradycardia, lymphocytosis and elevated CRP** (the last three help distinguish it from dengue). In endemic regions it is a recognised cause of **obscure fever / FUO, especially in children**.

Treatment

- ▶ **Drug of choice: doxycycline 100 mg orally twice daily** — produces rapid defervescence (often within 48 h, a near-diagnostic therapeutic response). **Minocycline 100 mg BID** is an equivalent tetracycline.
- ▶ **Duration:** continue for at least **3 days after the patient is afebrile** (regimens of **7–15 days**); **short courses risk relapse**.
- ▶ **Severe disease:** the INTREST trial (Varghese et al., *NEJM* 2023) found **no difference** between IV doxycycline and IV azithromycin monotherapy, but **combination doxycycline + azithromycin** lowered 28-day mortality, day-7 complications and day-5 persistent fever — combination is preferred in severe/complicated cases.
- ▶ **Alternatives / special groups:** **azithromycin 500 mg/day for 3 days** (similar efficacy, fewer adverse effects) and **chloramphenicol 500 mg QID** — both are the agents of choice in **pregnancy** and in **doxycycline allergy/intolerance**. Some Thai strains are relatively doxycycline/chloramphenicol-resistant and respond to **azithromycin + rifampicin**.
- ▶ **Supportive care:** ICU support for ARDS (ventilation), myocarditis, AKI (renal replacement) and shock as needed.

Setting	Regimen
Uncomplicated (DOC)	Doxycycline 100 mg PO BID (or minocycline 100 mg BID); ≥3 days after afebrile (7–15 days)
Severe / complicated	IV doxycycline + IV azithromycin combination (INTREST trial)
Pregnancy / doxy allergy	Azithromycin 500 mg/day ×3 or chloramphenicol 500 mg QID
Doxy/chloramphenicol-poor response (Thailand)	Azithromycin + rifampicin

Prevention: there is **no effective vaccine** (antigenic diversity limits vaccine development). Personal protection — **insect repellents on skin and clothing, protective clothing, avoidance of scrub**

vegetation — is key; routine antibiotic chemoprophylaxis is NOT recommended for asymptomatic travellers (CDC).

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Diagram 1 — The eschar with regional lymphadenopathy:** draw a limb/trunk with a central **black crusted eschar** surrounded by an **erythematous halo**, an arrow to the draining **enlarged regional lymph node**, and a faint **macular rash over the trunk**. Labels: *Eschar (tache noire)*, *Erythematous halo*, *Regional lymphadenopathy*, *Truncal maculopapular rash*, *Chigger bite site*.
- ▶ **Diagram 2 — Transmission cycle:** *Trombiculid mite (Leptotrombidium)* → **larval chigger bites human** → *Orientia tsutsugamushi* inoculated into skin → **endothelial infection** → **vasculitis** → systemic disease; with a side loop showing **transovarial transmission** keeping the mite as both vector and reservoir. Labels: *Chigger (larva)*, *Orientia tsutsugamushi*, *Transovarial transmission*, *Human (incidental host)*, *Endothelial vasculitis*.

Clinical / Diagnostic significance

- ▶ A leading, **treatable** cause of **acute undifferentiated febrile illness**, **FUO** and **sepsis** in the Asia-Pacific — empirical **doxycycline** should be started promptly on clinical/epidemiological suspicion without waiting for serology.
- ▶ **Always search for the eschar** in skin folds (axilla, groin, neck, genitalia, under breasts) — it is the single most useful diagnostic clue and is easily missed.
- ▶ **Eschar + thrombocytopenia + transaminitis + relative bradycardia** in a patient from an endemic area is a near-classic combination.
- ▶ **Untreated mortality** is significant (~6% classic; **10–30%** in severe hospitalised series). **Poor prognostic markers:** hypotension/vasopressor need, ICU admission, **age >60 years**, **absence of an eschar** (delays diagnosis), pregnancy, **leukocytosis** and **hypoalbuminaemia**.
- ▶ A **rapid response to doxycycline** (**defervescence in ~48 h**) is itself a useful diagnostic/therapeutic confirmation.

High-yield exam pointers

- ▶ Causative organism: ***Orientia tsutsugamushi** — *a Rickettsiaceae that lacks LPS, separating it from genus Rickettsia**.
- ▶ Vector = **larval trombiculid mite (chigger)**, *Leptotrombidium deliense*; reservoir maintained by **transovarial transmission**.
- ▶ Endemic area = “**tsutsugamushi triangle**”; incubation **6–21 days**.
- ▶ **Classic triad:** **eschar (tache noire) + regional lymphadenopathy + truncal maculopapular rash**, with **relative bradycardia**.

- ▶ Eschar present in only ~19–50% of cases — its absence does not exclude the disease.
- ▶ PCR of the eschar = most sensitive; IFA / indirect immunoperoxidase = gold-standard serology; Weil-Felix OX-K is the classic but insensitive test.
- ▶ Labs: thrombocytopenia, transaminitis, hyponatraemia, normal/low WBC.
- ▶ Doxycycline 100 mg BID is the drug of choice; doxycycline + azithromycin combination for severe disease (INTREST trial); azithromycin/chloramphenicol in pregnancy.
- ▶ Serious complications: ARDS/pneumonitis, myocarditis, meningoencephalitis, AKI, HLH.
- ▶ No vaccine; prevention is by mite-bite avoidance.

SOURCE & COVERAGE

- ▶ Harrison's Principles of Internal Medicine, 22e — "Rickettsial Diseases" (general rickettsial pathophysiology; *Scrub Typhus* section — *Orientia tsutsugamushi*, chigger/trombiculid biology, epidemiology, clinical features, eschar, diagnosis and treatment regimens including doxycycline + azithromycin combination).
- ▶ CDMT 2026 — "Viral & Rickettsial Infections" (Scrub Typhus: essentials of diagnosis, tsutsugamushi triangle, relative bradycardia, eschar frequency [~19%], laboratory findings, IFA/ELISA/PCR, differential diagnosis, prognosis/poor-prognostic factors, treatment including the INTREST trial, doxycycline/minocycline/azithromycin/chloramphenicol).
- ▶ Coverage note: The corpus emphasises IFA/indirect immunoperoxidase and PCR; it does not explicitly detail the Weil-Felix (*Proteus* OX-K) test or name the Karp/Gilliam/Kato serotypes — these are included here as universally accepted standard internal-medicine teaching and flagged accordingly. Numeric epidemiological values in Harrison's Table 192-1 were partly garbled in the text extract; figures quoted here are taken from the verified narrative text (incubation 6–21 days, untreated case-fatality ~6%).

Seroconversion Illness in HIV (Acute Retroviral Syndrome)

Asked in: Paper II Nov 2020 — RGUHS MD General Medicine

Definition / Introduction — *Seroconversion illness* (the **acute retroviral syndrome** / **acute HIV syndrome** / **primary HIV infection**) is the symptomatic, self-limiting acute viral illness that appears in the interval between acquisition of HIV and the appearance of detectable anti-HIV antibody. It develops ~3–6 weeks after primary infection in an estimated 50–70% of newly infected individuals, coincides with the burst of high-level plasma viremia and wide dissemination/seeding of lymphoid tissue, and clinically resembles **acute infectious mononucleosis**. Recognising it is a high-stakes opportunity: the patient is intensely infectious, standard antibody tests may still be negative, and early diagnosis permits immediate antiretroviral therapy (ART).

Pathogenesis & timing (why the illness occurs)

- ▶ After mucosal/parenteral entry there is a brief “eclipse” phase (virus replicating locally, not yet detectable in plasma); virus is then carried to draining lymph nodes and other lymphoid compartments rich in CD4+ T-cell targets, producing a **burst of high-level plasma viremia**.
- ▶ The symptomatic illness coincides with this **peak viremia** and the seeding of lymphoid organs; symptoms subside as the **HIV-specific immune response** (CD8+ CTL, then antibody/ADCC) develops and viremia is curtailed toward the viral “set-point.”
- ▶ **Immunologic perturbations:** initial fall in total lymphocytes and both CD4+ and CD8+ subsets; later a **transient selective expansion of CD8+ T cells** producing **inversion of the CD4:CD8 ratio**. CD4+ counts usually remain mildly depressed afterward.
- ▶ The magnitude of the initial viremic burst does **not** reliably correlate with subsequent rate of disease progression; however, ~10% of patients manifest a **fulminant** immunologic/clinical course after primary infection.
- ▶ **Opportunistic infections can occur even during this acute phase**, reflecting the transient profound immunodeficiency at peak viremia.
- ▶ Symptomatic seroconversion severe enough to seek medical attention has been **suggested to indicate increased risk of an accelerated course**, though this remains debated; primary infection (with or without an acute syndrome) is typically followed by **clinical latency / smouldering low-level disease activity**.

Clinical features

The picture is that of a non-specific acute viral syndrome (“mononucleosis-like”), typically lasting **one to several weeks** and resolving spontaneously. *Clinical findings in the acute HIV syndrome (Harrison Table 208-10):*

System	Manifestations
General	Fever, pharyngitis, lymphadenopathy (~70%), headache/retro-orbital pain, arthralgia/myalgia, lethargy/malaise, anorexia, weight loss
Dermatologic	Erythematous maculopapular rash (face/trunk), mucocutaneous ulceration (oral, anal, genital)
Gastrointestinal	Nausea, vomiting, diarrhoea
Neurologic	Aseptic meningitis , encephalitis , peripheral neuropathy, myelopathy, Guillain-Barré-like illness

- ▶ The combination of **fever + pharyngitis + generalised lymphadenopathy + maculopapular rash + painful mucocutaneous (oral/genital) ulcers** is the most suggestive cluster and distinguishes it from EBV/CMV mononucleosis (in which ulcers and rash without ampicillin are uncommon).

- ▶ Fever, rash, pharyngitis and myalgia are reported **less frequently in those infected by injection drug use** than by sexual contact.
- ▶ Most recover spontaneously, often left with only a mildly depressed CD4+ count; the illness is then followed by a prolonged **clinical latency** (median time to AIDS ~10 years untreated; average CD4 decline ~50/ μ L per year).

Laboratory diagnosis — the window period & marker kinetics

The central diagnostic problem is that **antibodies appear only ~3–12 weeks after infection**, so antibody-only tests may be falsely negative during seroconversion. Markers become detectable in a characteristic order:

Marker	Approx. time to detectability	Diagnostic role
HIV-1 RNA (NAT / viral load)	Earliest ($\approx$ 10 days; after the eclipse phase)	Confirms acute infection when antibody is negative
p24 antigen	Days–~2 weeks (before antibody)	Component of the 4th-generation combo assay
Anti-HIV antibody	~3–12 weeks (4th-gen detects in 99% by ~6 weeks; median ~2 weeks)	Basis of screening/confirmatory assays

- ▶ **Fiebig staging** describes the evolution of acute infection from **stage I (HIV RNA positive alone)** through to **stage VI (HIV RNA + full Western blot positive)**, charting the sequential appearance of RNA $\rightarrow$ p24 $\rightarrow$ antibody bands.
- ▶ **Recommended initial test:** a **fourth-generation HIV-1/2 antigen/antibody combination immunoassay** (detects HIV-1 & HIV-2 antibody **plus p24 antigen**) — narrows the window versus older antibody-only EIA.
- ▶ **CDC testing algorithm:** reactive 4th-gen combo $\rightarrow$ **HIV-1/HIV-2 antibody differentiation immunoassay** (e.g., *Bio-Rad Geenius*). If the differentiation assay is **negative or indeterminate but a NAT (HIV-1 RNA) is positive** $\rightarrow$ **diagnosis of acute HIV-1 infection**. A combo-reactive specimen with repeatedly negative differentiation and **undetectable NAT** is presumed **false-positive** (e.g., recent influenza vaccination, autoantibodies, pregnancy-related alloantibodies).
- ▶ **Caveat:** low-level viremia **<1000 copies/mL** on NAT may be a false positive — interpret cautiously.
- ▶ The screening EIA is highly sensitive (**>99.5%**) but imperfectly specific in low-risk populations, so a reactive screen **always** needs a more specific confirmatory step before a diagnosis is given. The older stand-alone **Western blot** has been superseded in the algorithm by the antibody **differentiation assay plus NAT**.

- ▶ **Supportive non-specific findings:** lymphopenia (and other cytopenias), transient atypical lymphocytosis, raised transaminases/ESR — reinforcing the mononucleosis-like character.

Differential diagnosis

- ▶ Epstein–Barr virus and CMV infectious mononucleosis; **acute toxoplasmosis**; **acute viral hepatitis**; **secondary syphilis**; **rubella/measles/parvovirus/enteroviral exanthems**; **streptococcal pharyngitis**; **acute aseptic meningitis** of other viral cause; and drug reactions.
- ▶ A high index of suspicion plus a careful sexual/exposure history is essential, because the antibody screen may still be negative — *a negative antibody test does not exclude acute HIV*.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Natural history curve (Pantaleo–Fauci graph):** X-axis = time (weeks → years); left Y-axis = CD4+ T-cell count (cells/ μ L), right Y-axis = HIV RNA copies/mL. Label: *Primary infection* → *Acute HIV syndrome (wide dissemination of virus; seeding of lymphoid organs)* with **peak plasma viremia** and **CD4 nadir**, then **partial CD4 rebound + fall of viremia to set-point**, *Clinical latency*, *Constitutional symptoms*, *Opportunistic diseases*, *Death*.
- ▶ **Diagnostic window / marker-kinetics timeline:** X-axis = days–weeks from infection; plot sequential appearance of HIV RNA → **p24 antigen** → **anti-HIV antibody**, mark the **eclipse phase** and **window period**, and annotate **Fiebig stages I–VI**.

Clinical / Diagnostic significance

- ▶ **Extreme transmissibility:** peak plasma (and genital) viral load during seroconversion makes onward transmission highly efficient — a key driver of epidemic spread; diagnosis enables counselling, partner notification and **treatment-as-prevention (U=U)**.
- ▶ **Treat immediately:** current guidance is to **start ART as soon as possible in everyone, including acute HIV infection, regardless of CD4 count** — rationale includes earlier viral suppression, blunting immune damage from the outset, limiting seeding of the latent reservoir, and reducing transmission.
- ▶ Obtain baseline **CD4 count**, **plasma HIV RNA (viral load)**, **genotypic resistance testing**, and screen for co-infections (**RPR/VDRL**, **hepatitis B and C**, **other STIs**) before/at ART initiation.
- ▶ Distinguish from **post-exposure prophylaxis (PEP)** scenarios: a person presenting with acute retroviral syndrome already has established infection (treat as such), not a candidate for PEP.
- ▶ Pitfall to avoid in exams and wards: **do not rely on a single antibody EIA** in a recently exposed symptomatic patient — add **p24/NAT**.

High-yield exam pointers

- ▶ Synonyms: **acute retroviral syndrome** = **acute HIV syndrome** = **primary HIV infection** = **seroconversion illness**.

- ▶ Occurs in ~50–70% of infections, ~3–6 weeks post-exposure; lasts 1 to several weeks; mononucleosis-like.
- ▶ Classic cluster: fever + pharyngitis + lymphadenopathy (~70%) + maculopapular rash + painful muco-cutaneous (oral/genital) ulcers; may include aseptic meningitis.
- ▶ Window period: antibodies appear ~3–12 weeks; HIV RNA is the earliest marker, then p24 antigen, then antibody.
- ▶ First-line test = 4th-generation Ag/Ab combo immunoassay (Ab + p24); confirm with HIV-1/2 differentiation assay; antibody-negative + NAT-positive = acute HIV.
- ▶ Fiebig stages I–VI track RNA → p24 → Western-blot positivity.
- ▶ Immunology: transient CD4 fall, CD8 expansion, CD4:CD8 inversion; ~10% have a fulminant course.
- ▶ Management = start ART immediately regardless of CD4; baseline CD4, viral load, resistance genotype, STI/hepatitis screen.
- ▶ A negative HIV antibody test does NOT exclude acute infection — pursue p24/NAT if clinically suspected.

SOURCE & COVERAGE

- ▶ Harrison's Principles of Internal Medicine, 22e — "Human Immunodeficiency Virus Disease: AIDS and Related Disorders" (Acute HIV Infection; Clinical Manifestations; Table 208-10 *Clinical Findings in the Acute HIV Syndrome*; Fig. 208-33 *The Acute HIV Syndrome*; Laboratory Diagnosis — 4th-generation EIA, p24 antigen, NAT, CDC algorithm Fig. 208-31).
- ▶ CDMT 2026 — "HIV Infection & AIDS" (laboratory testing algorithm and window-period kinetics, Table 36-2; recommendation to start ART in all, including acute infection).

Systemic Protozoal Infections

Asked in: Paper II May 2022 — RGUHS MD General Medicine

Definition / Introduction — Protozoa are microscopic single-celled eukaryotic parasites. *Systemic* (blood-and-tissue) protozoa are those that invade the bloodstream and deep organs rather than remaining confined to the gut lumen, producing disseminated, often life-threatening disease. Their defining feature is the capacity (like bacteria) to **multiply within the human host** and to evade immunity either by **antigenic variation** (*Trypanosoma brucei*) or by **intracellular survival** (*Plasmodium*, *Babesia*, *Leishmania*, *Toxoplasma*, *Trypanosoma cruzi*). A naïve patient suffering a first infection is usually the most severely affected, because partial immunity later limits parasite numbers; immunocompromised hosts (especially PLWH) are prone to dissemination, and several of these infections are **AIDS-defining**.

Classification of systemic (blood & tissue) protozoa

Organism	Disease	Vector / mode	Key target / hallmark
<i>Plasmodium</i> (6 species; esp. <i>P. falciparum</i>)	Malaria	Female <i>Anopheles</i> mosquito	Erythrocytes; cyclical fever, cerebral malaria
<i>Babesia</i>	Babesiosis	<i>Ixodid</i> (hard) ticks	Erythrocytes; severe in asplenia
<i>Trypanosoma cruzi</i>	Chagas disease	Reduviid (triatomine) bug faeces	Cardiomyopathy, megaesophagus/megacolon
<i>T. brucei gambiense</i> / <i>rhodesiense</i>	African trypanosomiasis (sleeping sickness)	Tsetse fly (<i>Glossina</i>)	Chancre, CNS invasion
<i>Leishmania</i> (>20 species)	Visceral / cutaneous / mucocutaneous leishmaniasis	Sandfly (<i>Phlebotomus</i>)	Intracellular amastigotes in macrophages
<i>Toxoplasma gondii</i>	Toxoplasmosis	Cat-faeces oocysts, tissue cysts, transplacental	Brain (ring-enhancing lesions), eye, fetus
<i>Naegleria</i> , <i>Acanthamoeba</i> , <i>Balamuthia</i>	Amebic meningoencephalitis	Free-living, fresh/brackish water, soil	CNS — almost universally fatal

- ▶ Three immune-evasion mechanisms underpin systemic spread: **antigenic variation**, **intracellular sequestration**, and **endothelial cytoadherence** (*P. falciparum*).
- ▶ Immunocompromise predisposes to disseminated infection with *Leishmania*, *Toxoplasma*, *Cryptosporidium* and *T. cruzi*.

Malaria (*Plasmodium*)

- ▶ Six *Plasmodium* species infect humans; the classically described are ***P. falciparum***, ***P. vivax***, ***P. ovale***, ***P. malariae*** and the zoonotic ***P. knowlesi***. *P. falciparum* dominates sub-Saharan Africa, causing >80% of infections and ~90% of malarial deaths.
- ▶ *P. falciparum* is uniquely dangerous because it **invades erythrocytes of all ages** (very high parasitaemia), **cytoadheres to vascular endothelium** (sequestration → organ damage), and is most prone to **drug resistance**. *P. vivax/ovale* invade only reticulocytes (lower parasitaemia) and form dormant liver **hypnozoites** causing relapse.

Feature	<i>P. falciparum</i>	<i>P. vivax</i> / <i>ovale</i>
RBC preference	All ages	Reticulocytes (<i>vivax</i> needs Duffy antigen)
Parasitaemia	Very high	Low (seldom >2%)

Feature	<i>P. falciparum</i>	<i>P. vivax</i> / <i>ovale</i>
Relapse (hypnozoite)	No	Yes — needs primaquine
Severe disease	Common	Uncommon

- ▶ **Severe falciparum malaria** (Table 231-2): cerebral malaria (unarousable coma >30 min post-convulsion, GCS <11), severe anaemia (Hb <5 g/dL), acidosis (lactate ≥5 mmol/L, “respiratory distress”), acute kidney injury (creatinine >265 μmol/L), noncardiogenic pulmonary oedema/ARDS, hypoglycaemia (<2.2 mmol/L; aggravated by quinine), shock, DIC/bleeding, **blackwater fever** (massive haemoglobinuria), and **hyperparasitaemia** (>5% in nonimmune, >10% in any patient).
- ▶ **Diagnosis:** Giemsa-stained **thick and thin blood films** remain the gold standard — thick film is sensitive (detects ~0.001% parasitaemia) and quantifies the parasite count, thin film allows species identification. **Rapid antigen tests** (PfHRP2-based dipsticks) are simple and sensitive but do not quantify parasitaemia and can be missed by *pfhrp2* deletions.
- ▶ **Treatment:** Uncomplicated falciparum malaria → an oral **artemisinin-based combination therapy (ACT)** (artemisinin derivative + a longer-acting partner drug). *P. vivax/ovale/malariae* and *P. knowlesi* → chloroquine (or ACT) plus, for vivax/ovale, **primaquine** for radical cure of liver hypnozoites (screen for G6PD deficiency first).
- ▶ **Severe malaria** → immediate parenteral **artesunate 2.4 mg/kg IV stat, repeated at 12 h and 24 h, then daily**; IV artesunate reduced mortality by ~22.5% versus quinine in African children. *Pfkelch13* mutations confer artemisinin resistance (SE Asia, now East Africa).

Leishmaniasis

- ▶ Caused by >20 species of **obligate intracellular** *Leishmania*, transmitted by sandflies; the parasite lives as non-flagellate **amastigotes** inside macrophages and as flagellate promastigotes in the vector. Three clinical syndromes: **visceral (VL)**, **cutaneous (CL)** and **mucocutaneous/mucosal (ML)**.
- ▶ **Visceral leishmaniasis (kala-azar, “black fever”)**: an AIDS-defining illness; presents with prolonged fever, **massive splenomegaly** (the cardinal feature), hepatomegaly, lymphadenopathy, weight loss, darkening of skin and hypergammaglobulinaemia/pancytopenia. >90% of global VL occurs in **India, Bangladesh, Sudan, Ethiopia and Brazil**.
- ▶ **Diagnosis:** demonstration of amastigotes in **splenic, bone-marrow or lymph-node aspirate smears**; serology with the **rK39** antigen (rapid point-of-care test, though it stays positive for years after cure).
- ▶ **Treatment:** **Pentavalent antimony** (sodium stibogluconate / meglumine antimoniate) remains the drug of choice in most regions, **but antimony resistance is widespread in Bihar (India)**, where **liposomal/deoxycholate amphotericin B** or oral **miltefosine** (the first effective oral

antileishmanial; teratogenic) is preferred. Combination regimens (e.g., single-dose liposomal amphotericin B followed by miltefosine or paromomycin) are used.

- ▶ **Post-kala-azar dermal leishmaniasis (PKDL)** follows VL on the Indian subcontinent as nodular/macular skin infiltration and is a parasite reservoir. **Mucocutaneous (espundia)** disease (New World *L. (Viannia) braziliensis*) destroys the nasal septum and palate and does not heal spontaneously.

Toxoplasmosis

- ▶ *Toxoplasma gondii* is an **obligate intracellular** parasite acquired by ingesting **oocysts** (cat faeces-contaminated food/water), **tissue cysts** (undercooked meat) or **transplacentally**. **Tachyzoites** cause acute, invasive disease; latent **bradyzoite tissue cysts** persist lifelong, predominantly in the CNS.
- ▶ **Immunocompetent host:** usually asymptomatic, or a self-limited infectious-mononucleosis-like illness; ocular disease (chorioretinitis) may occur.
- ▶ **Immunocompromised host (AIDS, transplant):** reactivation of latent cysts produces **toxoplasmic encephalitis** — multiple **ring-enhancing lesions** on contrast CT/MRI (the leading cause of focal brain lesions in advanced HIV); fatal unless treated.
- ▶ **Congenital toxoplasmosis:** from primary maternal infection; severity is greatest with early-gestation infection (visual, hearing and cognitive impairment), while late-infected infants may appear normal but develop **chorioretinitis** decades later.
- ▶ **Treatment:** **pyrimethamine + sulfadiazine + leucovorin (folinic acid)** is first-line for toxoplasmic encephalitis (typically ≥ 6 weeks); **clindamycin** substitutes for sulfadiazine (or TMP-SMX when pyrimethamine is unavailable). In pregnancy, **spiramycin** is used to prevent transmission before 18 weeks; pyrimethamine/sulfadiazine/folinic acid is used after seroconversion later in pregnancy.

Other systemic protozoa — trypanosomiasis, babesiosis, free-living amebae

- ▶ **Chagas disease (T. cruzi): transmitted in reduviid-bug faeces in Latin America; also via transfusion, transplantation and mother-to-child. After acute parasitaemia, the parasite multiplies intracellularly (amastigotes) in muscle and ganglion cells; a minority later develop chronic cardiomyopathy and megaoesophagus/megacolon*.*
- ▶ **African trypanosomiasis (sleeping sickness):** tsetse-fly-borne; a painful **chancre** at the bite is a clue. **T. b. gambiense** (West/Central Africa) causes chronic low-grade parasitaemia with late CNS invasion over months–years; **T. b. rhodesiense** (East Africa) causes high parasitaemia with early CNS invasion and death within weeks. Antigenic variation drives recurrent waves of parasitaemia.

- ▶ **Babesiosis:** *Babesia* infects erythrocytes (ixodid-tick borne, NE/Midwest USA); ranges from a nonspecific febrile illness to severe haemolytic disease in **asplenic** patients. Standard therapy is **atovaquone plus azithromycin**.
- ▶ **Free-living amebic CNS infection:** *Naegleria fowleri* (warm fresh water/hot springs) causes fulminant, usually fatal **primary amebic meningoencephalitis (PAM)** — pyogenic-looking CSF with motile trophozoites; *Acanthamoeba* and *Balamuthia mandrillaris* cause indolent **granulomatous amebic encephalitis (GAE)** with a space-occupying lesion, chiefly in the immunocompromised; *Acanthamoeba* also causes **keratitis** (corneal trauma, contact-lens wearers). **Miltefosine**-containing combinations are recommended despite a poor prognosis.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Plasmodium life cycle (mosquito–human):** label *sporozoites*, *hepatocyte (exo-erythrocytic schizont / hypnozoite)*, *merozoites*, *ring trophozoite*, *schizont*, *gametocytes*, *female Anopheles mosquito*.
- ▶ **Classification flow-box “Systemic protozoa”:** two columns — *Blood protozoa* (*Plasmodium*, *Babesia*, *Trypanosoma*) and *Tissue protozoa* (*Leishmania*, *Toxoplasma*, free-living amebae) — each labelled with vector and target organ.

Clinical / Diagnostic significance

- ▶ **Travel/exposure history is pivotal:** malaria must be the first consideration in any febrile returned traveller or immigrant from an endemic area; locally acquired malaria has re-emerged in parts of the USA.
- ▶ **Microscopy of stained blood/aspirate smears** is the unifying diagnostic tool (malaria — thick/thin films; VL — splenic/marrow amastigotes; African trypanosomiasis — bloodstream trypomastigotes).
- ▶ **Imaging:** contrast CT/MRI for toxoplasmic encephalitis (multiple ring-enhancing lesions) and amebic GAE (space-occupying lesion).
- ▶ **Asplenia and HIV/immunosuppression** convert several of these from mild to fulminant or AIDS-defining infections — a key management pearl.
- ▶ Severe falciparum malaria is a **medical emergency** requiring parenteral artesunate, glucose monitoring (hypoglycaemia), and watch for concomitant bacteraemia at high parasitaemia.

High-yield exam pointers

- ▶ Systemic protozoa **multiply within the host** and evade immunity by **antigenic variation** (*T. brucei*) or **intracellular survival** (*Plasmodium*, *Leishmania*, *Toxoplasma*).
- ▶ *P. falciparum* = highest mortality; invades all RBCs, cytoadherence/sequestration → **cerebral malaria**, **blackwater fever**, **ARDS**, **AKI**, **hypoglycaemia**.

- ▶ Severe malaria → IV artesunate 2.4 mg/kg at 0, 12, 24 h then daily; vivax/ovale relapse → primaquine (check G6PD).
- ▶ VL = kala-azar; cardinal sign massive splenomegaly; dx by rK39 + splenic/marrow amastigotes; antimony resistant in Bihar → amphotericin B / miltefosine.
- ▶ Toxoplasmic encephalitis = commonest cause of ring-enhancing brain lesions in AIDS; Rx pyrimethamine + sulfadiazine + folinic acid; spiramycin in early pregnancy.
- ▶ Chagas (reduviid bug) → cardiomyopathy + megaesophagus; African sleeping sickness (tsetse fly) → chancre + CNS disease.
- ▶ Naegleria → fatal PAM (warm freshwater); Acanthamoeba/Balamuthia → GAE + keratitis.
- ▶ AIDS-defining systemic protozoa: *visceral leishmaniasis, toxoplasmosis, cryptosporidiosis, disseminated T. cruzi***.

SOURCE & COVERAGE

Harrison 22e — Ch 228 “Introduction to Parasitic Infections” (primary); supplemented by Ch 230 “Amebiasis and Infection with Free-Living Amebae”, Ch 231 “Malaria”, Ch 233 “Leishmaniasis”, and Ch 235 “Toxoplasma Infections”. **Coverage note:** Ch 234 (Trypanosomiasis) text was not provided; the Chagas and African-trypanosomiasis content above is grounded in the Ch 228 overview only — specific antitrypanosomal drug regimens (e.g., benznidazole/nifurtimox, suramin/pentamidine/melarsoprol/eflornithine/fexinidazole) are standard textbook therapy but were not verifiable against the supplied chapters and are therefore omitted from the drug tables. The “six *Plasmodium* species” figure is from Ch 228; Ch 231 tabulates the five classical species (with *P. ovale* now split into two subspecies).

Tabulate the pathogens involved in viral encephalitis in India, the characteristic presentation of each infection and the management for each

Asked in: Paper II May 2025 — RGUHS MD General Medicine

Definition / Introduction — Encephalitis is inflammation of the brain *parenchyma* caused most often by a virus (occasionally by a primary autoimmune process), and is distinguished from meningitis by the presence of altered consciousness, behavioural change, focal neurological deficits and/or seizures. When the meninges are co-involved the term *meningoencephalitis* is used. In India the aetiologic spectrum is distinctive: **herpes simplex virus** dominates sporadic adult cases, while **Japanese encephalitis virus** is the single largest cause of epidemic encephalitis, and several India-relevant emerging agents (**Nipah**, **Chandipura**, **dengue**, **chikungunya**, **West Nile**, **Kyasanur Forest disease**) round out the picture. The

clinical importance lies in separating the *one treatable cause* (HSV) from the many supportively-managed arboviruses, since empirical acyclovir saves lives.

Aetiologic framework relevant to India

- ▶ **Sporadic, year-round, all ages:** herpesviruses — HSV-1 (commonest sporadic cause), VZV, EBV, CMV (immunocompromised).
- ▶ **Epidemic / seasonal arboviral (monsoon & post-monsoon):** Japanese encephalitis virus (JEV), West Nile virus (WNV), dengue (DENV 1–4), chikungunya virus (CHIKV) — all mosquito-borne.
- ▶ **Emerging zoonotic / regional outbreaks:** Nipah virus (Kerala, West Bengal), Chandipura virus (central/western India, paediatric), Kyasanur Forest disease virus (Karnataka, tick-borne).
- ▶ **Post-infectious / chronic:** measles → subacute sclerosing panencephalitis (SSPE); rubella → progressive rubella panencephalitis.
- ▶ **Other neurotropic:** rabies virus (encephalitic/paralytic), enteroviruses (EV-A71, EV-D68 → acute flaccid myelitis).

Tabulation — pathogen, vector/reservoir, characteristic presentation and management

Pathogen (family)	Vector / reservoir / epidemiology in India	Characteristic clinical presentation	Diagnosis	Management
Herpes simplex virus-1 (Herpesviridae)	None — sporadic, all seasons; commonest cause of sporadic fatal encephalitis	Acute febrile illness with <i>inferomedial frontotemporal</i> signs — olfactory/gustatory hallucinations, anosmia, bizarre behaviour, memory loss, aphasia, focal seizures	CSF lymphocytic pleocytosis ± RBCs; CSF HSV PCR (sens ~96%, spec ~99%); MRI T2/FLAIR temporal-lobe signal; EEG periodic temporal sharp-slow complexes (2–3 s)	IV acyclovir 10 mg/kg q8h × 21 days (neonates 20 mg/kg q8h); start empirically in all suspected viral encephalitis
Japanese encephalitis virus (Flaviviridae)	<i>Culex tritaeniorhynchus</i> mosquito; amplifiers = pigs + ardeid wading birds (herons); rice-field belt; monsoon/post-monsoon; children mainly	Largely subclinical; ~1% develop encephalitis — high fever, reduced sensorium, <i>parkinsonian/dystonic movement disorder</i> , seizures, acute flaccid paralysis; CFR ~20–30%	CSF lymphocytic pleocytosis; anti-JEV IgM (MAC-ELISA) in CSF/serum; MRI <i>thalamic</i> , substantia nigra & basal-ganglia lesions	Supportive (ICP, seizures, ventilation); no specific antiviral ; vaccine-preventable (SA14-14-2 live-attenuated;

Pathogen (family)	Vector / reservoir / epidemiology in India	Characteristic clinical presentation	Diagnosis	Management
				inactivated Vero/IXIARO)
Nipah virus (Paramyxoviridae, <i>Henipavirus</i>)	<i>Pteropus</i> fruit bats; date-palm sap, pig intermediate host; person-to-person & nosocomial spread; Kerala/W. Bengal outbreaks	Influenza-like prodrome → rapidly progressive encephalitis with reduced consciousness, brainstem signs, segmental myoclonus, dystonia; respiratory illness; CFR 67–92%; late relapse (3.4–7.5%)	ELISA (serum & CSF) and RT-PCR of urine/respiratory secretions (not blood)	Supportive; ribavirin used (unproven); strict barrier/contact-droplet isolation; outbreak containment
Chandipura virus (Rhabdoviridae)	Sandflies & mosquitoes; reservoir hedgehogs; central/western India; children; recurrent outbreaks	Rapid influenza-like onset (fever, vomiting, abdominal pain) → altered sensorium & seizures within hours; CFR ~45–80%; <i>virus/cells often NOT detectable in CSF</i>	RT-PCR/serology; CSF typically bland	Supportive intensive care only; high early mortality
Dengue virus 1–4 (Flaviviridae)	<i>Aedes aegypti</i> ; hyperendemic across India	Usually “break-bone fever”; neurological forms = dengue encephalopathy/encephalitis, reduced sensorium, seizures (often with thrombocytopenia, plasma leak)	NS1 antigen / RT-PCR (acute); IgM ELISA (convalescent); leukopenia, thrombocytopenia, raised AST	Supportive fluid management; avoid aspirin/NSAIDs (bleeding); no specific antiviral
Chikungunya virus (Togaviridae, <i>Alphavirus</i>)	<i>Aedes aegypti</i> / <i>Ae. albopictus</i>	Fever with severe migratory small-joint polyarthritides & rash; uncommon neuroinvasive disease (meningoencephalitis), esp. neonates/elderly	RT-PCR (acute) / IgM serology	Paracetamol + NSAIDs for arthralgia; supportive; FDA-approved live-attenuated vaccine exists
West Nile virus (Flaviviridae)	<i>Culex</i> mosquitoes; birds reservoir	Mostly subclinical; <1% neuroinvasive — encephalitis, meningitis, <i>poliomyelitis-like acute flaccid paralysis</i> , movement disorders	CSF WNV IgM (best test; reaches 70–80% by day 7); MRI thalamus/basal ganglia/brainstem	Supportive only; no proven antiviral

Pathogen (family)	Vector / reservoir / epidemiology in India	Characteristic clinical presentation	Diagnosis	Management
Varicella-zoster virus (Herpesviridae)	Reactivation; immunocompromised	Encephalitis via CNS <i>vasculopathy</i> — multifocal ischaemic/haemorrhagic infarcts; ± preceding zoster	CSF VZV PCR and CSF IgM (complementary)	IV acyclovir; consider adjunctive glucocorticoid (unproven)
Measles virus → SSPE (Paramyxoviridae)	Past measles in early childhood; latency 6–8 yr	Progressive cognitive decline, myoclonus, seizures, spasticity in 5–15 yr olds	EEG periodic high-voltage complexes (3–8 s); markedly raised CSF anti-measles antibody/oligoclonal bands	No definitive cure; isoprinosine ± intrathecal IFN-α; prevent via measles vaccination
Kyasanur Forest disease virus (Flaviviridae)	<i>Haemaphysalis</i> ticks; monkeys; Karnataka (Western Ghats)	Biphasic — haemorrhagic febrile illness then, in a minority, a second phase of <i>meningoencephalitis</i>	RT-PCR / IgM serology	Supportive; inactivated KFD vaccine used in India for prevention
Rabies virus (Rhabdoviridae)	Dog bite (commonest in India); bats	<i>Furious</i> rabies — hydrophobia, aerophobia, autonomic storm; <i>paralytic (dumb)</i> — ascending paralysis; near-100% fatal	Antigen in brain/nuchal skin biopsy; PCR of saliva/CSF	No effective therapy once symptomatic; prevention = post-exposure prophylaxis (wound care, vaccine, RIG)

Key India-specific entities — expanded points

- ▶ **HSV-1 encephalitis** is the *only* common viral encephalitis with effective specific therapy. NMDA-receptor antibodies appear in up to 25% of recovered patients and may cause relapse/worsening weeks later — this requires immunotherapy, not antiviral escalation.
- ▶ **Japanese encephalitis** is the most significant viral encephalitis of Asia (~68,000 cases and ~13,600–20,400 deaths/year). India runs a JE vaccination programme in endemic districts; pig/bird amplification and irrigated rice ecology drive transmission. A *parkinsonian movement disorder with bilateral thalamic MRI lesions* is the exam hallmark.
- ▶ **Nipah** is the highest-lethality entity (CFR up to ~92%) — recognise the date-palm-sap and fruit-bat exposure history, brainstem/myoclonic signs, and the public-health imperative of isolation and contact tracing.

- ▶ **Chandipura** is a peculiarly *Indian paediatric* rhabdoviral encephalitis with explosive course and high mortality, in which CSF is characteristically unremarkable for virus.

General diagnostic approach

- ▶ **CSF (mandatory unless raised ICP):** lymphocytic pleocytosis (>5 cells/ μL in $>95\%$), mildly raised protein, *normal glucose*; collect ≥ 20 mL, freeze 5–10 mL for PCR/metagenomics.
- ▶ **CSF PCR** is the primary test for HSV, VZV, CMV, EBV, HHV-6, enteroviruses; **arboviral diagnosis rests on virus-specific IgM** (CSF/serum, MAC-ELISA) since viraemia is transient.
- ▶ **Neuroimaging:** MRI temporal lobes $\rightarrow$ HSV; bilateral thalami/basal ganglia $\rightarrow$ flaviviruses (JE, WNV); deep-grey/brainstem $\rightarrow$ arboviral.
- ▶ **EEG:** periodic lateralised temporal complexes $\rightarrow$ HSV; SSPE periodic bursts.
- ▶ **Metagenomic next-generation sequencing (mNGS)** of CSF for obscure/immunocompromised cases.

Principles of management

- ▶ **Empirical IV acyclovir** in every patient with suspected viral encephalitis (especially with focal features) *while awaiting PCR* — discontinue if HSV excluded.
- ▶ **Supportive ICU care:** ICP monitoring, fluid restriction (avoid hypotonic fluids, watch SIADH), fever suppression, standard anticonvulsants, airway/ventilatory support, prophylaxis against aspiration, DVT and pressure ulcers.
- ▶ **Pathogen-specific:** CMV — ganciclovir + foscarnet; arboviruses (JE, WNV, dengue, chikungunya, Chandipura, Nipah) — supportive only.
- ▶ **Prevention is decisive:** JE vaccine (endemic districts), KFD vaccine (Karnataka), measles vaccine (prevents SSPE), rabies PEP, and vector control (mosquito-source reduction, repellents/DEET, bed-nets, full-sleeve clothing).

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Labelled axial MRI brain panels:** (1) *HSV* — asymmetric T2/FLAIR hyperintensity of right temporal lobe (label: temporal lobe, insula, cingulate gyrus); (2) *Japanese encephalitis* — bilateral thalamic T2/FLAIR lesions (label: thalamus, substantia nigra, basal ganglia).
- ▶ **Transmission-cycle schematic for JE:** label *Culex tritaeniorhynchus* mosquito $\rightarrow$ *amplifying hosts* (pig, ardeid wading bird/heron) $\rightarrow$ *dead-end host* (human), with rice-field habitat.

Clinical / Diagnostic significance

- ▶ The clinical priority is *not to miss treatable HSV*; a negative early (≤ 72 h) HSV CSF PCR does not exclude it — repeat in 1–3 days if suspicion is high.

- ▶ *Movement disorder + bilateral thalamic lesions* in an endemic child = JE until proven otherwise; *bat/date-palm-sap exposure with brainstem signs and respiratory failure* = Nipah (isolate immediately).
- ▶ Hypoglycorrhachia or persisting CSF neutrophilia should redirect toward bacterial, tuberculous, fungal or amoebic causes (*Naegleria*, *Balamuthia*).
- ▶ Autoimmune encephalitis (anti-NMDA-R, LGI1, CASPR2) is the key non-infective mimic and may follow HSV encephalitis.

High-yield exam pointers

- ▶ HSV-1 = **commonest sporadic**; JEV = **commonest epidemic** viral encephalitis in India.
- ▶ Acyclovir 10 mg/kg IV q8h × 21 days — memorise dose; start empirically, do not wait for PCR.
- ▶ JE: *Culex tritaeniorhynchus*; pig + ardeid-bird amplifiers; parkinsonism; bilateral thalamic MRI; anti-JEV IgM diagnostic; SA14-14-2 / IXIARO vaccines.
- ▶ Nipah: Henipavirus, *Pteropus* bats, date-palm sap, CFR 67–92%, PCR of urine/respiratory secretions (not blood), barrier nursing.
- ▶ Chandipura: Indian rhabdovirus, children, sandfly-borne, CFR 45–80%, CSF often bland.
- ▶ WNV diagnosis = CSF IgM (not PCR); KFD = Karnataka, *Haemaphysalis* tick, vaccine available.
- ▶ Arboviral encephalitides (JE, WNV, dengue, chikungunya, Chandipura, Nipah) → **supportive treatment only**; prevention via vaccine + vector control.
- ▶ SSPE = **late measles complication**, periodic EEG, raised CSF anti-measles antibody, preventable by vaccination.

SOURCE & COVERAGE

- ▶ Harrison's Principles of Internal Medicine, 22e — "Encephalitis" (HSV dosing, CSF/PCR/MRI/EEG, SSPE, differential diagnosis) and "Arthropod-Borne and Rodent-Borne Virus Infections" (Japanese encephalitis, West Nile, dengue, chikungunya, Chandipura, Kyasanur Forest disease epidemiology and presentation); "Common Viral Respiratory Infections"/Hendra–Nipah section (Henipavirus biology).
- ▶ CMDT 2026 — "Viral & Rickettsial Infections" (Japanese encephalitis essentials, diagnosis, vaccines and prognosis; Nipah virus clinical features, CFR, diagnostic ELISA/PCR; supportive management).

Coverage note: The spec flags India-specific epidemiology as thin, and this is accurate — Harrison/CMDT confirm the pathogens, vectors, presentations and management used above, but do **not** give India-state-wise incidence figures or the Indian national JE/AES surveillance data; those administrative specifics are outside the corpus and have not been fabricated. Chandipura,

Nipah-India and KFD are corpus-supported as Indian entities. Rabies is included as a universally-accepted neurotropic viral encephalitis though it is conventionally discussed separately.

Toxoplasmosis

Asked in: Paper IV May 2019 — RGUHS MD General Medicine

Definition / Introduction — Toxoplasmosis is a zoonosis caused by the obligate intracellular coccidian protozoan *Toxoplasma gondii*. The **cat (Felidae)** is the *definitive host* in which the sexual cycle and oocyst formation occur, while humans and other warm-blooded animals are *intermediate hosts*. Up to a third of the world's population is latently infected. Acute acquired infection is asymptomatic in 80–90% of immunocompetent persons, but the parasite persists lifelong as tissue cysts; the major clinical burden falls on three groups — the **immunocompromised** (reactivation encephalitis), the **fetus/newborn** (congenital toxoplasmosis), and persons with **ocular disease** (chorioretinitis).

Etiology, Life Cycle & Transmission

- ▶ **Organism & forms:** *T. gondii* exists in three forms — the rapidly dividing invasive **tachyzoite** (infects all nucleated cells except RBCs; causes tissue damage), the slow-replicating **bradyzoite** within **tissue cysts** (persist in CNS, skeletal/cardiac muscle, retina — the chronic/latent stage), and the environmentally hardy **oocyst** (sexual-stage product shed only in cat faeces, sporulating to 8 sporozoites after 2–3 days in air).
- ▶ **Life cycle:** The **enteroepithelial (sexual) cycle** occurs only in the cat intestine, producing unsporulated oocysts in faeces; an acutely infected cat may excrete up to **100 million oocysts/day**. In intermediate hosts the **asexual cycle** proceeds — ingested cysts/oocysts release organisms that transform into tachyzoites, disseminate, and ultimately encyst as bradyzoites (tissue cysts appear 7–10 days after infection).
- ▶ **Routes of transmission:**
 - **Oral (commonest):** ingestion of **tissue cysts** in raw/undercooked meat (lamb, pork, beef, venison) or **sporulated oocysts** from soil/water/food contaminated by cat faeces; also unpasteurised goat milk, untreated water, raw shellfish (filter-feeders concentrate oocysts).
 - **Transplacental** (tachyzoites) → congenital toxoplasmosis.
 - **Blood transfusion / solid-organ or haematopoietic stem-cell transplantation** (donor → seronegative recipient).
 - Rarely **laboratory accident** (needlestick, infected tissue).
- ▶ **Genotypes:** Northern-hemisphere strains are predominantly 3 clonal genotypes; **South/Central American strains are more virulent**, atypical, and cause severe ocular and even sepsis-like disease in immunocompetent hosts — a travel history is diagnostically important.

Pathogenesis, Pathology & Immune Response

- ▶ Released bradyzoites/sporozoites invade gut epithelium → transform into **tachyzoites** → disseminate as free organisms or inside phagocytes (“Trojan horse”) to lymph node, muscle, myocardium, retina, placenta and CNS. Hallmark lesion: **cell death and focal necrosis with surrounding mononuclear inflammation**.
- ▶ **Control is mainly cell-mediated**: a strong TH1 response with IL-12 and IFN- γ (plus CD4⁺ and cytolytic CD8⁺ T cells, activated macrophages) contains the parasite; humoral antibody is parasitocidal with complement (basis of the *Sabin-Feldman dye test*).
- ▶ In the **immunocompromised or fetal host**, failure of T-cell immunity (notably CD8⁺ loss) permits unchecked tachyzoite spread → **necrotizing encephalitis, pneumonitis, myocarditis**. Reactivation in AIDS is almost always from **spontaneous rupture of latent cysts** in the brain when CD4⁺ count <100/ μ L.
- ▶ **Pathology by site**: lymph node — *follicular hyperplasia with clusters of epithelioid histiocytes encroaching on germinal centres* (Piringer-Kuchinka pattern); CNS — necrotizing encephalitis with microglial nodules and cyst-bearing necrotic borders; eye — necrotizing retinochoroiditis; *T. gondii* is the commonest cause of posterior uveitis in immunocompetent persons.

Clinical Manifestations (Four Syndromes)

Syndrome	Host	Key features
1. Acute acquired	Immunocompetent	80–90% asymptomatic. Commonest sign = bilateral, non-tender cervical lymphadenopathy (also suboccipital, supraclavicular); mononucleosis-like illness — fever (<40°C), malaise, headache, sore throat, myalgia, atypical lymphocytosis. Self-limited over weeks–months; rarely pneumonitis, myocarditis, polymyositis, encephalitis (virulent strains)
2. Congenital	Fetus / newborn	Follows primary maternal infection in pregnancy . Transmission rises with gestational age (~15% 1st trimester → ~65% 3rd) but severity falls — early infection → abortion, stillbirth, severe disease; late → usually asymptomatic at birth. Classic <i>Sabin tetrad</i> : hydrocephalus, intracranial (diffuse) calcifications,

Syndrome	Host	Key features
		chorioretinitis, and convulsions; also microcephaly, intellectual disability, strabismus
3. Ocular	Any (congenital or acquired)	Retinochoroiditis — blurred vision, scotoma, photophobia, eye pain; fundus shows yellow-white cotton-like patches with overlying vitritis (<i>“headlight in the fog”</i>), healing to pigmented scars. Causes ~35% of chorioretinitis in US/Europe; recurrent flares, esp. South-American strains
4. Reactivation in immunocompromised	AIDS, transplant, immunosuppressed	Toxoplasmic encephalitis (TE) is the principal CNS opportunistic infection in AIDS — subacute fever, headache, altered mental status (75%), focal deficits/hemiparesis, seizures (33%); sites = basal ganglia, corticomedullary junction, brainstem . Also pneumonitis (mimics PJP), myocarditis, chorioretinitis. >95% of TE in AIDS is reactivation, typically at CD4 ⁺ <100/μL

Diagnosis

- **Serology (mainstay in immunocompetent):** Acute infection suggested by **simultaneous IgM + IgG**, seroconversion, or a 4-fold (≥ 16 -fold) titre rise. IgG (Sabin-Feldman dye test, IFA, ELISA) appears at 2–3 weeks, peaks 6–8 weeks, persists for life. IgM (double-sandwich IgM-ELISA, IgM-ISAGA) rises early but may **persist >1 year** — a positive IgM alone does not prove recent infection. **IgG avidity testing** (high avidity = infection >3–4 months ago) helps date infection in pregnancy. Circulating **IgA** favours acute/congenital infection.
- **Molecular:** PCR is the mainstay for detecting organism in **amniotic fluid** (congenital — replaced fetal blood sampling), CSF, blood, aqueous/vitreous humour, BAL. Highly specific but variably sensitive — a **negative PCR does not exclude** toxoplasmosis.
- **Histology / isolation:** demonstration of **tachyzoites** in tissue/fluid = acute infection; isolated cysts indicate only past/latent infection. Lymph-node biopsy shows the characteristic reactive pattern.
- **Immunocompromised (TE):** based on **clinical picture + positive IgG (IgM usually negative) + neuroimaging**. CT/MRI show **multiple ring-enhancing lesions** at the basal ganglia and

corticomedullary junction; MRI is most sensitive. Predictive value of a typical picture in a seropositive AIDS patient is ~80%. A favourable **empirical therapeutic trial** (>50% improve by day 3, >90% by day 7) is diagnostic; non-response or a **solitary lesion** suggests **primary CNS lymphoma** (EBV-positive CSF PCR) and warrants **stereotactic brain biopsy**.

- **Congenital/newborn:** persistence of IgG beyond 12 months, or positive IgM/IgA after the first week of life, is diagnostic; assess eyes, brain (imaging) and CSF as up to 25% are seronegative at birth.
- **Ocular:** typical retinal lesion + positive serum IgG; intra-ocular antibody production (Goldmann-Witmer coefficient) or ocular-fluid PCR/Western blot in atypical cases.

Treatment & Prophylaxis

- **Mechanism note:** anti-*Toxoplasma* drugs act only on **tachyzoites** — they control disease but **do not eradicate tissue cysts**. Folinic acid (**leucovorin**) is added to counter pyrimethamine marrow toxicity (NOT folic acid).

Setting	Regimen (from source)
Immunocompromised / TE (acute)	Pyrimethamine (200 mg load, then 50 mg/d if <60 kg, 75 mg/d if >60 kg) + sulfadiazine (1000 mg qid <60 kg; 1500 mg qid >60 kg) + leucovorin 10–25 mg/d, minimum 6 weeks. Sulfa intolerance → clindamycin 600 mg qid. Resource-poor / pyrimethamine unavailable → TMP-SMX (5 mg/kg TMP + 25 mg/kg SMX bid)
Ocular (immunocompetent)	Pyrimethamine + sulfadiazine or clindamycin × 6 weeks, ± prednisone; treat sight-threatening lesions (macula/optic disc)
Acute lymphadenopathy (immunocompetent)	Usually no therapy ; treat only if severe/persistent or visceral (2–4 weeks)
Pregnancy	Spiramycin 1 g tid until delivery for early acute infection (does not cross placenta; cuts transmission ~60%). After 18 weeks or documented fetal infection → pyrimethamine + sulfadiazine + folinic acid (pyrimethamine avoided in 1st trimester — teratogenic)
Congenital (neonate)	Pyrimethamine 1 mg/kg + sulfadiazine 100 mg/kg + folinic acid for 1 year; prednisone 1 mg/kg/d if indicated
Primary prophylaxis (AIDS)	If seropositive and CD4 ⁺ <100/μL → TMP-SMX 1 double-strength tab daily (also prevents PJP). Alternatives: dapsone-pyrimethamine, atovaquone ± pyrimethamine. Stop when CD4 ⁺ >200/μL for ≥3 months

Setting	Regimen (from source)
Secondary prophylaxis (maintenance)	Pyrimethamine + sulfadiazine (or clindamycin/TMP-SMX) + leucovorin until immune reconstitution; stop when CD4 ⁺ >200/ μ L for ≥ 6 months on ART (with repeat MRI)

Prevention

- ▶ **Cook meat** to a safe internal temperature (≈ 63 – 66°C ; ground meat/poultry higher) and rest; **freezing to -20°C** kills tissue cysts.
- ▶ Wash hands, fruits and vegetables; avoid raw shellfish and unpasteurised milk.
- ▶ **Cat-litter precautions:** change the litter box **daily** (fresh oocysts are non-infective for ~ 48 h before sporulation), preferably by a non-pregnant, HIV-negative person; wear gloves for gardening; keep cats indoors and feed only cooked/commercial food.
- ▶ Screen **donor and recipient** serology before transplantation; counsel seronegative pregnant and immunocompromised persons. Some countries screen pregnant women (France, Austria) and/or newborns (Denmark, Massachusetts).

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Life cycle of Toxoplasma gondii* (circular):* label Definitive host (cat) $\rightarrow$ enteroepithelial/sexual cycle $\rightarrow$ unsporulated oocyst in faeces $\rightarrow$ sporulated oocyst (8 sporozoites) **in soil/water**; Intermediate hosts (**human, sheep, pig, rodent, birds**) $\rightarrow$ tachyzoites (**acute, infect all nucleated cells**) $\rightarrow$ tissue cysts with bradyzoites **in CNS/muscle/retina**; **arrows for undercooked meat and transplacental** routes to humans.**
- ▶ **MRI brain in toxoplasmic encephalitis:** label **multiple ring-enhancing lesions, basal ganglia, corticomedullary junction, surrounding vasogenic oedema.**

Clinical / Diagnostic significance

- ▶ *T. gondii* is the **commonest cause of focal brain lesions / mass lesions in AIDS** — empirical anti-toxoplasma therapy with imaging follow-up is standard; failure to improve points to CNS lymphoma.
- ▶ A **solitary ring-enhancing lesion** or **negative Toxoplasma IgG** in an AIDS patient argues against TE and toward lymphoma/other diagnoses $\rightarrow$ consider early biopsy.
- ▶ In **pregnancy**, the IgM/IgG plus **avidity** panel and **amniotic-fluid PCR** guide the choice between spiramycin and pyrimethamine-based therapy and decisions on continuation of pregnancy.
- ▶ **Ocular toxoplasmosis** is the leading infectious cause of posterior uveitis; recurrence and macular involvement threaten vision.
- ▶ **Antiretroviral therapy** (immune reconstitution to CD4⁺ >200/ μ L) is the key to discontinuing both primary and secondary prophylaxis.

High-yield exam pointers

- ▶ Cat = definitive host; oocysts shed **only** in cat faeces; humans = intermediate host.
- ▶ Three forms: **tachyzoite** (acute, all nucleated cells, spares RBCs), **bradyzoite/tissue cyst** (latent), **oocyst** (sexual stage, environmental).
- ▶ Sabin-Feldman dye test = reference IgG serology; IgM-ISAGA and avidity date infection; PCR of amniotic fluid for congenital diagnosis.
- ▶ Sabin classic tetrad of congenital disease: **hydrocephalus, intracranial calcification, chorioretinitis, convulsions**; transmission ↑ but severity ↓ with later gestation.
- ▶ TE in AIDS at CD4⁺ <100/μL: **multiple ring-enhancing** basal-ganglia/corticomedullary lesions; >90% respond to empirical therapy by day 7.
- ▶ Pyrimethamine + sulfadiazine + leucovorin = standard; clindamycin if sulfa-intolerant; TMP-SMX alternative and the prophylactic agent of choice (covers PJP too).
- ▶ Spiramycin = drug of choice in early pregnancy (doesn't cross placenta); **avoid pyrimethamine in the 1st trimester**.
- ▶ Primary prophylaxis: TMP-SMX at CD4⁺ <100/μL; stop at CD4⁺ >200/μL ×3 months (primary) or ×6 months (secondary).
- ▶ Drugs kill tachyzoites **only** — never eradicate cysts; add **folinic acid (leucovorin)**, not folic acid.

SOURCE & COVERAGE

- ▶ **Harrison's Principles of Internal Medicine, 22e** — “Toxoplasma Infections” (etiology, life cycle, transmission, pathogenesis, immune response, clinical syndromes, serologic/PCR/imaging diagnosis, treatment doses, AIDS prophylaxis thresholds, prevention).
- ▶ **CMDT 2026** — “Protozoal & Helminthic Infections: Toxoplasmosis” (four clinical syndromes, current serologic/PCR algorithm, drug regimens, spiramycin in pregnancy, chemoprophylaxis) and HIV chapter for TE prophylaxis.
- ▶ *Coverage note:* The **Sabin classic tetrad** (hydrocephalus, intracranial calcification, chorioretinitis, convulsions) is universally accepted standard internal medicine; Harrison lists the component features (hydrocephalus, microcephaly, intellectual disability, chorioretinitis, epilepsy) without naming the eponymous tetrad. The *Goldmann-Witmer coefficient* and *Piringer-Kuchinka* lymph-node pattern are named per standard usage; Harrison/CMDT describe the underlying tests/histology.

Treatment and Prevention of Cholera

Asked in: Paper II Nov 2022 — RGUHS MD General Medicine

Definition / Introduction — Cholera is an acute, toxin-mediated diarrhoeal disease caused by *Vibrio cholerae* serogroup O1 or O139 (the serogroups with epidemic potential) that can, within hours, produce profound, rapidly progressive dehydration and death. The severe form is termed **cholera gravis**. Death results almost entirely from **hypovolaemic shock** and metabolic acidosis driven by massive secretory (rice-water) stool loss; consequently, prompt, aggressive fluid and electrolyte repletion converts a historically lethal illness into a self-limited one. Management therefore rests on two pillars — *rehydration* (the cornerstone) and *adjunctive antibiotics/zinc* — while prevention combines water-sanitation-hygiene (WASH) measures with oral cholera vaccination.

Principles of treatment — rehydration is paramount

- ▶ **Goal:** rapidly restore euvolaemia, then maintain hydration by replacing ongoing losses until diarrhoea stops. Treatment intensity is guided by the **degree of dehydration** (Table below) and the patient's age/weight.
- ▶ **Oral rehydration solution (ORS)** is the mainstay for mild–moderate dehydration. It exploits the **hexose–Na⁺ co-transport mechanism**: glucose (or galactose) is actively transported across the gut mucosa, dragging Na⁺ with it; Cl[−] and water follow passively. *This transport pathway remains intact even when cholera toxin is active*, which is why ORS works despite ongoing toxin-driven secretion.
- ▶ **WHO reduced (“low”)-osmolarity ORS** is now recommended for dehydrating diarrhoea of any cause. Composition (mmol/L): Na⁺ 75, K⁺ 20, Cl[−] 65, citrate 10, glucose 75 — **total osmolarity 245 mOsm/L**. Each sachet (added to 1 L safe water) contains NaCl 2.6 g, trisodium citrate dihydrate 2.9 g, KCl 1.5 g and anhydrous glucose 13.5 g.
- ▶ **Homemade ORS** (when sachets unavailable): 0.5 teaspoon (½ small spoonful) table salt + 6 level teaspoons table sugar in 1 L of safe water; supplement potassium via **bananas or green coconut water**.
- ▶ **Rice-based ORS** is considered superior to standard ORS specifically in cholera. ORS may be given by **nasogastric tube** if the patient cannot drink.
- ▶ **Continue feeding/breast-feeding** during treatment; encourage potassium-rich intake.

Dehydration assessment and fluid prescription

Degree	Key clinical findings	Fluid loss	Treatment
None/mild	Thirst only	<5% body wt	ORS to replace losses (e.g. ≥10 y: ½–1 cup, max 1 L/d)
Moderate	Thirst, postural hypotension, weakness, tachycardia, ↓skin turgor, dry mouth, no tears	5–10% body wt	ORS <i>ad libitum</i> , up to max 2 L/d (give within first 4 h; weight-based volumes)

Degree	Key clinical findings	Fluid loss	Treatment
Severe	Lethargy/unconsciousness (“floppiness”), weak/absent pulse, inability to drink, sunken eyes/fontanelles	>10% body wt	IV fluids (see below)

- ▶ **Severe dehydration** → IV resuscitation. Use **Ringer’s lactate** (best commercial choice because profound acidosis, pH <7.2, is common; if unavailable, normal saline). It *must* be supplemented with **potassium**, preferably given orally.
- ▶ **Volume schedule (WHO)**: give **100 mL/kg in the first 3 h** (first 6 h in children <12 months) — start rapidly then slow down — for a **total of 200 mL/kg in the first 24 h**. Continue until the patient is awake, can ingest ORS, and no longer has a weak pulse.
- ▶ Alternatively framed: in severely dehydrated patients (>10% body wt) the **total deficit can be replaced within the first 3–4 h**, with half in the first hour. **Transient muscle cramps and tetany are common** during rapid repletion.
- ▶ Thereafter switch to **oral therapy**, matching intake to output. Patients with continued large-volume diarrhoea may need prolonged IV fluids.
- ▶ **Hypokalaemia** can be severe but responds to K⁺ (IV or oral). *Where monitoring staff are inadequate, the oral route for both rehydration and potassium is safer than IV.*

Composition of cholera stool vs. replacement fluid

Fluid (mmol/L)	Na ⁺	K ⁺	Cl ⁻	Base
Adult cholera stool	135	15	100	45
Child cholera stool	100	25	90	30
Ringer’s lactate	130	4*	109	28

Ringer’s lactate is relatively K⁺- and base-poor versus stool, which is why additional potassium (oral preferred) is mandatory to replace stool losses.*

Adjunctive antibiotics and zinc

- ▶ Antibiotics are **not necessary for cure**, but an agent to which the organism is susceptible **shortens the duration and volume of fluid loss and hastens clearance of the organism from stool**. Hence give to patients with **moderate or severe dehydration**.

Class / drug	Adult dose	Paediatric dose
Azithromycin (macrolide; agent of choice)	Single 1-g oral dose	Single 20 mg/kg dose
Erythromycin (macrolide)	250 mg PO QID × 3 days	12.5 mg/kg/dose QID × 3 days
Doxycycline (tetracycline)	Single 300-mg dose (non-pregnant)	>8 y: single 4–6 mg/kg dose
Tetracycline	500 mg PO QID × 3 days (non-pregnant)	>8 y: 12.5 mg/kg/dose QID × 3 days
Ciprofloxacin (fluoroquinolone)	500 mg PO BID × 3 days	15 mg/kg BID × 3 days

- ▶ **Resistance caveats:** macrolides (azithromycin/erythromycin) are the **agents of choice**; resistance to **tetracyclines** is **widespread**, and **fluoroquinolone resistance is increasing** — use these only where susceptibility is confirmed.
- ▶ **Zinc** reduces the volume and severity of diarrhoea in young children, including cholera: <6 months → 10 mg/day for 10 days; 6 to <60 months → 20 mg oral zinc/day for 10 days.

Prevention — sanitation, surveillance and vaccines

- ▶ **General/public-health measures:** provision of safe water and sanitary disposal of faeces, **improved nutrition**, and care with **food preparation and storage** in the household significantly reduce incidence. Prevent spread by **infected or asymptomatic carriers** moving from endemic to non-endemic regions (the probable route of the 2010 Haiti outbreak).
- ▶ **Oral cholera vaccines (OCV)** — two types developed to maximise mucosal immunity: **oral killed vaccines** and **live attenuated vaccines**.
- ▶ **Three oral KILLED vaccines are WHO-prequalified:**
 - **BivWC (Shanchol; Shantha Biotechnics, Hyderabad, India)** — both biotypes/serotypes of *V. cholerae* O1 and O139, *without* supplemental cholera toxin B (CTB) subunit; manufacture being terminated.
 - **Euvichol / Euvichol-Plus (Eubiologics, Seoul, South Korea)** — currently supplies the vast majority of global control-programme vaccine.
 - **WC-rBS (Dukoral; Valneva, Sweden)** — both biotypes/serotypes of *V. cholerae* O1 supplemented with 1 mg recombinant CTB subunit per dose.
- ▶ **Killed-vaccine schedule/efficacy:** given as a 2- or 3-dose regimen, doses ~14 days apart, providing ~60–85% **protection** for the first few months. **Boosters:** WC-rBS after 2 years (≥6 y) or 6 months (children 2–5 y); BivWC gave ~60% **protection over 5 years** in a Kolkata study (~40% in children ≤5 y). Even a **single dose** confers some outbreak protection (40% all / 63% severe cholera over 6 months) but **no protection in children <5 y** with one dose. **Herd immunity** is predicted once coverage >50%; killed vaccines are **safe in high-HIV-prevalence populations**.

- ▶ **Live attenuated vaccine:** CVD 103-HgR (Vaxchora; Emergent BioSolutions) — derived from a classic strain that **lacks the cholera-toxin genes**; FDA-approved for travellers (ages 2–64 y) but **not WHO-prequalified**. Single oral dose; **90% and 80% efficacious** against severe cholera at 10 and 90 days post-vaccination in volunteer challenge.
- ▶ **Global strategy:** the Global Task Force on Cholera Control (GTFCC) strategy (launched 2017, WHO secretariat) aims to **cut cholera deaths by 90% and eliminate cholera in up to 20 countries by 2030**, integrating **WASH programmes + vaccination** and a **Global Vaccine Stockpile** (used mainly for *reactive*, often single-dose, campaigns owing to shortages).

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Diagram 1 — Hexose- Na^+ co-transport / basis of ORS.** Label: intestinal villus enterocyte; SGLT1 glucose- Na^+ co-transporter on apical membrane; **glucose; Na^+ ; Cl^- and H_2O following passively;** Na^+/K^+ -ATPase on basolateral membrane; note “*pathway intact despite cholera toxin.*” Contrast with adjacent crypt cell showing cholera-toxin $\rightarrow \uparrow \text{cAMP} \rightarrow \text{Cl}^-/\text{water}$ secretion (the diarrhoea).
- ▶ **Diagram 2 — Fluid-management flowchart by dehydration severity.** Boxes labelled: Assess dehydration $\rightarrow$ None-mild (ORS) / Moderate (ORS up to 2 L) / Severe (IV Ringer’s lactate 100 mL/kg in 3 h, total 200 mL/kg/24 h + oral K^+) $\rightarrow$ transition to maintenance ORS, with the endpoint “awake, drinking, normal pulse.”

Clinical / Diagnostic significance

- ▶ **Diagnosis:** suspect in any patient ≥ 5 y with acute watery diarrhoea in/near an endemic area, or with severe dehydration. Confirm by stool **dark-field microscopy** (darting motility, immobilised by specific antiserum), culture on TCBS or TTG agar, **Cary-Blair transport / alkaline-peptone water** enrichment, or **point-of-care antigen dipstick** in the field.
- ▶ **Labs reflect volume/electrolyte loss:** raised haematocrit (haemoconcentration), prerenal azotaemia, **bicarbonate < 15 mmol/L** with a high **anion gap** acidosis, arterial pH ~ 7.2 , and usually normal $\text{Na}^+/\text{K}^+/\text{Cl}^-$ — guiding the Ringer’s lactate + potassium choice.
- ▶ **Management pearl:** complications (acute tubular necrosis, shock) are *purely* a consequence of dehydration and are **averted by adequate fluid/electrolyte therapy** — the disease is then self-limited over a few days.

High-yield exam pointers

- ▶ **Rehydration is the single most important intervention; death is from hypovolaemic shock.**
- ▶ WHO low-osmolality ORS = 245 mOsm/L (Na 75, K 20, Cl 65, citrate 10, glucose 75).
- ▶ Severe case = **Ringer’s lactate**, 100 mL/kg in 3 h (6 h if < 12 mo), 200 mL/kg in 24 h, plus oral potassium.

- ▶ Rice-based ORS > standard ORS in cholera; ORS works via **glucose–Na⁺ co-transport** (intact despite toxin).
- ▶ Antibiotics are **adjunctive** (reduce stool volume/duration, hasten clearance) for **moderate/severe** dehydration — **azithromycin 1 g single dose** is first choice; tetracycline/FQ resistance rising.
- ▶ **Zinc**: 10 mg/day (<6 mo) or 20 mg/day (6–<60 mo) for **10 days** in children.
- ▶ **Three WHO-prequalified killed OCVs**: Shanchol (BivWC), Euvichol/Euvichol-Plus, Dukoral (WC-rBS, +CTB); live attenuated = **Vaxchora (CVD 103-HgR)**.
- ▶ **GTFCC 2017 goal**: 90% fewer deaths and elimination in up to 20 countries by **2030** via WASH + vaccine.

SOURCE & COVERAGE

Harrison's Principles of Internal Medicine, 22e — **Ch 173 “Cholera and Other Vibrioses”** (Waldor & Ryan); Tables 173-1 to 173-4 (dehydration assessment, treatment by severity, ORS and stool/IV electrolyte composition). All drug doses, ORS/Ringer's compositions, vaccine names and efficacy figures are taken directly from this chapter. *Coverage note*: the chapter fully covers this topic; SGLT1 is named in the diagram per universally accepted physiology (Harrison cites the “hexose–Na⁺ co-transport” mechanism without naming the transporter).

Tropical Pulmonary Eosinophilia

Asked in: Paper II Dec 2023 — RGUHS MD General Medicine

Definition / Introduction — Tropical pulmonary eosinophilia (TPE) is a distinct *hyper-responsive* syndrome that develops in a minority of individuals infected with the lymphatic-dwelling filarial nematodes **Wuchereria bancrofti** and **Brugia malayi**. It is characterised by paroxysmal nocturnal cough and wheeze, diffuse pulmonary infiltrates, intense peripheral blood eosinophilia (>3000/μL), markedly elevated serum IgE and antifilarial antibody, and a dramatic response to diethylcarbamazine (DEC). It is best understood as an *occult (amicrofilaraemic) filariasis* in which microfilariae are cleared from blood and trapped in the lungs, where they provoke an exuberant allergic-inflammatory reaction.

Etiology & Epidemiology

- ▶ **Causative parasites**: the lymphatic-dwelling filariae **W. bancrofti** and **B. malayi** — the same species that cause lymphatic filariasis. TPE is therefore one end of the clinical spectrum of bancroftian/brugian filariasis.
- ▶ **Vectors**: *Culex* mosquitoes (urban) and *Anopheles/Aedes* (rural) transmit *W. bancrofti*; *Mansonia* and *Anopheles* transmit *B. malayi*. Infective L3 larvae are deposited on skin during the mosquito bite.

- ▶ **Microfilarial periodicity:** both species are predominantly **nocturnally periodic** — microfilariae are scarce in peripheral blood by day and surge at night, which correlates with the characteristic *nocturnal* respiratory symptoms of TPE.
- ▶ **Adult worms** reside in afferent lymphatics or lymph nodes and may remain viable for **more than two decades**, providing a chronic antigenic stimulus.
- ▶ **Geography:** most cases reported from **India, Pakistan, Sri Lanka, Brazil, Guyana and Southeast Asia**. A history of residence in a filaria-endemic region is near-universal.
- ▶ **Trend:** the incidence of TPE has *declined over the past decade*, probably reflecting global mass drug administration (MDA) for elimination of lymphatic filariasis.

Pathogenesis & Pathology

- ▶ TPE represents a state of **immunological hyper-responsiveness** to the filarial parasite rather than uncontrolled infection.
- ▶ **Microfilariae and parasite antigens are rapidly cleared from the bloodstream by the lungs** — this *pulmonary sequestration* explains the cardinal paradox of TPE: blood is characteristically **amicrofilaraemic** despite active filarial infection.
- ▶ Clinical symptoms result from **allergic and inflammatory (hypersensitivity) reactions** elicited by the trapped/cleared parasites within the lung.
- ▶ A **prominent, eosinophil-enriched intra-alveolar infiltrate** develops; degranulating eosinophils release **cytotoxic, proinflammatory eosinophil granule proteins** that mediate much of the tissue damage (eosinophilic alveolitis).
- ▶ In some patients, trapping of microfilariae in other reticuloendothelial organs causes **hepatomegaly, splenomegaly or lymphadenopathy**.
- ▶ **If untreated**, the chronic eosinophilic inflammation progresses to **interstitial fibrosis** and irreversible, progressive pulmonary damage.

Clinical Features

- ▶ **History:** residence in / travel to a filaria-endemic area.
- ▶ **Respiratory:** **paroxysmal cough and wheezing**, classically **nocturnal** (paralleling the nocturnal periodicity of microfilariae); dyspnoea; may mimic bronchial asthma.
- ▶ **Constitutional:** weight loss, low-grade fever, malaise.
- ▶ **Lymphoreticular:** **lymphadenopathy**; sometimes hepatosplenomegaly.
- ▶ **Hallmark laboratory clue:** **pronounced blood eosinophilia** (>3000 eosinophils/ μL).
- ▶ Symptoms are subacute–chronic and, untreated, can persist for months with progressive pulmonary impairment.

Investigations & Diagnostic Criteria

- ▶ **Peripheral blood eosinophilia** $>3000/\mu\text{L}$ (often very high).
- ▶ **Serum IgE**: total IgE markedly elevated (Harrison quotes 4–40 KIU/mL); **antifilarial antibody titres markedly raised** — both are characteristic.
- ▶ **Absence of microfilariae in peripheral blood** (occult filariasis) — a key feature distinguishing TPE from classical microfilaraemic filariasis.
- ▶ **Chest imaging (X-ray / CT)**: may be normal, but generally shows **increased bronchovascular markings**; **diffuse miliary lesions or mottled opacities** may be seen in the **middle and lower lung fields**.
- ▶ **Pulmonary function tests**: **restrictive** abnormalities in most cases, with **obstructive** defects in about half; reduced diffusion capacity reflects interstitial involvement.
- ▶ **BAL**: eosinophilic alveolitis (intra-alveolar eosinophil-rich infiltrate).
- ▶ **Therapeutic trial**: prompt clinical and haematological response to DEC strongly supports the diagnosis.

The composite diagnostic picture: endemic-area residence + nocturnal cough/wheeze + extreme eosinophilia ($>3000/\mu\text{L}$) + very high IgE & antifilarial antibody + characteristic radiology + restrictive PFT + rapid response to DEC.

Differential Diagnosis

TPE is one of the **pulmonary infiltrates with eosinophilia (PIE)** syndromes and must be distinguished from the conditions Harrison lists below.

Condition	Distinguishing pointers
Bronchial asthma	Allergic; lower-grade eosinophilia; no antifilarial antibody; no endemic exposure
Löffler's syndrome	Transient, migratory infiltrates from larval transit (e.g. <i>Ascaris</i>); self-limited
Allergic bronchopulmonary aspergillosis (ABPA)	Central bronchiectasis, <i>Aspergillus</i> -specific IgE/precipitins, mucoid impaction
EGPA / Churg-Strauss (allergic granulomatosis with polyangiitis)	Asthma + eosinophilia + vasculitis; ANCA in a proportion; multi-organ involvement
Other systemic vasculitides	Notably polyarteritis (periarteritis) nodosa
Chronic eosinophilic pneumonia	"Photographic-negative" peripheral infiltrates; idiopathic; steroid-responsive
Hypereosinophilic syndromes (HESs)	Persistent eosinophilia $>1500/\mu\text{L}$ with multi-organ damage; no filarial serology

PIE classification (Harrison Ch 299) for framing the answer:

Group	Examples
Primary pulmonary eosinophilic disorders	Acute eosinophilic pneumonia; Chronic eosinophilic pneumonia; EGPA (Churg-Strauss); Hypereosinophilic syndrome
Known-cause / secondary (TPE belongs here)	Asthma & eosinophilic bronchitis; ABPA; drug/toxin reaction; Infection — parasitic/helminthic disease (includes TPE); non-parasitic infection

Treatment

- ▶ **Diethylcarbamazine (DEC)** is the drug of choice: **4–6 mg/kg daily for 14 days** (note this is a longer course than the standard active-filariasis regimen).
- ▶ **Symptoms usually resolve within 3–7 days** of starting therapy — the rapid response is both confirmatory and therapeutic.
- ▶ **Relapse occurs in ~12–25% of cases** (sometimes after an interval of several years) and **requires re-treatment**.
- ▶ **Goal:** early, complete treatment prevents progression to **interstitial fibrosis** and chronic restrictive lung disease.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Filarial life cycle highlighting pulmonary trapping in TPE** — labels: *Mosquito vector (Culex / Anopheles) → Infective L3 larvae deposited on skin → Adult worms in lymphatics / lymph nodes → Microfilariae released into blood (nocturnal periodicity) → Microfilariae & antigens cleared and TRAPPED in the lung → Eosinophil-enriched intra-alveolar infiltrate (eosinophilic alveolitis) → Hypersensitivity reaction / high IgE & antifilarial antibody → Untreated → interstitial fibrosis.*
- ▶ **Schematic chest X-ray of TPE** — labels: *Increased bronchovascular markings, diffuse miliary / mottled opacities in mid & lower zones, bilateral involvement, (may be normal in some cases).*

Clinical / Diagnostic significance

- ▶ TPE is an important, **eminently treatable** cause of chronic cough, wheeze and pulmonary infiltrates in patients from the Indian subcontinent — readily mistaken for refractory asthma or miliary tuberculosis.
- ▶ The **triad of extreme eosinophilia (>3000/ μ L), very high IgE/antifilarial antibody, and amicrofilaraemia** in an endemic-area resident is highly suggestive and should prompt a DEC trial.

- ▶ Early diagnosis prevents irreversible interstitial fibrosis; relapse mandates follow-up and re-treatment.
- ▶ Conceptually links to public-health filariasis control: falling TPE incidence mirrors the success of WHO MDA programmes.

High-yield exam pointers

- ▶ TPE = occult/amicrofilaraemic filariasis caused by *W. bancrofti* & *B. malayi*; microfilariae are cleared and trapped in the lungs (absent in peripheral blood).
- ▶ Classic clue triad: nocturnal paroxysmal cough/wheeze + eosinophilia $>3000/\mu\text{L}$ + markedly raised IgE & antifilarial antibody.
- ▶ Symptoms are nocturnal because of the nocturnal periodicity of microfilariae.
- ▶ CXR: increased bronchovascular markings; mid/lower-zone miliary or mottled opacities; may be normal. PFT: restrictive in most, obstructive in half.
- ▶ Endemic in India, Pakistan, Sri Lanka, Brazil, Guyana, SE Asia; incidence falling with MDA.
- ▶ DEC 4–6 mg/kg/day $\times$ 14 days; response in 3–7 days; relapse 12–25% needs re-treatment.
- ▶ Untreated $\rightarrow$ interstitial fibrosis and progressive restrictive lung disease.
- ▶ It is a secondary (known-cause) PIE — i.e. pulmonary infiltrates with eosinophilia due to a parasitic/helminthic infection.
- ▶ Pathology = eosinophilic alveolitis: cytotoxic eosinophil granule proteins drive the lung injury.
- ▶ Differentiate from asthma, Löffler's syndrome, ABPA, EGPA (Churg-Strauss), chronic eosinophilic pneumonia, HES.

SOURCE & COVERAGE

Harrison's Principles of Internal Medicine, 22e — Ch 240 "Filarial and Related Infections" (TPE epidemiology, pathology, clinical features, differential and DEC treatment; lymphatic filariasis etiology/vectors/periodicity) and Ch 299 "Hypersensitivity Pneumonitis and Pulmonary Infiltrates with Eosinophilia" (PIE classification framing). *Coverage note:* Ch 299 does not name TPE explicitly but lists "Infection — parasitic/helminthic disease" among secondary PIE syndromes; the male predominance and young-adult (2nd–4th decade) preponderance often cited for TPE are not stated in the provided chapters and are given as standard textbook context only.

Tropical Splenomegaly

Asked in: Paper II May 2022 — RGUHS MD General Medicine

Definition / Introduction — *Tropical splenomegaly* in internal-medicine usage refers to **Hyperreactive Malarial Splenomegaly (HMS)**, formerly called *Tropical Splenomegaly Syndrome (TSS)*. It is a **chronic complication of malaria** seen in long-term residents of malaria-endemic tropical regions, in whom an **aberrant, exaggerated immunologic response to repeated malarial infection** produces *massive splenomegaly*, hepatomegaly, marked **serum IgM** elevation and high malarial-antibody titres, with **anemia and hypersplenism**. It is a clinically important and *reversible* cause of massive splenomegaly that must be separated from haematologic malignancy.

Etiology & epidemiology

- ▶ **Cause:** chronic or repeated malarial infection in a genetically/immunologically predisposed host. Chronic malaria characteristically produces **hypergammaglobulinaemia, a normochromic normocytic anaemia, and (in some) splenomegaly**.
- ▶ **Host:** *residents of malaria-endemic areas in tropical countries* who mount an **abnormal immunologic response** to repeated infection — not a feature of acute single-episode malaria.
- ▶ **Geography:** holoendemic malarious belts of sub-Saharan Africa, Papua New Guinea, South-East Asia, the Indian subcontinent and Amazonia. Harrison notes that *in some tropical countries (e.g., New Guinea) the incidence of palpable splenomegaly may reach 60%* — emphasising that, in the tropics, a palpable spleen does not automatically equate with disease.
- ▶ **Implicated species:** *Plasmodium falciparum* and *P. malariae* are classically responsible (the (in Africa) peripheral B-cell lymphocytosis and chronic antigenic drive).

Pathogenesis (an immunologic, not a parasitic, disease)

The driving event is **uncontrolled, polyclonal B-cell over-production of IgM** in response to recurrent malarial antigen, with loss of normal T-cell suppressor control:

- ▶ Chronic infection → **marked elevation of serum IgM and malarial antibody titres**.
- ▶ Production of **cytotoxic IgM antibodies against CD8+ (suppressor) T lymphocytes** and antibodies to **CD5+ T lymphocytes**, with a resultant **increase in the CD4+ : CD8+ ratio**.
- ▶ Loss of suppressor-T-cell restraint → **uninhibited B-cell production of IgM** → formation of **cryoglobulins** (IgM aggregates and immune complexes).
- ▶ These immune complexes are cleared by the reticulo-endothelial (RE) system, stimulating **lymphoid hyperplasia and clearance (“work”) hypertrophy** of the spleen → progressive **massive splenomegaly**. **Hepatic sinusoidal lymphocytosis** is characteristic, and (in Africa) a **peripheral B-cell lymphocytosis** occurs.
- ▶ The same RE/lymphoid hyperplasia mechanism that enlarges the spleen drives **hypersplenism** (pooling and destruction of blood cells in congested, enlarged cords) → **anaemia and pancytopenia**.

This places HMS within the “**increased demand for splenic function / immune-and-RE hyperplasia**” mechanistic group of splenomegaly (Harrison Table 70-2), alongside other parasitic causes (leishmaniasis, trypanosomiasis).

Clinical features

- ▶ **Massive splenomegaly** — the dominant sign; the patient presents with an **abdominal mass** or a “**dragging**” sensation in the abdomen.
- ▶ **Occasional sharp abdominal pain** suggesting **perisplenitis** (capsular inflammation); massive enlargement may also cause early satiety and LUQ heaviness.
- ▶ **Hepatomegaly** is usually present alongside the splenomegaly.
- ▶ **Anaemia and some degree of pancytopenia (hypersplenism)** — fatigue, pallor, bleeding tendency.
- ▶ **Recurrent respiratory and skin infections** are common, and **many patients die of overwhelming sepsis** — the leading cause of death.
- ▶ Constitutional features (insidious onset over months–years); unlike acute malaria there is usually **no high parasitaemia** — in many cases **malaria parasites cannot be found on peripheral-blood smears by microscopy**.

Diagnosis: criteria & investigations

- ▶ **Peripheral smear:** often **negative for parasites** (low-grade/absent parasitaemia) — a negative film does NOT exclude HMS.
- ▶ **Serum immunoglobulins:** markedly raised **polyclonal IgM**; **high malarial antibody titres**.
- ▶ **Full blood count:** features of **hypersplenism** — splenomegaly with cytopenia(s), a **normal or hyperplastic bone marrow**, and response to splenectomy; anaemia ± leuko-/thrombocytopenia.
- ▶ **Liver/spleen histology:** **hepatic sinusoidal lymphocytosis** (a hallmark on liver biopsy); reactive lymphoid hyperplasia in the spleen.
- ▶ **Imaging — confirm and size the spleen:** **ultrasonography is the procedure of choice** (normal max cephalo-caudad diameter ≤13 cm; normal spleen <250 g and impalpable). The spleen is “**massively enlarged**” when palpable >8 cm below the left costal margin or weighs ≥1000 g. Bedside assessment uses **palpation** (bimanual / ballottement / *Middleton manoeuvre*) and **percussion** (*Nixon, Castell, Traube’s space*).
- ▶ **Therapeutic test: clinical and immunologic response (spleen regression, fall in IgM) to sustained antimalarial therapy** is itself a key diagnostic criterion and helps separate HMS from lymphoma.
- ▶ ****Fakunle diagnostic criteria** (standard tropical-medicine criteria — see Coverage note):* Major — (1) *gross splenomegaly (≥10 cm below costal margin) with no other local cause*; (2) *serum IgM ≥2 SD above the local mean*; (3) *high malarial antibody titres*; (4) *clinical and immunologic*

response to antimalarial therapy. Minor* — hepatic sinusoidal lymphocytosis, hypersplenism, normal-to-exaggerated lymphocyte responses, and familial clustering.

Differential diagnosis (causes of massive / tropical splenomegaly)

HMS must be distinguished from other causes of a *massive* spleen, especially haematologic malignancy (some HMS cases have been *mistaken for haematologic malignancy*):

Category	Conditions to exclude
Tropical infective	Visceral leishmaniasis (<i>kala-azar</i>), hepatic schistosomiasis, chronic malaria itself, trypanosomiasis
Haematologic malignancy	Chronic myeloid leukaemia, myelofibrosis with myeloid metaplasia, hairy-cell leukaemia, chronic lymphocytic leukaemia / lymphomas, polycythaemia vera
Infiltrative / storage	Gaucher's disease, amyloidosis, sarcoidosis, diffuse splenic haemangiomatosis
Congestive (portal HTN)	Cirrhosis, portal/splenic vein obstruction, " <i>Banti's disease</i> ", schistosomal periportal fibrosis
Immune	Autoimmune haemolytic anaemia, Felty's syndrome, SLE

Key separators: in HMS the smear is usually parasite-negative, IgM is very high, hepatic sinusoidal lymphocytosis is present, and the spleen **regresses on antimalarials** — features that argue against leishmaniasis (bone-marrow/splenic LD bodies), CML (Philadelphia chromosome, granulocytosis), and lymphoma (lymph-node/tissue biopsy).

Management & prognosis

- ▶ **Endemic-area residents: antimalarial chemoprophylaxis** (sustained/prolonged) — *results are usually good*, with gradual spleen regression and fall in IgM. Compliance over months is essential; relapse follows withdrawal.
- ▶ **Non-endemic settings (travellers/migrants): antimalarial treatment** is advised.
- ▶ **Standard regimens** (textbook practice — see Coverage note): long-term **proguanil** or **chloroquine** prophylaxis are the conventional agents; therapy is continued for a prolonged period with serial spleen-size and IgM monitoring.
- ▶ **Supportive:** treat anaemia/cytopenias of hypersplenism; aggressively investigate and treat intercurrent infection — **overwhelming sepsis is the chief killer**.
- ▶ **Splenectomy** is generally avoided (it does not treat the underlying immune disorder and adds lifelong infection risk); it is reserved for refractory hypersplenism/symptomatic massive splenomegaly, with appropriate pre-operative vaccination.

- **Prognosis / caveat:** in cases refractory to therapy, clonal lymphoproliferation may develop and can evolve into a malignant lymphoproliferative disorder — long-term follow-up is mandatory.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- **Diagram 1 — Spleen microanatomy (basis of culling/pitting & work hypertrophy).**
Labels: *splenic artery* → *central arteriole*, **white pulp** (B-cell follicle with germinal centre, marginal zone, peri-arteriolar T-cell sheath), **red pulp** (*pulp cords*, *pulp sinuses*), *sinusoidal slits/pores*, *reticulo-endothelial (macrophage) cells*, *splenic venous system*.
- **Diagram 2 — Pathogenesis flow of HMS.** Labels: *Repeated malarial infection* → *polyclonal B-cell activation* (↑IgM, cryoglobulins, immune complexes) → *anti-CD8 cytotoxic IgM* → *loss of suppressor T cells* → ↑CD4:CD8 ratio → *RE / lymphoid hyperplasia & clearance activity* → **massive splenomegaly + hepatomegaly + hypersplenism (anaemia, pancytopenia).**

Clinical / Diagnostic significance

- A reversible, treatable cause of massive splenomegaly in the tropics — early recognition averts unnecessary splenectomy or chemotherapy for a misdiagnosed “lymphoma.”
- The parasite-negative smear with very high IgM and antimalarial-responsive splenomegaly is the diagnostic signature.
- Demonstrates the spleen’s immune/RE “work hypertrophy” physiology and the concept of hypersplenism (splenomegaly + cytopenia + hyperplastic marrow + response to splenectomy).
- Carries a real risk of progression to clonal lymphoproliferative disease, mandating surveillance.

High-yield exam pointers

- *Tropical splenomegaly = Hyperreactive Malarial Splenomegaly (HMS) = old Tropical Splenomegaly Syndrome*; it is a **chronic complication of malaria** (*P. falciparum* / *P. malariae*).
- It is an **immunologic disorder**, NOT high parasitaemia — **smear is often parasite-negative**.
- Hallmarks: **massive splenomegaly + hepatomegaly + very high serum IgM + high malarial antibody titres + hepatic sinusoidal lymphocytosis** (+ peripheral B-cell lymphocytosis in Africa).
- Immunology: cytotoxic IgM vs CD8+ T cells, anti-CD5+ T-cell antibodies, ↑CD4:CD8 ratio, cryoglobulins.
- Presents as an abdominal “dragging” mass ± perisplenic pain, with **anaemia + pancytopenia** (hypersplenism); death is usually from overwhelming sepsis.
- **Massive spleen** = palpable >8 cm below the costal margin or ≥1000 g; **ultrasound** is the imaging of choice; normal spleen <250 g, ≤13 cm.
- Treatment = **prolonged antimalarial chemoprophylaxis/treatment** (good response in endemic areas); **avoid splenectomy**.

- ▶ Refractory cases may undergo **clonal lymphoproliferation** → **malignant lymphoproliferative disorder**.
- ▶ Remember the tropical massive-splenomegaly DDx: **kala-azar, schistosomiasis, CML, myelofibrosis, lymphoma/CLL, Gaucher's**.

SOURCE & COVERAGE

Harrison's Principles of Internal Medicine, 22e (2025) — Ch 231 “Malaria” (Chronic Complications of Malaria → *Hyperreactive Malarial Splenomegaly*: aetiology, immunopathogenesis, clinical features, treatment, lymphoma risk) and Ch 70 “Enlargement of Lymph Nodes and Spleen” (spleen structure/function, mechanisms of splenomegaly Table 70-2, massive-splenomegaly criteria and differential Table 70-3, hypersplenism, examination and imaging). **Coverage note (spec gap = true):** Harrison covers HMS only briefly within the Malaria chapter. Points **not explicitly in the provided Harrison text** but added as standard, universally-accepted tropical-medicine teaching, and flagged here: the **named* Fakunle diagnostic criteria*, the specific prophylactic drugs (proguanil / chloroquine) and the ≥ 10 cm spleen / IgM ≥ 2 SD thresholds, the role/avoidance of splenectomy**, and the detailed geographic distribution. All disease mechanisms, the IgM/CD8/CD5/CD4:CD8 immunology, clinical features, lymphoma risk, the “massively enlarged” definition (> 8 cm / ≥ 1000 g) and the splenomegaly differential are directly grounded in the two cited chapters.

Viral meningitis

Asked in: Paper III Nov 2019 — RGUHS MD General Medicine

Definition / Introduction — **Viral meningitis** is an acute inflammation of the leptomeninges and subarachnoid space (SAS) caused by viral infection, producing headache, fever and meningeal irritation **without** the profound alteration of consciousness, seizures, or focal deficits that characterise encephalitis. It is the commonest cause of the “**aseptic meningitis syndrome**” — a clinical-laboratory picture of meningeal inflammation (CSF lymphocytic pleocytosis, normal glucose, negative routine bacterial Gram's stain and culture) — and is, in the immunocompetent adult, a generally **benign, self-limiting** illness. *Enteroviruses* account for the great majority of identified cases.

Etiology

- ▶ A specific viral cause is now identifiable in **60–90%** of cases using CSF PCR, culture and serology; CSF *cultures* alone are positive in only 30–70%, and about two-thirds of culture-negative “aseptic” cases yield a virus on **CSF PCR**.

- ▶ **Most important / common agents:** *Enteroviruses* (coxsackieviruses, echoviruses, numbered enteroviruses), *varicella-zoster virus* (VZV), *herpes simplex virus* (HSV-2 > HSV-1), *HIV*, and *arboviruses* (notably West Nile virus, WNV).
- ▶ **Less common:** HSV-1, human herpesvirus 6 (HHV-6), cytomegalovirus (CMV), *lymphocytic choriomeningitis virus* (LCMV), mumps, Epstein-Barr virus (EBV), Zika and other non-WNV arboviruses.
- ▶ **Enteroviruses cause >85% of cases in which an agent is identified** — the single dominant cause.

Clinical manifestations

- ▶ **Cardinal features:** headache (almost invariable — frontal/retro-orbital, with **photophobia** and pain on eye movement), fever, and **nuchal rigidity** (often mild, only at the limit of neck anteflexion).
- ▶ **Constitutional:** malaise, myalgia, anorexia, nausea/vomiting, abdominal pain, diarrhoea; mild lethargy or drowsiness is common.
- ▶ **Red flags pointing AWAY from simple viral meningitis (suggest encephalitis or alternative diagnosis):** *stupor, coma, marked confusion, seizures, focal neurological signs*, or neuroimaging evidence of parenchymal involvement. These are NOT features of pure viral meningitis.
- ▶ **Etiological clues on examination** — search for exanthems, *hand-foot-mouth disease, herpangina*, pleurodynia, myopericarditis and haemorrhagic conjunctivitis (enterovirus); genital vesicles (HSV-2); chickenpox/shingles rash (VZV); parotitis/orchitis (mumps); cranial nerve palsies, especially V, VII, VIII (HIV).

Epidemiology

- ▶ Estimated incidence $\geq 75,000$ cases/year in the United States (not a nationally reportable disease).
- ▶ In temperate climates there is a marked **summer–autumn (non-winter) predominance**, reflecting the seasonality of *enterovirus* and *arbovirus* infection; peak monthly incidence ~ 1 case/100,000.
- ▶ **Seasonal/host clues:** enteroviruses — summer/fall, children <15 yr; arboviruses — summer/early fall, geographic clusters; **mumps** — late winter/early spring, males (M:F 3:1); LCMV — late fall/winter, exposure to house mice (*Mus musculus*), pet/laboratory rodents or their excreta.

CSF and laboratory diagnosis

- ▶ CSF examination is the single most important test. Typical viral profile:

Parameter	Viral (aseptic) meningitis	Contrast: pyogenic bacterial
Opening pressure	Normal/mildly raised (100–350 mmH ₂ O)	>180 mmH ₂ O (often markedly)

Parameter	Viral (aseptic) meningitis	Contrast: pyogenic bacterial
Cell type	Lymphocytic pleocytosis	Polymorphonuclear (PMN)
Cell count	Typically 25–500/ μ L (occasionally thousands with LCMV/mumps)	100–10,000/ μ L
Glucose	Normal	Low (<2.2 mmol/L; CSF/serum <0.4)
Protein	Normal/mildly raised (0.2–0.8 g/L)	High (>0.45 g/L)
Gram's stain	Negative	Positive in >60%

- **Exceptions to remember:** PMNs may *predominate in the first 48 h*, especially **echovirus 9, WNV, eastern equine encephalitis virus, and mumps** — a PMN pleocytosis occurs in ~45% of WNV meningitis and may persist a week before shifting to lymphocytes. PMN pleocytosis with low glucose also occurs with CMV in the immunocompromised.
- **Hypoglycorrhachia (low CSF glucose)** is atypical but occurs in 10–30% of mumps and LCMV cases (rarely echovirus/enterovirus, HSV-2, VZV). A lymphocytic pleocytosis *with low glucose* should still raise TB, fungal, *Listeria*, or neoplastic meningitis.
- **CSF PCR** — **diagnostic procedure of choice** for enteroviral and HSV CNS infection; far more sensitive than culture. Enteroviral RT-PCR sensitivity >95%, highest within 48 h, falling rapidly after day 5. The **FilmArray Meningitis/Encephalitis multiplex panel** detects HSV-1, HSV-2, enteroviruses, VZV, HHV-6 and human Parechovirus — but **NOT** CMV, WNV, LCMV or EBV.
- **Serology:** mainstay for **arboviruses (WNV)** — demonstration of **virus-specific IgM in CSF** or seroconversion (CSF WNV IgM more sensitive [>80% in neuroinvasive disease] than CSF RT-PCR ~70%); serology less useful for high-seroprevalence herpesviruses.
- **Viral culture** of CSF is generally poor-yield; ancillary isolation — enterovirus/adenovirus in stool; arbovirus/enterovirus/LCMV in blood; mumps/CMV in urine; enterovirus/mumps/adenovirus in throat washings. Stool enterovirus shedding persists weeks and is *not by itself diagnostic*.
- **Other tests:** full blood count, liver/renal function, ESR, C-reactive protein, electrolytes, glucose, amylase/lipase (mumps). **Neuroimaging (MRI > CT)** is not mandatory in uncomplicated cases but is indicated for altered consciousness, seizures, focal signs, atypical CSF, or immunocompromise. CSF **oligoclonal bands** can occur.

Specific viral etiologies — exam pearls

- ▶ **Enteroviruses** — >85% of identified cases; benign outside the neonatal period; supportive treatment, recovery without sequelae. Chronic/severe infection in neonates and the **hypo-/agammaglobulinaemic**.
- ▶ **HSV** — second to enteroviruses overall (~5% of cases, higher in adults / non-summer). In adults uncomplicated meningitis is mostly **HSV-2**, whereas **HSV-1 causes ~90% of HSV encephalitis**. Meningitis occurs in ~25–35% of **women** and ~10–15% of **men** at primary genital herpes; ~20% develop recurrent attacks. Most **recurrent (“benign lymphocytic”) aseptic meningitis — including cases formerly called Mollaret’s meningitis — is due to HSV** (diagnosed by CSF PCR; cultures often negative).
- ▶ **VZV** — suspect with concurrent chickenpox/shingles, but increasingly recognised **without rash**; frequency 3–20% across series.
- ▶ **Arboviruses (WNV, St. Louis, California group)** — geographic/seasonal clusters; avian deaths can be sentinel for WNV; diagnosis by CSF IgM.
- ▶ **Mumps** — parotitis/orchitis/oophoritis/raised lipase-amylase; clinical meningitis in 10–30% of parotitis; pleocytosis can exceed 1000/μL; incidence fell >95% after vaccination.
- ▶ **HIV** — aseptic meningitis in 5–10% at primary (seroconversion) infection; **cranial nerve V, VII, VIII palsies** are more frequent than with other viruses.
- ▶ **LCMV** — rodent exposure; leukopenia, thrombocytopenia, abnormal LFTs; may show marked pleocytosis and hypoglycorrhachia.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Meningeal anatomy / lumbar puncture site (labelled):** scalp — skull — **dura mater** — **arachnoid mater** — **subarachnoid space (CSF, site of inflammation)** — **pia mater** — cerebral cortex; plus a spine schematic marking the **L3–L4 / L4–L5 interspace** for LP below the conus medullaris.
- ▶ **CSF interpretation flow-box (labelled):** “Meningeal signs → LP” → branch A *Lymphocytes + normal glucose + negative Gram’s stain* = **VIRAL/aseptic** → CSF PCR / WNV IgM; branch B *PMN + low glucose + positive Gram’s* = **bacterial**; branch C *Lymphocytes + low glucose* = **TB / fungal / Listeria / neoplastic**.

Clinical / Diagnostic significance

- ▶ **Differential diagnosis is the crux** — exclude mimics of aseptic meningitis: untreated/partially-treated bacterial meningitis; early TB, fungal or *T. pallidum* (neurosyphilis); *Mycoplasma*, *Listeria*, *Brucella*, *Coxiella*, *Leptospira*, *Rickettsia*; parameningeal foci; neoplastic meningitis; and non-infectious inflammatory disease (drug-induced hypersensitivity meningitis, SLE, sarcoidosis, Behçet’s, uveomeningitic syndromes).

- ▶ **Distinguishing bacterial from aseptic:** CSF protein >0.5 g/L and serum procalcitonin >0.5 ng/mL (sensitivity/specificity ~89%) favour bacterial; the validated **Bacterial Meningitis Score** predicts very low bacterial probability (NPV 99.7%) when *all* of — negative CSF Gram's stain, CSF neutrophils <1000/μL, CSF protein <80 mg/dL, peripheral ANC <10,000/μL, and no seizures — are met.
- ▶ **Treatment is principally supportive:** analgesics, antipyretics, antiemetics, fluid/electrolyte care. Empirical antibacterial (± aciclovir) cover is continued until bacterial meningitis is excluded.
- ▶ **Specific antiviral therapy** (benefit data limited): **IV aciclovir 15–30 mg/kg/day in 3 divided doses** for seriously ill HSV/VZV (and severe EBV) cases, stepping down to oral aciclovir 800 mg five times daily, famciclovir 500 mg tid, or valaciclovir 1000 mg tid for a total 7–14 days; mild cases — oral agents alone. *No proven specific therapy* for arboviral (e.g., WNV) disease. **HIV meningitis** → antiretroviral therapy. Per CMDT, antiviral therapy for aseptic meningitis in immunocompetent hosts is of *uncertain benefit* (self-limiting), and long-term oral valaciclovir prophylaxis does **NOT** prevent recurrent HSV-2 aseptic meningitis.
- ▶ **Special hosts:** patients with deficient humoral immunity (e.g., X-linked agammaglobulinaemia) should receive **immunoglobulin (IM γ-globulin or IVIg)**; intraventricular Ig (Ommaya reservoir) has been used for refractory chronic enteroviral meningitis.
- ▶ **Admission criteria:** immunocompetent patients with a classic CSF profile and no red flags may be managed at home with follow-up; **hospitalise** the immunocompromised and any with altered consciousness, seizures, focal signs, or atypical CSF.
- ▶ **Prevention:** vaccination prevents meningitis from **poliovirus, mumps, measles, rubella and varicella**; the recombinant zoster vaccine (Shingrix) is recommended for VZV prevention.

High-yield exam pointers

- ▶ **Aseptic meningitis** = lymphocytic pleocytosis + normal glucose + negative routine bacterial Gram's stain/culture; **viral causes are the commonest**.
- ▶ **Enteroviruses** cause >85% of identified viral meningitis; **summer–autumn** peak; children.
- ▶ **CSF PCR (RT-PCR) is the test of choice**; enteroviral RT-PCR best within **48 h**, declines after day 5.
- ▶ **HSV-2** = leading cause of recurrent / **Mollaret's** aseptic meningitis; **HSV-1** = **encephalitis**.
- ▶ **Early PMN predominance** can occur with **echovirus 9, WNV, EEE, mumps**; ~45% of WNV meningitis has CSF neutrophilia.
- ▶ **Low CSF glucose** in viral meningitis suggests **mumps or LCMV** (10–30%) — but always reconsider TB/fungal/Listeria.
- ▶ **Arbovirus (WNV) diagnosis** = **CSF virus-specific IgM** (more sensitive than CSF RT-PCR).
- ▶ **Profound coma, seizures or focal deficits** → think **encephalitis**, not pure meningitis.

- Treatment is **supportive**; aciclovir for HSV/VZV; **IVIg** for agammaglobulinaemia; antiretrovirals for HIV. **Prognosis in adults is excellent.**

SOURCE & COVERAGE

- **Harrison's Principles of Internal Medicine, 22e** — “Acute Meningitis” (Viral Meningitis section: clinical manifestations, etiology, CSF/PCR/serology, specific viral etiologies, treatment, prognosis; comparison data from the Bacterial Meningitis section of the same chapter).
- **CMDT 2026** — “Viral & Rickettsial Infections” (enteroviral syndromes; antiviral/valaciclovir-prophylaxis caveat for HSV-2 aseptic meningitis) and “Nervous System Disorders” (current management framing).

What are the methods used to measure antimicrobial activity in the lab?

Asked in: Paper I 06 Apr 2026 — RGUHS MD General Medicine

Definition / Introduction — *Antimicrobial susceptibility testing (AST)* comprises the standardised in-vitro laboratory methods that quantify the activity of an antimicrobial agent against a bacterial isolate, expressed chiefly as the **minimal inhibitory concentration (MIC)** — the lowest drug concentration that inhibits visible growth of a microorganism under standardised laboratory conditions. AST converts a raw MIC into a clinically actionable category — *susceptible (S)*, *intermediate (I)*, or *resistant (R)* — by comparison with regulatory **breakpoints**, and thereby guides directed (pathogen-targeted) therapy, defines local resistance for the **antibiogram**, and underpins pharmacokinetic–pharmacodynamic (PK/PD) dosing. Methods are broadly **diffusion-based**, **dilution-based (quantitative)**, **automated/rapid phenotypic**, **specialised (bactericidal/synergy)**, and **molecular/genotypic**.

Core endpoints the laboratory measures

- **MIC** — lowest concentration inhibiting growth with a standardised inoculum and growth conditions; the central quantitative endpoint, reported in µg/mL (e.g., vancomycin MIC of 2 µg/mL flags reduced susceptibility in *S. aureus*).
- **Minimal bactericidal concentration (MBC)** — lowest concentration that **kills ≥99.9% (≥3 log₁₀)** of the original inoculum; distinguishes bactericidal from bacteriostatic action.
- **Breakpoint** — the MIC value(s) set by advisory bodies (**CLSI, EUCAST**) that partition isolates into S/I/R; derived from MIC distributions of clinical isolates, drug PK/delivery to the infection site, and clinical-trial outcome data. “Susceptible” predicts likely response to an appropriately dosed drug; “resistant” predicts poor/no response.

- ▶ **Bacteriostatic vs bactericidal** — inhibition of growth vs killing; bactericidal agents are preferred where host defences are impaired or limited (neutropenia, **meningitis**, **endocarditis**).
- ▶ **Tolerance** — organism inhibited but not killed (failure to activate autolysins); operationally an **MBC/MIC ratio ≥ 32** .
- ▶ **Postantibiotic effect (PAE)** — delayed regrowth of surviving bacteria after drug exposure (prominent with aminoglycosides), supporting extended-interval dosing.

Diffusion methods (qualitative / semi-quantitative)

- ▶ **Disk diffusion (Kirby–Bauer)** — standard inoculum (turbidity matched to the 0.5 McFarland standard) is lawn-spread on **Mueller–Hinton agar**; antibiotic-impregnated paper disks are applied; after **16–18 h** at **35 °C** the **zone of inhibition diameter (mm)** is measured and interpreted as S/I/R against CLSI/EUCAST tables. Cheap, flexible, the workhorse of most laboratories; gives a category, **not** a numeric MIC.
- ▶ **Gradient diffusion (E-test / epsilometer) — a plastic strip carrying a predefined exponential antibiotic gradient is laid on inoculated agar; an elliptical inhibition zone forms and the MIC is read where the ellipse intersects the strip**. Combines the simplicity of diffusion with a quantitative MIC; useful for fastidious organisms and for confirming key MICs (e.g., penicillin/pneumococcus, vancomycin/staphylococci).
- ▶ **D-test (double-disk approximation)** — erythromycin and clindamycin disks placed adjacently; flattening (“D” shape) of the clindamycin zone reveals **inducible clindamycin (MLS_B) resistance**.

Dilution (quantitative) methods — the reference for MIC and MBC

- ▶ **Broth dilution** — antibiotic prepared in **doubling (two-fold) serial dilutions** in Mueller–Hinton broth; each tube/well inoculated to a standard density ($\sim 5 \times 10^5$ CFU/mL); the **MIC is the lowest concentration with no visible turbidity** after overnight incubation.
 - *Macrodilution* uses tubes (labour-intensive); *microdilution* uses **96-well microtitre plates** and is the practical reference standard, allowing many drug/dilution combinations per plate.
- ▶ **Agar dilution** — antibiotic incorporated into agar plates at doubling dilutions; multiple isolates spot-inoculated onto each plate; MIC = lowest concentration inhibiting visible growth. Efficient when many isolates are tested against one drug (reference method for some organisms, e.g., *N. gonorrhoeae*).
- ▶ **MBC determination** — aliquots from the clear (no-growth) broth-dilution tubes are subcultured to drug-free agar; colony counts identify the lowest concentration giving **$\geq 99.9\%$ kill = MBC**; the **MBC/MIC ratio** defines tolerance.

Method	Output	Quantitative MIC?	Typical use
Disk diffusion (Kirby–Bauer)	Zone diameter → S/I/R	No	Routine first-line testing
E-test (gradient strip)	MIC (µg/mL)	Yes	Confirm key/borderline MICs, fastidious organisms
Broth microdilution	MIC (µg/mL)	Yes	Reference standard MIC
Agar dilution	MIC (µg/mL)	Yes	Reference for many isolates / one drug
Automated (VITEK 2, Phoenix, MicroScan)	MIC + S/I/R, hours	Yes	High-throughput routine labs

Automated, specialised and bactericidal methods

- ▶ **Automated systems** — VITEK 2, BD Phoenix, MicroScan use micro-volume broth-microdilution cards/panels with **turbidimetric/colorimetric growth monitoring** and software interpretation, delivering identification + MIC in hours; the basis of most clinical antibiograms.
- ▶ ***Serum bactericidal titre (Schlichter test)*** — highest dilution of the patient's serum (during therapy) that kills the infecting organism; historically used to gauge adequacy of therapy in endocarditis/osteomyelitis.
- ▶ **Synergy testing** —
 - *Checkerboard titration* → **fractional inhibitory concentration (FIC) index**: ≤ 0.5 = synergy, $> 0.5-4$ = indifference/additivity, > 4 = antagonism.
 - *Time-kill curves* → a $\geq 2 \log_{10}$ (≥ 100 -fold) greater kill by the combination vs the most active single agent defines synergy; also profiles bactericidal kinetics and PAE.
- ▶ **β -lactamase detection** — chromogenic **nitrocefin** test gives a rapid colour change with β -lactamase-producing organisms (e.g., *H. influenzae*, gonococci, staphylococci).
- ▶ **Screening / breakpoint agars** — e.g., oxacillin/cefoxitin screen for MRSA, vancomycin-screen agar; **population analysis profiling** detects **heteroresistant VISA (hVISA)**, which is *not detectable by routine susceptibility testing*.

Molecular / genotypic methods (detect resistance determinants)

- ▶ **Targeted nucleic-acid amplification (PCR/NAAT)** for resistance genes — *mecA* (methicillin resistance in *S. aureus*), *vanA/vanB* (VRE), *bla*_{KPC} / NDM / OXA-48 carbapenemases, *bla*_{CTX-M} (ESBL).
- ▶ **GeneXpert (Xpert MTB/RIF)** — simultaneous detection of *M. tuberculosis* and **rifampicin resistance** (*rpoB*); for mycobacteria, phenotypic AST uses **liquid culture** (BACTEC MGIT) and the **agar proportion method**.

- ▶ **MALDI-TOF mass spectrometry** — rapid species identification (and adjunctive resistance detection, e.g., carbapenemase hydrolysis assays).
- ▶ **Whole-genome sequencing (WGS)** — comprehensive resistome and epidemiological typing.
- ▶ Caveat: genotype predicts phenotype only for known mechanisms; **phenotypic AST remains the standard** because a gene may be present but unexpressed, or resistance may arise by uncharacterised routes.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Disk-diffusion (Kirby–Bauer) plate** — Mueller–Hinton agar with confluent bacterial lawn; several antibiotic disks; clear circular *zone of inhibition* around a sensitive disk vs growth up to the edge of a resistant disk. Labels: *Mueller–Hinton agar, antibiotic disk, zone of inhibition (mm), confluent lawn (0.5 McFarland inoculum), susceptible, resistant*.
- ▶ **Broth microdilution row + MIC/MBC schematic** — a row of wells/tubes with doubling antibiotic concentrations: turbid (growth) wells then the first clear well = **MIC**; subculture of clear wells to agar with the first plate showing $\geq 99.9\%$ kill = **MBC**. Labels: *doubling dilutions ($\mu\text{g/mL}$), turbid = growth, first clear well = MIC, subculture $\rightarrow$ MBC, MBC/MIC ≥ 32 = tolerance*.

Clinical / Diagnostic significance

- ▶ Obtain specimens for culture **before** starting antibiotics so AST can convert empirical therapy into narrow-spectrum **directed therapy**, reducing toxicity, resistance selection, and *C. difficile* risk.
- ▶ MIC + breakpoint individualise drug choice — e.g., pneumococcal endocarditis treated by **penicillin MIC** (penicillin if MIC ≤ 2 $\mu\text{g/mL}$; ceftriaxone/vancomycin if higher); **meningitis breakpoints** are stricter (penicillin MIC 0.06 $\mu\text{g/mL}$) because of limited CSF penetration.
- ▶ The **MIC anchors PK/PD targets**: aminoglycosides $\rightarrow$ **C_{max}/MIC** (concentration-dependent); β -lactams $\rightarrow$ **T > MIC** (time-dependent); fluoroquinolones & vancomycin $\rightarrow$ **AUC/MIC** (e.g., AUC/MIC > 30 maximises fluoroquinolone kill of *S. pneumoniae*; > 125 for gram-negatives).
- ▶ The **cumulative antibiogram** (local S/I/R rates, usually annual) guides empirical regimens and stewardship; therapeutic drug monitoring (e.g., vancomycin) is interpreted against the MIC.
- ▶ Recognise the **MBC/MIC ratio** (tolerance) and **hVISA** as reasons for clinical failure despite a “susceptible” routine report.

High-yield exam pointers

- ▶ **MIC = lowest concentration inhibiting visible growth; MBC = lowest killing $\geq 99.9\%$ ($\geq 3 \log_{10}$).**
- ▶ **Kirby–Bauer disk diffusion**: Mueller–Hinton agar, **0.5 McFarland inoculum**, 16–18 h/35 °C, read **zone diameter** $\rightarrow$ S/I/R; gives a category, *not* an MIC.

- ▶ **Broth microdilution** = reference standard for numeric MIC; **agar dilution** for many isolates/one drug; E-test gives MIC by gradient diffusion.
- ▶ **Breakpoints** are set by CLSI / EUCAST; categories are S / I / R.
- ▶ **Tolerance** = MBC/MIC ≥ 32 ; **synergy** = FIC index ≤ 0.5 (checkerboard) or $\geq 2 \log_{10}$ extra kill (time-kill).
- ▶ **Automated systems**: VITEK 2, BD Phoenix, MicroScan (turbidimetric microdilution).
- ▶ **Molecular**: PCR for *mecA*, *vanA/B*, KPC/NDM/OXA; Xpert MTB/RIF for rifampicin resistance; MALDI-TOF for rapid ID; phenotypic AST still the gold standard.
- ▶ hVISA is missed by routine AST — needs **population analysis profiling**.

SOURCE & COVERAGE

- ▶ **Harrison's Principles of Internal Medicine, 22e** — “*Treatment and Prophylaxis of Bacterial Infections*” (MIC definition; bacteriostatic vs bactericidal; PK/PD indices C_{max}/MIC, T>MIC, AUC/MIC; postantibiotic effect; antibiogram); “*Bacterial Resistance to Antimicrobial Agents*” (MIC, breakpoints, S/I/R interpretation, resistance mechanisms); “*Infective Endocarditis*” (vancomycin/penicillin MICs, meningitis breakpoints, hVISA not detected by routine testing); diagnostic-microbiology content (*mecA*/NAAT detection).
- ▶ **CMDT 2026** — *Anti-infective Treatment* (mechanism/“tolerance”, MIC-targeted dosing) and *Common Problems in Infectious Diseases & Antimicrobial Therapy*.

Coverage note: The corpus (Harrison 22e, CMDT 2026) is pharmacology- and resistance-focused and covers the **endpoints** (MIC, breakpoints, S/I/R, bacteriostatic/bactericidal, tolerance, PK/PD, antibiogram, hVISA, *mecA*/NAAT) but is **thin on the step-by-step laboratory procedures**. The procedural detail of disk diffusion (Kirby–Bauer), broth macro-/micro-dilution, agar dilution, E-test, MBC determination, serum bactericidal titre, checkerboard/time-kill synergy, β -lactamase/nitrocefin and D-tests, automated systems and MALDI-TOF/WGS is supplied here from **universally accepted standard clinical microbiology (CLSI/EUCAST methodology)** and is faithful to that standard.

Respiratory system

Acute interstitial pneumonia

Asked in: Paper III May 2022 · Paper III Jul 2020 (2×) — RGUHS MD General Medicine

Definition / Introduction — *Acute interstitial pneumonia (AIP)*, historically termed *Hamman-Rich syndrome*, is a rare and often fatal idiopathic interstitial pneumonia (IIP) characterised by the **acute**

onset of respiratory distress and hypoxemia in a previously healthy individual, with diffuse alveolar damage (DAD) as its histopathologic hallmark. It is essentially the idiopathic (cryptogenic) counterpart of ARDS: the clinical, radiologic, and pathologic picture is indistinguishable from ARDS but no precipitating cause is identified. AIP is grouped among the *acute/subacute* idiopathic interstitial pneumonias and carries a mortality of >50% within 6 months of presentation.

Where AIP sits — classification of interstitial lung disease

The interstitial lung diseases (ILDs / diffuse parenchymal lung diseases) are first divided into those of known and unknown cause; AIP belongs to the largest “unknown cause” group, the idiopathic interstitial pneumonias (IIPs).

ILD of known cause	ILD of unknown cause
Exposure — asbestosis, silicosis, radiation, drugs (methotrexate, amiodarone, nitrofurantoin, bleomycin, chemotherapeutics)	Idiopathic interstitial pneumonias (IIPs) — IPF, NSIP, RB-ILD, DIP, COP, AIP, lymphocytic interstitial pneumonia
Systemic / CTD — RA, scleroderma, polymyositis-dermatomyositis, SLE, Sjögren	Granulomatous — sarcoidosis
Granulomatous with vasculitis — GPA (Wegener’s), Churg-Strauss; HP	Other — LAM, pulmonary alveolar proteinosis, Langerhans cell histiocytosis, pleuroparenchymal fibroelastosis

- ▶ Among IIPs, AIP is one of only a few that **present acutely (days–weeks)**; most IIPs (e.g., IPF) are chronic and indolent.
- ▶ Other ILDs that can present *acutely* and enter the differential of AIP: **eosinophilic pneumonia**, **hypersensitivity pneumonitis (HP)**, **granulomatosis with polyangiitis (GPA)**, and an **acute exacerbation of IPF**.
- ▶ Because of overlapping clinical, imaging, and histopathologic features, a **multidisciplinary diagnosis** (pulmonologist + radiologist + pathologist ± rheumatologist) is the accepted standard for all IIPs, AIP included.

Clinical features & natural history

- ▶ **Demographics / onset:** AIP affects previously healthy adults with **no antecedent lung disease**; onset is abrupt.
- ▶ A **prodrome resembling an acute upper respiratory tract infection** (viral-like illness — fever, myalgia, cough) is common and precedes rapidly worsening dyspnea.
- ▶ **Acute respiratory distress and refractory hypoxemia** develop over days to a few weeks, frequently progressing to respiratory failure requiring mechanical ventilation.
- ▶ **Course / prognosis:** fulminant — **mortality >50% within 6 months**; **recurrences are common** in survivors. Importantly, those who do recover can show **substantial recovery of lung function**.

- ▶ **Physical signs (general to ILD):** end-inspiratory fine **bibasal crackles (rales)**; tachypnea, cyanosis and signs of advanced disease (digital clubbing, cor pulmonale) reflect severity.
- ▶ A central diagnostic difficulty is that AIP is **hard to distinguish from ARDS and from an acute exacerbation of an unsuspected underlying pulmonary fibrosis** — making AIP largely a diagnosis of exclusion.

Investigations

- ▶ **HRCT thorax (standard of care):** the most common findings are **patchy, bilateral ground-glass opacities**, with **dependent regions of air-space consolidation** — a picture that mirrors ARDS.
- ▶ **Pulmonary function tests:** like other ILDs, AIP produces a **restrictive defect** — reduced TLC, symmetrically reduced FEV1 and FVC (preserved/normal FEV1:FVC ratio), and a reduced DLCO; in the acute setting testing is often limited by the patient's critical status.
- ▶ **Arterial blood gases:** type I respiratory failure with widened A-a gradient.
- ▶ **Exclusion work-up (essential, as AIP is idiopathic):** rule out infection (including *Pneumocystis*, viral, atypical pneumonia), left heart failure, diffuse alveolar hemorrhage, drug toxicity and CTD — via cultures, BAL, echocardiography and **immune serologies** (e.g., anti-CCP, ANA).
- ▶ **Bronchoscopy + BAL:** chiefly used to **exclude infection and alveolar hemorrhage**; bronchoscopic samples are generally insufficient to *diagnose* an IIP.
- ▶ **Surgical (VATS) lung biopsy:** the only way to confirm DAD; however it carries a **short-term mortality of up to ~5%**, which is **higher in acutely presenting patients** — so the decision must weigh diagnostic yield against risk.

Histopathology — diffuse alveolar damage (DAD)

- ▶ The defining lesion of AIP on surgical lung biopsy is **diffuse alveolar damage (DAD)** — the same pattern seen in ARDS and in **acute exacerbations of underlying pulmonary fibrosis**.
- ▶ DAD classically evolves through two phases (*standard histology, see Coverage note*):
 - **Exudative (acute) phase** — interstitial/alveolar edema, capillary congestion, and **hyaline membranes** lining alveolar ducts.
 - **Organising (proliferative) phase** — **type II pneumocyte hyperplasia**, fibroblastic proliferation and loose interstitial fibrosis; this temporally *uniform* fibrosis helps separate AIP from the temporally heterogeneous UIP of IPF.

Differential diagnosis — AIP vs ARDS vs acute exacerbation of IPF

Feature	AIP (Hamman-Rich)	ARDS	Acute exacerbation of IIP/IPF
Precipitating cause	None identified (idiopathic)	Identifiable insult (sepsis, aspiration,	Occurs on known underlying pulmonary fibrosis

Feature	AIP (Hamman-Rich)	ARDS	Acute exacerbation of IIP/IPF
		trauma, pancreatitis, etc.)	
Prior lung disease	Absent	Usually absent	Present (e.g., IPF)
Onset	Acute, days–weeks	Acute (≤ 1 week of insult)	Acute (< 30 days)
HRCT	Bilateral ground-glass + dependent consolidation	Bilateral infiltrates / consolidation	New ground-glass + consolidation superimposed on fibrosis (honeycombing/reticulation)
Histology	DAD	DAD	DAD ($\pm$ organising pneumonia)
Mortality	$> 50\%$ at 6 months	Variable	Very high ($> 85\%$)

Treatment

- **Predominantly supportive** — AIP is managed like ARDS: **supplemental oxygen and mechanical ventilation** with lung-protective strategy, treatment of intercurrent infection, and supportive ICU care.
- **There is no proven drug therapy for AIP.**
- **Glucocorticoids** are *often given* (e.g., high-dose corticosteroids) but are **not clearly effective**, and the supporting evidence — extrapolated from other forms of DAD such as ARDS — is **controversial**.
- General supportive measures applicable to progressive ILD (oxygen, pulmonary rehabilitation) and, in highly selected survivors with progressive fibrosis, consideration of **lung transplantation**.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- **HRCT thorax (axial) in AIP** — labels: *bilateral ground-glass opacities; dependent (posterior/basal) air-space consolidation; relatively preserved non-dependent lung; absence of honeycombing.*
- **Histology of diffuse alveolar damage (DAD)** — labels: *alveolar space; hyaline membranes lining alveolar duct (exudative phase); type II pneumocyte hyperplasia; fibroblastic proliferation / interstitial thickening (organising phase); congested alveolar capillary.*

Clinical / Diagnostic significance

- AIP must be considered in any **previously healthy patient with rapidly progressive dyspnea, hypoxemia and bilateral infiltrates** once infection and cardiac failure are excluded — it is

frequently misdiagnosed as community-acquired pneumonia, COPD exacerbation or heart failure.

- ▶ It is a **diagnosis of exclusion**: clinically and radiologically identical to ARDS, so the absence of an ARDS trigger and the histologic demonstration of DAD (when biopsy is feasible) clinch the diagnosis.
- ▶ Recognising AIP carries **prognostic weight** (high early mortality, frequent recurrence) and shapes **goals-of-care discussions**, while reminding the clinician that no specific pharmacotherapy is established.
- ▶ Distinguishing AIP from an **acute exacerbation of IPF** matters because the latter implies pre-existing fibrosis and an even worse outlook; HRCT background fibrosis is the key discriminator.

High-yield exam pointers

- ▶ AIP = Hamman-Rich syndrome = **idiopathic ARDS**; histology = **diffuse alveolar damage (DAD)**.
- ▶ One of the **idiopathic interstitial pneumonias**; among the few IIPs with an **acute** presentation.
- ▶ **Prodrome** mimicking an upper respiratory tract viral illness is characteristic.
- ▶ **HRCT**: bilateral **ground-glass opacities + dependent consolidation**.
- ▶ **PFT**: restrictive pattern — ↓TLC, ↓FVC, ↓DLCO.
- ▶ **Mortality >50% within 6 months; recurrences common**; survivors may regain substantial lung function.
- ▶ **No proven drug therapy** — care is **supportive ± mechanical ventilation**; glucocorticoids used but unproven/controversial.
- ▶ Key differentials: **ARDS** (identifiable cause) and **acute exacerbation of IPF/IIP** (underlying fibrosis, mortality >85%).
- ▶ Confirmatory test = **surgical/VATS lung biopsy showing DAD**, but biopsy mortality is higher in acutely ill patients.

SOURCE & COVERAGE

Harrison's Principles of Internal Medicine, 22e — Ch 304 "Interstitial Lung Disease" (AIP / Hamman-Rich subsection under *Acute or Subacute IIPs*; plus the chapter's general sections on ILD classification, history/examination, PFTs, HRCT, lung biopsy, and acute exacerbations of IIPs).

Coverage note (spec.gap = true): Harrison 22e covers AIP only briefly. The chapter explicitly supports: the Hamman-Rich eponym; classification among IIPs; acute respiratory-distress presentation with viral-like prodrome; >50% 6-month mortality with frequent recurrence and possible functional recovery; HRCT (ground-glass + dependent consolidation); DAD histology;

difficulty distinguishing from ARDS and acute exacerbation of fibrosis; and supportive treatment with no proven drug therapy and unproven glucocorticoids. Items added from universally accepted standard internal medicine but **not detailed in the provided chapter** (flagged here): the two-phase microscopic anatomy of DAD (exudative phase with hyaline membranes → organising/proliferative phase with type II pneumocyte hyperplasia and fibroblast proliferation), and the framing of AIP as a “diagnosis of exclusion.” These are accurate standard histopathology/diagnostic concepts; specific case definitions/criteria (e.g., Katzenstein/ATS-ERS formal diagnostic criteria) were not asserted as they are not given in the provided text.

Acute Pulmonary Embolism

Asked in: Paper III Nov 2019 — RGUHS MD General Medicine

Definition / Introduction — Pulmonary embolism (PE) is obstruction of the pulmonary arterial tree by thrombus that has usually embolised from a lower-limb deep-venous thrombosis (DVT); DVT and PE together constitute **venous thromboembolism (VTE)**. PE is “*the great masquerader*” — its symptoms and signs are non-specific, so a structured, probability-based pathway (clinical score → D-dimer → imaging → risk stratification → therapy) is essential. Acute PE spans a wide spectrum from clinically silent subsegmental clot to fulminant **massive** PE with cardiogenic shock and death from acute right-ventricular (RV) failure.

Aetiology and Pathophysiology

- ▶ **Virchow’s triad** — venous stasis, hypercoagulability and endothelial injury, usually with an inflammatory trigger, drive thrombus formation; activated platelets release microparticles that recruit neutrophils and form **neutrophil extracellular traps**, promoting thrombin generation.
- ▶ **Inherited thrombophilias** (autosomal dominant): *factor V Leiden* (activated protein C resistance) and the *prothrombin gene mutation* are commonest; antithrombin, protein C and protein S deficiencies are rarer but stronger.
- ▶ **Acquired**: antiphospholipid syndrome (APS — venous *and* arterial thrombosis, often needs lifetime anticoagulation), cancer, surgery/trauma, immobility, obesity, oestrogens, pregnancy and the first 6–12 weeks postpartum, long-haul travel, smoking, COPD, CKD, and inflammatory disease (IBD, RA).
- ▶ **Embolisation**: leg thrombi detach, traverse the vena cava and right heart, and lodge in the pulmonary arteries; *paradoxical* arterial embolism may occur through a patent foramen ovale.
- ▶ **Consequences**:

- *Gas exchange* — arterial hypoxaemia (present in ~85%) and a widened alveolar–arterial O₂ gradient from V/Q mismatch, increased alveolar dead space, right-to-left shunting and surfactant loss; reflex hyperventilation lowers PaCO₂.
- *Haemodynamics* — mechanical obstruction plus vasoconstrictors (serotonin, thromboxane A₂, endothelin) raise pulmonary vascular resistance → ↑RV wall tension → RV dilation, septal bowing into the LV, impaired LV filling, ↓cardiac output and hypotension. RV pressure overload also compresses the right coronary artery → **RV microinfarction** (troponin release) and BNP elevation from myocardial stretch.

Clinical Features and Classification

- ▶ **Symptoms** — unexplained **dyspnoea** is the most common (absent in ~25%); pleuritic chest pain (~⅓), cough, haemoptysis (modest), and syncope/pre-syncope with large emboli. Three PIOPED syndromes: *pleuritic pain/haemoptysis* (~60%), *isolated dyspnoea* (~25%), *circulatory collapse* (~10%).
- ▶ **Signs** — tachypnoea (commonest sign, RR >20), tachycardia, accentuated pulmonary component of S2, RV heave, crackles; with RV failure — raised JVP, fixed/narrow split S2, S3/S4, cyanosis and hypotension. Coexisting DVT (calf “charley-horse”, unilateral swelling/tenderness) is clinically apparent in only ~10%.
- ▶ **Severity classification (ESC / Harrison)** — guides every management decision:

Category	Frequency	Haemodynamics	RV / biomarkers	Prognosis
Massive (high-risk)	5–10%	SBP <90 mmHg / shock / arrest	Severe RV failure	High mortality
Submassive (intermediate-risk)	20–25%	Normotensive	RV dysfunction ± ↑troponin/BNP	May deteriorate abruptly
Low-risk	65–75%	Normotensive	Normal RV, normal biomarkers	Excellent

- ▶ *Special forms*: pulmonary infarction (peripheral, exquisitely pleuritic), and **non-thrombotic PE** — fat (long-bone/pelvic fracture), amniotic fluid, air, tumour, cement/bony fragment (after hip/knee replacement).

Diagnostic Approach

- ▶ **Step 1 — Pre-test probability**: *Wells score* (validated in ambulatory, not hospitalised, patients): clinical signs of DVT 3, alternative diagnosis less likely than PE 3, HR >100 = 1.5, immobilisation/surgery <4 wks = 1.5, prior PE/DVT 1.5, haemoptysis 1, cancer 1; **high likelihood if score >4**. Revised Geneva (objective only), PERC (8 items — excludes PE in low-risk ED patients) and the **YEARS** algorithm refine selection.

- ▶ **Step 2 — D-dimer:** quantitative ELISA, sensitivity >95%; a normal result *rules out* PE in low/intermediate probability. Not specific (raised in MI, sepsis, cancer, pregnancy, post-op) and unhelpful in inpatients. Use the **age-adjusted cut-off** ($\text{age} \times 10 \text{ ng/mL}$) in patients >50 yrs with low/intermediate probability. High-probability patients skip D-dimer and go straight to imaging.
- ▶ **Step 3 — Imaging:**
 - **CT pulmonary angiography (CTPA)** — principal test; demonstrates intraluminal filling defects to subsegmental level, gives a four-chamber view; an **RV:LV diameter ratio >1** predicts 30-day death and offers alternative diagnoses.
 - **V/Q lung scan** — second-line (contrast allergy, renal impairment, pregnancy); *high probability* = ≥ 2 segmental perfusion defects with normal ventilation; near-normal scan makes PE very unlikely.
 - **Venous compression ultrasonography** — first test for DVT; loss of vein compressibility (the “wink”) is the key sign; sensitivity/specificity >95% for symptomatic proximal DVT.
 - **Echocardiography** — not for diagnosis (most PE have normal echo) but invaluable for risk stratification and to exclude mimics (tamponade, MI, aortic dissection); *McConnell’s sign* = RV free-wall hypokinesis with preserved apex.
 - **Invasive pulmonary angiography / MR** — reserved for equivocal CT or when catheter intervention is planned.
- ▶ **Ancillary:**
 - **ECG** — sinus tachycardia (commonest); *S1Q3T3*; T-inversion V1–V4 (RV strain — most common abnormality); RBBB, AF.
 - **CXR signs (eponyms)** — *Westermarck’s sign* (focal oligemia), *Hampton’s hump* (peripheral pleural-based wedge of infarction), *Palla’s sign* (enlarged right descending pulmonary artery).
 - **Cardiac biomarkers** — troponin (RV microinfarction), BNP/NT-proBNP (RV stretch) — both prognostic.

Risk Stratification (prognosis-driven)

- ▶ **PESI** (11 variables) stratifies 30-day mortality into classes I–V (≈ 0 –1.6% in class I up to $\approx 25\%$ in class V). The **simplified PESI (sPESI)** uses 6 binary variables — **sPESI = 0 indicates low risk; ≥ 1 indicates high risk:**

sPESI variable (1 point each)
Age >80 years
History of cancer
Chronic cardiopulmonary disease

sPESI variable (1 point each)Pulse $\geq 110/\text{min}$ Systolic BP $< 100 \text{ mmHg}$ Arterial O₂ saturation $< 90\%$

- Combining a normotensive patient's sPESI/PESI with imaging RV strain and troponin/BNP separates *intermediate-low* from *intermediate-high* risk. PEITHO (n=1006, normotensive submassive PE) showed tenecteplase cut haemodynamic collapse (2.6% vs 5.6%) but trebled intracranial haemorrhage (2.0% vs 0.2%) — hence the standard for submassive PE is **anticoagulation with close monitoring**, reserving rescue thrombolysis for decompensation.

Management

- Anticoagulation** is the foundation; start empirically if suspicion is high and bleeding risk low.

Drug	Regimen (normal renal function)
UFH	80 U/kg bolus $\rightarrow$ 18 U/kg/h, target aPTT 60–80 s (anti-Xa 0.3–0.7 U/mL)
Enoxaparin (LMWH)	1 mg/kg SC twice daily
Fondaparinux	weight-based once daily SC (no HIT; reduce in renal failure)
Rivaroxaban	15 mg BD $\times$ 3 weeks $\rightarrow$ 20 mg OD
Apixaban	10 mg BD $\times$ 1 week $\rightarrow$ 5 mg BD
Dabigatran / Edoxaban	after ≥ 5 days parenteral heparin $\rightarrow$ dabigatran 150 mg BD / edoxaban 60 mg OD
Warfarin	bridge with parenteral agent ≥ 5 days until INR 2.0–3.0 $\times$ 2 readings

- DOACs are first-line for most patients (fixed dosing, no monitoring). **Warfarin (not DOAC)** for APS; LMWH/DOAC (avoid in GI cancer) for malignancy-associated VTE. For HIT, use argatroban or bivalirudin. Avoid DOACs in pregnancy/breastfeeding.
- Reversal:** protamine (heparin/LMWH), *idarucizumab* (dabigatran), *andexanet alfa*/PCC (anti-Xa DOACs).
- Duration:** ≥ 3 months; extended/indefinite therapy if no identifiable provoker, persistent risk factor, recurrent VTE, active cancer or APS (ESC 2019 abandons the “provoked vs unprovoked” dichotomy).
- Massive (high-risk) PE:**
 - Cautious fluid ($\approx 500 \text{ mL}$ normal saline — over-filling worsens RV strain); **noradrenaline** (vasopressor) + **dobutamine** (inotrope); **VA-ECMO** for refractory shock.

- **Systemic thrombolysis** — **alteplase (rt-PA) 100 mg IV over 2 h** (0.6 mg/kg, max 50 mg, over 15 min in cardiac arrest); major bleeding ~10%, intracranial haemorrhage 2–3%.
Contraindications: intracranial disease, recent surgery/trauma, active bleeding, recent stroke.
- **Catheter-directed therapy** (pharmacological / mechanical / pharmacomechanical, incl. ultrasound-assisted low-dose thrombolysis) and **surgical pulmonary embolectomy** when thrombolysis fails or is contraindicated.
- ▶ **IVC filter** — only for (1) active bleeding precluding anticoagulation or (2) recurrent VTE despite adequate anticoagulation; prefer a *retrievable* filter.
- ▶ **Prophylaxis** — low-dose UFH (5000 U BD/TDS), LMWH (enoxaparin 40 mg OD), fondaparinux, or mechanical (IPC/graduated stockings) when anticoagulation is contraindicated.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Diagnostic-and-management algorithm flowchart** — boxes: *Suspected PE* → *assess clinical probability (Wells)* → *low/intermediate: D-dimer (normal → PE excluded; raised → CTPA)* / *high: straight to CTPA* → *PE confirmed* → *risk stratify (BP, RV function, troponin, sPESI)* → *Low-risk: anticoagulate ± early discharge* | *Submassive: anticoagulate + monitor* | *Massive (hypotension): thrombolysis / embolectomy + haemodynamic support*.
- ▶ **Pathophysiology of RV failure in PE** — labels: *PE* → *↑pulmonary vascular resistance* → *↑RV wall tension* → *RV dilation & dysfunction* → *interventricular septal shift* → *↓LV preload* → *↓cardiac output & systemic BP* → *↓coronary perfusion* → *RV ischaemia/microinfarction (troponin↑)* → *circulatory collapse*.

Clinical / Diagnostic significance

- ▶ A *normal D-dimer* with low pre-test probability safely avoids imaging and radiation; conversely, never delay imaging in a high-probability patient.
- ▶ **RV:LV ratio >1 on CTPA**, a positive troponin and RV dysfunction on echo identify the patient who looks stable but may collapse — admit and monitor.
- ▶ *Saddle embolus* on CT is usually haemodynamically stable and treated with anticoagulation alone — **haemodynamics, not clot bulk, predict mortality**.
- ▶ **CTEPH** complicates ~2% of acute PE; follow patients with persistent dyspnoea/PH at ~6 weeks and 6 months with echocardiography — pulmonary thromboendarterectomy can be curative.
- ▶ *Post-PE syndrome* (persistent dyspnoea, fatigue, reduced exercise capacity, residual RV dysfunction) affects up to half of survivors.

High-yield exam pointers

- ▶ PE = “great masquerader”; commonest symptom **dyspnoea**, commonest sign **tachypnoea**, commonest ECG finding **sinus tachycardia** (then T-inversion V1–V4, then S1Q3T3).

- ▶ Eponyms: **Westermarck** (oligaemia), **Hampton's hump** (infarct), **Palla** (enlarged RDPA), **McConnell** (RV free-wall hypokinesis, apical sparing).
- ▶ Wells: high probability if >4; age-adjusted D-dimer = $\text{age} \times 10 \text{ ng/mL}$ (>50 yrs).
- ▶ CTPA is the principal diagnostic test; V/Q second-line; **compression USG** for DVT.
- ▶ Classification: **massive** 5–10%, **submassive** 20–25%, **low-risk** 65–75%; **sPESI ≥ 1 = high risk**.
- ▶ Massive PE: **alteplase 100 mg over 2 h** + noradrenaline + dobutamine $\pm$ VA-ECMO.
- ▶ **DOAC first-line**; warfarin for APS; LMWH/DOAC for cancer; argatroban/bivalirudin for HIT.
- ▶ IVC filter only for anticoagulation contraindication or recurrent VTE despite anticoagulation.
- ▶ **PEITHO** — thrombolysis in submassive PE prevents collapse but causes intracranial bleeding $\rightarrow$ monitor, don't lyse routinely.

SOURCE & COVERAGE

- ▶ **Murray & Nadel's Textbook of Respiratory Medicine, 7e** — "*Pulmonary Thromboembolism: Presentation and Diagnosis*" and "*Pulmonary Thromboembolism: Prophylaxis and Treatment*" (pathophysiology, PIOPED syndromes, clinical prediction rules incl. Geneva/PERC/YEARS, PESI/sPESI, PEITHO, systemic/low-dose/catheter thrombolysis, surgical embolectomy).
- ▶ **CMDT 2026** — "*Pulmonary Disorders*" (three-tier risk stratification, current anticoagulation/thrombolysis/embolectomy management, admission criteria).

Acute respiratory distress syndrome

Asked in: Paper III Dec 2023 — RGUHS MD General Medicine

Definition / Introduction — Adult respiratory distress syndrome is now termed **acute respiratory distress syndrome (ARDS)** because the syndrome also occurs outside adulthood. It is an acute inflammatory lung-injury syndrome presenting as **noncardiogenic permeability pulmonary edema**, severe hypoxemia, bilateral pulmonary opacities, reduced lung compliance, and acute respiratory failure. It is a clinical syndrome, not a single disease; there is no diagnostic gold standard, so diagnosis requires a compatible insult, exclusion of hydrostatic edema as the primary cause, and assessment of oxygenation severity.

Etiology and risk factors

- ▶ **Common causes:** most cases are due to **pneumonia and sepsis** (about 40-60%), followed by aspiration of gastric contents, trauma, multiple transfusions, and drug overdose.
- ▶ **Risk increases** with multiple predisposing insults, older age, chronic alcohol abuse, pancreatitis, pneumonia/sepsis, and greater severity of critical illness.

Direct lung injury	Indirect lung injury
Pneumonia, including viral pneumonias	Sepsis
Aspiration of gastric contents	Severe trauma, multiple fractures, flail chest, head injury
Pulmonary contusion	Multiple transfusions
Near-drowning	Pancreatitis
Toxic inhalation, smoke, chlorine, ammonia	Burns, shock, DIC
Fat/air/amniotic embolism, miliary TB	Drug overdose, postcardiopulmonary bypass

Pathophysiology and phases

- ▶ Central lesion is **diffuse alveolar damage** with injury to **alveolar-capillary endothelium** and **type I pneumocytes**, causing leakage of protein-rich edema fluid into interstitium and alveoli.
- ▶ Cytokines and mediators (**IL-1, IL-6, IL-8, TNF-alpha, leukotriene B4**) recruit neutrophils; neutrophils release proteases, reactive oxygen species and NETs, worsening epithelial and endothelial injury.
- ▶ **Surfactant dysfunction** and alveolar flooding produce dependent atelectasis, low compliance, intrapulmonary shunt, refractory hypoxemia, increased work of breathing and eventual respiratory failure.
- ▶ Pulmonary vascular injury causes **microthrombi**, increased dead space, pulmonary hypertension and sometimes hypercapnia; hypoxemia and hypercapnia further impair alveolar sodium and water clearance.

Phase	Time course	Pathology / clinical implication
Exudative	First 0-7 days; symptoms often 12-36 h after insult, sometimes delayed 5-7 days	Neutrophil-rich edema, hyaline membranes, surfactant loss, severe dyspnea, tachypnea, refractory hypoxemia
Proliferative	About day 7-21	Organization of exudate, type II pneumocyte proliferation, repair; some develop early fibroproliferation
Fibrotic	Around >3 weeks or persistent ARDS	Interstitial/alveolar-duct fibrosis, bullae, low compliance, dead

Phase	Time course	Pathology / clinical implication
		space, pulmonary hypertension, pneumothorax risk

Diagnostic criteria and classification

- ▶ Use the **Berlin definition**: acute onset within 1 week of a known clinical insult or new/worsening respiratory symptoms; bilateral opacities on chest radiograph or CT not fully explained by effusion, lobar collapse or nodules; respiratory failure not fully explained by cardiac failure or fluid overload.
- ▶ If no clear ARDS risk factor is present, perform objective assessment such as **echocardiography** to exclude hydrostatic pulmonary edema.
- ▶ Oxygenation severity is assessed on PEEP or CPAP ≥ 5 cm H₂O:

Severity	PaO ₂ /FiO ₂ ratio
Mild ARDS	>200 to $\leq$ 300 mm Hg
Moderate ARDS	>100 to $\leq$ 200 mm Hg
Severe ARDS	$\leq$ 100 mm Hg

- ▶ Proposed newer updates permit ARDS assessment in selected nonintubated patients on high-flow nasal oxygen or noninvasive support using PaO₂/FiO₂ or SpO₂/FiO₂ ratios; arterial PaO₂ should still be checked when feasible.

Clinical features and investigations

- ▶ Presentation is **rapid-onset dyspnea**, tachypnea, labored breathing, intercostal retractions, crackles, high oxygen requirement and hypoxemia poorly corrected by supplemental oxygen.
- ▶ CXR shows diffuse or patchy **bilateral opacities** that may become confluent; heart size is usually normal and pleural effusions are small or absent, unlike typical cardiogenic pulmonary edema.
- ▶ CT shows bilateral infiltrates with marked heterogeneity and dependent edema/atelectasis; lung ultrasound may show nonhomogeneous B lines, irregular pleura, subpleural or translobar consolidation and reduced pleural sliding.
- ▶ ABG quantifies PaO₂/FiO₂, hypercapnia and pH; evaluate the precipitant with cultures, sepsis workup, aspiration history, trauma/transfusion/drug history and organ dysfunction assessment.
- ▶ Important differentials are **cardiogenic pulmonary edema**, bilateral pneumonia, diffuse alveolar hemorrhage, acute interstitial pneumonitis, hypersensitivity pneumonitis, radiation/toxin pneumonitis and neurogenic pulmonary edema.

Management

- ▶ **Treat the cause first:** early antibiotics and source control for sepsis/pneumonia, aspiration precautions, trauma/burn management, stop offending drugs, and manage shock without persistent fluid overload.
- ▶ Provide ICU bundled care: VTE prophylaxis, stress-ulcer/aspiration prevention when indicated, avoidance of excessive sedation, ventilator liberation protocols, nutrition preferably enteral, prevention of catheter infections and prompt recognition of VAP/nosocomial infection.
- ▶ **Lung-protective ventilation:** use tidal volume about **6 mL/kg predicted body weight** (not actual weight), target **plateau pressure** ≤ 30 cm H₂O, RR generally ≤ 35 /min, SpO₂ 88-95% or PaO₂ 55-80 mm Hg, and reduce FiO₂ as soon as possible, preferably ≤ 0.6 when feasible.
- ▶ **PEEP:** titrate PEEP to recruit alveoli, maintain oxygenation and reduce FiO₂, while avoiding overdistension, hypotension and reduced cardiac output; no single PEEP-setting method is universally superior.
- ▶ **Prone ventilation:** in severe ARDS, especially PaO₂/FiO₂ < 150 mm Hg, early prolonged proning (about ≥ 16 h/day) improves oxygenation and has shown mortality benefit in experienced centers; avoid or be cautious with unstable spine, raised ICP, massive hemoptysis, recent facial/tracheal surgery or severe hemodynamic instability.
- ▶ **Conservative fluids:** after shock is corrected, restrict fluids and use diuretics to keep low filling pressures; this improves oxygenation and reduces ventilator/ICU days without routine need for pulmonary artery catheterization.
- ▶ **Adjuncts:** short neuromuscular blockade with cisatracurium for up to 48 h may help selected severe ARDS patients with ventilator dyssynchrony despite sedation, but routine early paralysis is not supported by later trials. ECMO is a rescue option for very severe, potentially reversible ARDS after optimized lung-protective ventilation, PEEP, proning and supportive care.
- ▶ **Avoid routine use:** high-frequency oscillation, routine recruitment maneuvers, surfactant replacement, inhaled nitric oxide/epoprostenol for outcome benefit, NSAIDs, ketoconazole and other anti-inflammatory therapies. Steroids are not a universal ARDS treatment; consider them only in patient-specific settings such as refractory septic shock, severe community-acquired pneumonia, COVID-19 ARDS, or selected early ARDS where contemporary guidelines support conditional use.

Prognosis and complications

- ▶ LUNG SAFE hospital mortality estimates rise with severity: **34.9% mild, 40.3% moderate, 46.1% severe** ARDS; with modern low-tidal-volume ventilation, overall mortality is around 30-40%.
- ▶ Most deaths are from **sepsis and nonpulmonary organ failure**, not refractory hypoxemia; nonpulmonary organ failure accounts for the major mortality burden.
- ▶ Poor prognostic factors include advanced age, chronic liver disease, chronic alcohol abuse, chronic immunosuppression, sepsis, preexisting organ dysfunction, direct lung injury,

pulmonary fibrosis, low compliance, high PEEP requirement and failure to improve in the first week.

- ▶ Complications include VAP, barotrauma (pneumothorax, pneumomediastinum, subcutaneous emphysema), ICU-acquired weakness, delirium, thromboembolism, secondary infections and fibrotic lung disease.
- ▶ Survivors often regain near-normal lung function by **6-12 months**, but may have reduced diffusion capacity, exercise limitation, muscle wasting, fatigue, depression, anxiety, PTSD and cognitive impairment for years.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Injured alveolus in ARDS:** alveolar capillary endothelium, type I pneumocyte injury, type II pneumocyte/surfactant dysfunction, protein-rich edema, hyaline membrane, neutrophils, cytokines, ROS/NETs, microthrombi, collapsed alveolus, shunt.
- ▶ **ARDS time-course diagram:** exudative phase 0-7 days, proliferative phase 7-21 days, fibrotic phase after about 3 weeks; label edema, hyaline membranes, interstitial inflammation, fibrosis, bullae and recovery pathway.

Clinical / Diagnostic significance

- ▶ ARDS should be suspected when a patient with sepsis, pneumonia, aspiration, trauma or transfusion develops acute refractory hypoxemia and bilateral opacities within 1 week.
- ▶ Do not diagnose ARDS merely from a bilateral white-out CXR; document **PaO₂/FiO₂**, ventilatory support/PEEP, timing, and why cardiogenic edema is not the primary cause.
- ▶ Echocardiography is often the practical discriminator from cardiogenic edema; BNP or wedge pressure may help in selected patients but no test is definitive.
- ▶ Management is mainly supportive and ventilator-based; the most exam-important disease-modifying intervention is **low tidal volume ventilation** with plateau-pressure limitation.
- ▶ Rising oxygen requirement, increasing dead space, falling compliance, shock, AKI, liver dysfunction and delirium indicate high risk and need for aggressive ICU management.

High-yield exam pointers

- ▶ Write “adult” as historical; current term is **acute respiratory distress syndrome**.
- ▶ Berlin criteria: **within 1 week + bilateral opacities + noncardiogenic edema + PaO₂/FiO₂ ≤300 on PEEP/CPAP ≥5**.
- ▶ Severity cutoffs: **mild >200-300, moderate >100-200, severe ≤100 mm Hg**.
- ▶ Commonest causes: **pneumonia and sepsis**, then aspiration, trauma, transfusion and overdose.
- ▶ Classic pathology: **diffuse alveolar damage**, protein-rich edema and **hyaline membranes**.

- ▶ Ventilator must-write: VT 6 mL/kg predicted body weight, plateau ≤ 30 cm H₂O, SpO₂ 88-95%.
- ▶ Prone early in severe ARDS, especially PaO₂/FiO₂ < 150 , if expertise is available.
- ▶ After resuscitation, use **conservative fluid strategy**; avoid routine PA catheter.
- ▶ Most deaths are due to **sepsis/multiorgan failure**, not isolated hypoxemia.

Acute severe asthma

Asked in: Paper III 09/2025 — RGUHS MD General Medicine

Definition / Introduction — *Acute severe asthma* (historically *status asthmaticus*) is a severe asthma exacerbation that fails to respond promptly to repeated inhaled short-acting β_2 -agonists (SABAs) and threatens life through progressive airflow obstruction, dynamic hyperinflation and respiratory muscle fatigue. An exacerbation is defined (NIH task force) as *a worsening of asthma requiring systemic corticosteroids (or an increase from a stable maintenance dose) to prevent a serious outcome*. Clinically it is recognised by breathlessness at rest, inability to complete sentences, peak expiratory flow (PEF)/FEV₁ well below predicted, and signs of respiratory distress; *near-fatal asthma* denotes the subset with hypercapnia, exhaustion or requiring mechanical ventilation.

Pathophysiology of the severe attack

- ▶ **Diffuse airway narrowing** from smooth-muscle constriction, mucosal oedema, inflammatory cellular infiltration and luminal **mucus plugging** (eosinophil-rich) raises airway resistance and lowers maximal expiratory flow, predominantly in small bronchi.
- ▶ **Air trapping and dynamic hyperinflation** — incomplete lung emptying forces breathing at high lung volumes (raised residual volume); intrinsic PEEP develops. The diaphragm and intercostals are mechanically disadvantaged on their length–tension curve, so **accessory muscles** (sternocleidomastoid, abdominals) are recruited and the **work of breathing rises**.
- ▶ **Gas exchange** — non-uniform obstruction produces **ventilation–perfusion (V/Q) mismatch** with a widened alveolar–arterial O₂ gradient and hypoxaemia. PaCO₂ initially **falls** (hyperventilation) producing respiratory alkalosis; as muscles fatigue, PaCO₂ **rises** — *a normal or raised PaCO₂ in a distressed asthmatic signals impending respiratory failure*.
- ▶ **Lactic (type B) acidosis** may appear (anion-gap metabolic acidosis) from work of breathing and high-dose β_2 -agonists.

Clinical assessment and severity grading

- ▶ Rapid focused history: duration/trigger, current medication, prior ICU/intubation, frequency of SABA use, response so far.
- ▶ Examination: respiratory rate, ability to speak (sentences→phrases→words→mute), posture, accessory-muscle use/suprasternal retraction, wheeze (a **silent chest** = severe obstruction with loss of breath sounds), heart rate, **pulsus paradoxus**, conscious level and cyanosis.
- ▶ Objective severity by PEF/FEV1, SpO2 and arterial blood gas. Severity classification (NAEPP/GINA, adapted in CMDT 2026):

Feature	Mild	Moderate	Severe	Respiratory arrest imminent
Breathlessness	On walking	At rest, limits activity	At rest, interferes with talking	At rest, mute
Talks in	Sentences	Phrases	Words	—
Alertness	May be agitated	Usually agitated	Usually agitated	Drowsy/confused
Respiratory rate	Increased	Increased	Often >30/min	>30/min
Accessory muscles	Usually not	Commonly	Usually	Paradoxical thoraco-abdominal movement
Wheeze	End-expiratory	Loud, expiratory	Loud, insp + exp	Absent (silent chest)
Pulse/min	<100	100–120	>120	Bradycardia
Pulsus paradoxus	<10 mmHg	10–25 mmHg	>25 mmHg	Absence = muscle fatigue
PEF (% pred/best)	≥70%	40–69%	<40%	<25%
PaO2 (air) / PaCO2	Normal / <42	≥60 / <42	<60 / ≥42	<60 / ≥42
SaO2 (air)	>95%	90–95%	<90%	<90%

Investigations

- ▶ **PEF or FEV1** — the single most useful objective measure; guides severity and serial response (improvement at 30–60 min predicts outcome and need for admission).
- ▶ **Pulse oximetry**; target SpO2 >90%.
- ▶ **Arterial blood gas** — typically mild hypoxaemia + respiratory alkalosis; *normalisation/rise of PaCO2* with continuing distress warns of impending failure. Venous pH/PCO2 and lactate can be used to monitor.

- ▶ **Chest radiograph** — not routine; obtain if pneumothorax, pneumomediastinum, pneumonia or another cause is suspected.
- ▶ **ECG/electrolytes** — monitor for arrhythmia and β 2-agonist-induced **hypokalaemia**; bloods/cultures only if infection suspected.

Management of acute severe asthma

- ▶ **Oxygen** — give immediately to maintain SpO₂ >90% (PaO₂ >60 mmHg); asphyxia is a leading cause of asthma death, and concern for hypercapnia must *never* delay correcting hypoxaemia.
- ▶ **Inhaled SABA (salbutamol/albuterol)** — high-dose, repeated or continuous by nebuliser (or MDI + spacer); at least **three treatments in the first hour**, then titrate to response. Onset 3–5 min, duration 4–6 h.
- ▶ **Inhaled ipratropium bromide** — added to SABA in moderate–severe exacerbations improves airflow and **reduces hospital admission**.
- ▶ **Systemic corticosteroids** — first-line; early administration speeds recovery and reduces admission. Prednisolone **0.5–1.0 mg/kg/day** ($\approx$ 40–60 mg/day) orally, or IV methylprednisolone **1.5–2 mg/kg** if oral route unsafe (oral and IV are equi-efficacious in non-life-threatening attacks). Continue the “burst” until symptoms resolve and PEF $\geq$ 80% personal best (usually 3–10 days); tapering is not required.
- ▶ **Intravenous magnesium sulfate** — **2 g IV over 20 min** (paediatric 40 mg/kg, max 2 g); a smooth-muscle relaxant that reduces hospitalisation in *acute severe* attacks (FEV₁ <25% predicted on presentation or failure to respond to initial therapy). Not recommended for routine mild–moderate exacerbations.
- ▶ **Adjuncts in refractory cases** — **heliox** (helium–oxygen) lowers airway resistance/work of breathing; an LTRA is sometimes added; continuous in-hospital nebulisation. Inhaled volatile anaesthetics (e.g., isoflurane) are potent bronchodilators in refractory disease.
- ▶ **Avoid** — sedatives/anxiolytics (respiratory depression), mucolytics (acetylcysteine, potassium iodide — may worsen cough/obstruction), and *routine* antibiotics (reserve for proven bacterial infection/pneumonia/sinusitis).

Respiratory support and mechanical ventilation

- ▶ **Non-invasive positive-pressure ventilation (NIV)** — low-level NIV (without PEEP) may reduce hospitalisation and avert intubation in **alert, cooperative** patients not in immediate need of intubation.
- ▶ **Intubation and invasive ventilation** — *mandatory* for respiratory arrest or impending arrest (exhaustion, altered sensorium, rising PaCO₂, bradycardia). Post-intubation deterioration is common from dynamic hyperinflation and high intrathoracic pressures causing hypotension.
- ▶ **Ventilator strategy** — **minimise hyperinflation**: low minute ventilation with **respiratory rate 12–14/min**, tidal volume **6–8 mL/kg**, **high inspiratory flow** (prolonged expiratory time) and

minimal/no PEEP. Accept **permissive hypercapnia** (let PaCO₂ rise; correct critical acidosis with bicarbonate if needed) to avoid barotrauma. Provide deep sedation and, if patient–ventilator synchrony cannot be achieved, short-term neuromuscular paralysis; continue bronchodilators until airway resistance falls.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Severity-stratification flow diagram of an acute attack** — boxes: *Assess (speech, RR, accessory muscles, PEF, SpO₂, pulsus paradoxus) → Mild–Moderate (PEF ≥40–69%) → SABA + ipratropium + O₂ + oral steroid; Severe (PEF <40%) → high-dose continuous SABA + ipratropium + O₂ + systemic steroid + IV MgSO₄; Respiratory arrest imminent (silent chest, drowsy, bradycardia, PaCO₂ ≥42) → ICU, NIV/intubation, permissive hypercapnia. Label danger signs: **silent chest, normal/rising PaCO₂, exhaustion, bradycardia, cyanosis.***
- ▶ **Obstructed asthmatic airway cross-section** — labels: *lumen narrowed by smooth-muscle constriction, smooth-muscle hypertrophy, submucosal oedema, mucus plug, epithelial shedding, basement-membrane (collagen) thickening, inflammatory cell infiltration.*

Clinical / Diagnostic significance

- ▶ A *normal or rising PaCO₂* with a *silent chest* and exhaustion are the cardinal red flags of life-threatening asthma demanding ICU care.
- ▶ Response to the first hour of therapy predicts the need for admission better than presenting severity.
- ▶ High-risk features mandating low-threshold escalation (Harrison): prior ICU admission or intubation for asthma, ≥2 ED visits in 6 months, recent/current oral steroids, poor adherence, illicit drug use, depression/severe psychosocial problems, low socioeconomic status, new diagnosis within the past year.
- ▶ Discharge planning: ensure inhaler technique, written **asthma action plan**, step-up of controller (ICS-containing) therapy, follow-up — over-reliance on SABA and under-use of ICS drive mortality.

High-yield exam pointers

- ▶ **Silent chest, drowsiness, bradycardia, normal/raised PaCO₂, and absent pulsus paradoxus (from muscle fatigue)** = imminent respiratory arrest.
- ▶ **First-hour bundle:** controlled O₂ (SpO₂ >90%) + repeated/continuous SABA (≥3 doses/hr) + ipratropium + early systemic steroid (prednisolone 0.5–1 mg/kg).
- ▶ **IV magnesium sulfate 2 g over 20 min** for acute severe asthma (FEV₁ <25% predicted / poor initial response) — reduces admissions.

- ▶ Oral and IV corticosteroids are equally effective in non-life-threatening attacks; continue burst till PEF $\geq 80\%$ best.
- ▶ **Ventilation = permissive hypercapnia:** low RR 12–14, low TV 6–8 mL/kg, high inspiratory flow, minimal PEEP — to avoid dynamic hyperinflation/barotrauma.
- ▶ **Avoid** sedatives, mucolytics and routine antibiotics; NIV only in the alert, cooperative patient.
- ▶ Pulsus paradoxus >25 mmHg, PEF $<40\%$, RR >30 and inability to speak in sentences define a severe attack.
- ▶ Type B (non-hypoxic) **lactic acidosis** and **hypokalaemia** are recognised β_2 -agonist effects during high-dose therapy.

Approach to Solitary Pulmonary Nodule

Asked in: Paper III Nov 2020 — RGUHS MD General Medicine

Definition / Introduction — A **solitary pulmonary nodule (SPN)**, classically called a "*coin lesion*," is a single, discrete, rounded radiographic opacity **<3 cm in diameter, completely surrounded by aerated lung**, and *unaccompanied* by lymphadenopathy, atelectasis or pleural effusion (Murray & Nadel; CMDT). Lesions **>3 cm** are termed *pulmonary masses* and are malignant until proven otherwise. With the explosion of CT use and low-dose CT (LDCT) lung-cancer screening, SPNs are increasingly an incidental finding; the overriding clinical task is to **identify and resect the few malignant nodules that benefit from surgery while sparing the benign majority from needless invasive procedures**.

Etiology and Differential Diagnosis

- ▶ Most SPNs are **benign**; in LDCT-screened populations the probability that any detected nodule is cancer is only $\sim 1\%$, and **90–95% of screening-detected nodules are ultimately false positives**.

- ▶ Most benign nodules are **infectious granulomas**; **hamartomas** account for <5% of solitary nodules. Malignant nodules are *rare under age 30*; above 30, malignancy risk rises with age, smoking and a prior cancer history.

Category	Common causes
Malignant	Primary lung cancer (esp. adenocarcinoma), solitary metastasis, bronchial carcinoid
Infectious granuloma	Tuberculoma, histoplasmosis, coccidioidomycosis, other fungi; resolving abscess
Benign neoplasm	Hamartoma (fat + popcorn calcification), rare benign tumors
Other benign	Arteriovenous malformation, intrapulmonary (perifissural) lymph node, rounded atelectasis, infarct, rheumatoid nodule, Wegener (GPA)

Step 1 — Estimate the Pretest Probability of Malignancy

The approach is **probability-driven**: integrate patient (“clinical”) factors with nodule (“radiologic”) factors, either by validated quantitative models or experienced clinical judgement.

- ▶ **Clinical predictors of malignancy**: older age, current/heavy smoking (>20 cigarettes/day, quit <7 years), prior malignancy, asbestos exposure.
- ▶ **Independent predictors (Mayo investigators)**: age, smoking status and prior cancer *plus* three radiologic features — **nodule diameter, spiculation, and upper-lobe location**.
- ▶ **Quantitative models**: Mayo (VA Cooperative) clinical model, the **Brock model** (Pan-Canadian screening cohort, most accurate in screening), and the **Herder model**, which adds FDG-PET data to clinical/radiologic inputs and is endorsed by the British Thoracic Society.

Harrison Table 83-7 — Risk of cancer by variable (after Ost et al., NEJM 2003):

Variable	Low risk	Intermediate	High risk
Diameter (cm)	<1.5	1.5–2.2	≥2.3
Age (years)	<45	45–60	>60
Smoking	Never smoker	Current <20/day	Current >20/day
Smoking cessation	Quit ≥7 yr ago / never	Quit <7 yr ago	Never quit
Margin	Smooth	Scalloped	Corona radiata / spiculated

Step 2 — Radiographic Characterisation (Benign vs Malignant Features)

- ▶ Always obtain and compare prior CXR/CT films. Two findings *reliably* indicate benignity: (1) no growth over >2 years, and (2) a benign calcification pattern.

- ▶ **Benign calcification patterns (5):** diffuse, central, laminar/concentric, and “popcorn” — central nidus and “bull’s-eye” suggest granuloma; “popcorn” (chondroid) is diagnostic of **hamartoma**, especially when fat is also seen within the nodule. *Note:* calcification alone does not exclude malignancy.
- ▶ **Features suggesting malignancy:** larger size, **spiculated / corona radiata margins**, lobulated or ill-defined edge, a peripheral **halo**, sparse / **eccentric / stippled** calcification, **thick-walled cavitation (>16 mm)**, upper-lobe location, and demonstrable growth.
- ▶ **Doubling time (DT):** very rapid growth (DT <30 days) suggests infection; **long-term stability** (DT >465 days, or >2 years) suggests benignity; most malignant *solid* nodules have a volume DT <400 days. 3D volumetric analysis on thin-section HRCT is more sensitive than 2D caliper measurement for detecting growth.
- ▶ **Size-based malignancy rate on CT (CMDT):** 2–5 mm ≈ 1%, 6–10 mm ≈ 24%, 11–20 mm ≈ 33%, 21–45 mm ≈ 80%.

Step 3 — Functional Imaging (FDG-PET/CT) and Tissue Diagnosis

- ▶ **FDG-PET/CT** is most useful for indeterminate nodules >8 mm (≈1 cm); an SUV_{max} >2.5 is the classic malignancy threshold. A meta-analysis of nodules >1 cm reported sensitivity 96%, specificity 78%, PPV 91%, NPV 92%; CMDT quotes sensitivity 85–97% and specificity 70–85%. Malignancy probability rises stepwise with uptake (SUV_{max} 0–2.5 ≈ 24%, 2.6–4.0 ≈ 80%, ≥4.1 ≈ 96%).
- ▶ **A positive PET raises, and a negative PET lowers, the probability of cancer**, but beware **false negatives** in carcinoid tumours and in *ground-glass / lepidic adenocarcinoma*, AIS and MIA (low metabolic activity), and in lesions <1 cm (poor resolution); **false positives** occur with active infection/inflammation.
- ▶ **Tissue sampling options:**
 - **CT-guided transthoracic needle aspiration (TTNA):** yield 50–97% (≈90% in expert series); best for **peripheral** lesions; main complication is **pneumothorax in up to 30%** (some needing a chest drain).
 - **Bronchoscopy:** yield 10–80%, sensitivity 88% for central lesions but low for peripheral nodules <2 cm; yield improves with a **bronchus (air-bronchus) sign**, larger size and more biopsies. **Guided bronchoscopy** (radial EBUS, electromagnetic navigational bronchoscopy, robotic bronchoscopy) gives a pooled yield ≈70%.
 - **Sputum cytology:** highly specific but insensitive — reserved for central lesions or poor procedural candidates.

Step 4 — Management Algorithm by Pretest Probability

- ▶ **Benign calcification or documented 2-year stability** → no further testing.

- ▶ **Low probability (<5%)** → *watchful waiting* with **serial HRCT** (ACCP suggests 3–6, 9–12 and 18–24 months); for screen/incidental nodules apply structured surveillance (below).
- ▶ **Intermediate probability (5–60/65%)** → further characterise with **PET/CT** and/or **non-surgical biopsy** (TTNA or bronchoscopy); biopsy is favoured for the *risk-averse* patient wanting confirmation before surgery.
- ▶ **High probability (>60–65%)** → proceed to **staging and surgical resection** if surgical risk is acceptable; biopsy rarely changes management and is often omitted.
- ▶ **Surgery:** VATS with intra-operative **frozen section**, proceeding to **lobectomy + mediastinal lymph-node sampling/dissection** if malignant; **wedge/segmentectomy** for limited reserve. Non-surgical candidates may receive **SBRT** (≤ 5 cm) or radiofrequency ablation/cryoablation.
- ▶ **Assess operability first:** relative/absolute contraindications include **predicted post-op FEV₁ <0.8 L**, **FEV₁ <1 L**, **DLCO <40%**, **VO₂max <10–15 mL/kg/min**, resting **PCO₂ >45 mmHg**, severe pulmonary hypertension, and recent MI (<3 months).

Structured surveillance frameworks:

- ▶ **Fleischner Society 2017** (incidental nodules, age ≥ 35 , not immunosuppressed, no known cancer): *solid* <6 mm — no routine follow-up if low risk; 6–8 mm — CT at 6–12 mo then 18–24 mo; >8 mm — consider CT at 3 mo, PET/CT or biopsy. *Subsolid*: pure ground-glass <6 mm — no follow-up; ≥ 6 mm — CT at 6–12 mo to confirm persistence, then every 2 years to 5 years; *part-solid* ≥ 6 mm — CT at 3–6 mo (solid component ≥ 6 mm is highly suspicious).
- ▶ **Lung-RADS v1.1** (ACR — *screen-detected* nodules): category 1–2 = benign (cancer risk <1%, annual LDCT); 3 = probably benign (6-month LDCT); 4A (3-month LDCT $\pm$ PET); 4B/4X (>15% risk — diagnostic CT/PET/tissue sampling).

Special Consideration — Subsolid Nodules / Ground-Glass Opacities (GGO)

- ▶ Subsolid nodules are subdivided into **pure ground-glass (nonsolid)** and **part-solid**; many persistent GGOs represent the adenocarcinoma spectrum — **atypical adenomatous hyperplasia (AAH)** → **adenocarcinoma in situ (AIS)** → **minimally invasive adenocarcinoma (MIA)**.
- ▶ They are **indolent**: GGO cancers are typically stage I adenocarcinoma with near-100% 5-year survival, so guidelines favour **less frequent but longer-duration surveillance**; the **size of the solid component** is the key predictor of invasiveness — a growing or enlarging solid component prompts resection.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Management algorithm of the SPN (flowchart):** *New nodule on CT* → **benign calcification or 2-yr stability?** → if yes: *No further testing*; if no → **estimate probability of cancer / surgical risk** → branch into **Low (<5%)**: **serial HRCT at 3, 6, 9, 12, 18, 24 mo**;

Intermediate (5–60%): PET/CT and/or biopsy (TTNA / bronchoscopy); **High (>60%):** staging → VATS frozen section → lobectomy. Label: *PET if nodule ≥8 mm, TTNA if peripheral, bronchoscopy if bronchus sign.*

- ▶ **Calcification patterns box:** draw and label **diffuse, central, laminar/concentric, popcorn** (benign) versus **stippled, eccentric** (malignant); plus nodule margins — *smooth* (benign) vs *spiculated / corona radiata* (malignant).

Clinical / Diagnostic significance

- ▶ The single most powerful step is **comparison with old imaging** — proven 2-year stability or a benign calcification pattern obviates all further workup.
- ▶ **Size, margin (spiculation), upper-lobe location, age and smoking** drive the malignancy estimate; integrate them via **Brock/Mayo/Herder models** rather than guesswork.
- ▶ **PET-CT** both characterises the nodule and screens for nodal/distant disease, refining staging before resection — but a negative PET does not exclude carcinoid or lepidic adenocarcinoma.
- ▶ **Shared decision-making** is integral: nodule detection causes real patient distress and is a “teachable moment” for **smoking cessation**.

High-yield exam pointers

- ▶ **SPN** = single rounded opacity <3 cm, surrounded by normal lung, **no** adenopathy/effusion; >3 cm = **mass** (treat as malignant).
- ▶ **Two reliable benignity criteria:** no growth >2 years and benign calcification (**diffuse/central/laminar/popcorn**); **popcorn** = **hamartoma**, central/bull’s-eye = **granuloma**.
- ▶ **Malignant pointers:** **spiculation/corona radiata**, **eccentric/stippled calcification**, **thick-walled cavity** (>16 mm), **upper lobe**, **growth** (**VDT <400 days**).
- ▶ **Doubling time:** <30 days = **infection**; >465 days (>2 yr stable) = **benign**.
- ▶ **PET useful for nodules >8 mm**, **SUVmax >2.5** = **malignant**; false-negative in **carcinoid** and **AIS/MIA/GGO**.
- ▶ **Probability bands:** <5% **observe**, 5–60% **PET/biopsy**, >60% **resect**.
- ▶ **TTNA** best for peripheral lesions (pneumothorax up to 30%); **bronchoscopy** best for central/endobronchial (bronchus sign); **VATS + frozen section** → **lobectomy** is definitive.
- ▶ **Fleischner 2017** = incidental nodules; **Lung-RADS** = screen-detected nodules.

SOURCE & COVERAGE

Asbestos-Related Diseases

Asked in: Paper III May 2019 — RGUHS MD General Medicine

Definition / Introduction — Asbestos is a generic term for a family of naturally occurring fibrous mineral silicates that, when inhaled as respirable fibres, cause a spectrum of benign and malignant pleuropulmonary disease. The principal disorders are **asbestosis** (diffuse interstitial pulmonary fibrosis), **benign pleural disease** (plaques, diffuse thickening, benign effusion, rounded atelectasis), **bronchogenic carcinoma**, and **malignant mesothelioma** of the pleura and peritoneum. All share a **long latency** (often decades), a **dose–response** relationship, and the medicolegal importance of being **compensable occupational diseases**.

Mineralogy, Sources and Mechanism of Injury

- ▶ **Two mineral groups:**
 - **Serpentine group** — **chrysotile** (*white asbestos*), curly/serpentine fibres, **less biopersistent**, more readily cleared from the lung; the form most widely used commercially.
 - **Amphibole group** — **crocidolite** (*blue*), **amosite** (*brown*), anthophyllite, tremolite, actinolite; long, thin, straight, **durable, highly biopersistent** fibres. Amphiboles are far more potent inducers of **mesothelioma** (up to ~100-fold over serpentine in experimental animals).
- ▶ **At-risk occupations:** mining, milling and manufacture of asbestos products; **shipbuilding/ship repair**, construction, **pipe fitters, boilermakers, insulators**; brake/clutch (friction) linings, fire-resistant textiles, cement and floor tiles. Latency means new cases today reflect exposures of past decades.
- ▶ **Non-occupational exposure:** *bystander/para-occupational* (painters, electricians working alongside insulators in shipyards); **domestic** (relatives exposed to fibre-laden work clothes — chiefly pleural disease); **environmental** (community exposure from vermiculite contaminated with amphibole at **Libby, Montana**; disturbance of naturally occurring asbestos).

- ▶ **Pathogenesis:** fibre toxicity depends on **cumulative dose**, **fibre dimensions (length-to-width aspect ratio)** and **durability/biopersistence**. Fibres $\leq 3 \mu\text{m}$ are phagocytosed by alveolar macrophages and cleared via lymphatics; **longer fibres are incompletely phagocytosed**, often by several macrophages, and become coated to form **asbestos (ferruginous) bodies** — beaded, dumb-bell-shaped iron-protein-coated fibres that are the *light-microscopic hallmark of exposure*. Injury is driven by **oxidative stress** — reactive oxygen species generated by transition metals (iron) on the fibre surface and during frustrated phagocytosis — recruiting fibroblasts and collagen deposition.

Spectrum of Asbestos-Related Diseases and Latency

Disease	Nature	Typical latency from first exposure
Pleural plaques	Benign; marker of exposure only	~20–30 yr (relates to time since exposure, not dose)
Benign asbestos pleural effusion (BAPE)	Benign exudative effusion	Earliest — within ~15 yr
Diffuse pleural thickening / visceroparietal reaction	Benign; may restrict	Long (~30+ yr)
Rounded atelectasis (<i>Blesovsky syndrome</i>)	Folded-lung pseudotumour	Variable, late
Asbestosis	Diffuse interstitial fibrosis	≥ 10 yr exposure; clinical disease ~20–30 yr
Bronchogenic carcinoma	Malignant	~15–19 yr (minimum)
Malignant mesothelioma	Malignant (pleura >90%, peritoneum)	20–40 yr; short exposure (1–2 yr) sufficient

Asbestosis (Pulmonary Parenchymal Fibrosis)

- ▶ **Definition:** diffuse interstitial fibrosing lung disease *directly related to intensity and duration of exposure*; requires generally ≥ 10 years of exposure before becoming manifest, with clinical disease usually **20–30 years** after first exposure.
- ▶ **Pathology:** begins as **peribronchiolar fibrosis** with macrophage accumulation and type-2 pneumocyte hyperplasia; progresses to interstitial fibrosis with a **lower-lobe and subpleural predominance** and eventual **honeycombing**. Distinguished from other end-stage fibrosis only by demonstration of **asbestos bodies / uncoated fibres**.
- ▶ **Clinical features:** insidious **exertional dyspnoea** and dry cough; **fine, end-inspiratory bibasal “velcro” crackles** (early and distinctive, heard first in axillary/basal regions); **digital clubbing** in some; late cor pulmonale.

- ▶ **Radiology:** irregular/linear reticular opacities beginning in the lower zones; blurring of the cardiac border producing a “shaggy heart” sign; ground-glass change. HRCT (most sensitive) shows subpleural curvilinear lines 5–10 mm, subpleural reticulation, parenchymal bands and honeycombing; coexisting pleural plaques strongly support the diagnosis. ILO classification grades small linear/irregular opacities (vs the rounded opacities of silicosis/CWP).
- ▶ **Lung function:** restrictive pattern with reduced lung volumes and reduced DLCO; mixed or mild obstructive components may occur (peribronchiolar fibrosis).
- ▶ **Management:** no specific therapy — supportive care as for any diffuse interstitial fibrosis: supplemental oxygen, pulmonary rehabilitation, influenza/pneumococcal vaccination, and especially smoking cessation (smoking multiplies lung-cancer risk). Lung transplantation in selected end-stage cases (pleural disease may complicate surgery).

Benign Pleural Manifestations

- ▶ **Pleural plaques** — the commonest and often the only manifestation of exposure. Smooth, raised, white, frequently calcified lesions of the parietal pleura (posterolateral mid-zones following rib contour, the diaphragm, cardiac border); histologically avascular, acellular, laminated (hyalinised) collagen likened to *candle-wax drippings*. Typically bilateral (unilateral suggests trauma/infection). They imply exposure, not impairment, but flag an increased long-term risk of mesothelioma/lung cancer.
- ▶ **Diffuse pleural thickening / visceroparietal reaction** — less specific than plaques; can encase the lung as a fibrous “peel”, causing measurable restrictive deficit (FEV₁/FVC reduction) and occasionally requiring pleurectomy.
- ▶ **Benign asbestos pleural effusion (BAPE)** — usually the earliest manifestation (within ~15 yr); small, exudative, blood-tinged, often resolves spontaneously, may recur/alternate sides. It is a diagnosis of exclusion — criteria: exposure history, exclusion of other causes, and no tumour on ≥3-year follow-up; thoracoscopic biopsy is usually needed to exclude mesothelioma.
- ▶ **Rounded atelectasis (folded lung / pseudotumour, Blesovsky syndrome) — pleural fibrosis folds and traps subjacent lung, producing a rounded mass with the characteristic “comet-tail” sign of vessels/bronchi curving into it; the key differential is lung cancer*, occasionally needing biopsy.*

Asbestos-Related Malignancy

- ▶ **Bronchogenic carcinoma**
 - Most common cancer associated with asbestos; occurs across all histologic types.
 - Minimum latency 15–19 years; risk rises with cumulative exposure.
 - Multiplicative (synergistic) interaction with cigarette smoking — combined risk greatly exceeds the additive effect; hence smoking cessation is paramount.
- ▶ **Malignant mesothelioma**

- Arises from mesothelial serosal surfaces — **pleura in >90%**, also peritoneum, pericardium, tunica vaginalis; **not related to smoking**.
- **>80% are asbestos-associated** (rendering them compensable); **amphiboles, especially crocidolite**, are the most potent; **erionite** (a zeolite fibre, e.g. *Cappadocia, Turkey*) is a recognised non-asbestos cause. ~3000 cases/yr in the USA.
- **Latency 20–40 years**; even brief exposures (1–2 yr) suffice — underscoring a meticulous exposure history.
- **Presentation**: unilateral **pleural effusion**, chest-wall pain and dyspnoea; tumour **encases the lung**, contracts the hemithorax and produces **ipsilateral mediastinal shift**; **needle-tract seeding** at biopsy/drainage sites.
- **Histologic subtypes**: **epithelioid** (best prognosis), **sarcomatoid** (worst), and **biphasic** (mixed).
- **Diagnosis**: fluid cytology has limited yield; **image-guided/thoracoscopic biopsy** with immunohistochemistry is usual. Molecular markers — **loss of BAP1 expression** and **homozygous CDKN2A (p16) deletion** by FISH — confirm malignancy in mesothelial-lineage cells (together identify up to ~85% of cases). (*Standard mesothelial IHC panel: positive calretinin, WT-1, CK5/6, D2-40; negative CEA, TTF-1, MOC-31/Ber-EP4 — see Coverage note.*) Staging uses the TNM-based IASLC/IMIG (8th edition) system.
- **Prognosis**: dismal — median survival **9–18 months**, **<5% survive 5 years**; sarcomatoid histology, poor performance status and weight loss predict worse outcome.
- **Treatment (palliative intent)**: first-line **cisplatin + pemetrexed** (an antifolate) with **folic acid + vitamin B₁₂** supplementation improved median survival (**12.1 vs 9.3 months** vs cisplatin alone); adding **bevacizumab** (anti-VEGF) further improved survival (MAPS: **18.8 vs 16.1 months**). **Extrapleural pneumonectomy (EPP)** is *harmful/not recommended* (MARS trial — worse survival); **pleurectomy/decortication** and **talc pleurodesis/indwelling pleural catheter** for effusion control are the mainstays; immune-checkpoint inhibitors remain largely investigational.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Asbestos (ferruginous) body** — draw a central thin asbestos fibre coated by an iron-protein layer giving a **beaded, dumb-bell / drumstick shape**. Labels: *core asbestos fibre, iron-protein (haemosiderin) coat, beaded/segmented body, engulfing alveolar macrophage*.
- ▶ **Chest radiograph of asbestos-related disease** — outline both lungs. Labels: *bilateral calcified diaphragmatic pleural plaques, lower-zone irregular/reticular opacities (asbestosis), “shaggy/indistinct heart border”, blunted costophrenic angle (effusion/thickening), rounded atelectasis with comet-tail sign*.

Clinical / Diagnostic significance

- ▶ **Exposure history is paramount** — occupation, duration, latent interval, and para-occupational/domestic/environmental sources; correlate with imaging.
- ▶ **Pleural plaques = marker of past exposure, not impairment**; their presence beside lower-zone fibrosis strongly supports asbestosis over idiopathic pulmonary fibrosis.
- ▶ **HRCT is the key imaging tool** — detects early parenchymal fibrosis, distinguishes pleural plaque from subpleural fat, and characterises rounded atelectasis.
- ▶ **Any unilateral exudative effusion in an asbestos-exposed patient is mesothelioma until proven otherwise** — proceed to thoracoscopic biopsy.
- ▶ **Smoking cessation** disproportionately reduces lung-cancer risk because of the multiplicative interaction; mesothelioma risk is unaffected by smoking.
- ▶ **Medicolegal/compensation**: documented asbestosis, lung cancer with exposure, and mesothelioma are **compensable**; primary prevention via exposure limits, substitution, engineering controls and surveillance is the only effective strategy given the absence of cure.

High-yield exam pointers

- ▶ **Amphiboles (crocidolite) → mesothelioma**; chrysotile is less biopersistent and more readily cleared.
- ▶ **Asbestos/ferruginous body** = beaded iron-coated fibre = light-microscopic hallmark of exposure (not of disease severity).
- ▶ **Asbestosis** = lower-zone, subpleural fibrosis with **velcro crackles, clubbing, restrictive PFT, low DLCO**; HRCT subpleural curvilinear lines 5–10 mm.
- ▶ **Pleural plaques** are bilateral, parietal, calcified (“candle-wax”), and the **commonest** manifestation.
- ▶ **BAPE** = earliest manifestation (<15 yr); diagnosis of exclusion needing 3-yr tumour-free follow-up.
- ▶ **Lung cancer latency 15–19 yr; mesothelioma latency 20–40 yr**; mesothelioma not smoking-related, lung cancer **synergistic** with smoking.
- ▶ **Mesothelioma**: epithelioid best / **sarcomatoid worst** prognosis; **BAP1 loss + CDKN2A/p16 deletion** confirm diagnosis; median survival ~12 months.
- ▶ **Cisplatin + pemetrexed (+ folate/B₁₂) ± bevacizumab** is first-line; **EPP is harmful (MARS)**.
- ▶ **>80% of mesotheliomas are asbestos-associated → compensable.**

SOURCE & COVERAGE

- ▶ **Harrison’s Principles of Internal Medicine, 22e** — “Occupational and Environmental Lung Disease” (asbestos-related diseases section, lung cancer/mesothelioma associations)

and latencies); “*Neoplasms of the Lung*” and “*Pleural and Mediastinal Diseases / Mesothelioma*” for malignancy.

- ▶ **Murray & Nadel’s Textbook of Respiratory Medicine, 7e** — “*Pneumoconioses*” (asbestosis, pleural plaques, diffuse pleural fibrosis, benign asbestos pleural effusion, rounded atelectasis, pathogenesis and fibre biology) and “*Pleural Malignancy*” (mesothelioma — aetiology, subtypes, BAP1/CDKN2A diagnostics, staging, MARS/MAPS trials, chemotherapy and immunotherapy).
- ▶ **CMDT 2026** — “*Pulmonary Disorders*” (pneumoconioses/asbestosis clinical features, imaging and management; asbestos as carcinogen and cause of mesothelioma).

Coverage note: The corpus emphasises modern molecular diagnostics for mesothelioma (BAP1 loss, CDKN2A/p16 deletion) rather than the conventional immunohistochemistry panel; the marker panel cited (calretinin/WT-1/CK5/6/D2-40 positive, CEA/TTF-1/MOC-31 negative) is included as universally accepted diagnostic pathology supplementing the textbook content.

Bronchial asthma

Asked in: Paper III Nov 2019 — RGUHS MD General Medicine

Definition / Introduction — Bronchial asthma is a chronic, heterogeneous disease characterised by **episodic, largely reversible airway obstruction, airway hyperresponsiveness (AHR)** and, in most patients, **airway inflammation** (commonly eosinophilic/type 2). Clinically it presents as recurrent wheeze, dyspnoea, chest tightness and cough that vary in intensity over time and with triggers. In a subset, persistent inflammation and airway remodelling produce a fixed (irreversible) component. It affects ~262 million people worldwide and remains the commonest chronic respiratory disease with significant morbidity and preventable mortality.

Aetiology, risk factors and triggers

- ▶ **Heritable predisposition** — heritability 25–80%; complex polygenic inheritance interacting with environment and epigenetic change. Reproducible risk loci include ****ORMDL3/GSDMB** (17q21 region)*, ADAM33, DPP-10, TSLP, IL-33, ST2 (IL-33 receptor), IL-13, IL6R and HLA-DQB1*. Atopy (genetic tendency to specific IgE production) explains roughly half of asthma; key allergens are house dust mite, indoor fungi, cockroach and animal danders.
- ▶ **Predisposing exposures (development of disease)** — allergen exposure in the atopy-prone, occupational sensitisers (occupational asthma = 10–25% of adult-onset disease), air pollution (NO₂, CO), respiratory infections (rhinovirus, RSV, *Mycoplasma*), tobacco (maternal/active smoking), obesity, diet/vitamin D, and high-intensity exercise in elite athletes.

- ▶ **Triggers (provoke acute narrowing)** — allergens, irritants/smoke, viral infections, **exercise and cold dry air**, air pollution, drugs (β -blockers including ophthalmic drops, aspirin/NSAIDs, ACE-inhibitor cough), occupational agents, and hormonal/perimenstrual and pregnancy-related changes.
- ▶ **Special syndromes** — *Reactive airways dysfunction syndrome (RADS)* after a single high-concentration irritant exposure (non-sensitised, neutrophilic); *allergic bronchopulmonary aspergillosis (ABPA)* from IgE sensitisation to *Aspergillus fumigatus*.

Pathophysiology and airway inflammation

- ▶ **Airway hyperresponsiveness** — exaggerated bronchoconstriction to stimuli (e.g. histamine, methacholine) that do not affect normal airways; partly smooth-muscle and partly structural (wall thickening).
- ▶ **Acute obstruction** — smooth-muscle contraction, mucosal/submucosal **oedema**, and luminal **mucus plugging** narrow the airway.
- ▶ **Chronic obstruction / remodelling** — smooth-muscle hypertrophy and hyperplasia, **subepithelial collagen and matrix deposition (basement-membrane thickening)**, goblet-cell metaplasia with mucus hypersecretion, epithelial denudation, vascular and neuronal proliferation — together producing a fixed component.
- ▶ **Type 2 (T2-high) inflammation** — the dominant pattern; driven by **CD4⁺ Th2 cells and ILC2s** producing **IL-4, IL-5 and IL-13**. *IL-4* drives B-cell isotype switching to **IgE**; *IL-5* controls eosinophil formation, recruitment and survival; *IL-13* induces AHR, mucus hypersecretion and goblet-cell metaplasia. Epithelial **alarmins (TSLP, IL-25, IL-33)** activate ILC2s, so even “non-allergic” irritant/viral exposures can drive eosinophilia.
- ▶ **Mediators** — **cysteinyl leukotrienes (LTC₄, LTD₄, LTE₄)** from eosinophils/mast cells are potent bronchoconstrictors and mucus secretagogues; prostaglandin D₂, nitric oxide and reactive oxygen species amplify inflammation; chemokines (eotaxin, RANTES, TARC) recruit cells.
- ▶ **Non-type 2 inflammation** — **neutrophilic** (IL-6, IL-8, IL-17, TNF- α ; severe/steroid-refractory, RADS, sometimes *Mycoplasma*-associated and macrolide-responsive) or **pauci-granulocytic** asthma with no obvious infiltrate.

Clinical features and classification

- ▶ **Symptoms** — episodic wheeze, breathlessness, chest tightness, cough and mucus; often nocturnal or early-morning, and provoked by triggers. Between attacks examination may be normal; during attacks — tachypnoea, tachycardia, prolonged expiration, accessory-muscle use; a “**silent chest**” signifies severe, life-threatening obstruction.
- ▶ **Classification by inflammatory phenotype/endotype** — allergic (early-onset, atopic) vs late-onset eosinophilic, aspirin-exacerbated, obesity-related, and neutrophilic/non-T2; this **endotype-based nosology guides biologic selection**.

- ▶ **Assessment of control (GINA — past 4 weeks)** — based on four items: daytime symptoms >2×/week, any night waking due to asthma, reliever need >2×/week, and any activity limitation.

Level of control	Criteria (over past 4 weeks)
Well controlled	None of the four components
Partly controlled	1–2 components present
Uncontrolled	3–4 components present

- ▶ **Goals of therapy** — symptoms ≤2×/week, nocturnal waking ≤2×/month, reliever use ≤2×/week, ≤1 exacerbation/year, normal lung function and activity, minimal side-effects.

Diagnosis and investigations

- ▶ **Spirometry** — obstructive pattern: ↓FEV₁, ↓FEV₁/FVC below the lower limit of normal; flow-volume loop shows expiratory **scalloping**. **Reversibility**: ≥10% increase in FEV₁ % predicted after a β₂-agonist (older criterion: ≥12% and ≥200 mL rise). Diurnal PEF **variability** >20% supports the diagnosis.
- ▶ **Bronchoprovocation** (when spirometry non-diagnostic) — **methacholine challenge**: ≥20% fall in FEV₁ at a concentration ≤8 mg/mL (Harrison: PD₂₀ cumulative dose ≤400 µg); a negative test has ~95% negative predictive value. Mannitol or exercise/cold-air challenge (≥10% FEV₁ fall) are alternatives.
- ▶ **Biomarkers of type 2 inflammation** — blood eosinophils ≥300 cells/µL; FeNO elevated (>35–40 ppb untreated indicates T2 inflammation; suppressed by ICS, useful for adherence); total/specific IgE and skin/RAST testing for atopy.
- ▶ **Red-flag results** — IgE >1000 IU/mL with eosinophils >500/µL → consider ABPA; extreme eosinophilia → eosinophilic granulomatosis with polyangiitis (EGPA).
- ▶ **Classic sputum findings (universally accepted)** — *Curschmann spirals* (mucus casts), *Charcot-Leyden crystals* (eosinophil-derived), and *Creola bodies* (sloughed epithelial clusters).
- ▶ **Differential / “asthma mimics”** — heart failure (“cardiac asthma”), COPD, α₁-antitrypsin deficiency, inducible laryngeal obstruction (vocal-cord dysfunction), foreign body, bronchiectasis, tracheobronchomalacia, EGPA.

Acute severe asthma (status asthmaticus) and its grading

- ▶ A normal or rising PaCO₂ in a distressed asthmatic (who should be hypocapnic from tachypnoea) signals **impending respiratory failure**.

Feature	Moderate	Severe	Respiratory arrest imminent
Breathlessness / talks in	On walking; sentences	At rest; phrases/words	Mute

Feature	Moderate	Severe	Respiratory arrest imminent
Position / accessory muscles	Can lie down; usually none	Sits upright; usually present	Paradoxical thoraco-abdominal
Wheeze	End-expiratory	Loud throughout	Silent chest
Pulse; pulsus paradoxus	100–120; may be present	>120; often >25 mmHg	Bradycardia (fatigue)
PEF/FEV1 % predicted	40–69%	<40%	<25%
SaO ₂ (air)	90–95%	<90% (± cyanosis)	<90%

- **Management of exacerbation** — high-flow oxygen to correct hypoxaemia; repeated/continuous nebulised SABA (≥3 doses in the first hour) ± ipratropium; systemic corticosteroids (prednisone 40–60 mg/day, taper over 1–2 weeks). IV magnesium sulphate 2 g over 20 min for acute severe asthma (FEV1 <25% predicted or non-responders). Consider NIV/heliox; if intubated, use lung-protective, low-rate/low-volume “permissive hypercapnia” ventilation to limit airway pressures. Antibiotics only with clear infection.

Stepwise (GINA) pharmacotherapy and biologics

- **Reliever shift (AIR — Anti-Inflammatory Reliever)** — GINA now recommends as-needed ICS-formoterol (only formoterol, owing to rapid onset) or ICS-SABA at *all* steps, replacing SABA-alone, because SABA monotherapy increases asthma death.
- **Controller ladder** — ICS are the cornerstone of all persistent asthma. Step 1–2: as-needed/low-dose ICS-formoterol; Step 3: low-dose ICS-formoterol maintenance; Step 4: medium-dose ICS-formoterol; Step 5: high-dose ICS-LABA + add-on LAMA (e.g. tiotropium), and biologics ± macrolide/low-dose OCS as last resort.
- **Bronchodilators** — SABA (salbutamol/albuterol; onset 3–5 min, lasts 4–6 h); LABA (salmeterol, formoterol; ~12 h — never as monotherapy in asthma); ultra-LABA (vilanterol, indacaterol, olodaterol; 24 h, only with ICS). Theophylline is now rarely used (narrow therapeutic window).
- **Other controllers** — leukotriene modifiers (montelukast/zafirlukast; zileuton) — useful in exercise-induced and aspirin-exacerbated respiratory disease (AERD); cromolyn (paediatric, mast-cell stabiliser).
- **Biologics for severe T2 asthma** — omalizumab (anti-IgE), mepolizumab/reslizumab (anti-IL-5), benralizumab (anti-IL-5Rα), dupilumab (anti-IL-4Rα, blocks IL-4/IL-13), tezepelumab (anti-TSLP, also effective in some T2-low disease). They reduce exacerbations by ~50–70% in correctly selected (biomarker-guided) patients.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Cross-section of normal vs asthmatic bronchus** — label: *epithelium with denudation/shedding, goblet-cell metaplasia + mucus plug in lumen, thickened/sub-epithelial collagen (basement-membrane) deposition, sub-mucosal oedema, smooth-muscle hypertrophy & hyperplasia, cellular (eosinophil) infiltration, vascular and neuronal proliferation, narrowed lumen.*
- ▶ **Type 2 inflammatory cascade** — label: *allergen/irritant → epithelial alarmins (TSLP, IL-25, IL-33) → ILC2 and Th2 cells → IL-4 (IgE switch), IL-5 (eosinophils), IL-13 (AHR, mucus); IgE on mast cells → cysteinyl-leukotrienes → bronchoconstriction, with arrows to the corresponding biologics (omalizumab, anti-IL-5, dupilumab, tezepelumab).*

Clinical / Diagnostic significance

- ▶ Confirm diagnosis objectively with **reversible obstruction or AHR** before lifelong therapy — >1/3 of physician-labelled “asthma” does not meet criteria.
- ▶ **Phenotyping by eosinophils/FeNO/IgE** directs precision biologic therapy and predicts response.
- ▶ Identify and treat **comorbidities** that make asthma refractory: chronic rhinosinusitis ± nasal polyposis, GERD, obesity, OSA, anxiety/depression, vocal-cord dysfunction.
- ▶ **Nasal polyps + adult asthma → suspect AERD (Samter triad)**: avoid aspirin/NSAIDs, use leukotriene modifiers ± aspirin desensitisation/biologics.
- ▶ In **pregnancy**, treat actively — inhaled salbutamol, budesonide, beclomethasone and fluticasone are well-established; uncontrolled asthma is far more dangerous to mother and fetus than the drugs.

High-yield exam pointers

- ▶ Triad of asthma: **reversible airway obstruction + airway hyperresponsiveness + airway inflammation.**
- ▶ **ICS are the cornerstone**; SABA-only treatment increases mortality — GINA now uses ICS-formoterol as reliever (AIR) at every step.
- ▶ **Reversibility** = $\geq 10\%$ rise in FEV1 % predicted (or $\geq 12\%$ and ≥ 200 mL); **PEF diurnal variability** $> 20\%$.
- ▶ Key T2 cytokines: **IL-4 (IgE), IL-5 (eosinophils), IL-13 (AHR/mucus)**; alarmins = TSLP, IL-25, IL-33.
- ▶ **ABPA**: IgE > 1000 IU/mL, eosinophils $> 500/\mu\text{L}$, central bronchiectasis — treat with itraconazole + steroids.
- ▶ Acute severe asthma red flags: **silent chest, pulsus paradoxus > 25 mmHg, normal/rising PaCO_2 , bradycardia.**

- ▶ Acute treatment: O₂ + nebulised SABA + ipratropium + systemic steroids; IV MgSO₄ 2 g in severe cases.
- ▶ Biologics by endotype: omalizumab (IgE), mepolizumab/benralizumab (IL-5/IL-5R), dupilumab (IL-4Rα), tezepelumab (TSLP).
- ▶ High asthma-death risk: prior ICU/intubation, ≥2 ED visits in 6 months, recent OCS, psychosocial problems.

SOURCE & COVERAGE

- ▶ **Harrison's Principles of Internal Medicine, 22e** — “Asthma” (pathophysiology, type 2/non-type 2 inflammation, genetics, diagnosis, GINA/NAEPP step therapy, biologics, status asthmaticus, AERD, pregnancy).

Acute Respiratory Distress Syndrome — Causes, Pathophysiology, Diagnostic Criteria and Management

Asked in: Paper III 15 Apr 2026 — RGUHS MD General Medicine

Definition / Introduction — Acute respiratory distress syndrome (ARDS) is a clinical syndrome of rapid-onset severe dyspnoea, refractory hypoxaemia and bilateral pulmonary infiltrates caused by diffuse, increased-permeability (non-cardiogenic) pulmonary oedema arising from direct or indirect lung injury. The pathological substrate is **diffuse alveolar damage (DAD)**, and the physiological hallmarks are intrapulmonary shunting, reduced lung compliance and increased dead space. First described by *Ashbaugh* and colleagues in 1967, it is currently defined by the **Berlin criteria (2012)** and complicates ~10% of ICU admissions, with hospital mortality of 35–46%.

Etiology / Causes

Over 80% of cases arise from a few disorders — **pneumonia and sepsis (~40–60%)**, aspiration of gastric contents, trauma, multiple transfusions and drug overdose. Causes are classified by mechanism of injury:

Direct (pulmonary) lung injury	Indirect (extrapulmonary) lung injury
Pneumonia — bacterial, viral (influenza, COVID-19)	Sepsis (commonest single cause)

Direct (pulmonary) lung injury	Indirect (extrapulmonary) lung injury
Aspiration of gastric contents	Severe trauma — multiple fractures, flail chest, head trauma
Pulmonary contusion	Multiple blood transfusions (>15 units/24 h; TRALI)
Toxic inhalation injury	Acute pancreatitis
Near-drowning	Cardiopulmonary bypass
Reperfusion injury (post-lung transplant)	Drug overdose; burns

- ▶ **Predisposing/severity modifiers:** older age, **chronic alcohol abuse** (relative risk ~2.0, and higher mortality), active or passive cigarette smoke, and severity of critical illness — trauma patients with an **APACHE II score ≥ 16** have a 2.5-fold increased risk. The presence of **more than one risk factor** multiplies the risk.
- ▶ ARDS arising from **direct** lung injury carries nearly **twice** the mortality of indirect causes; trauma-associated ARDS has the best prognosis and end-stage liver disease the worst.

Pathophysiology

The natural history evolves through **three overlapping phases** (exudative → proliferative → fibrotic).

- ▶ **Exudative phase (day 0–7):** injury to **alveolar capillary endothelium** and **type I pneumocytes** disrupts the tight alveolar barrier, allowing **protein-rich exudate** into the interstitium and alveoli. Pro-inflammatory cytokines (IL-1, IL-6, IL-8, TNF- α) and lipid mediators (**leukotriene B4**) recruit **neutrophils**, which release proteases, reactive oxygen species and **neutrophil extracellular traps (NETs)**. Condensed plasma proteins, debris and inactivated surfactant form **hyaline membranes** (the histological correlate of DAD). Microvascular injury causes obliteration by **microthrombi**.
- ▶ **Physiological consequences:** alveolar flooding and dependent atelectasis cause **right-to-left intrapulmonary shunt** → **hypoxaemia refractory to oxygen**, **reduced compliance** (“stiff lungs”, increased work of breathing), and **increased dead space** from microvascular occlusion → **hypercapnia** and **pulmonary hypertension**. Loss/inactivation of **surfactant** promotes further alveolar collapse; **hypoxia impairs alveolar Na^+/K^+ -ATPase-dependent fluid clearance**.
- ▶ **Proliferative phase (day 7–21):** organisation of exudate, **type II pneumocyte proliferation** (synthesising new surfactant and differentiating into type I cells), and a shift from neutrophil- to lymphocyte-predominant infiltrate. Most patients begin to recover here.
- ▶ **Fibrotic phase (>2–3 weeks):** in a subset, alveolar and interstitial **fibrosis**, acinar disruption with **bullae**, and intimal fibroproliferation causing vascular occlusion and pulmonary hypertension; predicts higher mortality and risk of pneumothorax.

- **Important nuances:** DAD is found in only ~50% of ARDS at biopsy/autopsy. Latent-class analysis identifies two **subphenotypes** — a **hypoinflammatory** and a **hyperinflammatory** (high IL-6/IL-8, low protein C, vasopressor-dependent, higher mortality) phenotype that respond differently to PEEP, fluids and statins. Mechanical ventilation itself propagates injury — **ventilator-induced lung injury (VILI)** via **volutrauma** (overdistension), **barotrauma**, **atelectrauma** (cyclic opening/closing) and **biotrauma** (cytokine release driving multi-organ failure).

Diagnostic criteria — Berlin definition (2012)

All four must be satisfied; severity is graded by oxygenation on PEEP/CPAP ≥ 5 cmH₂O.

Domain	Requirement
Timing	Within 1 week of a known insult or new/worsening respiratory symptoms
Chest imaging	Bilateral opacities (CXR or CT) not fully explained by effusion, lobar/lung collapse or nodules
Origin of oedema	Respiratory failure not fully explained by cardiac failure or fluid overload ; if no risk factor, objective testing (e.g. echocardiography) to exclude hydrostatic oedema
Oxygenation (PaO ₂ /FiO ₂ on PEEP ≥ 5)	Mild 200–300 mmHg · Moderate 100–200 mmHg · Severe ≤ 100 mmHg

- The Berlin definition **abolished the term “acute lung injury (ALI)”** and removed the pulmonary-artery wedge-pressure requirement (≤ 18 mmHg of the older AECC definition).
- **Proposed updates (2023) / new global definition (2024):** allow diagnosis in **non-intubated** patients on **high-flow nasal oxygen** (≥ 30 L/min) or NIV/CPAP, permit **SpO₂/FiO₂ (S/F) ratios** (≤ 315 if SpO₂ $\leq 97\%$) and **lung ultrasound** as imaging, easing diagnosis in resource-limited settings.
- **Key differentials:** cardiogenic pulmonary oedema (look for cardiomegaly, effusions, vascular redistribution; BNP/echocardiography), bilateral pneumonia, diffuse alveolar haemorrhage, acute interstitial pneumonia and neurogenic pulmonary oedema.

Management strategies

Mortality reduction stems chiefly from **lung-protective ventilation and meticulous supportive critical care** — there is **no proven pharmacotherapy that reduces mortality**.

- **Treat the precipitating cause** — source control, antibiotics for sepsis/pneumonia; ICU “bundle” care (VTE, GI and aspiration prophylaxis, minimised sedation, enteral nutrition, infection prevention).

- ▶ **Lung-protective ventilation (cornerstone, Evidence A):** the ARDSNet (ARMA) trial showed low tidal volume 6 mL/kg predicted body weight with plateau pressure ≤ 30 cmH₂O reduced mortality (31% vs 40%) versus 12 mL/kg. Target SpO₂ 88–95%, pH ≥ 7.30 (permissive hypercapnia), and the lowest FiO₂ (aim < 0.6) to avoid oxygen toxicity. **Driving pressure (P_{plat} – PEEP)** may be the strongest predictor of survival.
- ▶ **PEEP / open-lung strategy (Evidence B):** PEEP is titrated (PEEP–FiO₂ table) to recruit atelectatic lung, reduce atelectrauma and lower FiO₂; **higher PEEP is safe and improves oxygenation in severe ARDS** but no trial shows a clear mortality benefit. **Routine recruitment manoeuvres are not recommended** (harmful when combined with high PEEP).
- ▶ **Prone positioning (Evidence B):** the PROSEVA trial showed prolonged proning (> 16 h/day) in severe ARDS (PaO₂/FiO₂ < 150) reduced 28-day mortality (16% vs 33%). Requires an experienced team; contraindicated in unstable spinal injury.
- ▶ **Conservative fluid management:** FACTT trial — conservative fluids/diuresis (CVP < 4 or PAOP < 8 mmHg) gave more ventilator-free and ICU-free days without increasing shock or dialysis. **Pulmonary artery catheters are not routinely indicated.** Transfuse to Hb ≥ 7 g/dL only.
- ▶ **Neuromuscular blockade (selective):** early cisatracurium $\times 48$ h improved survival in severe ARDS (ACURASYS 90-day mortality 31.6% vs 40.7%) but the confirmatory ROSE trial (with light sedation control) showed no benefit — reserve for **ventilator dyssynchrony** despite deep sedation.
- ▶ **Corticosteroids:** not routinely advised historically, but the DEXA-ARDS trial (dexamethasone 20 mg/day $\times 5$ then 10 mg/day $\times 5$) increased ventilator-free days (12.3 vs 7.5) and lowered 60-day mortality (21% vs 36%); **2024 ATS guidelines** give a **conditional recommendation** for corticosteroids, most useful within **< 14 days**, in severe CAP, and in COVID-19.
- ▶ **ECMO (rescue):** CESAR favoured referral to an ECMO centre; EOLIA showed a non-significant mortality reduction (35% vs 46%, with high crossover) — ECMO is a **salvage option for very severe, refractory ARDS**, not first-line.
- ▶ **Therapies NOT recommended / ineffective:** surfactant replacement, **inhaled nitric oxide / epoprostenol** (transiently improve oxygenation, no survival benefit; iNO risks renal dysfunction — rescue only), β_2 -agonists (salbutamol — harmful), high-frequency oscillatory ventilation, statins (except possibly the hyperinflammatory subphenotype), and immunonutrition/ ω -3 supplements.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Time-course of ARDS (three phases):** an x-axis “Day 0 $\rightarrow$ 2 $\rightarrow$ 7 $\rightarrow$ 14 $\rightarrow$ 21” with overlapping bands labelled Exudative (alveolar oedema, neutrophils, hyaline membranes), Proliferative (interstitial inflammation, type II pneumocyte proliferation, early fibrosis) and Fibrotic (fibrosis, bullae).

- ▶ **Injured alveolus (exudative phase):** label alveolar capillary, damaged endothelium, injured type I pneumocyte, type II pneumocyte, protein-rich oedema fluid in alveolus, hyaline membrane, migrating neutrophil with proteases/ROS/NETs, activated macrophage, platelet–fibrin microthrombus, and inactivated surfactant — contrasted with a normal alveolus.

Clinical / Diagnostic significance

- ▶ **Bedside diagnosis** hinges on excluding **cardiogenic oedema** — echocardiography/BNP when no clear ARDS risk factor; CT shows characteristic **dependent, heterogeneous** consolidation guiding lung-protective ventilation.
- ▶ **Mortality (LUNG SAFE):** mild 34.9%, moderate 40.3%, severe 46.1%; most deaths (>80%) are from **sepsis and non-pulmonary multi-organ failure**, not refractory hypoxaemia — emphasising that survival depends on holistic critical care.
- ▶ **Complications:** ventilator-associated pneumonia (30–65%), **barotrauma** (pneumothorax/pneumomediastinum, 12–13%), and **ICU-acquired weakness**.
- ▶ **Recovery:** survivors usually regain near-normal lung function by 6–12 months, but **persistent exercise limitation, muscle weakness, depression and PTSD** are common — warranting post-ICU follow-up.

High-yield exam pointers

- ▶ **Berlin triad:** acute (≤ 1 week) + bilateral opacities + non-cardiogenic oedema; severity by $\text{PaO}_2/\text{FiO}_2$ on PEEP ≥ 5 (Mild ≤ 300 , Moderate ≤ 200 , Severe ≤ 100).
- ▶ **Pathology = diffuse alveolar damage;** phases = **exudative** $\rightarrow$ **proliferative** $\rightarrow$ **fibrotic**.
- ▶ **Two cornerstones with mortality benefit:** **low tidal volume** (6 mL/kg PBW, $\text{P}_{\text{plat}} \leq 30$) and **prone positioning in severe ARDS** (PROSEVA).
- ▶ **Conservative fluids** (FACTT) $\rightarrow$ more ventilator-free days; PA catheter not routine.
- ▶ **VILI mechanisms:** volutrauma, barotrauma, atelectrauma, biotrauma.
- ▶ **Cisatracurium** (ACURASYS+, ROSE–) and **ECMO** (EOLIA) are selective/rescue, not routine.
- ▶ **No drug reliably cuts mortality;** corticosteroids (dexamethasone) are a **conditional** option in early ARDS.
- ▶ **Commonest causes:** **sepsis and pneumonia;** commonest cause of death: **multi-organ failure**.

SOURCE & COVERAGE

- ▶ **Harrison's Principles of Internal Medicine, 22e** — “Acute Respiratory Distress Syndrome” (etiology, Berlin criteria, three-phase pathophysiology,

ARDSNet/PROSEVA/ACURASYS/ROSE, evidence-based recommendations, prognosis) and “Mechanical Ventilatory Support”.

- ▶ **Murray & Nadel’s Textbook of Respiratory Medicine, 7e** — “Acute Respiratory Distress Syndrome” (AECC→Berlin evolution, DAD/neutrophil and NET pathobiology, subphenotypes, VILI, detailed ventilation/PEEP/proning/NMB/ECMO trial data, DEXA-ARDS, long-term outcomes).

Complications of Bronchiectasis

Asked in: Paper III Jun 2024 — RGUHS MD General Medicine

Definition / Introduction — Bronchiectasis is an *irreversible* dilation of the medium-to-large airways (cylindrical/tubular, varicose, or cystic/saccular) driven by Cole’s “vicious cycle/vortex” of impaired mucociliary clearance, chronic infection, transmural neutrophilic inflammation and progressive airway-wall destruction. Although recurrent suppurative infection is the defining feature, the clinical burden of the disease comes largely from its **complications**, which are best grouped as pulmonary, cardiovascular, systemic/extrapulmonary and microbiological. These determine quality of life, lung-function decline and mortality, and several severity scores are built around them.

Overview — complications grouped by system

System	Key complications
Airway / pulmonary	Acute infective exacerbations; chronic bacterial colonisation (esp. <i>Pseudomonas aeruginosa</i>); haemoptysis (incl. massive/life-threatening); progressive airflow obstruction → chronic respiratory failure; recurrent pneumonia, lung abscess, empyema; pneumothorax
Microbiological	Antimicrobial resistance from repeated courses; superinfection with non-tuberculous mycobacteria (NTM); <i>Aspergillus</i> — ABPA, mucoid impaction, aspergilloma/chronic pulmonary aspergillosis
Cardiovascular	Chronic hypoxaemic pulmonary hypertension → cor pulmonale (right-heart failure); excess cardiovascular and cerebrovascular events
Systemic / extrapulmonary	Secondary (AA) amyloidosis; IgA nephropathy; anaemia of chronic disease; weight loss/cachexia;

System	Key complications
	digital clubbing; reduced QOL, fatigue, depression, sleep-disordered breathing
Functional / prognostic	Frequent-exacerbator phenotype; accelerated FEV ₁ decline; increased hospitalisation and ~2-fold excess mortality

Pulmonary and airway complications

- ▶ **Acute exacerbations** are the commonest and most important clinical event. They are characterised by a change in sputum — *increased volume and purulence* — with worsening cough/dyspnoea; classical signs of infection (fever, new infiltrates) may be absent. Commonly implicated organisms are *Haemophilus influenzae*, *Pseudomonas aeruginosa*, *Staphylococcus aureus* and *Moraxella catarrhalis*. The **frequent-exacerbator phenotype** (≥ 3 exacerbations/year) is the strongest predictor of future exacerbations and carries poorer QOL, more hospitalisations and higher, exacerbation-proportional mortality.
- ▶ **Chronic colonisation / Pseudomonas aeruginosa infection* — *P. aeruginosa colonises damaged airways, forms biofilms (exopolysaccharide glycocalyx, quorum sensing) and evades host defences. It is a marker of disease severity, frequent exacerbation, accelerated decline and confers an approximately three-fold increased risk of death**.
- ▶ **Antimicrobial resistance** — recurrent infection with repeated courses of antibiotics drives multidrug resistance, sometimes forcing combinations of independently toxic agents.
- ▶ **Haemoptysis** — the **most common complication**; recurrent infection injures superficial bronchial-mucosal vessels causing bleeding that ranges from streaking to **massive, life-threatening haemoptysis** (bleeding is from the high-pressure **bronchial arterial** circulation). Discussed separately below.
- ▶ **Progressive airflow obstruction and chronic respiratory failure** — mild-to-moderate obstruction overlaps with COPD; FEV₁ in non-CF bronchiectasis declines at ~50–55 mL/year (vs 20–30 mL/year in healthy controls), eventually causing chronic hypoxaemia/hypercapnia and end-stage respiratory failure requiring long-term oxygen or transplantation.
- ▶ **NTM superinfection** — *Mycobacterium avium* complex (MAC) and *M. abscessus* both **cause and complicate** bronchiectasis; bronchiectasis is the best-recognised predisposing condition for pulmonary NTM. NTM may be a coloniser or true pathogen, and chronic macrolide monotherapy risks inducing **macrolide-resistant NTM** — hence NTM must be excluded before long-term macrolides are started.
- ▶ **Aspergillus-related disease** — damaged/central airways may develop **ABPA** (immune-mediated, mucoid impaction, central bronchiectasis) or, within residual cavities (e.g., post-TB), an **aspergilloma/chronic pulmonary aspergillosis** causing recurrent haemoptysis, weight loss and fatigue.

- ▶ **Suppurative spread** — necrotising infection of bronchiectatic lung can produce **recurrent pneumonia, lung abscess, parenchymal scarring, pneumatocles and empyema**; pneumothorax occurs in cystic disease and in connective-tissue-associated bronchiectasis (e.g., Marfan syndrome).

Massive haemoptysis — recognition and management (high-yield)

- ▶ Defined by life-threatening volume/rate; the airway, not exsanguination, is the immediate threat, so the priorities are **airway protection and gas exchange**.
- ▶ **Stepwise management**: secure the airway (often **intubation**, with the bleeding lung dependent / lateral decubitus to protect the non-bleeding lung); resuscitate and correct coagulopathy; **localise the source** with chest CT-angiogram and/or bronchoscopy; achieve haemostasis.
- ▶ **Definitive control**: **bronchial artery embolisation** is first-line for control; bronchoscopic measures (balloon tamponade, topical vasoconstrictors, laser) may temporise; **surgical resection** is reserved for refractory or localised disease.

Cardiovascular, renal and systemic complications

- ▶ **Pulmonary hypertension and cor pulmonale** — chronic hypoxaemia, parenchymal destruction and vascular remodelling raise pulmonary arterial pressure; sustained pressure load produces **right-ventricular hypertrophy and failure (cor pulmonale)** — a recognised late sequela of chronic suppurative/fibrotic lung disease (e.g., post-tuberculous bronchiectasis).
- ▶ **Secondary (AA) amyloidosis** — long-standing suppuration with sustained serum amyloid-A (acute-phase) elevation can deposit AA fibrils in kidney, liver and spleen, classically presenting as nephrotic-range proteinuria and renal failure; a classic, now-uncommon complication of chronic neglected bronchiectasis.
- ▶ **IgA nephropathy** — chronic bronchiectasis is among the systemic conditions associated with mesangial IgA deposition; usually clinically silent but occasionally causes glomerular disease.
- ▶ **Systemic burden** — anaemia of chronic disease, **weight loss/cachexia**, fatigue and **digital clubbing**; patients carry excess **cardiovascular, cerebrovascular and malignancy risk**, gastro-oesophageal reflux, sleep-related complications, and high rates of anxiety/depression with markedly reduced quality of life (captured by the QOL-B instrument).

Prognosis and severity-scoring tools

- ▶ Bronchiectasis confers an approximately **two-fold excess mortality** versus age/sex-matched controls.
- ▶ Validated multidimensional scores predict mortality and hospitalisation:
 - **FACED score** — FEV₁, Age, Chronic colonisation (*P. aeruginosa*), radiographic Extension (number of lobes), Dyspnoea (mMRC).

- **Bronchiectasis Severity Index (BSI)** — incorporates the above plus **prior hospitalisation and exacerbation frequency**.
- (The E-FACED adds the Exacerbation dimension to FACED.)
- ▶ The strongest adverse prognostic markers are chronic *P. aeruginosa* infection, frequent exacerbations, lower FEV₁, greater radiographic extent and higher dyspnoea grade.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Cole's "vicious vortex" of bronchiectasis (link to complications):** draw a four-node cycle — label *Impaired mucociliary clearance / ciliary dysfunction* → *Chronic bacterial infection & biofilm (Pseudomonas)* → *Transmural neutrophilic inflammation (elastase, proteases, ROS)* → *Airway-wall destruction & dilation* — with outward arrows to the major complications: **Haemoptysis, Exacerbations, Respiratory failure, Cor pulmonale, Amyloidosis**.
- ▶ **Cross-section of a bronchiectatic airway:** label *dilated lumen with retained mucus*, *destroyed wall (loss of elastin, smooth muscle, cartilage)*, *hypertrophied/eroded bronchial arteries (source of haemoptysis)*, *peribronchial inflammation, adjacent pulmonary artery*; alongside, sketch the CT "**signet-ring sign**" (airway:vessel diameter ≥ 1.5) and "**tram-track**" dilated airways.

Clinical / Diagnostic significance

- ▶ **HRCT** is the diagnostic standard and quantifies disease extent (a FACED/BSI input); look for tram-tracks, signet-ring sign, lack of tapering, tree-in-bud and cystic change.
- ▶ **Sputum surveillance** (bacterial, AFB/NTM, fungal cultures) is essential — isolating *P. aeruginosa* or NTM changes prognosis and therapy; exclude NTM before chronic macrolides and obtain an ECG to exclude long QT before macrolide therapy.
- ▶ Work up the **underlying cause** (sweat chloride/CFTR, immunoglobulins, α_1 -antitrypsin, nasal NO/ciliary studies, *Aspergillus* IgE/IgG + eosinophils, autoantibodies) because cause-specific therapy (IgG replacement, ABPA steroids/antifungals, CFTR modulators) modifies complications.
- ▶ Management aimed at the vicious cycle — **airway clearance** (physiotherapy, oscillatory PEP/flutter, hypertonic saline), treating exacerbations (7–14 day antibiotics), long-term suppressive/macrolide therapy for frequent exacerbators, pulmonary rehabilitation, and vaccination (influenza, pneumococcal, COVID, RSV) — reduces exacerbations and lung-function decline. *Note: DNase (dornase) helps in CF but is not recommended (possibly harmful) in non-CF bronchiectasis.*

High-yield exam pointers

- ▶ **Haemoptysis is the commonest complication;** massive haemoptysis arises from eroded bronchial arteries — manage by airway protection + **bronchial artery embolisation**.

- ▶ Chronic **Pseudomonas** colonisation = severity marker, faster decline, ~3× **mortality**; FEV₁ falls 50–55 mL/yr in non-CF disease.
- ▶ **Frequent-exacerbator phenotype** (≥3/yr) predicts future exacerbations, hospitalisation and death.
- ▶ Late systemic complications: **cor pulmonale**, **secondary (AA) amyloidosis**, IgA nephropathy, anaemia, cachexia, clubbing.
- ▶ NTM both causes and complicates bronchiectasis; beware macrolide-resistant NTM — exclude NTM before chronic macrolides.
- ▶ **ABPA / aspergilloma** are *Aspergillus*-related complications; aspergilloma in old cavities causes recurrent haemoptysis.
- ▶ Severity/prognosis scores: **FACED** (FEV₁, Age, Colonisation, Extension, Dyspnoea), **E-FACED**, and **BSI**; overall ~2× excess mortality.
- ▶ Exacerbation = increased sputum **volume** + **purulence** (fever/infiltrate often absent).

SOURCE & COVERAGE

- ▶ **Harrison's Principles of Internal Medicine, 22e** — “Bronchiectasis” (complications: haemoptysis, antimicrobial resistance, FEV₁ decline, NTM); “Nontuberculous Mycobacterial Infections”; “Tuberculosis” (post-TB bronchiectasis, pulmonary hypertension, aspergilloma); “Glomerular Diseases” (IgA nephropathy association); “Lung Abscess” / “Pneumonia” (empyema, pneumatoceles, abscess).
- ▶ **Murray & Nadel's Textbook of Respiratory Medicine, 7e** — “Bronchiectasis” (vicious vortex, biofilms, *Pseudomonas* ~3× mortality, frequent-exacerbator phenotype, FACED/BSI scores, ~2× excess mortality, cardiovascular/cerebrovascular/GERD/malignancy morbidity).
- ▶ **CMDT 2026** — “Bronchiectasis” (haemoptysis as commonest complication and its management; *Pseudomonas* as severity marker; ≥3 exacerbations/year and mortality) and “Allergic Bronchopulmonary Aspergillosis”.

Coverage note: The dedicated bronchiectasis chapters describe haemoptysis, exacerbations/colonisation, lung-function decline and excess mortality in detail. **Secondary (AA) amyloidosis** and **cor pulmonale** are universally accepted classical complications of chronic suppurative bronchiectasis; in this corpus they are grounded indirectly (amyloidosis via the systemic AA mechanism; pulmonary hypertension explicitly in the post-tuberculous lung-disease section) rather than stated verbatim within the bronchiectasis chapters.

Describe etiology, clinical features, GOLD criteria in Chronic Obstructive Pulmonary Disease (COPD) and treatment of COPD exacerbation

Asked in: Paper III Jun 2024 — RGUHS MD General Medicine

Definition / Introduction — Chronic obstructive pulmonary disease (COPD) is a heterogeneous, preventable and treatable disease state characterised by **persistent respiratory symptoms and chronic airflow obstruction that is not fully reversible and is usually progressive**, arising from airway and/or alveolar abnormalities caused by significant exposure to noxious particles or gases. It encompasses three overlapping processes in varying proportion: **emphysema** (anatomic destruction of alveoli with airspace enlargement), **chronic bronchitis** (chronic cough and phlegm, clinically defined) and **small airway disease** (narrowed, reduced bronchioles). Diagnosis requires **spirometry**. Globally COPD affects an estimated 480 million people and is the third to fourth leading cause of death worldwide.

Etiology and risk factors

- ▶ **Cigarette smoking** — the dominant risk factor in the developed world; causes a dose-dependent (pack-year) accelerated decline in FEV1 (≈ 66 mL/yr in men, 54 mL/yr in women vs ≈ 30 and 22 mL/yr in quitters). Only $\sim 15\%$ of FEV1 variability is explained by pack-years, implying additional host factors; $\sim 15\%$ of smokers develop disabling disease. Cigar/pipe, **vaping and inhaled cannabis** are emerging concerns.
- ▶ **Biomass fuel smoke** — combustion of wood/dung for cooking in poorly ventilated dwellings; the leading cause in the developing world, especially in **women** and never-smokers.
- ▶ **Occupational exposures (VGDF)** — vapours, gases, dusts, fumes; coal mining, gold mining and cotton-textile dust are implicated (coal dust independently causes emphysema).
- ▶ **$\alpha 1$ -antitrypsin ($\alpha 1$ AT) deficiency** — the proven genetic cause; the **PiZ** phenotype (ZZ or Z/null) gives severe deficiency (~ 1 in 3000), serum $\alpha 1$ AT < 11 $\mu\text{mol/L}$ (~ 50 mg/dL); accounts for $\sim 1\%$ of COPD and causes early-onset, lower-zone **panlobular emphysema**.
- ▶ **Other genetics** — > 80 GWAS loci including *HHIP* (chr 4), the chr 15 cluster (nicotinic acetylcholine receptor, *IREB2*) and *FAM13A* (Wnt/ β -catenin).
- ▶ **Airway hyperresponsiveness / asthma, respiratory infections** (childhood pneumonia, tuberculosis-associated airflow limitation, HIV), **air pollution**, and **abnormal lung development / early-life passive smoke exposure** (maternal smoking, low maximal attained lung function).

Pathology and pathogenesis

- ▶ **Large airways** — mucus-gland enlargement, goblet-cell hyperplasia and squamous metaplasia $\rightarrow$ cough and sputum (chronic bronchitis).

- ▶ **Small airways (≤ 2 mm)** — goblet-cell metaplasia, smooth-muscle hypertrophy, fibrosis, mucus plugging and luminal narrowing; this is the **major site of increased airflow resistance** and the earliest lesion.
- ▶ **Parenchyma (emphysema)** — destruction of respiratory bronchioles, alveolar ducts and alveoli. Pathologic types: **centrilobular** (upper-lobe, smoking-related), **panlobular** (lower-lobe, $\alpha 1$ AT deficiency) and **paraseptal** (subpleural).
- ▶ **Disease mechanisms** — four interrelated events: chronic inhalational injury in susceptible hosts → inflammatory/immune cell recruitment → **protease–antiprotease imbalance** (the *elastase:antielastase* hypothesis; neutrophil elastase, MMP-12) and **oxidant–antioxidant imbalance** (oxidant inactivation of HDAC2, NRF2/SOD3 dysfunction) → structural cell death (ceramide, mTOR/Rtp801, senescence) → **ineffective repair** of elastin and matrix → airspace enlargement.

Pathophysiology

- ▶ **Airflow obstruction** — chronically reduced FEV1 and FEV1/FVC ratio that does not normalise after bronchodilator (fixed obstruction).
- ▶ **Hyperinflation** — air trapping ($\uparrow$ residual volume, $\uparrow$ RV/TLC), then $\uparrow$ TLC; flattens the diaphragm, shortening fibres and increasing work of breathing.
- ▶ **Gas exchange** — **V/Q mismatch** causes hypoxaemia (shunt minimal, hence corrected by modest O_2). P_{aO_2} usually stays near normal until FEV1 $< 50\%$ predicted; P_{aCO_2} rises only when FEV1 $< 25\%$ predicted. Sustained pulmonary hypertension → **cor pulmonale** typically when FEV1 $< 25\%$ and $P_{aO_2} < 55$ mmHg.

Clinical features

- ▶ **Symptoms** — the classic triad of **chronic cough, sputum production and progressive exertional dyspnoea**; symptoms often precede presentation by years. Arm work above shoulder level is poorly tolerated.
- ▶ **Signs** — early examination may be normal. Advanced: prolonged expiration, expiratory wheeze, **barrel chest**, poor diaphragmatic excursion, accessory-muscle use, **tripod posture**, pursed-lip breathing, cyanosis, cachexia (poor prognostic sign) and signs of cor pulmonale (raised JVP, pedal oedema). **Digital clubbing is NOT a feature** of COPD and mandates a search for another cause (especially lung cancer).
- ▶ **Two classic phenotypes** (most patients overlap):

Feature	Type A — “Pink Puffer” (emphysema-predominant)	Type B — “Blue Bloater” (bronchitis-predominant)
Main symptom	Severe dyspnoea, onset after ~50 yr; scant cough	Chronic productive cough, frequent infective exacerbations; onset 30s–40s
Build	Thin, recent weight loss, distressed, accessory-muscle use	Overweight, cyanotic, comfortable at rest, peripheral oedema
Chest	Quiet, no adventitious sounds	Noisy — rhonchi, wheezes
Pao ₂ / Paco ₂	Near normal (65–75 / 35–40 mmHg)	↓Pao ₂ (45–60), ↑Paco ₂ (50–60 mmHg)
Haemoglobin	Normal	Elevated (secondary polycythaemia)
CXR	Hyperinflation, flat diaphragms, ↓vascular markings	“Dirty lungs”, ↑interstitial markings, diaphragms not flat
Dlco / cor pulmonale	Reduced Dlco; late cor pulmonale	Normal Dlco; early, marked cor pulmonale

Diagnosis and GOLD criteria

- ▶ **Diagnostic requirement** — post-bronchodilator FEV₁/FVC <0.70 on spirometry confirms persistent airflow obstruction (some authorities prefer the lower limit of normal / Z-score to reduce mis-classification).
- ▶ **GOLD spirometric grades** (severity of obstruction, all require FEV₁/FVC <0.70):

Grade	Severity	Post-bronchodilator FEV ₁ (% predicted)
GOLD 1	Mild	≥80%
GOLD 2	Moderate	50–79%
GOLD 3	Severe	30–49%
GOLD 4	Very severe	<30%

- ▶ **GOLD “ABE” assessment tool** — combines symptom burden with exacerbation risk to guide therapy. **Symptoms:** mMRC ≥2 or CAT ≥10 = high; **Exacerbation risk:** ≥2 moderate exacerbations or ≥1 leading to hospitalisation in the past year = high.
 - **Group A** — low symptoms, low risk → a bronchodilator.
 - **Group B** — high symptoms, low risk → LABA + LAMA.
 - **Group E** — high exacerbation risk (any symptoms) → LABA + LAMA; add ICS if blood eosinophils ≥300/μL.

- ▶ **mMRC dyspnoea scale:** 0 (breathless only on strenuous exertion) to 4 (too breathless to leave the house/dress).
- ▶ **Other assessment** — ABG (ventilatory failure = $\text{Paco}_2 > 45$ mmHg), Dlco (reduced in emphysema), CBC (eosinophils guide ICS; raised Hct = chronic hypoxaemia), chest CT (defines emphysema pattern, screens for cancer), serum $\alpha 1\text{AT}$ in all COPD/early-onset disease, 6-minute walk and the multidimensional **BODE index** (Body-mass index, Obstruction, Dyspnoea, Exercise capacity) — a better predictor of mortality than FEV1 alone.

Treatment of COPD exacerbation

- ▶ **Definition** — an acute worsening of respiratory symptoms (increased dyspnoea, cough, sputum volume/purulence) beyond day-to-day variation, usually over < 14 days. Strongest predictor = a prior exacerbation.
- ▶ **Precipitants** — respiratory infection (viral in $> 50\%$; bacteria — *Streptococcus pneumoniae*, *Haemophilus influenzae*, *Moraxella catarrhalis*), air pollution, non-adherence; consider **pulmonary embolism** (increased incidence) and pneumothorax mimics.
- ▶ **Indications for hospital admission** — respiratory acidosis/hypercapnia, new or worsening hypoxaemia, severe underlying COPD, serious comorbidity (e.g. heart failure), frequent-exacerbator phenotype, inadequate home support.
- ▶ **Management:**
 - **Controlled oxygen** — target SpO_2 88–92%; recheck ABG at 30–60 min for CO_2 retention. Hypoxaemia is more dangerous than hypercapnia — never withhold needed O_2 .
 - **Bronchodilators** — aggressive short-acting β_2 -agonist (salbutamol) + short-acting muscarinic antagonist (ipratropium), usually nebulised initially.
 - **Systemic glucocorticoids** — prednisone 40 mg orally for 5 days (0.5 mg/kg/day; 5 days non-inferior to 10–14 days) — shortens recovery, improves lung function and reduces relapse; watch for hyperglycaemia.
 - **Antibiotics** — for moderate/severe exacerbations, guided by the **Anthonisen criteria** (increased dyspnoea + increased sputum volume + increased sputum purulence; greatest benefit when all three present, or when ventilated), for 5–7 days. Choice per local susceptibility; cover *Pseudomonas* (e.g. piperacillin-tazobactam, levofloxacin) when risk factors present.
 - **Non-invasive positive-pressure ventilation (NIPPV)** — first-line for acute respiratory acidosis ($\text{Paco}_2 > 45$ mmHg and $\text{pH} \leq 7.35$); reduces mortality, need for intubation, complications and length of stay.
 - **Invasive mechanical ventilation** — for severe distress, refractory hypoxaemia/hypercapnia or acidosis despite NIPPV, impaired consciousness, respiratory arrest or haemodynamic instability; beware **auto-PEEP** — allow adequate expiratory time.

- ▶ **Prognosis** — mechanical ventilation in an exacerbation carries 17–49% in-hospital mortality; ~20% are re-hospitalised within 30 days, 45% within a year, and ~20% die within the year after discharge. Influenza, pneumococcal, COVID-19 and RSV vaccination plus smoking cessation reduce future exacerbations.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Emphysema subtypes / CT patterns** — three labelled lung-acinus panels: (A) **Centrilobular** — dilated airspaces around the respiratory bronchiole, *upper-lobe, smoking*; (B) **Panlobular** — uniform acinar destruction, *lower-lobe, α 1AT deficiency*; (C) **Paraseptal** — subpleural airspaces along pleural margins. Label respiratory bronchiole, alveolar duct, alveolus, pleura.
- ▶ **GOLD ABE assessment grid** — Y-axis “Exacerbation history” (≥ 2 moderate or ≥ 1 hospitalisation = high), X-axis “Symptoms” (mMRC/CAT). Boxes labelled A, B, E; side column labelled GOLD 1–4 with FEV1 thresholds (≥ 80 , 50–79, 30–49, < 30).

Clinical / Diagnostic significance

- ▶ **Spirometry** (post-bronchodilator FEV1/FVC < 0.70) is mandatory — clinical features alone over- and under-diagnose COPD.
- ▶ Distinguish from **asthma** (reversible obstruction), **bronchiectasis** (recurrent pneumonia, clubbing, hemoptysis), **cystic fibrosis** and central airway obstruction.
- ▶ **Three interventions improve survival** — smoking cessation, long-term oxygen in chronic hypoxaemia (Pao₂ ≤ 55 mmHg, or ≤ 59 with cor pulmonale/erythrocytosis; ≥ 15 h/day), and lung volume reduction (surgical/endobronchial valve) in selected upper-lobe emphysema; triple inhaled therapy reduces mortality in selected patients.
- ▶ **Blood eosinophil count** individualises ICS use; clubbing or hemoptysis should prompt evaluation for **lung cancer**.

High-yield exam pointers

- ▶ COPD = persistent symptoms + non-fully-reversible airflow obstruction; diagnosis needs post-bronchodilator FEV1/FVC < 0.70 .
- ▶ GOLD grades 1–4 by FEV1 %predicted (≥ 80 / 50–79 / 30–49 / < 30); management by ABE groups using mMRC/CAT + exacerbation history.
- ▶ α 1AT deficiency $\rightarrow$ early-onset **panlobular**, lower-zone emphysema; serum < 11 μ mol/L (~ 50 mg/dL), PiZ; IV augmentation ~ 60 mg/kg weekly.
- ▶ **Centrilobular** = upper-lobe, smoking; **panlobular** = lower-lobe, α 1AT.
- ▶ **Pink puffer** (emphysema, thin, normal gases) vs **blue bloater** (bronchitis, cyanotic, hypercapnic, cor pulmonale).

- ▶ Exacerbation: **prednisone 40 mg × 5 days**, antibiotics 5–7 days by **Anthonisen criteria**, O₂ target 88–92%, NIPPV when pH ≤ 7.35 & PaCO₂ > 45.
- ▶ **Clubbing** is **NOT** part of COPD — investigate for malignancy.
- ▶ **BODE index** predicts mortality better than FEV₁ alone.

SOURCE & COVERAGE

- ▶ Harrison's Principles of Internal Medicine, 22e — “Chronic Obstructive Pulmonary Disease” (definition, pathology/pathogenesis, GOLD spirometric grades [Table 303-1] and ABE tool, exacerbation management).
- ▶ Murray & Nadel's Textbook of Respiratory Medicine, 7e — “COPD: Pathogenesis and Natural History” and “COPD: Diagnosis and Management” (GOLD classification figure, Anthonisen criteria, corticosteroid/antibiotic dosing, LTOT thresholds, BODE).
- ▶ CMDT 2026 — “Pulmonary Disorders” (pink puffer/blue bloater Table 9-7, diagnostic tests, hospitalised-exacerbation regimen, NIPPV).

Pathogenesis of Bronchiectasis

Asked in: Paper I Nov 2020 — RGUHS MD General Medicine

Definition / Introduction — Bronchiectasis is an *irreversible*, abnormal dilatation (ectasia) and destruction of the bronchial wall, involving the lung focally or diffusely. It is classically categorised morphologically as **cylindrical/tubular** (commonest), **varicose**, or **cystic/saccular**. It is not a single disease but the common structural end-point of many insults, the great majority operating through a self-perpetuating “**vicious cycle**” (Cole) of impaired mucociliary clearance → microbial colonisation → chronic neutrophilic inflammation → airway-wall destruction. The pathogenesis must therefore be understood as the interaction of a **predisposing host/structural defect**, **microbial persistence**, and an **unresolved inflammatory (protease-driven) response**.

Normal defences whose failure permits bronchiectasis

- ▶ The airway is continuously protected by the **mucociliary escalator**, an effective **cough**, **secretory IgA**, and epithelial **antimicrobial peptides** (lysozyme, secretory leukocyte protease inhibitor, defensins, cathelicidin), backed by resident/recruited phagocytes (macrophages, neutrophils) and T-effector lymphocytes.
- ▶ Airway patency normally depends on **negative intrapleural pressure** transmitted via interstitial *tethering*, plus the **cartilaginous rings** of large/medium bronchi.
- ▶ Bronchiectasis develops when one or more of these are compromised — by an inherited/structural defect, immunodeficiency, mechanical obstruction, fibrotic traction, or an overwhelming/repeated infection — allowing the vicious cycle to be established.

Three fundamental mechanical mechanisms (traction, pulsion, weakness)

- ▶ **Traction bronchiectasis** — *retractile (centrifugal) forces* of a fibrosing/scarring parenchyma pull the airways open. Seen with idiopathic pulmonary fibrosis, post-radiation fibrosis, sarcoidosis and post-tuberculous scarring.
- ▶ **Pulsion bronchiectasis** — intense *intraluminal* inflammation and mucoid impaction balloon the airway from within; the prototype is **allergic bronchopulmonary aspergillosis (ABPA)**, where an immune reaction to *Aspergillus* lodged in central airways, with thick mucoid plugs, dilates the proximal bronchi.
- ▶ **Weakness of the airway wall** — loss of structural integrity, either *acquired* (post-infectious destruction of elastin/muscle/cartilage with regional volume loss) or *congenital* — e.g. **Mounier-Kuhn syndrome** (tracheobronchomegaly from atrophy of airway *elastic fibres*), **Williams-Campbell syndrome** (absent cartilage in segmental/subsegmental bronchi), Marfan syndrome, relapsing polychondritis. Weak, collapsible airways also cripple the cough mechanism, impeding secretion clearance and feeding the infective cycle.

The “vicious cycle / vicious vortex” — the central engine of pathogenesis

- ▶ The most widely cited mechanism (Cole) is a **self-amplifying cycle**: a susceptible airway with **poor mucociliary clearance** → **microbial colonisation/infection** of the bronchial tree → **chronic inflammation** → **airway-wall damage** → still poorer clearance → perpetuation.
- ▶ A single severe infection (*Bordetella pertussis*, *Mycoplasma pneumoniae*, measles, adenovirus, necrotising bacterial pneumonia) can initiate the cycle by causing the index airway injury; thereafter the process becomes self-sustaining and *infection-independent of the original trigger*.
- ▶ Recent reframing as a “**vicious vortex**” (a tetrad in which each factor perpetuates the other three):
 - ▶ **Airway epithelial & ciliary dysfunction with mucus hypersecretion**
 - ▶ **Chronic infection**, itself driving further mucus hypersecretion
 - ▶ **Inflammation** causing permanent airway injury and dilatation
 - ▶ **Resultant bronchiectatic airways** with impaired mucociliary clearance, which feed back into (1)–(3).
- ▶ Certain organisms — especially ***Pseudomonas aeruginosa**, *nontuberculous mycobacteria (NTM, mainly Mycobacterium avium complex)* and *Aspergillus** — preferentially colonise damaged airways and evade host defence, accelerating the vortex.

Cellular & molecular mediators — the protease–antiprotease imbalance

- ▶ The dominant inflammatory cell is the **neutrophil**, recruited by epithelial- and macrophage-derived chemokines/cytokines — **interleukin-8 (IL-8)**, **macrophage inflammatory protein-2 (MIP-2)**, **TNF- α** — with a prominent **Th17** axis.
- ▶ Activated/necrotic neutrophils release **neutrophil elastase**, **matrix metalloproteinases (MMPs)**, other proteases and **reactive oxygen species** that directly digest the airway wall, producing the classic 1950s-described pathology: **small-airway wall inflammation with larger-airway destruction and dilatation, and loss of elastin, smooth muscle and cartilage**.
- ▶ **Neutrophil elastase** is pivotal — it causes *ciliary dysfunction*, *mucous-gland hyperplasia* and *mucus hypersecretion* (worsening clearance), and **disables host defence**: it cleaves **Fc γ receptors** and **complement receptor 1** from neutrophils and digests **immunoglobulin** and **complement** off bacterial surfaces → impaired **opsonisation** and bacterial killing. It also inhibits **efferocytosis** (macrophage clearance of apoptotic neutrophils) by cleaving phosphatidylserine, so inflammation fails to resolve.
- ▶ Normally, **antiproteases** — chiefly **α 1-antitrypsin** — neutralise neutrophil elastase and enhance bacterial killing; a **protease–antiprotease imbalance** (excess elastase or **α 1-antitrypsin deficiency**) tips the balance toward wall destruction (bronchiectasis $\pm$ emphysema). Necrotic neutrophils also liberate highly viscous **DNA**, increasing sputum viscosity and inspissation.

Microbial colonisation and biofilms

- ▶ Mere colonisation is *insufficient* for bronchiectasis (smokers' chronic bronchitis carries a similar flora — *H. influenzae*, *S. pneumoniae*, *Moraxella* — without bronchiectasis); an *additional* host/structural disturbance is required to establish chronic transmural infection.
- ▶ **Biofilms** are central to chronicity: *P. aeruginosa* attaches to the airway surface and grows within an **exopolysaccharide matrix** (**glycocalyx / alginate**) that shields it from immune cells and antibiotics. Behaviour is coordinated by **quorum sensing** (cell–cell signalling), and biofilm-embedded bacteria can survive antibiotic concentrations up to **1000 $\times$ the MIC**.
- ▶ Chronic *P. aeruginosa* infection (often a mucoid, alginate-producing phenotype) is a marker of severe disease — more exacerbations, faster FEV₁ decline and roughly **three-fold increased mortality**.

Aetiology-specific pathways (mapping cause → mechanism)

Pattern / Cause	Mechanism in pathogenesis
Focal (foreign body, tumour, broncholith, extrinsic node compression)	Localised airway obstruction → distal stasis, infection, post-obstructive dilatation
Diffuse — infection (post-pertussis/measles/adenovirus; TB, NTM/MAC; necrotising pneumonia)	Direct wall destruction initiating the vicious cycle

Pattern / Cause	Mechanism in pathogenesis
Cystic fibrosis	CFTR anion-channel defect → reduced $\text{Cl}^-/\text{HCO}_3^-$ & water secretion → depleted periciliary/airway-surface liquid , ciliary collapse, viscid mucus, defective bacterial killing (low ASL pH) → relentless neutrophilic infection
Primary ciliary dyskinesia (Kartagener's)	Structural/functional ciliary defect → primary mucociliary clearance failure
Immunodeficiency (CVID, hypogammaglobulinaemia, IgG-subclass/IgA deficiency, HIV)	Recurrent infection from defective humoral defence → cycle
$\alpha 1$ -antitrypsin deficiency	Loss of antiprotease screen → unopposed elastase wall damage
ABPA & autoimmune/CTD (RA, Sjögren)	Immune-mediated bronchial-wall injury (pulsion / inflammatory)
Fibrosis (IPF, post-radiation), aspiration, Mounier-Kuhn/Williams-Campbell	Traction / recurrent chemical injury / congenital wall weakness

- **Anatomic distribution offers aetiological clues:** *upper zones* — CF, TB, sarcoid; *mid zones* — NTM/MAC and PCD; *lower zones* — idiopathic, chronic aspiration, hypogammaglobulinaemia, $\alpha 1$ -antitrypsin deficiency, CTD; *central airways* — ABPA, Mounier-Kuhn, Williams-Campbell.
- Up to 25–50% of referred cases remain **idiopathic** after full workup.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- **“Vicious vortex” wheel diagram** — a central airway with four arrows forming a closed loop, labelled: (1) *Epithelial & ciliary dysfunction + mucus hypersecretion* → (2) *Chronic infection (Pseudomonas/NTM, biofilm)* → (3) *Neutrophilic inflammation (elastase, MMPs, ROS, IL-8, TNF- α , Th17)* → (4) *Airway-wall destruction & dilatation (loss of elastin, smooth muscle, cartilage)* → back to (1). Add a side-box: *predisposing defect — impaired MCC / immunodeficiency / obstruction / wall weakness / fibrotic traction*.
- **Cross-sectional airway comparison** — label: *normal bronchus* (intact epithelium, cilia, smooth muscle, cartilage, basement membrane) vs *bronchiectatic airway* (loss of cilia, goblet-cell/mucous-gland hyperplasia, mucus/biofilm plug, neutrophil infiltrate, destroyed muscle & cartilage, dilated thickened wall). Include the three morphological types: *cylindrical, varicose, cystic/saccular*.

Clinical / Diagnostic significance

- Explains the cardinal clinical picture: **chronic productive cough with copious purulent sputum, recurrent infective exacerbations, haemoptysis** (erosion of dilated bronchial vessels — the commonest complication), crackles, wheeze and **digital clubbing**.

- ▶ Rationalises a **mechanism-directed workup**: sweat chloride/CFTR genetics (CF), immunoglobulins ± vaccine-challenge (CVID), α 1-antitrypsin level/phenotype, nasal NO/ciliary studies (PCD), *Aspergillus* IgE/IgG + eosinophils (ABPA), RF/autoantibodies (CTD), and sputum culture including mycobacteria.
- ▶ **HRCT** is the diagnostic gold standard — *signet-ring sign* (broncho-arterial diameter ratio ≥ 1.5), tram-track lines, lack of tapering, airways within 1 cm of pleura, wall thickening, and *tree-in-bud* (small-airway secretions).
- ▶ The protease-driven, *Pseudomonas*/biofilm-sustained cycle is the **therapeutic target**: airway clearance/hygiene, treat exacerbations, long-term **macrolides** (anti-inflammatory + anti-quorum-sensing/biofilm action), inhaled antibiotics for *Pseudomonas*, and disease-specific therapy (CFTR modulators in CF, steroids ± itraconazole in ABPA, immunoglobulin replacement in CVID). Untreated, FEV₁ declines ~50–55 mL/year (vs 20–30 mL/year normally), comparable to COPD.

High-yield exam pointers

- ▶ Bronchiectasis = **irreversible** bronchial dilatation; morphology = **cylindrical** > **varicose** > **cystic**.
- ▶ Central mechanism = **Cole's vicious cycle**, modernised as the “**vicious vortex**” tetrad.
- ▶ Three mechanical routes = **traction**, **pulsion** (ABPA), **weakness** (Mounier-Kuhn / Williams-Campbell).
- ▶ Key effector = **neutrophil elastase** → ciliary dysfunction, mucus hypersecretion, impaired opsonisation/efferocytosis; balanced by **α 1-antitrypsin** (protease–antiprotease imbalance).
- ▶ Wall pathology = **loss of elastin, smooth muscle and cartilage**.
- ▶ ****Pseudomonas aeruginosa*** (*mucoïd/alginate, biofilm, quorum sensing*) = *chronicity* + ~3× *mortality*; MIC survival up to 1000×*.
- ▶ **Focal** = **obstruction**; **diffuse** = **systemic/infectious**; distribution clues — upper (CF/TB), mid (NTM/PCD), lower (aspiration/immunodeficiency/AAT), central (ABPA/Mounier-Kuhn).
- ▶ 25–50% remain idiopathic; CF/CFTR variants and NTM are increasingly recognised drivers.

SOURCE & COVERAGE

Discuss clinical features, diagnosis and management of Pulmonary Thromboembolism

Asked in: Paper III May 2022 — RGUHS MD General Medicine

Definition / Introduction — Pulmonary thromboembolism (PE) is the lodgement, in the pulmonary arterial circulation, of thrombus that has usually embolised from a deep-venous thrombosis (DVT) of the lower limbs; together DVT and PE constitute **venous thromboembolism (VTE)**. When a DVT detaches from its site of formation it travels through the vena cava, right atrium and right ventricle to obstruct the pulmonary arteries, producing acute PE. PE is termed “*the great masquerader*” because its symptoms and signs are non-specific, and it remains a major cause of cardiovascular death, chronic disability and emotional distress. Notably, many patients with PE have no demonstrable DVT because the leg thrombus has already embolised entirely to the lungs.

Classification (severity stratification) of PE

Risk stratification is central because it directs both prognosis and the intensity of therapy.

Category	Proportion	Defining features	Prognosis
Massive (high-risk) PE	5–10%	Systemic arterial hypotension ; extensive thrombosis affecting <i>at least half</i> the pulmonary vasculature; dyspnoea, syncope, hypotension, cyanosis are hallmarks; may present in cardiogenic shock	Can die from multisystem organ failure
Submassive (intermediate-risk) PE	20–25%	RV dysfunction despite <i>normal</i> systemic arterial pressure; right heart failure plus elevated cardiac biomarkers (troponin) signals high risk of deterioration	Guarded; needs close monitoring
Low-risk PE	65–75%	Normotensive, normal RV function and haemodynamics	Excellent prognosis

- ▶ **DVT classification:** Lower-extremity DVT usually begins in the **calf** and may propagate proximally to the popliteal, femoral and iliac veins. Leg DVT is **~10 times** more common than upper-extremity DVT (the latter often precipitated by pacemakers, defibrillators or indwelling central venous/PICC catheters).

Pathophysiology (to anchor the clinical features)

- ▶ **Gas exchange:** the commonest abnormalities are **arterial hypoxaemia** and a widened **alveolar–arterial O₂ gradient**; anatomical and physiological **dead space increase** because ventilated lung is not perfused.
- ▶ **Increased pulmonary vascular resistance** from mechanical obstruction and from platelet-released vasoconstrictors (e.g. **serotonin**); **alveolar hyperventilation** (irritant-receptor reflex), **increased airway resistance** (bronchoconstriction) and **decreased compliance** (oedema, haemorrhage, surfactant loss).
- ▶ **RV failure cascade:** rising pulmonary artery pressure raises RV wall tension → **RV dilation, stretch and dysfunction** with release of **brain natriuretic peptide (BNP)**. The interventricular **septum bulges into the LV**, impairing LV filling. High RV wall tension compresses the **right coronary artery**, causing **RV microinfarction** with **troponin** release. LV underfilling lowers cardiac output and systemic pressure → circulatory collapse and death.

Clinical features

- ▶ **PE — most common symptom is unexplained breathlessness (dyspnoea).** Suspect PE when overt congestive heart failure or pneumonia fails to improve with standard therapy.
- ▶ **Pulmonary infarction** usually indicates a *small, peripheral* PE; it is *exquisitely painful* (pleuritic) because the thrombus lodges near the pleural nerves, and may cause haemoptysis.
- ▶ **DVT — most common symptom is a cramp or “charley horse” in the lower calf** that persists and intensifies over days. Physical signs may be only mild calf tenderness; massive DVT presents with marked thigh swelling, tenderness and erythema.
- ▶ **Phlegmasia cerulea dolens** — the most serious form of DVT — produces a diffusely oedematous, cyanotic limb.
- ▶ **May-Thurner syndrome** — recurrent left thigh oedema (especially in young women) from right iliac artery compression of the left iliac vein.
- ▶ **Superficial venous thrombosis** — erythema, tenderness and a *“palpable cord”*; visible chest-wall veins are *Urschel’s sign*; carries risk of extension to the deep system.

Diagnosis

Clinical probability first — apply the *Wells point-score* (validated in ambulatory, not hospitalised, patients). Patients with **low** probability of DVT or **low-to-moderate** probability of PE proceed to D-

dimer; a normal D-dimer rules out VTE without imaging. **High** clinical likelihood → *skip D-dimer and image directly*.

Wells score — PE	Points
Signs/symptoms of DVT	3.0
Alternative diagnosis less likely than PE	3.0
Heart rate >100/min	1.5
Immobilisation >3 days; surgery within 4 weeks	1.5
Prior PE or DVT	1.5
Haemoptysis	1.0
Cancer	1.0

High clinical likelihood of PE if score exceeds 4. (For DVT: low if ≤0, moderate 1–2, high ≥3.)

Blood tests

- **Quantitative plasma D-dimer (ELISA)**: sensitivity >95% for PE; an excellent “*rule-out*” test when pretest probability is low, but **not specific** (also raised in MI, pneumonia, sepsis, cancer, post-operative state, pregnancy) — hence rarely useful in hospitalised patients.
- **Age-adjusted D-dimer**: for patients >50 years with low/intermediate probability, the upper limit of normal = $\text{age} \times 10 \text{ ng/mL}$ (e.g. 700 ng/mL at age 70); reduces unnecessary CT angiograms. *Does not apply to suspected DVT.*
- **Cardiac biomarkers**: troponin rises with RV microinfarction; BNP/NT-proBNP rises with myocardial stretch.

ECG — sinus tachycardia is commonest; the classic **S1Q3T3** pattern (S in I, Q in III, inverted T in III) is *specific but insensitive*; RV strain produces **T-wave inversion in V1–V4**, the most common abnormality of a large PE.

Imaging

Modality	Key diagnostic point
CT pulmonary angiography (CTPA)	<i>Principal</i> test for PE; visualises intraluminal filling defects; RV/LV diameter ratio >1 indicates increased 30-day mortality; defines alternative lung diagnoses
Venous ultrasonography	First-line for DVT; primary criterion is loss of vein compressibility ; thrombus is homogeneous, central, low echogenicity
Chest X-ray	Often near-normal; classic signs — Westermarck’s sign (focal oligoemia), Hampton’s hump (pleural-

Modality	Key diagnostic point
	based triangular density of infarction), Palla's sign (enlarged right descending pulmonary artery)
V/Q lung scan	Second-line (for those unable to receive contrast); high probability = ≥ 2 segmental perfusion defects with normal ventilation (~90% certain)
Echocardiography	Not reliable to <i>diagnose</i> PE (most echos normal) but detects mimics (MI, tamponade, dissection); best indirect sign is McConnell's sign — RV free-wall hypokinesis with normal/hyperkinetic RV apex
MR (venography/angiography)	When US/pelvic imaging equivocal; unreliable for small segmental/subsegmental PE
Invasive pulmonary angiography / contrast phlebography	Reserved for non-diagnostic CT or when an interventional procedure (catheter thrombolysis/embolectomy) is planned

Management / Treatment

Risk-stratify, then treat. Haemodynamic instability, RV dysfunction on echo, RV enlargement on CT, and troponin elevation portend high risk despite anticoagulation. Normotension with normal RV → secondary prevention (anticoagulation); normotension with RV hypokinesis → individualised therapy; hypotension → primary therapy (thrombolysis/embolectomy).

Anticoagulation — the cornerstone. Three strategies: (1) parenteral UFH/LMWH/fondaparinux bridged to warfarin; (2) parenteral agent for 5 days then switch to **dabigatran** (direct thrombin inhibitor) or **edoxaban** (anti-Xa); (3) **oral monotherapy** with **rivaroxaban** or **apixaban** (anti-Xa) with a loading phase.

Agent	Regimen (normal renal function)
Unfractionated heparin (UFH)	Bolus 80 U/kg, then 18 U/kg/h infusion; target aPTT 60–80 s (anti-Xa 0.3–0.7 U/mL)
Enoxaparin (LMWH)	1 mg/kg SC twice daily; no routine monitoring
Fondaparinux	Weight-based once-daily SC; reduce in renal impairment; <i>does not cause HIT</i>
Warfarin	Start 5 mg, titrate to INR 2.0–3.0; overlap parenteral agent ≥ 5 days until two INRs ≥ 1 day apart are therapeutic
Rivaroxaban	15 mg twice daily $\times$ 3 weeks, then 20 mg once daily with dinner
Apixaban	10 mg twice daily $\times$ 1 week, then 5 mg twice daily

Agent	Regimen (normal renal function)
Dabigatran / Edoxaban	After 5 days parenteral: dabigatran 150 mg bid / edoxaban 60 mg once daily

- ▶ **Heparin-induced thrombocytopenia (HIT):** use IV direct thrombin inhibitors **argatroban** (hepatic) or **bivalirudin** (renal), or subcutaneous fondaparinux.
- ▶ **Reversal of bleeding:** protamine sulfate for heparin/LMWH; **idarucizumab** for dabigatran; **andexanet alfa** / **prothrombin complex concentrate** for anti-Xa DOACs (watch for rebound thrombosis).
- ▶ **DOAC cautions:** avoid in pregnancy/breast-feeding; **warfarin** (not DOACs) is standard for antiphospholipid syndrome; uncertain in ESRD/cirrhosis.

Massive (high-risk) PE

- ▶ **Volume:** cautious 500 mL normal saline (over-filling worsens RV ischaemia and septal shift).
- ▶ **Vasoactives:** **norepinephrine** (raises systemic pressure) + **dobutamine** (raises RV inotropy, lowers filling pressures); consider **veno-arterial ECMO**.
- ▶ **Systemic fibrinolysis:** FDA-approved 100 mg tPA (**alteplase**) IV over 2 h; effective up to 14 days post-PE; major bleeding ~10%, intracranial haemorrhage 2–3%. Contraindications: intracranial disease, recent surgery, trauma.
- ▶ **Catheter-directed therapy** (pharmacologic, mechanical or pharmacomechanical, e.g. ultrasound-facilitated low-dose thrombolysis — lower bleeding) and **surgical pulmonary embolectomy** for selected patients.

Adjuncts and special situations

- ▶ **IVC filter** (preferably retrievable) — only for (1) active bleeding precluding anticoagulation, or (2) recurrent VTE despite intensive anticoagulation.
- ▶ **Cancer-associated VTE:** LMWH monotherapy or a DOAC (apixaban/edoxaban; avoid DOAC in GI cancer), continued until cancer-free.
- ▶ **Duration:** ESC 2019 abandons the “*provoked/unprovoked*” dichotomy; extended anticoagulation for first PE with no identifiable, persistent, or minor transient risk factor.
- ▶ **CTEPH** develops in ~2% of acute PE — follow survivors with pulmonary hypertension by echocardiography; treat with **pulmonary thromboendarterectomy** (operative mortality 1–5% at expert centres).
- ▶ **Prevention:** low-dose UFH or LMWH is the commonest in-hospital prophylaxis (see Table 290-7 regimens by surgical/medical risk).

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Pathophysiology of PE (flow diagram):** label — *Embolus in pulmonary artery* → ↑ RV pressure overload → ↑ RV wall tension → RV dysfunction + RV ischaemia/infarction → septal shift compressing LV → ↓ LV preload → ↓ cardiac output → ↓ systemic & coronary perfusion → circulatory collapse.
- ▶ **Integrated diagnostic algorithm:** label — *Suspect DVT/PE* → assess clinical likelihood (Wells) → low/not-high: D-dimer (normal = stop; high = image) vs high: image directly → CTPA / venous ultrasound / V/Q scan → treat.

Clinical / Diagnostic significance

- ▶ A normal/near-normal chest X-ray with profound hypoxaemia is itself a clue to PE.
- ▶ RV/LV ratio >1 on CT and troponin/BNP elevation identify the submassive group needing escalated monitoring (not just routine anticoagulation).
- ▶ McConnell's sign and S1Q3T3 are high-yield bedside/echo pointers to a large PE.
- ▶ The age-adjusted D-dimer is a practical tool that safely reduces CTPA use in older outpatients.
- ▶ Post-PE syndrome (persistent dyspnoea, fatigue, reduced exercise capacity, RV dysfunction) affects ~half of survivors — warrants follow-up.

High-yield exam pointers

- ▶ Most common symptom: PE = **unexplained dyspnoea**; DVT = **calf cramp**/"charley horse."
- ▶ PE severity classes: massive 5–10%, submassive 20–25%, low-risk 65–75%.
- ▶ D-dimer sensitivity >95%, a *rule-out* test only; age-adjusted cut-off = age × 10 ng/mL (>50 yrs).
- ▶ ECG: S1Q3T3 (specific, insensitive); commonest abnormality is T-inversion V1–V4.
- ▶ CXR triad: Westermarck's sign, Hampton's hump, Palla's sign.
- ▶ Echo indirect sign of PE: McConnell's sign.
- ▶ UFH: bolus 80 U/kg, infusion 18 U/kg/h, target aPTT 60–80 s; warfarin target INR 2–3.
- ▶ Massive PE: alteplase 100 mg IV over 2 h; ICH risk 2–3%; vasopressor norepinephrine + inotrope dobutamine.
- ▶ IVC filter indications: bleeding precluding anticoagulation OR recurrent VTE despite anticoagulation.
- ▶ CTEPH in ~2% → pulmonary thromboendarterectomy.

SOURCE & COVERAGE

Harrison's Principles of Internal Medicine, 22e (2025) — Ch 290 "Deep-Venous Thrombosis and Pulmonary Thromboembolism" (Samuel Z. Goldhaber). Coverage note: the chapter fully supports clinical features, diagnosis and management as written. PESI/sPESI prognostic scoring

and the Wells DVT sub-criteria are referenced only via Table 290-2; the PE Wells table reproduced above is verbatim from the source. Standard universally-accepted points (e.g. haemoptysis/pleuritic pain with pulmonary infarction) are consistent with the text.

Discuss Pulmonary Rehabilitation Post Severe COVID Pneumonia

Asked in: Paper III May 2025 — RGUHS MD General Medicine

Definition / Introduction — *Pulmonary rehabilitation (PR)* is a comprehensive, multidisciplinary, patient-centred intervention—built on a thorough assessment followed by patient-tailored therapies that include, but are not limited to, **exercise training, education and behaviour change**—designed to improve the physical and psychological condition of people with chronic respiratory disease and to promote long-term adherence to health-enhancing behaviours (ATS/ERS definition). Survivors of **severe COVID-19 pneumonia** frequently leave hospital with prolonged dyspnoea, profound deconditioning, ICU-acquired weakness, impaired exercise capacity and psychological morbidity, so they constitute a logical—though relatively new—indication for PR. Although disease-specific COVID PR protocols are still evolving and largely expert-opinion based, the well-validated framework of PR (derived chiefly from COPD and post-exacerbation/post-ICU rehabilitation) is directly applicable.

Rationale — the systemic legacy of severe COVID pneumonia

- ▶ **Pulmonary:** severe COVID pneumonia causes ARDS with bilateral ground-glass opacities/consolidation; survivors of severe acute pulmonary injury may have **persisting respiratory impairment** (residual fibrosis, reduced diffusing capacity, exertional hypoxaemia and breathlessness).
- ▶ **Critical-illness sequelae:** prolonged mechanical ventilation, sedation and immobility produce ICU-acquired weakness, **skeletal-muscle deconditioning and debility related to hospitalisation and critical illness**, which explicitly warrant rehabilitation.
- ▶ **Recovery is slow:** ~80% of symptomatic infections resolve within 2 weeks, but **severe disease often needs several months** for recovery, and a subset develop persisting/recurring symptoms.
- ▶ **Long COVID** (a chronic condition present ≥ 3 months after infection): commonest features are **fatigue (32%), smell/taste disorder (22%), dyspnoea (16%), headache (12%), memory impairment (11%), hair loss (10%) and sleep disorder (10%)** — fatigue, cognitive deficits, cough, dyspnoea and chest pain dominate.
- ▶ **Extrapulmonary:** persisting cardiac injury, thromboembolic risk (PE/DVT), encephalopathy/ICU delirium, and high rates of anxiety, depression, post-traumatic symptoms and sleep disturbance — all of which PR is designed to address.

Definition, goals and evidence base of PR

- ▶ PR provides improvements in dyspnoea, exercise tolerance and health status **exceeding those of any other therapy for COPD, despite no direct effect on lung function** — explained by treating the *systemic* manifestations (limb-muscle dysfunction, deconditioning, fear of dyspnoea-producing activity, poor pacing/coping). The same systemic-illness logic applies after severe COVID pneumonia.
- ▶ **Goals:** increase exercise tolerance, reduce dyspnoea and fatigue, reduce anxiety/depression, increase self-efficacy and self-management, improve health-related quality of life (QOL), and reduce health-care utilisation.
- ▶ **Proven benefits of PR (RCT/Cochrane level):**

Improved	Reduced
Exercise capacity (endurance, strength, peak workload), balance	Dyspnoea
Functional/ADL & physical-activity performance	Fatigue
Self-efficacy, self-management, disease knowledge	Anxiety / depression
Quality of life	Urgent health-care use & hospitalisations
Survival (when delivered after hospitalisation for COPD exacerbation)	Health-care costs

- ▶ Cochrane data (COPD): exercise training increased **6-minute walk distance by 43.9 m** (95% CI 32.6–55.6), increased maximal exercise capacity by 6.8 W, and improved SGRQ by a mean of –6.9 units (exceeding the 4-unit MCID). Following a hospitalised COPD exacerbation, post-discharge PR reduces mortality (~42% relative reduction; Lindenauer *JAMA* 2020 — PR within 90 days of discharge, HR 0.63) — the evidence template for offering early PR to severe-COVID-pneumonia survivors.

Patient assessment, candidacy and pre-rehab screening

- ▶ **Referral triggers** relevant after severe COVID: severe dyspnoea/fatigue, decreased exercise tolerance/low physical-activity levels, difficulty with ADLs, impaired health status, and **recovery from an acute event requiring hospitalisation**.
- ▶ **Pre-enrolment evaluation:** medical history, examination, record review, and baseline assessment of exercise capacity, symptoms and health status; screen specifically for **persisting cardiac injury, arrhythmia, residual VTE/anticoagulation status, and exertional desaturation** (pulse oximetry) before prescribing exercise.
- ▶ **Absolute contraindications:** unstable angina or arrhythmia; unstable bone fracture; **communicable infectious disease** (i.e. the patient must be past the infectious period for COVID-19 before joining group/centre-based PR); unstable psychiatric condition posing harm.

- ▶ **Relative contraindications:** severe cognitive impairment, lack of motivation, severe progressive neurological disease, severe anaemia, and severe debilitating fatigue that would prevent participation.
- ▶ Patients with a **wide range of impairment benefit**, including those needing supplemental oxygen — so even oxygen-dependent COVID survivors are candidates.

Core components of the programme

Component	Content
Exercise training (<i>cornerstone</i>)	Lower- & upper-limb aerobic (cycling/walking), resistance (weights/bands/machines), interval training; balance training; adjuncts — neuromuscular electrical stimulation (NMES), whole-body vibration, yoga/Tai Chi
Education / self-management	Disease & medication/inhaler education, oxygen and (where relevant) NIV use, exacerbation recognition + written action plan , pacing & energy conservation
Psychosocial support	Coping/relaxation, anxiety & depression management, cognitive-behavioural techniques; refer significant psychiatric illness onward
Nutritional support	Assessment of body composition/BMI; supplementation (esp. if low fat-free mass) combined with resistance training to rebuild muscle
Breathing training & airway clearance	Pursed-lip breathing (inhale through nose, exhale over 4–6 s through pursed lips), body-forward positioning, inspiratory-muscle training (selected cases), chest physiotherapy/PEP devices for sputum
Physical-activity promotion	Coaching, pedometers/accelerometers, tele-coaching to translate gains into daily activity and sustain long-term behaviour change

- ▶ Exercise is the cornerstone because severe respiratory illness causes **skeletal-muscle dysfunction** (loss of muscle mass/strength, reduced type-I fibres, mitochondrial/capillary loss) that is *reversible with training* — the key therapeutic target after a deconditioning ICU stay.
- ▶ Education beyond exercise has not been shown to add to traditional outcomes, but improves engagement, completion and self-management — important in this anxious, symptom-burdened group.

Exercise prescription and delivery settings

- ▶ Prescription (typical, individualised to baseline field-test capacity):

Modality	Frequency	Intensity	Duration
Endurance (aerobic)	3–5×/week (ideal)	60–80% of maximal work rate	20–60 min/session
Interval training	3–4×/week	80–100% of maximal work rate	45–60 min total
Resistance training	2–3×/week	Fraction of 1-repetition maximum	progressed as tolerated

- ▶ **Interval training** (e.g. 20–30 s high-intensity alternating with 30–40 s low-intensity/rest) gives gains comparable to continuous training and **suits patients with severe dyspnoea or markedly limited capacity** — a practical option for the most deconditioned COVID survivors.
- ▶ **Supplemental oxygen** for resting/exertional hypoxaemia maintains safety and allows higher training intensity; optimise any bronchodilator therapy first.
- ▶ Most programmes run **8–12 weeks**. **Settings**: outpatient/community (most evidence; usually 2–3 sessions/week over 6–8 weeks), **inpatient** (for complex/nursing-dependent patients; 5–6 days/week for 2–6 weeks), and **home-based/tele-rehabilitation**.
- ▶ **COVID-specific delivery**: interest in **home-based PR and tele-rehabilitation** rose during the pandemic because most centre-based programmes were suspended (inability to maintain social distancing); home confinement itself worsened functional status. **Optimal rehabilitation strategy for COVID-19 survivors is not yet defined**, but expert-panel physiotherapy recommendations (e.g. Thomas *et al*, acute-hospital physiotherapy management of COVID-19) and home-exercise recommendations have been published, supporting a staged, individualised, symptom-titrated approach with monitoring for **post-exertional symptom worsening**.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Flow diagram** — “From severe COVID pneumonia to recovery via PR”: boxes/labels — Severe COVID pneumonia (ARDS) → ICU / mechanical ventilation → ICU-acquired weakness + deconditioning + persisting dyspnoea/hypoxaemia + long-COVID fatigue/cognitive symptoms → Referral & baseline assessment (6MWT, mMRC, SpO₂, HADS, screen cardiac/VTE) → Multidisciplinary PR (Exercise training [aerobic/resistance/interval] + Education/self-management + Psychosocial + Nutrition + Breathing/airway clearance + Physical-activity promotion) → Outcomes: ↑exercise capacity & QOL, ↓dyspnoea/anxiety, ↑self-efficacy → Long-term maintenance (home/tele-rehab).
- ▶ **“Wheel of PR components”**: central hub labelled *Pulmonary Rehabilitation*, six spokes labelled — *Exercise training (cornerstone)*, *Education / self-management*, *Psychosocial support*, *Nutritional support*, *Breathing training & airway clearance*, *Physical-activity promotion*.

Clinical / Diagnostic significance

- ▶ **Outcome assessment** (mandatory minimum domains = exercise capacity, dyspnoea, health status): field tests — **6-minute walk test (6MWT)** and **incremental shuttle walk test**; **cardiopulmonary exercise testing** where available; exertional dyspnoea by **Borg/VAS**; symptom burden by **modified MRC (mMRC)** score; QOL by **Chronic Respiratory Questionnaire (CRQ)**, **St George's Respiratory Questionnaire (SGRQ)**, **COPD Assessment Test (CAT)**; mood by **Hospital Anxiety and Depression Scale (HADS)**; plus muscle strength (dynamometry), timed up-and-go and sit-to-stand tests, and body composition.
- ▶ **Safety/monitoring** during exercise: continuous pulse oximetry for desaturation, heart-rate/Borg-guided intensity, and vigilance for cardiac symptoms (given COVID myocardial injury) and post-exertional fatigue.
- ▶ **Investigations that guide rehab** in severe-COVID survivors: serial spirometry and **DLCO** (restrictive/diffusion defects), **HRCT** for residual fibrosis/ground-glass change, echocardiography/troponin if cardiac injury suspected, and D-dimer/imaging for residual VTE.
- ▶ **Maintenance**: short-term gains decline after the programme unless exercise continues; home-based and “booster” PR, tele-rehabilitation, activity diaries and pedometers help sustain benefit.

High-yield exam pointers

- ▶ **ATS/ERS definition** of PR (comprehensive intervention: assessment → tailored therapies including exercise training, education, behaviour change) — write it verbatim.
- ▶ **Exercise training is the cornerstone**; PR improves dyspnoea/exercise/QOL **despite no change in FEV₁** because it treats systemic/skeletal-muscle dysfunction.
- ▶ **Prescription numbers**: endurance 3–5×/week at **60–80% max work rate, 20–60 min**; resistance 2–3×/week; programme 8–12 weeks.
- ▶ **6MWD improves by ~44 m** with PR (Cochrane); post-hospitalisation PR **improves survival** (Lindenauer *JAMA* 2020, HR 0.63) — rationale for early post-COVID rehab.
- ▶ **Six core components**: exercise, education/self-management, psychosocial, nutrition, breathing/airway clearance, physical-activity promotion.
- ▶ **Long COVID** = symptoms ≥3 months; commonest = **fatigue 32%, smell/taste 22%, dyspnoea 16%**.
- ▶ **Absolute contraindications**: unstable angina/arrhythmia, unstable fracture, **communicable infectious disease** (wait out the COVID infectious period), unstable psychiatric illness.
- ▶ Settings: outpatient (most evidence), inpatient (complex), **home/tele-rehabilitation (expanded during COVID)**; optimal COVID-specific protocol still expert-opinion based.
- ▶ Outcome tools: 6MWT, mMRC/Borg, CRQ/SGRQ/CAT, HADS.

SOURCE & COVERAGE

- ▶ **Murray & Nadel's Textbook of Respiratory Medicine** — “Pulmonary Rehabilitation” (definition/ATS-ERS, components, exercise prescription, settings, outcomes, COVID-19 home-based/tele-rehabilitation and post-critical-illness rehabilitation; post-exacerbation PR survival).
- ▶ **Harrison's Principles of Internal Medicine, 22e** — “SARS-CoV-2 and COVID-19” (severe disease/ARDS, mechanical ventilation, recovery timeline, persisting respiratory/cardiac impairment, long COVID, neuropsychiatric sequelae).
- ▶ **CMDT 2026** — “Viral & Rickettsial Infections” (COVID-19: long COVID prevalence and symptom frequencies, convalescent management).

Coverage note: As flagged in the spec, the corpus does not contain a dedicated *post-severe-COVID* PR protocol; COVID-specific guidance in the sources is limited and expressly described as **expert-opinion based with “optimal strategies unknown.”** This answer therefore applies the validated PR framework (Murray, COPD/post-exacerbation/post-ICU and non-COPD evidence) to the severe-COVID survivor, using COVID-specific epidemiology and sequelae from Harrison/CMDT. Exercise-prescription numbers, the proven-benefit data and contraindications are COPD-derived (the established evidence base) and are extrapolated to the COVID context; the caution regarding post-exertional symptom worsening reflects standard current practice rather than a corpus-quoted COVID protocol.

Pulmonary Embolism: Risk Factors and Management

Asked in: Paper III May 2025 — RGUHS MD General Medicine

Definition / Introduction — Pulmonary embolism (PE) is occlusion of the pulmonary arterial tree by material — most often a thrombus that has detached from a deep vein and embolised through the right heart. Together with deep-venous thrombosis (DVT) it constitutes **venous thromboembolism (VTE)**, the third commonest cardiovascular cause of death. PE is a “*great masquerader*” with non-specific presentation, so management hinges on a structured diagnostic and risk-stratification pathway followed by anticoagulation, with reperfusion reserved for high-risk disease.

Risk factors (enumerate)

The substrate is **Virchow's triad** — venous stasis, hypercoagulability and endothelial injury/inflammation — with inflammation now recognised as a central trigger.

Category	Examples
Inherited (genetic) thrombophilia	Factor V Leiden (activated protein C resistance — commonest); prothrombin gene mutation;

Category	Examples
	deficiencies of antithrombin, protein C, protein S (rare)
Acquired thrombophilia	Antiphospholipid syndrome (APS — venous <i>and</i> arterial thrombosis; often warrants lifelong anticoagulation)
Stasis / immobility	Bed-rest, post-operative state, stroke, long-haul air travel (“ <i>economy-class syndrome</i> ”), sedentary lifestyle (prolonged television watching)
Surgery / trauma	Major orthopaedic surgery (hip/knee replacement, hip fracture), pelvic/long-bone fracture, major general surgery
Malignancy	Active cancer (lung, brain, pancreas, leukaemia); erythropoiesis-stimulating agents; chemotherapy
Hormonal	Oestrogen-containing contraceptives, postmenopausal HRT, pregnancy and the first 6–12 weeks postpartum, high-dose fertility injections
Inflammation-linked illness (Table 290-1)	Inflammatory bowel disease (ulcerative colitis, Crohn’s), rheumatoid arthritis, psoriasis, type-2 diabetes/metabolic syndrome, pneumonia, sepsis, acute coronary syndrome, acute stroke
Other comorbid	Obesity, cigarette smoking, systemic hypertension, COPD, chronic kidney disease, elevated LDL/lipoprotein(a), air pollution, blood transfusion, indwelling central venous catheters/PICC (upper-limb DVT)

- ▶ Carotid plaque **doubles** incident VTE risk; VTE, MI and stroke share inflammation, hypercoagulability and endothelial injury, and each more than doubles the risk of the others.
- ▶ **Non-thrombotic** PE (relevant to the differential and to “embolism” broadly): fat (long-bone fracture), air (neurosurgery, central lines), amniotic fluid (labour), tumour, septic emboli (right-sided endocarditis), talc (IV drug use), bone-cement (arthroplasty).

Classification and risk stratification (drives management)

Class	Frequency	Definition	Prognosis
Massive (high-risk)	5–10%	Systemic hypotension (SBP <90 mmHg ≥15 min or drop ≥40 mmHg); thrombus ≥50% of pulmonary vasculature; syncope,	High mortality

Class	Frequency	Definition	Prognosis
		cyanosis, cardiogenic shock	
Submassive (intermediate-risk)	20–25%	Normotensive but RV dysfunction (echo/CT) $\pm$ troponin/BNP rise	Risk of abrupt deterioration
Low-risk	65–75%	Normotensive, normal RV, normal biomarkers	Excellent

- **Clinical probability** — *Wells score* (PE): signs/symptoms of DVT 3, alternative diagnosis less likely 3, HR >100 = 1.5, immobilisation/surgery within 4 weeks 1.5, prior PE/DVT 1.5, haemoptysis 1, cancer 1 (PE-likely if >4). *PERC* rule can exclude PE in very-low-risk patients meeting all 8 criteria.
- **Mortality prognostication** — *Simplified PESI* (*sPESI*): age >80, cancer, chronic cardiopulmonary disease, pulse ≥ 110 , SBP <100, SaO₂ <90% (each = 1). Score 0 = low 30-day mortality (consider outpatient/early discharge); ≥ 1 = higher risk. *Hestia criteria* also screen for home-treatment eligibility.

Diagnostic approach (essential before treatment)

- **D-dimer ELISA**: sensitivity >95%; a normal value rules out PE in low/intermediate pretest probability. Use **age-adjusted cut-off** (age $\times$ 10 ng/mL) in patients >50 years; unhelpful in inpatients (frequently raised).
- **CT pulmonary angiography (CTPA)** — principal/gold-standard imaging; an RV:LV diameter ratio >1 predicts increased 30-day mortality. **V/Q scan** when contrast is contraindicated. **Compression venous ultrasound** for DVT.
- **ECG**: sinus tachycardia (commonest), *S1Q3T3*, T-inversion V1–V4 (RV strain). **CXR**: often normal; *Westermarck's sign* (oligaemia), *Hampton's hump* (infarct), *Palla's sign* (enlarged descending pulmonary artery). **Echo**: *McConnell's sign* (RV free-wall hypokinesis with apical sparing). **Troponin/BNP** raised in ~25% — risk markers.

Management — anticoagulation (cornerstone)

Anticoagulation prevents clot propagation and recurrence while endogenous fibrinolysis dissolves existing thrombus; start empirically when clinical suspicion is high and bleeding risk low, before confirmation. **DOACs are first-line** for most patients.

Drug	Regimen (normal renal function)
Unfractionated heparin (UFH)	80 U/kg bolus then 18 U/kg/h; target aPTT 60–80 s (anti-Xa 0.3–0.7 U/mL). Preferred if unstable, renal failure, or reperfusion may be needed

Drug	Regimen (normal renal function)
Enoxaparin (LMWH)	1 mg/kg SC twice daily (no monitoring unless obese/CKD)
Dalteparin / Tinzaparin	200 U/kg od (or 100 U/kg bid) / 175 U/kg od
Fondaparinux	Weight-based SC od (5/7.5/10 mg for <50/50–100/>100 kg); does not cause HIT
Rivaroxaban	15 mg bid × 3 weeks → 20 mg od (oral monotherapy)
Apixaban	10 mg bid × 1 week → 5 mg bid (oral monotherapy)
Edoxaban	After ≥5 days parenteral → 60 mg od (30 mg if CrCl 15–50 or <60 kg)
Dabigatran	After ≥5 days parenteral → 150 mg bid (direct thrombin inhibitor)
Warfarin	Overlap with parenteral ≥5 days until INR ≥2 on two readings; target INR 2.0–3.0

- ▶ Heparin-induced thrombocytopenia (HIT) suspected/proven: use **argatroban** (hepatic) or **bivalirudin** (renal) — IV direct thrombin inhibitors — or **fondaparinux**.
- ▶ Reversal: protamine for heparin/LMWH; **idarucizumab** for dabigatran; **andexanet alfa** (or PCC) for anti-Xa DOACs; vitamin K/FFP/PCC for warfarin.
- ▶ DOACs are contraindicated in **pregnancy/lactation**; **warfarin** (not DOAC) remains standard for APS.

Management of high-risk (massive) and intermediate-risk PE

- ▶ Supportive care (massive PE): cautious volume — only ~500 mL normal saline (excess fluid worsens RV wall stress and septal shift); **noradrenaline** (vasopressor of choice) plus **dobutamine** (inotrope); **veno-arterial ECMO** or percutaneous RV assist for refractory shock.
- ▶ Systemic thrombolysis — indicated for massive PE without contraindication: **alteplase 100 mg IV over 2 h** (bolus 0.6 mg/kg, max 50 mg over 15 min if cardiac arrest imminent). Major bleeding ~10%, intracranial haemorrhage 2–3%. *Absolute contraindications*: prior intracranial haemorrhage, structural cerebrovascular lesion/neoplasm, ischaemic stroke <3 months, active bleeding, recent significant head trauma/surgery.
- ▶ Intermediate-risk (submassive) PE: routine thrombolysis is **controversial** — in *PEITHO*, tenecteplase reduced haemodynamic collapse (2.6% vs 5.6%) but increased intracranial bleeding (2.0% vs 0.2%) with no survival benefit; preferred strategy is anticoagulation with **close monitoring**, reserving rescue thrombolysis for deterioration.

- ▶ **Catheter-directed therapy** (pharmacologic, mechanical, or pharmacomechanical/ultrasound-facilitated low-dose thrombolysis) — lower bleeding than systemic lysis; for high-risk patients or intermediate-risk at risk of collapse.
- ▶ **Surgical pulmonary embolectomy** — when thrombolysis is contraindicated/failed, or for clot-in-transit/mobile intracardiac thrombus.
- ▶ **IVC filter** — only two firm indications: (1) active bleeding precluding anticoagulation, (2) recurrent VTE despite therapeutic anticoagulation. Use **retrievable** filters and remove when anticoagulation resumes.

Special situations and duration of anticoagulation

- ▶ **Minimum 3 months** for all PE. Continued (extended/indefinite) anticoagulation is decided by recurrence risk vs bleeding risk (ESC 2019 abandons the “provoked/unprovoked” dichotomy):

Recurrence risk after stopping	Examples
Low (<3%/yr)	Major surgery/trauma (transient) → stop at 3 months
Intermediate (3–8%/yr)	Minor surgery, hospitalisation, pregnancy/oestrogen, long-haul flight, IBD, no identifiable factor
High (>8%/yr)	Active cancer, antiphospholipid syndrome → indefinite anticoagulation

- ▶ **Cancer-associated VTE**: LMWH or a DOAC (apixaban/edoxaban; avoid DOAC if GI/luminal cancer) until cancer-free.
- ▶ **Pregnancy**: weight-adjusted LMWH is preferred (UFH peri-delivery); warfarin, DOACs and fondaparinux are contraindicated. Thrombolysis only for life-threatening PE.
- ▶ **Isolated subsegmental PE with no DVT and low recurrence risk**: surveillance without anticoagulation is acceptable.

Prevention (prophylaxis)

- ▶ **Universal in-hospital VTE prophylaxis** unless contraindicated: UFH 5000 U SC bid/tid or enoxaparin 40 mg od (or dalteparin/fondaparinux 2.5 mg od) for medical and high-risk surgical patients.
- ▶ **Major orthopaedic surgery**: aspirin 81 mg, rivaroxaban 10 mg od, apixaban 2.5 mg bid, dabigatran, LMWH or warfarin; extended prophylaxis after hip/knee replacement.
- ▶ **Mechanical** (intermittent pneumatic compression ± graduated stockings) when anticoagulation is contraindicated; early ambulation always.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Acute PE management algorithm** — boxes/labels: *Suspected PE* → *assess for hypotension/shock/arrest*; if YES → *supportive care* (O_2 , fluids 500 mL, noradrenaline + dobutamine) + *systemic thrombolysis / embolectomy*; if NO → *confirm with CTPA* → *risk-stratify* (sPESI, RV function, troponin): **Low** → **anticoagulate (DOAC) ± early discharge**; **Intermediate** → **anticoagulate + monitor**; **High/massive** → **reperfusion**.
- ▶ **Pathophysiology of PE** — labels: *Pulmonary artery obstruction* → $\uparrow$ PVR / $\uparrow$ RV afterload → *RV wall tension* $\uparrow$ → *RV dilatation & dysfunction* → *interventricular septal shift* → $\downarrow$ LV filling → $\downarrow$ cardiac output → $\downarrow$ coronary perfusion → *RV ischaemia/microinfarction* (troponin $\uparrow$) → *circulatory collapse*.

Clinical / Diagnostic significance

- ▶ Empirical anticoagulation before confirmation in high pretest probability prevents early recurrent (often fatal) PE.
- ▶ Haemodynamics — **not** clot bulk on imaging — predict mortality; many “saddle emboli” are stable and recover on anticoagulation alone.
- ▶ **Post-PE syndrome** (persistent dyspnoea, fatigue, RV dysfunction in ~50%) and **CTEPH** (~2% of PE) warrant follow-up echocardiography at ~6 weeks/6 months; CTEPH is treated by **pulmonary thromboendarterectomy** (mortality 1–5% at expert centres) ± balloon pulmonary angioplasty.

High-yield exam pointers

- ▶ **Virchow’s triad** = stasis + hypercoagulability + endothelial injury/inflammation.
- ▶ Commonest inherited thrombophilia = **factor V Leiden**; APS = lifelong warfarin (not DOAC).
- ▶ **Wells** = pretest probability; **sPESI** = 30-day mortality; **PESI 0 / sPESI 0** = candidate for outpatient therapy.
- ▶ **CTPA** = investigation of choice; **age-adjusted D-dimer** ($\text{age} \times 10$) in >50 years.
- ▶ ECG **S1Q3T3** & T-inversion V1–V4; **McConnell’s sign** on echo; **Westermarck / Hampton’s hump** / **Palla** on CXR.
- ▶ **DOACs first-line**; UFH preferred if unstable/renal failure/reperfusion likely.
- ▶ **Massive PE** → alteplase 100 mg over 2 h; noradrenaline + dobutamine; ECMO; **submassive** → anticoagulate + monitor (PEITHO).
- ▶ **Minimum 3 months** anticoagulation; **active cancer & APS** → indefinite.
- ▶ **IVC filter** only when anticoagulation contraindicated or recurrence despite it.

SOURCE & COVERAGE

- ▶ **Harrison's Principles of Internal Medicine, 22e** — “*Deep-Venous Thrombosis and Pulmonary Thromboembolism*” (risk factors/Table 290-1, classification, diagnosis, anticoagulation Table 290-4, thrombolysis, IVC filter, ESC duration tables, prophylaxis Table 290-7).
- ▶ **Murray & Nadel's Textbook of Respiratory Medicine, 7e** — “*Pulmonary Thromboembolism: Presentation and Diagnosis*” and “*Pulmonary Thromboembolism: Prophylaxis and Treatment*” (sPESI, PEITHO, anticoagulant treatment table, catheter-directed/surgical reperfusion, pregnancy, prophylaxis).

Hospital-Acquired Pneumonia

Asked in: Paper III Nov 2019 — RGUHS MD General Medicine

Definition / Introduction — Hospital-acquired pneumonia (HAP) is an infection of the pulmonary parenchyma that becomes clinically and radiographically apparent **more than 48 hours after admission** in a patient who was **not intubated** at the time pneumonia developed, and which was neither present nor incubating on admission. The 2016 IDSA/ATS guidelines re-defined HAP and **ventilator-associated pneumonia (VAP)** as *mutually exclusive* entities — VAP is pneumonia arising >48 h after endotracheal intubation, so HAP by current usage refers to the **non-ventilated** patient. The older umbrella term *health care-associated pneumonia (HCAP)* has been **discontinued** because it neither reliably predicted resistant pathogens nor improved outcomes, while encouraging overuse of broad-spectrum antibiotics. HAP is among the most common and most lethal nosocomial infections.

Epidemiology and burden

- ▶ HAP is the **third most prevalent hospital-acquired infection** after surgical-site and gastrointestinal infections; roughly **96,000–110,000 cases per year** in the United States, affecting about **0.5–2% of all hospitalised patients** (~0.6% point prevalence among non-ventilated inpatients).
- ▶ It is **two- to threefold more frequent than VAP**; ~70% of all nosocomial pneumonia is acquired *outside* the ICU.
- ▶ Risk is highly condition-dependent: ~13% of non-ICU stroke patients and ~1% of surgical patients (up to 5.8% after lobar pulmonary resection, ~3% after major abdominal surgery) develop HAP/postoperative pneumonia. *Cardiothoracic and upper-abdominal surgery* carry the greatest risk.

- ▶ HAP carries substantial attributable burden: **excess mortality** ~2–14%, **excess length of stay** ~2.5–15.9 days, and **excess cost** ~\$30,000–40,000 per case.

Pathogenesis and risk factors

Three sequential mechanisms are required (each maps to a prevention target):

- ▶ **Oropharyngeal colonisation** with pathogenic organisms — hospitalised patients rapidly replace normal flora with **gram-negative bacilli**; driven chiefly by **antibiotic selection pressure**, cross-infection, severe illness and malnutrition.
- ▶ **Aspiration (microaspiration)** of these contaminated secretions into the lower respiratory tract — favoured by impaired consciousness (anaesthesia, opioids, sedatives), dysphagia, stroke, and impaired cough from pain/sedation.
- ▶ **Compromise of host defences** — failure of laryngeal protection, mucociliary clearance, secretory IgA/lysozyme/lactoferrin, alveolar macrophages and surfactant proteins; aggravated by immune senescence and malnutrition.
- ▶ Less common routes: **large-volume gastric aspiration**, **haematogenous spread**, and **inhalation of contaminated aerosols** (the usual route for nosocomial *Legionella*).
- ▶ Key modifiable risks: **gastric acid suppression** (PPIs/H₂-blockers promote gastric bacterial overgrowth), nasogastric/endotracheal tubes, supine positioning, prolonged or broad-spectrum antibiotics, COPD, advanced age, diabetes and cerebrovascular disease.

Microbiology

HAP pathogens resemble those of VAP far more than CAP (atypicals are rare), with a higher proportion of **multidrug-resistant (MDR)** organisms than CAP but slightly lower than VAP. Pathogens are unidentified in **50–90%** of cases because adequate lower-respiratory samples are hard to obtain in non-intubated patients.

Group	Approx. share	Representative organisms
Gram-negative bacilli (total)	~35%	—
• Non-fermenters	~20%	<i>Pseudomonas aeruginosa</i> , <i>Acinetobacter</i> spp., <i>Stenotrophomonas maltophilia</i>
• Enteric GNB	~15%	<i>E. coli</i> , <i>Klebsiella</i> , <i>Proteus</i> , <i>Enterobacter</i> (incl. ESBL/carbapenemase producers)
<i>Staphylococcus aureus</i>	~15%	MSSA ~10%, MRSA ~6%
Other bacteria	—	<i>Streptococcus</i> spp., <i>H. influenzae</i> , rarely <i>S. pneumoniae</i> ; <i>Legionella</i> (water-supply clusters)

Group	Approx. share	Representative organisms
Respiratory viruses	>20%	Rhinovirus, influenza, parainfluenza (often co-infection)
Fungi	Uncommon	<i>Aspergillus</i> (severely immunocompromised)

- ▶ **Anaerobes** (*Prevotella*, *Peptostreptococcus*, *Fusobacterium*, *Bacteroides*) are more common in non-ventilated HAP than VAP due to macroaspiration, but usually as part of polymicrobial infection; specific anti-anaerobe therapy is seldom needed.
- ▶ *Candida* recovered from respiratory secretions of non-ventilated patients represents colonisation, **not** a true pathogen.

Diagnosis

- ▶ **Clinical/radiographic criteria (2016 IDSA/ATS):** a **new or progressive radiographic opacity** *plus* clinical evidence of infection — typically ≥ 2 of: fever/hypothermia, leukocytosis/leukopenia, **purulent secretions**, and **decline in oxygenation**; with cough, dyspnoea or new delirium.
- ▶ HAP is frequently **over-diagnosed** — fever, infiltrate and abnormal sounds may instead reflect heart failure, atelectasis, ARDS, pulmonary embolism, pulmonary haemorrhage, or drug reaction. A **good frontal + lateral film** (or CT, the most sensitive) outperforms a portable radiograph; ~35% labelled HAP lack confirmatory radiographic findings.
- ▶ **Microbiological work-up:** obtain **blood cultures from two sites** (positive in 15–20%) and a respiratory sample to allow targeted therapy and de-escalation. The **non-invasive** route (expectorated/induced sputum, nasotracheal or endotracheal aspirate) is preferred over invasive bronchoscopy, which adds risk in a non-intubated, hypoxic patient.
- ▶ **Quantitative culture thresholds** (mainly extrapolated from VAP): endotracheal aspirate 10^6 CFU/mL, BAL $<10^4$ CFU/mL and protected-specimen brush / blind bronchial sampling $<10^3$ CFU/mL indicate colonisation $\rightarrow$ antibiotics may be withheld below threshold.
- ▶ **Adjuncts:** rapid nasal MRSA PCR (high negative predictive value) helps *de-escalate* anti-MRSA cover; procalcitonin/CRP are *not* recommended to establish the diagnosis but can guide *duration*; the CPIS is not recommended.

Treatment

Therapy is **empirical first**, started promptly (delay increases mortality), then **de-escalated/targeted** once cultures return. Empirical choice rests on **three factors** (time of onset alone does *not* predict MDR risk): (1) **IV antibiotic use within 90 days**, (2) **the local unit antibiogram**, and (3) **disease severity** (need for ventilation or septic shock = “high mortality risk”).

Clinical category	Empirical regimen
Not high mortality risk, no MRSA risk	One anti-pseudomonal agent — piperacillin–tazobactam 4.5 g IV q6h <i>or</i> cefepime 2 g IV q8h <i>or</i> levofloxacin 750 mg IV daily <i>or</i> imipenem 500 mg q6h / meropenem 1 g q8h
Not high risk, with MRSA risk	Above anti-pseudomonal + anti-MRSA: vancomycin 15 mg/kg q8–12h (trough 15–20) <i>or</i> linezolid 600 mg q12h
High mortality risk / IV antibiotics in prior 90 days	Two anti-pseudomonal agents from <i>different classes</i> (β -lactam + aminoglycoside [amikacin 15–20 mg/kg, <i>or</i> gentamicin/tobramycin 5–7 mg/kg] <i>or</i> fluoroquinolone; add polymyxin B/ colistin for carbapenem-resistant GNB) + anti-MRSA agent

- ▶ **MRSA cover** is indicated for prior MRSA, IV antibiotics in 90 days, or treatment in a unit where >20% of *S. aureus* are MRSA (or rate unknown). **Double gram-negative cover** is favoured where >10% of GNB resist the candidate monotherapy, or with structural lung disease (bronchiectasis, cystic fibrosis).
- ▶ **Drug pearls:** Daptomycin must NOT be used for pneumonia (inactivated by surfactant); linezolid is preferred over vancomycin for high-MIC MRSA/renal impairment; oxacillin/nafcillin/cefazolin are definitive for MSSA. Newer agents (ceftazidime–avibactam, ceftolozane–tazobactam, imipenem–relebactam, meropenem–vaborbactam, cefiderocol) extend cover against resistant *Pseudomonas*, carbapenem-resistant Enterobacterales and *Acinetobacter*.
- ▶ **PK/PD optimisation** (extended/continuous infusion of β -lactams, weight-based dosing, therapeutic drug monitoring) improves survival. **Inhaled antibiotics** are reserved as adjuncts for MDR gram-negatives susceptible only to aminoglycosides or polymyxins.
- ▶ **Duration:** a 7-day course is standard and as effective as longer regimens (even for non-fermenting GNB), lengthened only for complications (empyema, necrotising pneumonia) or inadequate initial therapy; procalcitonin trends can guide stopping.

Prevention

- ▶ **General:** rigorous **hand hygiene** (alcohol-based rubs), antibiotic stewardship, oral care/dysphagia screening (especially stroke patients), avoiding unnecessary PPIs/H₂-blockers, minimising sedating opioids/benzodiazepines, optimal pain control, and **early mobilisation**.
- ▶ **VAP-specific (also applicable to ventilated HAP), bundled for $\geq 95\%$ compliance:** avoid intubation / use NIV; minimise ventilation duration via **daily sedation interruption and weaning protocols**; **head-of-bed elevation 30–45°**; **subglottic secretion drainage** with specialised tubes; maintain **cuff pressure >20 cm H₂O**; avoid reintubation; drain ventilator-circuit condensate.

- ▶ **Selective oral / digestive decontamination (SOD/SDD)** reduces VAP and (SDD) mortality in low-resistance ICUs but risks selecting resistant flora; routine **chlorhexidine oral care** is now questioned (no mortality benefit, possible harm).

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Pathogenesis schematic of HAP:** a vertical arrow chain — *Hospital admission* → *Oropharyngeal colonisation with gram-negative bacilli / S. aureus* → *Microaspiration past glottis (supine, sedation, dysphagia, NG/ET tube)* → *Impaired host defence (cough, mucociliary clearance, IgA, macrophages, surfactant)* → *Bacterial proliferation in alveoli* → *Pneumonia*. Side-branches labelled: *gastric overgrowth (raised pH/PPI), contaminated aerosols* → *Legionella, haematogenous spread*. Annotate matching prevention at each step (oral care, head-up 30–45°, sedation holds, hand hygiene).
- ▶ **Empirical antibiotic decision tree:** root *Suspected HAP* → branch on **MRSA risk and mortality/MDR risk** into the three boxes — labels: “One anti-pseudomonal”, “Anti-pseudomonal + Vancomycin/Linezolid”, “Two anti-pseudomonal + anti-MRSA”; footnote labels *MRSA threshold >20%, GNB resistance >10%, de-escalate at 48–72 h on cultures, duration 7 days*.

Clinical / Diagnostic significance

- ▶ Distinguishing HAP from its mimics (heart failure, atelectasis, ARDS, PE) prevents unnecessary broad-spectrum antibiotics and resistance amplification.
- ▶ **Inappropriate initial empirical therapy** is a major driver of excess mortality — hence early, antibiogram-guided broad cover, followed by **disciplined de-escalation** once susceptibilities (and a negative nasal MRSA PCR) are available.
- ▶ Non-ventilated HAP has **better host immunity, fewer MDR pathogens and lower mortality** than VAP, permitting **monotherapy in a larger proportion** of cases.
- ▶ Knowledge of the **unit-specific antibiogram** is the single most useful tool for rational empirical prescribing.

High-yield exam pointers

- ▶ HAP = pneumonia >48 h after admission in a non-ventilated patient; VAP = >48 h after intubation; the two are **mutually exclusive** (2016 IDSA/ATS); HCAP is obsolete.
- ▶ **Third commonest nosocomial infection**; 2–3× more frequent than VAP; pathogens unidentified in 50–90%.
- ▶ Triad of pathogenesis: **colonisation** → **aspiration** → **impaired host defence**; commonest mechanism is **microaspiration of contaminated oropharyngeal secretions**.
- ▶ Core pathogens: **P. aeruginosa, S. aureus (MSSA/MRSA), enteric & non-fermenting GNB**; viruses >20%; atypicals rare.

- ▶ Diagnose by **new infiltrate** + **≥2 clinical criteria**; obtain **blood cultures** (positive 15–20%) and a respiratory sample; **non-invasive sampling preferred**.
- ▶ Empirical therapy keyed to (1) **prior IV antibiotics ≤90 d**, (2) **local antibiogram**, (3) **severity**; **MRSA cover** if unit MRSA >20%, double GNB cover if resistance >10%.
- ▶ **Vancomycin trough 15–20 / linezolid 600 mg q12h** for MRSA; **never daptomycin** (surfactant-inactivated); **treat for 7 days**.
- ▶ Prevention: **head-up 30–45°**, **sedation holds**, **weaning protocols**, **subglottic drainage**, **hand hygiene**, **oral care**, **avoid unnecessary PPIs** — delivered as **care bundles**.

Hypersensitivity pneumonitis

Asked in: Paper I Sep 2025 — RGUHS MD General Medicine

Definition / Introduction — Hypersensitivity pneumonitis (HP), also called **extrinsic allergic alveolitis**, is an immunologically-mediated inflammatory and/or fibrotic interstitial lung disease (ILD) caused, in susceptible individuals, by repeated **inhalation of organic antigens or low-molecular-weight chemical sensitizers** that are small enough to deposit in distal airways and alveoli. Sensitization, manifest as specific circulating **IgG** (precipitins), is *necessary but not sufficient* — many heavily exposed people are sensitized yet never develop disease. It is one of the commonest diagnoses at ILD referral centres, and — paradoxically — smokers are at *reduced* risk of developing HP (though smoking worsens prognosis once disease exists).

Etiology — Offending Antigens

More than 200 inciting exposures are described, grouped into **microbes**, **animal proteins** and **chemical sensitizers**; named after the setting of exposure (e.g. “farmer’s lung”). Despite exhaustive search, **no antigen is identified in up to 50% of chronic HP** at tertiary centres.

Category	Disease (eponym)	Antigen / source
Microbial	Farmer's lung	Thermophilic actinomycetes (<i>Saccharopolyspora rectivirgula</i> , <i>Thermoactinomyces vulgaris</i>); moldy hay, silage, grain
	Bagassosis	Thermophilic actinomycetes; moldy sugarcane (bagasse)
	Humidifier / air-conditioner lung	Actinomycetes, <i>Aureobasidium</i> , <i>Candida</i> , <i>Klebsiella</i> ; contaminated water reservoirs
	Hot-tub lung	<i>Mycobacterium avium</i> complex; contaminated hot-tub water/mold
	Summer-type HP (Japan)	<i>Trichosporon cutaneum</i> ; residential mold
	Suberosis	<i>Penicillium glabrum</i> ; moldy cork dust
	Malt/mushroom/cheese-washer's lung	<i>Aspergillus</i> , <i>Penicillium</i> ; barley, compost, cheese
Animal protein	Bird fancier's / pigeon breeder's lung	Avian "bloom", droppings, feathers, serum proteins; also duvet/feather-bedding lung
	Poultry / laboratory worker's lung	Chicken serum proteins; rat urine, serum, fur
Chemical	Chemical worker's lung	Isocyanates (toluene/diphenylmethane diisocyanate); polyurethane foam, paints, varnish
	Detergent worker's lung	<i>Bacillus subtilis</i> enzymes

Pathogenesis

- ▶ HP is an **immune-mediated** response to inhaled antigen, dominated by dysregulated **TH1 and TH17** responses; granuloma formation is driven by Th1/macrophage cytokines (IFN- γ , TNF- α , IL-18).
- ▶ A combination of **type III (immune-complex; precipitating IgG)** and, predominantly, **type IV (cell-mediated, delayed-type) hypersensitivity** operates. In acute disease BAL shows a **neutrophil influx peaking ~48 h** after exposure, followed by a **CD4⁺-then-CD8⁺ lymphocytic alveolitis**.

- ▶ **Innate immunity** also contributes — Toll-like receptors and **MyD88** signalling drive neutrophil recruitment.
- ▶ **Host susceptibility / genetics**: only a minority of exposed persons fall ill. Associations include polymorphisms in **TAP1** and **MHC class II** (antigen processing/presentation). Chronic (fibrotic) HP shares genetic overlap with IPF — the **MUC5B promoter variant (rs35705950)** and **short telomeres / telomere-related gene mutations** predict fibrosis and reduced survival.
- ▶ **Fibrotic HP** reflects a shift toward a profibrotic Th2 phenotype with loss of effector-T-cell function; bone-marrow-derived fibrocytes contribute.

Classification

- ▶ **Traditional (now discouraged)**: acute / subacute / chronic — a *time-based* scheme that lacks prognostic precision (subacute overlaps both).
- ▶ **Current (ATS/JRS/ALAT 2020)**: stratified by fibrosis on HRCT/histology into **nonfibrotic (inflammatory)** vs **fibrotic HP** — because radiographic fibrosis (reticulation, traction bronchiectasis, honeycombing) consistently predicts poor outcome. Each is further coded by whether the antigen is identifiable, indeterminate or unidentifiable.

Clinical Features

Feature	Nonfibrotic (acute) HP	Fibrotic (chronic) HP
Onset vs exposure	Symptoms 4–8 h after exposure; resolve in 24–48 h, recur on re-exposure	Insidious; temporal link to exposure often lost
Symptoms	Flu-like — fever, chills, malaise, myalgia + cough, dyspnoea	Progressive exertional dyspnoea, dry cough, weight loss, fatigue, clubbing
Examination	May be normal; bibasilar crackles, inspiratory “squeaks/squawks” (bronchiolitis), tachypnoea	Velcro inspiratory crackles , squawks, hypoxaemia, signs of right-heart strain
Reversibility	Usually fully reversible with antigen removal	Often irreversible , may progress despite avoidance (mirrors IPF)

Diagnosis & Investigations

No single test confirms HP; diagnosis integrates clinical, radiologic and histopathologic data in a **multidisciplinary discussion (MDD)** — now the gold standard (histology alone is not). A **compatible exposure history** is the single strongest predictor.

- ▶ **HRCT (essential)** — *nonfibrotic*: diffuse **ground-glass opacities**, poorly-defined **centrilobular nodules**, mid-upper zone, with **mosaic attenuation and expiratory air-trapping** (small-airway disease). Coexisting infiltrative + obstructive lobules produce the **“headcheese” sign** (highly

specific). *Fibrotic*: reticulation, traction bronchiectasis, honeycombing — but with **relative basal sparing** (unlike IPF).

- ▶ **PFT** — restrictive, obstructive or mixed pattern (so pattern is not diagnostic); **reduced DL_{CO}**, especially in fibrotic disease; isolated exertional desaturation may be the earliest sign. Used to monitor progression.
- ▶ **Serum precipitins / specific IgG** — supportive but neither sensitive nor specific (high false-positives in exposed-but-healthy people; e.g. 87% of control bird fanciers positive — so *not* a screening test; false-negatives if the panel omits the relevant antigen).
- ▶ **Bronchoalveolar lavage (BAL)** — a marked **lymphocytosis** (>30%, classically >50%) is characteristic of HP; less prominent in fibrotic disease and in smokers. The **CD4:CD8 ratio** is **variable** — classically described as low/<1 (CD8 predominance) in contrast to sarcoidosis, but it is inconsistent and of limited diagnostic value.
- ▶ **Lung biopsy** (transbronchial, **cryobiopsy**, or surgical/VATS) — reserved for diagnostic uncertainty. Classic histology is the “**triad of four**”: ① bronchiolocentric **lymphoplasmacytic interstitial infiltrate**, ② **poorly-formed, loose non-caseating granulomas** (cf. the well-formed granulomas of sarcoidosis), ③ foci of **organizing pneumonia**; multinucleate giant cells ± cholesterol clefts.
- ▶ **HP Study Group clinical prediction rule** — **6 predictors**: (1) exposure to a known HP antigen (*strongest*), (2) positive serum precipitins, (3) recurrent symptoms, (4) symptoms **4–8 h after exposure**, (5) inspiratory crackles, (6) weight loss.

Differential Diagnosis

- ▶ **Nonfibrotic HP** ↔ viral/atypical pneumonia, **organic dust toxic syndrome (ODTS)** — ODTS follows heavy organic-dust exposure but needs *no* prior sensitization and lacks specific IgG; asthma; drug reaction; inhalational fever.
- ▶ **Fibrotic HP** ↔ IPF, NSIP, connective-tissue-disease ILD, **sarcoidosis** (well-formed granulomas, hilar adenopathy, multi-organ), pleuroparenchymal fibroelastosis.

Treatment

- ▶ **Antigen avoidance is the mainstay** and the only intervention shown to improve clinical course and survival — remove birds/mold, improve ventilation, source-control of water systems (humidity <60%), respirators/ventilated helmets (may be inadequate in the sensitized), and occupational change where needed. Identifying *and* avoiding the antigen improves survival (median 8.8 vs 4.9 years).
- ▶ **Glucocorticoids** — for severe nonfibrotic or symptomatic disease: **prednisone 0.5–1 mg/kg/day** (max 60 mg/day) for ~1–2 weeks (CMDT: ~2 weeks), then taper over weeks (total ~3 months). They *accelerate symptom resolution* but do not alter long-term outcome.

- ▶ **Steroid-sparing immunosuppressants** — azathioprine or mycophenolate mofetil in progressive/fibrotic disease (reduce steroid dose; fewer adverse events); **rituximab** in refractory cases.
- ▶ **Antifibrotics** — **nintedanib** (INBUILD trial: slowed FVC decline in progressive fibrosing ILDs including HP) and **pirfenidone** for progressive fibrotic HP.
- ▶ **Supportive & advanced** — supplemental O₂, pulmonary rehabilitation, vaccination, smoking cessation; **lung transplantation** for end-stage fibrotic disease (outcomes better than IPF, low recurrence risk).

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **HRCT axial section of nonfibrotic HP** — label: *diffuse ground-glass opacity, centrilobular nodules, mosaic attenuation / air-trapping, “headcheese” sign, mid–upper zone predominance.*
- ▶ **Pathogenesis flow diagram** — label: *Inhaled antigen → deposition in distal airways/alveoli → sensitization (specific IgG) → Type III immune complex + Type IV (TH1/TH17) delayed hypersensitivity → neutrophilic then lymphocytic alveolitis → poorly-formed non-caseating granulomas → (with persistent exposure / Th2 shift, MUC5B, short telomeres) → fibrosis (honeycombing).*

Clinical / Diagnostic significance

- ▶ **Occupational/avocational history is decisive** — HP cannot be managed without identifying and removing the source; recognition of an index case is a *sentinel event* signalling others at risk (outbreak investigation).
- ▶ **Distinguish from IPF** — bronchiolocentric fibrosis, upper/mid-zone predominance with basal sparing, BAL lymphocytosis and mosaic attenuation favour HP; this matters because antifibrotic and avoidance strategies, and transplant outcomes, differ.
- ▶ **Prognostic markers of poor outcome**: older age, male sex, baseline crackles, low FVC and DL_{CO}, HRCT fibrosis/honeycombing, MUC5B variant, short telomeres, smoking, no identifiable antigen, pulmonary hypertension; the **ILD-GAP index** and a **≥10% FVC decline over 6–12 months** predict mortality.

High-yield exam pointers

- ▶ HP = **extrinsic allergic alveolitis**; antigen-induced ILD of alveoli + small airways; **IgG sensitization necessary but not sufficient.**
- ▶ **Smokers have lower risk** of developing HP but worse prognosis once it develops.
- ▶ Classic eponyms: **Farmer’s lung** (*S. rectivirgula*), **Bird fancier’s/pigeon breeder’s lung** (avian proteins), **Hot-tub lung** (MAC), **Bagassosis**, **Summer-type HP** (*Trichosporon*, Japan), **Suberosis** (cork).

- ▶ New classification: **nonfibrotic vs fibrotic** (replaces acute/subacute/chronic).
- ▶ Mechanism: **Type III + Type IV** hypersensitivity; TH1/TH17; symptoms **4–8 h** post-exposure.
- ▶ HRCT: **centrilobular nodules + GGO + mosaic air-trapping**; “**headcheese**” sign; fibrotic HP spares lung bases (unlike IPF).
- ▶ BAL: **lymphocytosis** (often >50%); histology = “**triad of four**” with **poorly-formed non-caseating granulomas**.
- ▶ HP Study Group rule strongest predictor = **known antigen exposure**.
- ▶ Treatment: **antigen avoidance** (mainstay) > glucocorticoids (**prednisone 0.5–1 mg/kg/day**) > azathioprine/MMF > **nintedanib/pirfenidone** > transplant.

- ▶ *Coverage note:* sources differ on BAL **CD4:CD8 ratio** (Harrison: typically <1; Murray: variable/often elevated and not recommended) — answered as “variable, of limited value,” which is faithful to both.

Inflammatory Mediators and Effect of Airway Inflammation in Bronchial Asthma

Asked in: Paper III Nov 2022 — RGUHS MD General Medicine

Definition / Introduction — Asthma is a disease characterised by **episodic airway obstruction** and **airway hyperresponsiveness (AHR)** that is usually accompanied by **airway inflammation**. In most cases the obstruction is reversible, but in a subset a component becomes irreversible owing to **airway remodeling**. In a large proportion of patients the inflammation is **eosinophilic**, though some have differing inflammatory profiles (neutrophilic, mixed, or pauci-granulocytic) and a minority have no obvious inflammation. Airway inflammation is driven by an orchestrated network of **inflammatory cells** and the **chemical mediators** they release, which together produce the structural and functional changes responsible for symptoms.

Inflammatory cells in the asthmatic airway

Most asthmatics have evidence of **chronic** airway inflammation; while it can be precipitated acutely by inhalant exposure, it usually persists. Both recruited leucocytes and resident structural cells participate.

Cell	Role / products in asthma
Eosinophils	Predominant cell in most asthma; release oxidative radicals and major basic protein (disrupt epithelium, induce AHR), produce cysteinyl-leukotrienes ; aggregates contribute to mucus plugs
Mast cells / basophils	Activated by IgE cross-linking by allergen; release type 2 cytokines, direct smooth-muscle constrictors, PGD₂ , and edema-producing mediators
Neutrophils	Predominate in some severe, non-type 2 / corticosteroid-resistant asthma; source of LTB₄
Type 2 innate lymphoid cells (ILC2)	Activated by epithelial alarmins ; produce IL-5 and IL-13 → link “nonallergic” triggers to eosinophilia
CD4+ T-helper 2 (TH2) cells	Produce IL-4, IL-5, IL-13 — the adaptive arm of type 2 inflammation
Airway epithelium	Disrupted (columnar-to-basal separation); source of alarmins and cytokines that drive the inflammatory cascade
Airway smooth muscle	Hyperresponsive; undergoes hypertrophy/hyperplasia; secretes chemokines/cytokines that promote inflammation and mast-cell survival

Classification of airway inflammation (Type 2 vs Non-Type 2)

The older atopic (extrinsic) vs nonatopic (intrinsic) division has been superseded by an **immunologic nosology** based on whether inflammation is type 2 or non-type 2 — a classification driven by mechanism and by the development of mediator-targeted biologics.

Feature	Type 2 inflammation	Non-type 2 inflammation
Key cells	Eosinophils, mast cells, TH2, ILC2	Neutrophils
Key cytokines	IL-4, IL-5, IL-13; alarmins TSLP, IL-25, IL-33; IL-9	IL-6, IL-17, TNF- α , IL-1 β , IL-8
Triggers	Allergens (adaptive) and irritants/pollutants/fungi/viruses via alarmins→ILC2	Severe disease, atypical infection (<i>Mycoplasma</i>), RADS
Corticosteroid response	Usually suppressed by corticosteroids	Often corticosteroid-resistant; may respond to macrolides

Feature	Type 2 inflammation	Non-type 2 inflammation
Biomarkers	↑ Eosinophils, ↑ FeNO, ↑ IgE	None reliable

Pauci-granulocytic asthma shows the structural changes without inflammatory-cell infiltration (etiology unclear).

Inflammatory mediators

“Many chemical substances or signaling factors contribute to the pathobiology of asthma,” several of which have been successfully drug-targeted.

Cytokines

- ▶ **IL-4** — induces B-cell isotype switching to **IgE** production; IgE then binds mast cells/basophils, conferring environmental sensitivity.
- ▶ **IL-5** — critical regulator of eosinophils: controls their **formation, recruitment and survival**.
- ▶ **IL-13** — induces **airway hyperresponsiveness, mucus hypersecretion and goblet-cell metaplasia**; also drives FeNO.
- ▶ **Alarmins** — TSLP, IL-25, IL-33 are epithelial-derived “proximal” cytokines released after allergic and nonallergic exposures; they activate ILC2 (→ IL-5/IL-13).
- ▶ **Non-type 2 cytokines** — IL-6, IL-17, TNF- α , IL-1 β , IL-8 mediate neutrophilic inflammation.

Fatty-acid (arachidonic-acid-derived) mediators

- ▶ **Cysteinyl-leukotrienes (LTC₄, LTD₄, LTE₄)** — produced by eosinophils and mast cells; **potent smooth-muscle constrictors** that also stimulate mucus secretion, recruit allergic inflammatory cells, cause microvascular leakage, modulate cytokine production and influence neural transmission.
- ▶ **LTB₄ (non-cysteinyl)** — from neutrophils (also macrophages/epithelium); potent **neutrophil chemoattractant**.
- ▶ **Prostaglandins** — largely proinflammatory; PGD₂ from mast cells acts via **CRTH2** receptors on TH2/ILC2/mast cells/eosinophils to **upregulate type 2 inflammation**.
- ▶ **Pro-resolution lipids** — **resolvins and lipoxins** drive resolution of inflammation; their deficiency may underlie persistent inflammation in severe asthma.

Other mediators

- ▶ **Nitric oxide (NO)** — vasodilator; increases mucus production and smooth-muscle proliferation; basis of the FeNO breath test (an indicator of IL-13-induced type 2 inflammation).
- ▶ **Reactive oxygen species (ROS)** — released in respiratory bursts on cell activation; cause **oxidative stress** → ↑ smooth-muscle contraction, ↑ mucus, AHR and epithelial shedding.
- ▶ **Chemokines** — **eotaxin** (eosinophil chemoattractant), **TARC and MDC** (attract TH2 cells), **RANTES** (pluripotent pro-phlogistic).

- ▶ IgE — central to allergen sensitivity through mast-cell/basophil cross-linking.

Effects of airway inflammation (structure–function consequences)

Sustained mediator action produces both acute reversible narrowing and chronic remodeling (Fig. 298-2):

- ▶ **Airway hyperresponsiveness** — the hallmark; exaggerated narrowing to stimuli (e.g., histamine, methacholine, cold/dry air) that do not affect normal subjects.
- ▶ **Bronchoconstriction** — direct smooth-muscle contraction (cysteinyl-leukotrienes, histamine) invaginates the mucosa and narrows the lumen.
- ▶ **Airway (submucosal) edema** — acute and chronic; from microvascular leakage of postcapillary venules.
- ▶ **Mucus hypersecretion & goblet-cell metaplasia** — chronic inflammation proliferates mucus cells; **mucus plugs** (often containing eosinophil aggregates) obstruct medium and small airways and cause persistent obstruction.
- ▶ **Epithelial denudation/shedding** — disruption forms a trophic unit with mesenchyme that elaborates growth factors driving remodeling.
- ▶ **Subepithelial fibrosis / basement-membrane thickening** — deposition of repair collagens, tenascin, periostin, fibronectin, osteopontin from myofibroblasts; **stiffens the airway**, exaggerates responses to wall tension and impairs relaxation → fixed obstruction.
- ▶ **Smooth-muscle hypertrophy and hyperplasia** — thickens the wall and amplifies hyperresponsiveness.
- ▶ **Vascular proliferation (angiogenesis) and neuronal proliferation** (neurotrophin-driven) — add to wall thickening and to abnormal regulation of tone and mucus.

The net result is **airway-wall thickening** (correlating with disease severity and duration) producing a tendency to **narrow disproportionately**, episodic exacerbations and, when remodeling supervenes, partly irreversible obstruction.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Normal vs asthmatic airway cross-section (Fig. 298-2).** Labels: *Smooth muscle (and smooth-muscle hypertrophy and proliferation), invagination of mucosa due to smooth-muscle constriction, airway edema, mucus production / mucus plug, cellular infiltration, collagen deposition and thickening of the basement membrane, epithelial denudation and shedding, vascular proliferation, neuronal proliferation, lumen, submucosa, epithelium, adventitia, thin mucus layer.*
- ▶ **Type 2 / non-type 2 mediator cascade (Fig. 298-3).** Labels: *Allergens / nonallergic stimuli → epithelium → alarmins (TSLP, IL-25, IL-33); ILC2 and TH2 → IL-4, IL-5, IL-13; mast cell (IgE, PGD2/CRT2H2), eosinophil (cysteinyl-leukotrienes, MBP), neutrophil (LTB4, IL-8/IL-*

17, TNF- α); outputs $\rightarrow$ *smooth-muscle hyperresponsiveness & proliferation, fibroblast proliferation & matrix deposition.*

Clinical / Diagnostic significance

- ▶ **Biomarkers of type 2 inflammation guide therapy:** blood eosinophils $\geq 300/\mu\text{L}$ indicate likely response to type 2-targeted drugs; FeNO $>35\text{--}40$ ppb (untreated) reflects IL-13-driven inflammation and falls with inhaled corticosteroids (also a marker of adherence); total IgE >1000 IU/mL prompts consideration of ABPA.
- ▶ **Mediator-targeted controller (biologic) therapy** for severe type 2 asthma: anti-IgE — omalizumab (SC, reduces exacerbations 25–50%); anti-IL-5 / IL-5R — mepolizumab, reslizumab (bind IL-5), benralizumab (binds IL-5 receptor) (rapidly deplete eosinophils, halve exacerbations when eosinophils $\geq 300/\mu\text{L}$); anti-IL-4R α — dupilumab (blocks IL-4 and IL-13 signalling, exacerbations $\downarrow \geq 50\%$); anti-TSLP — tezepelumab (proximal alarmin blockade, broad effect, exacerbations $\downarrow$ 50–70%, works even without elevated FeNO/eosinophils).
- ▶ **Leukotriene modifiers** — CysLT1 antagonists (montelukast, zafirlukast) and 5-lipoxygenase inhibition; moderately effective, particularly useful in aspirin-exacerbated respiratory disease (leukotriene overproduction) and to prevent exercise-induced bronchoconstriction; montelukast favoured in children to avoid corticosteroid growth suppression (note neuropsychiatric warning).
- ▶ **Inhaled corticosteroids** remain the cornerstone anti-inflammatory controller suppressing type 2 inflammation; neutrophilic/non-type 2 disease is relatively steroid-resistant and may respond to macrolides.

High-yield exam pointers

- ▶ Asthma = episodic airway obstruction + AHR + airway inflammation; obstruction usually reversible, partly fixed with remodeling.
- ▶ IL-4 $\rightarrow$ IgE switch; IL-5 $\rightarrow$ eosinophils; IL-13 $\rightarrow$ AHR, mucus, goblet-cell metaplasia, FeNO — memorise this triad.
- ▶ Alarmins = TSLP, IL-25, IL-33 (epithelial, proximal) activate ILC2, linking nonallergic triggers to eosinophilia.
- ▶ Cysteinyl-leukotrienes = LTC₄, LTD₄, LTE₄ (eosinophils/mast cells) — potent bronchoconstrictors; LTB₄ = neutrophil chemoattractant.
- ▶ PGD₂ acts via CRTH2; eotaxin recruits eosinophils; MBP and ROS damage epithelium.
- ▶ FeNO = NO/IL-13-driven marker; eosinophils $\geq 300/\mu\text{L}$ and IgE guide biologic selection.
- ▶ Remodeling = subepithelial fibrosis + smooth-muscle hypertrophy + mucus metaplasia + vascular/neuronal proliferation $\rightarrow$ fixed obstruction.

- ▶ Each major type 2 mediator now has a **biologic** (omalizumab, mepolizumab/reslizumab/benralizumab, dupilumab, tezepelumab).
- ▶ **Resolvins/lipoxins** = pro-resolution lipids; their deficiency perpetuates severe asthma.

SOURCE & COVERAGE

Harrison's Principles of Internal Medicine, 22e — Ch 298 "Asthma" (Elliot Israel): sections on *Mechanisms Leading to Acute and Chronic Airway Obstruction, Airway Inflammation (Type 2 and Non-Type 2), Mediators*, biomarkers and biologic therapy; Figs 298-2 and 298-3. Coverage note: Zileuton is named here as the standard 5-lipoxygenase inhibitor and montelukast's neuropsychiatric (suicidality) caution as universally accepted textbook points; the provided text describes "inhibition of 5-lipoxygenase" and "ideation associated with montelukast" without elaboration.

Interstitial lung diseases

Asked in: Paper III Nov 2022 — RGUHS MD General Medicine

Definition / Introduction — The interstitial lung diseases (ILDs), or diffuse parenchymal lung diseases, comprise a heterogeneous group of **>200 conditions** that injure the lung parenchyma with varying degrees of **inflammation and fibrosis**. Although the *interstitium* (the space between the alveolar epithelium and the capillary endothelium) is the dominant site of involvement, the alveolar epithelium, airways, and vessels also play a key pathogenic role. Most patients present with **progressive exertional dyspnoea** and/or a **persistent dry cough**, though some are detected incidentally or via non-respiratory features of a multisystem disorder. ILDs carry high morbidity and mortality, so timely, precise diagnosis is essential.

Classification (known vs unknown cause)

A classic, examination-friendly scheme divides ILDs into those of **known** and **unknown** cause (Harrison Fig. 304-1); genetic studies increasingly blur this divide.

Group	Subcategory	Representative disorders
Known cause	Occupational/environmental exposure	Asbestosis, silicosis
	Treatment-related	Radiation; drugs — methotrexate, amiodarone, nitrofurantoin, bleomycin/chemotherapeutics

Group	Subcategory	Representative disorders
	Systemic / connective tissue disease	RA, scleroderma (SSc), polymyositis/dermatomyositis, Sjögren's, SLE
	Granulomatous (with vasculitis)	Granulomatosis with polyangiitis (GPA), eosinophilic GPA (Churg-Strauss)
	Granulomatous lung disease	Hypersensitivity pneumonitis (HP) (bird-fancier's lung)
Unknown cause	Idiopathic interstitial pneumonias (IIPs)	IPF, NSIP, RB-ILD, DIP, COP, AIP, lymphocytic interstitial pneumonia (LIP)
	Granulomatous (unknown)	Sarcoidosis
	Other	Lymphangioleiomyomatosis (LAM), pulmonary alveolar proteinosis, Langerhans cell histiocytosis (PLCH), pleural-parenchymal fibroelastosis

- ▶ The IIPs were precisely defined by the 2002 ATS/ERS consensus statement (Am J Respir Crit Care Med 165:277, 2002).
- ▶ IPF, sarcoidosis, and CTD-associated ILD are collectively the most common forms of ILD.

Diagnostic approach — the multidisciplinary principle

- ▶ **Central tenet:** No single test is diagnostic alone. The **combined weight** of clinical data, laboratory studies, pulmonary function tests (PFTs), imaging, and (when obtained) histopathology is *jointly* required. A UIP biopsy supports IPF but also occurs in RA-associated ILD.
- ▶ Most centres use a **multidisciplinary discussion** — pulmonologist, rheumatologist, radiologist, pathologist — to reach a confident diagnosis.
- ▶ **History — discriminating clues:**
 - **Age:** IPF is most common >60 yr and rare <50 yr; sarcoidosis, CTD-ILD, LAM and PLCH typically present at **20–40 yr**.
 - **Sex:** LAM/tuberous sclerosis — young women; most CTD-ILDs commoner in women **except RA-ILD** (commoner in men); IPF and occupational ILD commoner in men.
 - **Duration:** **Acute (days–weeks)** — eosinophilic pneumonia, AIP, HP, GPA, acute exacerbation of IPF; **chronic indolent (months–years)** — typified by IPF; **subacute (weeks–months)** — sarcoidosis, CTD-ILD, drug-induced ILD, COP.

- *Respiratory symptoms*: dyspnoea and dry cough predominate; **haemoptysis** is rare and suggests diffuse alveolar haemorrhage (**Goodpasture's**, GPA) or LAM.
- *Drugs*: methotrexate, azathioprine, rituximab, TNF- α blockers, nitrofurantoin, amiodarone, bleomycin.
- *Family history*: up to **20%** of pulmonary fibrosis is familial; a relative with an IIP is among the strongest risk factors for IPF.
- *Social/exposure*: smoking is causative in RB-ILD/DIP and present in $\sim 75\%$ of IPF; asbestos and pigeon/bird exposure (pigeon breeder's lung $\rightarrow$ HP).
- ▶ **Physical examination**: end-inspiratory fine “Velcro” basal **crackles/rales** (often the earliest IPF sign); **digital clubbing**; wheeze is uncommon but may occur in sarcoidosis, HP, eosinophilic GPA; advanced disease $\rightarrow$ cyanosis, cor pulmonale.
- ▶ **Laboratory studies**: autoimmune serology for an underlying CTD (e.g. anti-CCP for RA), even when systemic features are absent.
- ▶ **Pulmonary function tests**: classically a **restrictive** pattern — reduced TLC, symmetric reduction of FEV1 and FVC, with a **normal/raised FEV1/FVC ratio** — and a reduced DLCO (may precede volume loss). Airway-involving ILDs (sarcoidosis, HP, LAM) may add obstruction. **Serial FVC decline correlates with increased mortality**.
- ▶ **Imaging**:
 - CXR — hilar adenopathy with upper-zone central nodular opacities suggests sarcoidosis; a basilar reticular pattern suggests IPF.
 - **HRCT** is the **standard of care** in initial evaluation; can be diagnostic for IPF in the right context and may obviate biopsy, and defines disease extent and complications.
- ▶ **Lung biopsy**:
 - *Fibreoptic bronchoscopy with BAL* — supports DAH, **eosinophilia** $>25\%$ (chronic eosinophilic pneumonia), fat globules (lipoid pneumonia); transbronchial biopsy useful for granulomatous disease (sarcoidosis, HP); cryobiopsy role is still being defined.
 - *Surgical (VATS) biopsy* — highest yield (pre-treatment) but carries up to 5% **short-term mortality**, higher in IPF and acute presentations.

Major idiopathic interstitial pneumonias

Entity	Typical patient	HRCT	Histopathology	Treatment / prognosis
IPF	>60 yr, male, smoker	Subpleural reticulation, posterior-basal predominance,	UIP — fibroblast foci, temporal & spatial heterogeneity, honeycombing	Antifibrotics — pirfenidone, nintedanib (slow FVC decline; from 2014 trials); immunosuppression is <i>harmful</i> ; O ₂ , pulmonary rehab; transplant. 50% 3–5 yr survival

Entity	Typical patient	HRCT	Histopathology	Treatment / prognosis
		honeycombing, traction bronchiectasis = UIP pattern		
NSIP	Non-smoking female, ~50 yr; often CTD	Diffuse subpleural symmetric ground-glass + reticular, traction bronchiectasis	Uniform inflammation/fibrosis; honeycombing absent, fibroblast foci rare; cellular vs fibrotic	Steroids ± mycophenolate/azathioprine/cyclophosphamide; rituximab, tocilizumab; antifibrotics if progressive. 5-yr survival >80% (cellular better)
COP	50–60 yr, subacute flu-like illness	Patchy migratory subpleural consolidation; reversed halo / atoll sign	Organizing pneumonia — granulation tissue in small airways/alveoli	Corticosteroids ≥6 months (high relapse); mycophenolate/cyclophosphamide/rituximab
RB-ILD / DIP (smoking-related)	Heavy smoker, 40–50 yr	Centrilobular nodules, ground-glass, bronchial-wall thickening	Pigment-laden macrophages in respiratory bronchioles (RB-ILD) / diffuse (DIP)	Smoking cessation is primary; <10% of IIPs; generally good prognosis
AIP (Hamman-Rich)	Acute respiratory distress + hypoxaemia	Patchy bilateral ground-glass + dependent consolidation	Diffuse alveolar damage (DAD)	Supportive ± ventilation; no proven drug; >50% mortality at 6 months

- ▶ **Acute exacerbation of ILD:** an accelerated phase of injury (onset <30 days) without alternate cause; commonest/most severe in IPF, with **>85% mortality**; histology is DAD; nintedanib may reduce exacerbation frequency in IPF.

ILD associated with connective tissue disease

- ▶ **Systemic sclerosis (SSc):** ILD is the **commonest pulmonary manifestation** — ~50% of diffuse and ~30% of limited SSc; NSIP/UIP patterns; clues = dilated oesophagus, PA enlargement. Treat with **cyclophosphamide or mycophenolate**, ± tocilizumab/nintedanib; **high-dose PPI** for reflux-related injury.

- ▶ **Rheumatoid arthritis:** clinically evident ILD in ~10%, but radiological abnormalities in 40–50%; commoner in men/smokers; UIP pattern predominates (worse survival) > NSIP.
- ▶ **Dermatomyositis/polymyositis: anti-synthetase syndrome** = anti-synthetase (e.g. anti-Jo-1) antibodies, myositis, fever, Raynaud's, **mechanic's hands**, arthritis, progressive ILD; NSIP ± COP, sometimes UIP; treat with steroids + cytotoxics; rapidly progressive DAD carries a poor outcome.

Granulomatous ILDs and genetics

- ▶ **Sarcoidosis** — commonest granulomatous ILD; **noncaseating granulomas** (caseation should prompt search for infection); multisystem (see Ch. 379).
- ▶ **Hypersensitivity pneumonitis** — granulomatous reaction to inhaled organic (bird-fancier's lung) or inorganic dusts (see Ch. 299).
- ▶ **Granulomatous vasculitides** — GPA (Wegener's): lung nodules, ENT and glomerulonephritis, haemoptysis; eosinophilic GPA (Churg-Strauss): asthma, chronic sinusitis, peripheral eosinophilia.
- ▶ **Genetics:** the MUC5B promoter variant is present in ~20% of Caucasians and 35–45% of IPF patients (~sixfold risk); telomere-related genes (TERT, TERC, RTEL1) and surfactant genes (SFTPA2); sarcoidosis — HLA, IL12B, BTNL2; LAM — TSC1/TSC2; Hermansky-Pudlak syndrome (autosomal recessive: pulmonary fibrosis + oculocutaneous albinism + bleeding diathesis + nystagmus).

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Classification algorithm of ILD** (Fig. 304-1): a branching tree with the trunk “ILD” splitting into “Known cause” (branches: *Occupational* — asbestosis, silicosis; *Treatment-related* — radiation, methotrexate, amiodarone, nitrofurantoin, chemotherapeutics; *Systemic/CTD* — RA, scleroderma, polymyositis/dermatomyositis; *Granulomatous with vasculitis* — GPA, Churg-Strauss; HP) and “Unknown cause” (branches: *IIPs* — IPF, NSIP, RB-ILD, DIP, COP, AIP, LIP; *Sarcoidosis*; *Other* — LAM, alveolar proteinosis, Langerhans cell histiocytosis, pleural-parenchymal fibroelastosis).
- ▶ **UIP-pattern HRCT chest** (lower-zone slice): label *subpleural reticulation*, *posterior-basal predominance*, *honeycombing*, *traction bronchiectasis*.

Clinical / Diagnostic significance

- ▶ **Pattern-recognition decides therapy and prognosis:** a UIP/IPF diagnosis mandates **antifibrotics** and *avoidance of immunosuppression* (proven harmful), whereas **cellular NSIP** and COP respond well to immunosuppression — misclassification is dangerous.
- ▶ **HRCT + multidisciplinary review** can confidently diagnose IPF and spare a high-risk surgical biopsy.

- ▶ **Serial FVC and DLCO** are the practical tools for monitoring progression and predicting mortality.
- ▶ Always **screen for an occult CTD** (serology, examination) — ILD may be its first manifestation by years.
- ▶ **Lung transplantation** remains the standard of care for advanced/rapidly progressive ILD in eligible patients.

High-yield exam pointers

- ▶ ILD = >200 disorders; hallmark = restrictive PFT (↓TLC, ↓FVC, normal/↑ FEV1/FVC) with reduced DLCO.
- ▶ **UIP pattern** (subpleural, basal, honeycombing, traction bronchiectasis, fibroblast foci, temporal/spatial heterogeneity) = IPF — but also seen in RA.
- ▶ **IPF**: >60 yr, male, smoker; prevalence 50–200/100,000; 50% 3–5-yr survival; treat with **pirfenidone/nintedanib**.
- ▶ **NSIP**: non-smoking woman, CTD-associated, ground-glass dominant, honeycombing absent, 5-yr survival >80%.
- ▶ **COP**: subacute flu-like, **reversed halo (atoll) sign**, steroid-responsive ≥6 months.
- ▶ **AIP** = **Hamman-Rich** = idiopathic DAD, ARDS-like, >50% 6-month mortality.
- ▶ **Acute exacerbation of IPF**: onset <30 days, DAD, mortality >85%.
- ▶ **Anti-synthetase syndrome**: anti-Jo-1, myositis, fever, Raynaud's, **mechanic's hands**, ILD.
- ▶ **MUC5B** promoter variant — strongest common genetic risk factor for IPF (~6-fold).

SOURCE & COVERAGE

Harrison 22e — Ch 304 “Interstitial Lung Disease.” (Cross-references within the chapter: sarcoidosis Ch 379, hypersensitivity pneumonitis Ch 299, systemic sclerosis Ch 372, RA Ch 370, inflammatory myopathies Ch 377.) Coverage note: All classification, patterns, drugs, eponyms and numbers above are drawn from Ch 304; sarcoidosis and HP are only summarised here as Ch 304 defers their detail to Chs 379 and 299 (not provided), so granuloma-staging/specific sarcoid management is intentionally brief. The descriptor “*Velcro crackles*” is standard textbook terminology added for emphasis (Ch 304 states “end-inspiratory fine crackles, or rales”).

Lung Abscess

Asked in: Paper III Jul 2020 — RGUHS MD General Medicine

Definition / Introduction — A **lung abscess** is localised **necrosis and cavitation of lung parenchyma** following **microbial infection**, producing a pus-filled cavity. Abscesses may be single or multiple but

are usually marked by a **single dominant cavity >2 cm in diameter**, classically containing an **air–fluid level**. Most are a consequence of **aspiration of oropharyngeal anaerobes** in a susceptible host, and although their incidence has fallen sharply in the antibiotic era they remain an important cause of morbidity and mortality.

Classification

- ▶ **By origin:**
 - **Primary (~80%)** — arises from **aspiration**, predominantly **anaerobic**, in a host with **no underlying pulmonary/systemic disease**; occurs in immunocompetent individuals.
 - **Secondary** — develops on a background of an **underlying condition**: a **post-obstructive process** (bronchial tumour, foreign body) or a **systemic/immunocompromising state** (HIV, transplant, malignancy). Microbiology is broader and outcomes worse.
- ▶ **By chronicity:** **Acute (<4–6 weeks)** vs **chronic (~40% of cases; symptoms >1 month)**.
- ▶ **By microbiology:** defined by the isolate (e.g., *Pseudomonas* abscess); when **no pathogen is recovered (~40%)** it is termed a **nonspecific lung abscess** (anaerobes presumed). A **putrid lung abscess** = foul-smelling breath/sputum/empyema and is **virtually diagnostic of anaerobic infection**.
- ▶ **Special form: Necrotising pneumonia** = multiple small (<2 cm) cavities within an area of consolidation; lies on the same pathological continuum.

Etiology, Risk Factors and Microbiology

- ▶ **Cardinal risk factor = aspiration.** Predisposing states (CMDT/Harrison):
 - **Impaired consciousness / depressed gag** — alcoholism, drug overdose, sedatives, seizures, general anaesthesia, head trauma, stroke/CNS disease.
 - **Impaired deglutition** — bulbar dysfunction, neuromuscular disease, oesophageal dysmotility, strictures or tumours.
 - **Gastric distension / GERD, the recumbent position, and tracheal or nasogastric tubes** that breach airway defences.
- ▶ **Poor oral hygiene is pivotal:** colonisation of **gingival crevices** by anaerobes and microaerophilic streptococci (gingivitis, periodontal disease) supplies the inoculum. Abscess is considered **rare in the edentulous patient** — if it occurs without teeth, **suspect an obstructing bronchial lesion (malignancy)**.

Clinical setting	Typical pathogens
Primary (aspiration)	Anaerobes — <i>Peptostreptococcus</i> , <i>Prevotella</i> (incl. <i>P. melaninogenica</i>), <i>Bacteroides</i> (usually not <i>B. fragilis</i>), <i>Fusobacterium nucleatum</i> , <i>milleri</i> -group streptococci; microaerophilic streptococci

Clinical setting	Typical pathogens
Secondary / immunocompromised	<i>Staphylococcus aureus</i> , gram-negative rods (<i>Pseudomonas aeruginosa</i> , Enterobacteriaceae, <i>Klebsiella pneumoniae</i>), <i>Nocardia</i> , <i>Aspergillus</i> , Mucorales, <i>Cryptococcus</i> , <i>Legionella</i> , <i>Rhodococcus equi</i> , <i>Pneumocystis jirovecii</i>
Embolic	<i>S. aureus</i> (tricuspid endocarditis); <i>Fusobacterium necrophorum</i> (Lemierre's syndrome)
Endemic	<i>M. tuberculosis</i> , <i>M. avium</i> , <i>M. kansasii</i> ; <i>Coccidioides</i> , <i>Histoplasma</i> , <i>Blastomyces</i> ; parasites (<i>Entamoeba histolytica</i> , <i>Paragonimus westermani</i> , <i>Strongyloides</i>)
Miscellaneous	<i>S. aureus</i> post-influenza/viral infection; <i>Actinomyces</i>

- ▶ Primary abscesses are typically **polymicrobial**; with optimal anaerobic technique, isolate recovery is reported as high as 78%.

Pathogenesis

- ▶ **Primary abscess**: aspirated **anaerobes/microaerophilic streptococci** from the gingival crevices reach the parenchyma in a host with a large aspirated burden or poor clearance → **pneumonitis** (aggravated by gastric-acid injury) → over 7–14 days the bacteria produce **parenchymal necrosis and cavitation**. Anaerobes act **synergistically** in polymicrobial infection to amplify tissue destruction.
- ▶ **Secondary abscess**: a **bronchial obstruction** (tumour, foreign body) blocks clearance of secretions distally; or **impaired host defence** allows opportunists to cavitate.
- ▶ **Septic embolic abscess**: seeding from **right-sided (tricuspid) endocarditis** (*S. aureus*), or **Lemierre's syndrome** — oropharyngeal *F. necrophorum* infection spreads to the **carotid sheath** → **septic thrombophlebitis of the internal jugular vein** with showering of septic pulmonary emboli.
- ▶ **Location reflects gravity**: the dependent segments — **posterior segments of the upper lobes and superior segments of the lower lobes** — are most affected; the **right lung** > left because the **right main bronchus** is wider, shorter and less angulated.

Clinical Features

- ▶ **Anaerobic (typical primary) abscess** — **indolent, subacute**: low-grade fever, cough, sputum over weeks, with **night sweats, fatigue, weight loss and anaemia**; a subset expectorate **foul-tasting / foul-smelling (putrid) sputum**, occasionally pleuritic pain or haemoptysis.
- ▶ ***Non-anaerobic (e.g., S. aureus, Klebsiella) abscess** — **more fulminant*** course with high fever and rapid progression.

- ▶ **Examination:** fever, poor dentition / gingival disease, amphoric or cavernous breath sounds, digital clubbing (chronic), an absent gag reflex; crackles, egophony or dullness if an effusion coexists.

Investigations and Diagnosis

- ▶ **Imaging is the cornerstone.**
 - **Chest radiograph** — thick-walled cavity with an air–fluid level and surrounding consolidation in a dependent segment.
 - **CT chest** — superior definition, detects cavitation early, distinguishes a peripheral abscess from empyema (a treatment-critical distinction), and screens for an underlying obstructing lesion/malignancy.

Feature	Lung abscess	Empyema	Malignant cavity	Septic emboli
Shape	Round (equal in all views)	Oblong/lenticular	Variable, often nodular	Multiple nodules 1–3 cm
Inner wall	Ragged/"shaggy", irregular	Smooth lining	Nodular, thick (≥ 16 mm)	Cavities at differing stages
Effect on lung	Destroys parenchyma; no compression	Compresses adjacent lung	—	Subpleural wedge infarcts
Air–fluid level	Present	May split pleura	Variable	—

- ▶ **Microbiology:** expectorated sputum Gram stain + aerobic, mycobacterial and fungal culture (anaerobic cultures often falsely negative unless rapidly transported/plated). Thoracentesis if effusion present (uncontaminated specimen + excludes empyema). Blood cultures + echocardiography when septic emboli/endocarditis suspected. Molecular methods (e.g., 16S rRNA gene amplification) may improve pathogen identification.
- ▶ **Bronchoscopy** — performed early when bronchial obstruction (tumour/foreign body) is suspected, in non-responders, and in immunocompromised hosts (BAL for opportunists); also therapeutic. Risk: spillage of pus into the contralateral lung.
- ▶ **CT-guided transthoracic needle aspiration** — clean culture specimen, considered early for abscesses >4 cm; risks pneumothorax and bronchopleural fistula.
- ▶ **Endemic/HIV settings:** examine induced sputum for TB early. ANCA if a vasculitis (granulomatosis with polyangiitis) is suspected.

Treatment

- ▶ **Empirical antibiotics must cover anaerobes AND microaerophilic streptococci:**
 - Clindamycin 600 mg IV TID $\rightarrow$ 300 mg PO QID — superior to penicillin in trials (oral anaerobes elaborate β -lactamase); or

- A β -lactam/ β -lactamase inhibitor (ampicillin-sulbactam, piperacillin-tazobactam) IV $\rightarrow$ oral amoxicillin-clavulanate on stabilisation; or a carbapenem.
- Metronidazole alone fails — it misses the microaerophilic streptococci of the mixed flora. Meropenem monotherapy also lacks reliable streptococcal cover. Moxifloxacin 400 mg/day PO is as effective as ampicillin-sulbactam in small trials. CMDT second-line: 3rd-generation cephalosporin + metronidazole, or a fluoroquinolone.
- Targeted cover for monomicrobial isolates: MSSA — cefazolin/nafcillin/oxacillin; MRSA — linezolid (alternative vancomycin; avoid daptomycin — inactivated by surfactant/poor lung penetration).
- ▶ Duration: prolonged — commonly 4–6 weeks, ranging up to 14 weeks; continue until the cavity has cleared or regressed to a small stable scar on imaging (≥ 6 weeks linked to better outcomes).
- ▶ Response: clinical improvement by 3–4 days, defervescence by 7–10 days. 10–20% fail to respond; an abscess >6 –8 cm is less likely to respond to antibiotics alone.
- ▶ Drainage / surgery (~10% of cases): indicated for failure of medical therapy, massive/life-threatening haemoptysis, bronchopleural fistula, empyema, large cavity (>6 cm), or an obstructed bronchus.
 - Percutaneous (CT/US-guided) catheter drainage — for abscess >4 cm, peripheral, or poorly draining lesions, and in poor surgical candidates; place the affected lung dependent to limit spillage. Risks: pneumothorax, haemothorax, pleural seeding/empyema.
 - Endoscopic (bronchoscopic pigtail) drainage — for central lesions or coagulopathy.
 - Surgical resection — lobectomy preferred to segmentectomy (avoids residual necrotic tissue/re-infection); VATS for peripheral lesions; a double-lumen endotracheal tube protects the contralateral lung.
- ▶ Relieve the obstruction and treat the predisposing condition in secondary abscess.

Complications and Prognosis

- ▶ Complications: massive/life-threatening haemoptysis (from hypertrophied bronchial arteries), empyema and bronchopleural fistula, pneumatoceles, bronchiectasis, mediastinitis, recurrence, massive aspiration of cavity contents, and metastatic infection — brain abscess / stroke (clots bypass the pulmonary filter; brain-abscess risk markedly raised, adjusted OR ≈ 8.2).
- ▶ Prognosis: mortality of primary abscess is as low as 2% (overall 15–20% historically); secondary abscess mortality reaches ~75%. Poor prognostic markers: age >60 years, malignancy-related abscess, aerobic organisms, sepsis at presentation, symptom duration >8 weeks, and abscess size >6 cm.
- ▶ Prevention: airway protection, oral hygiene/dental care, minimised sedation with head-of-bed elevation in aspiration-prone patients, and pathogen-specific prophylaxis in selected immunocompromised hosts.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Labelled chest CT / radiograph of a lung abscess:** cavity wall, air–fluid level, surrounding consolidation/ground-glass opacity, ragged inner lining, dependent location (posterior segment right upper lobe). Labels: *Cavity, Air–fluid level, Thick irregular wall, Surrounding consolidation, Right upper lobe (posterior segment)*.
- ▶ **Pathogenesis flow diagram:** *Aspiration of gingival anaerobes → Pneumonitis (7–14 days) → Parenchymal necrosis → Cavitation with air–fluid level → Complications (empyema, haemoptysis, brain abscess).*

Clinical / Diagnostic significance

- ▶ Distinguishing abscess from empyema on CT is treatment-defining — a tube thoracostomy placed inadvertently into an abscess can create a **bronchopleural fistula**; empyema mandates drainage.
- ▶ A lung abscess in an edentulous patient, or one failing therapy, demands bronchoscopy to exclude an obstructing carcinoma or foreign body.
- ▶ Putrid sputum at the bedside is essentially pathognomonic of **anaerobic** infection and guides empirical therapy.
- ▶ Multiple/peripheral cavities at different stages point to **septic emboli** — look for tricuspid endocarditis or Lemierre's syndrome; obtain blood cultures and echocardiography.

High-yield exam pointers

- ▶ Cavity >2 cm with air–fluid level; primary ~80%, chronic ~40%, nonspecific (culture-negative) ~40%.
- ▶ Right lung > left; posterior upper / superior lower segments (dependent).
- ▶ Anaerobes + microaerophilic streptococci → clindamycin (or β -lactam/ β -lactamase inhibitor) preferred; penicillin/metronidazole monotherapy inadequate.
- ▶ Putrid sputum = anaerobic; edentulous abscess = suspect tumour.
- ▶ Lemierre's syndrome = *Fusobacterium necrophorum*, internal-jugular septic thrombophlebitis.
- ▶ Antibiotics 4–6 weeks (up to ~14); treat until radiographic resolution/scar.
- ▶ Surgery/drainage if failure, >6 cm, massive haemoptysis, empyema, BPF, obstruction.
- ▶ Mortality: primary ~2%, secondary up to ~75%; poor signs — age >60, sepsis, aerobes, >8 weeks, >6 cm.

SOURCE & COVERAGE

- ▶ **Harrison's Principles of Internal Medicine, 22e** — “Lung Abscess” (definition, classification, Table 132-1 microbial causes, pathogenesis, Lemierre's syndrome, antibiotic regimens and durations, prognosis, prevention).
- ▶ **Murray & Nadel's Textbook of Respiratory Medicine, 7e** — “Lung Abscess” (radiographic differentiation from empyema/malignancy/septic emboli, microbiology, targeted MSSA/MRSA therapy, percutaneous and endoscopic drainage, surgical indications, brain-abscess association).

Management of Acute Respiratory Distress Syndrome

Asked in: Paper III Nov 2020 — RGUHS MD General Medicine

Definition / Introduction — Acute respiratory distress syndrome (ARDS) is a clinical syndrome of rapid-onset severe dyspnoea, refractory hypoxaemia and diffuse bilateral pulmonary infiltrates due to diffuse alveolar–capillary injury that is not fully explained by cardiac failure or volume overload. It results from a high-permeability (non-cardiogenic) pulmonary oedema following direct (e.g. pneumonia, aspiration, toxic inhalation) or indirect (e.g. sepsis, pancreatitis, multiple transfusions) lung injury. There is **no specific pharmacotherapy that improves survival**; management is therefore built on aggressive treatment of the precipitating cause plus meticulous, evidence-based supportive care, with **lung-protective mechanical ventilation as the only intervention of proven mortality benefit**.

Diagnostic framework & severity grading (Berlin definition, 2012)

Establishing the diagnosis and severity is the first step because it dictates the ladder of therapy (proning/NMB/ECMO are reserved for the more severe categories).

Berlin criterion	Requirement
Timing	Within 1 week of a known clinical insult or new/worsening respiratory symptoms
Chest imaging	Bilateral opacities (X-ray or CT) not fully explained by effusions, lobar/lung collapse or nodules
Origin of oedema	Respiratory failure not fully explained by cardiac failure/fluid overload; if no risk factor present, exclude hydrostatic oedema objectively (e.g. echocardiography)

Berlin criterion	Requirement
Oxygenation (on PEEP/CPAP ≥ 5 cmH ₂ O)	Mild: $200 < \text{PaO}_2/\text{FiO}_2 \leq 300$; Moderate: $100 < \text{PaO}_2/\text{FiO}_2 \leq 200$; Severe: $\text{PaO}_2/\text{FiO}_2 \leq 100$ mmHg

- ▶ Pulmonary-artery wedge-pressure criterion of the older AECC definition has been **dropped** (PA catheters no longer routine); the term *acute lung injury (ALI)* has been **abolished**.
- ▶ Proposed 2023/2024 updates allow **non-intubated** patients on high-flow nasal oxygen (≥ 30 L/min) or NIV, the **SpO₂/FiO₂ (S/F) ratio** (≤ 315 if SpO₂ $\leq 97\%$) and **lung ultrasound** to be used in resource-limited settings.
- ▶ Natural history runs through three overlapping phases: **exudative** ($\approx$ first 7 days; alveolar oedema, hyaline membranes, diffuse alveolar damage), **proliferative** ($\approx$ day 7–21; type-II pneumocyte proliferation, early organisation) and **fibrotic** (after ≈ 3 –4 weeks; alveolar-duct/interstitial fibrosis, bullae, pulmonary hypertension).

General principles & supportive care

- ▶ **Treat the precipitating cause** — antibiotics and source control for sepsis/pneumonia, surgical débridement/drainage where indicated (both lung and abdomen should be excluded as septic foci).
- ▶ ICU “**bundled care**”: VTE prophylaxis, stress-ulcer prophylaxis, head-of-bed elevation to 30–45° and aspiration precautions, prevention of central-line infection, **daily sedation interruption** and minimisation of unnecessary procedures.
- ▶ **Enteral nutrition** via the enteral route when feasible; trophic and full feeding give equivalent outcomes, and **immunonutrition / omega-3 supplementation is not recommended**.
- ▶ **Transfusion:** maintain haemoglobin ≥ 7 g/dL (restrictive threshold); higher levels confer no benefit.

Lung-protective mechanical ventilation (cornerstone of therapy)

Most patients fatigue and require intubation, though high-flow nasal oxygen / NIV may avert this in milder disease. The aim is adequate gas exchange **while limiting ventilator-induced lung injury (VILI)** — *volutrauma* (alveolar overdistension), *barotrauma* (high pressure), *atelectrauma* (cyclic collapse–reopening) and *biotrauma* (mechano-inflammatory cytokine release).

- ▶ **Low tidal volume (ARMA/ARDSNet trial):** tidal volume **6 mL/kg predicted body weight** with **plateau pressure ≤ 30 cmH₂O** reduced mortality from 39.8% to 31.0% versus 12 mL/kg — the single landmark survival benefit. *Predicted body weight (kg): men = $50 + 0.91 \times (\text{height cm} - 152.4)$; women = $45.5 + 0.91 \times (\text{height cm} - 152.4)$.*
- ▶ **Mode:** volume assist-control is standard; pressure-control is equivalent.
- ▶ **PEEP / “open-lung”:** PEEP prevents atelectrauma and recruits dependent lung, allowing a lower FiO₂ (reduce O₂ toxicity). Higher PEEP is **safe and improves oxygenation but trials show no**

clear mortality benefit; set using the ARDSNet PEEP–FiO₂ table. Favour higher PEEP in severe ARDS (P/F <150) provided haemodynamics tolerate it.

- ▶ **Driving pressure** (plateau – PEEP) may matter more than absolute tidal volume; keeping it low (commonly targeted ≤15 cmH₂O) is associated with better survival.
- ▶ **Permissive hypercapnia**: accept a rising PaCO₂ to protect the lung, keeping pH ≥7.30 (the survival-positive ARDSNet trial treated acidosis aggressively, so avoid marked hypercapnia where possible; caution if raised intracranial pressure).
- ▶ **Oxygenation targets**: SpO₂ 88–95% / PaO₂ 55–80 mmHg using the lowest FiO₂ (aim <0.6).

ARDSNet ventilation protocol	Setting
Mode	Volume assist-control
Tidal volume	≤6 mL/kg predicted body weight
Plateau pressure	≤30 cmH ₂ O
Respiratory rate	6–35/min, titrated to pH 7.30–7.45
Oxygenation goal	PaO ₂ 55–80 mmHg or SpO ₂ 88–95%
PEEP/FiO ₂	Pre-set escalating combinations

Adjuncts for moderate–severe / refractory ARDS

- ▶ **Prone positioning** — for early, severe ARDS (P/F <150 mmHg): improves V/Q matching and lung homogeneity. The **PROSEVA trial** (prone ≥16 h/day) cut 28-day mortality markedly (16% vs 33%). Requires an experienced team; *unstable spinal injury is an absolute contraindication*; watch for tube/line dislodgement and pressure sores.
- ▶ **Neuromuscular blockade** — early **cisatracurium** infusion for 48 h improves patient–ventilator synchrony and abolishes injurious “reverse triggering”. **ACURASYS** showed a 90-day mortality benefit (31.6% vs 40.7%) but **ROSE** (light-sedation control) showed none — hence reserve NMB for severe ARDS with refractory dyssynchrony/high respiratory drive, **not routine use**.
- ▶ **ECMO / extracorporeal life support** — *salvage* for very severe, refractory hypoxaemia, refractory respiratory acidosis or barotrauma. **VV-ECMO** for isolated respiratory failure, **VA-ECMO** when circulatory support is also needed, **ECCO₂R** for CO₂ removal. **CESAR** showed benefit from referral to an ECMO centre; **EOLIA** showed a non-significant mortality reduction (35% vs 46%, with 28% control crossover). Select patients with a **reversible illness, good prior functional/neurological status, no contraindication to anticoagulation**.
- ▶ **Inhaled pulmonary vasodilators** (nitric oxide, epoprostenol/prostacyclin) — transiently improve oxygenation with **no survival benefit** (NO may worsen renal function); rescue use only.
- ▶ **Recruitment manoeuvres** and **high-frequency oscillatory ventilation** are **not recommended** — recruitment + high PEEP and HFOV increased mortality in trials.

Fluid management, pharmacotherapy & evidence summary

- **Conservative fluid strategy (FACTT):** in patients **not in shock**, fluid restriction and diuresis to a low filling pressure (CVP <4 / PAOP <8 mmHg) gave more ventilator-free and ICU-free days without more shock or dialysis. Use **balanced crystalloids**; **pulmonary-artery catheters are not routinely indicated**.
- **Corticosteroids** — historically discouraged, but contemporary evidence (DEXA-ARDS: **dexamethasone 20 mg/day ×5 then 10 mg/day ×5**) showed more ventilator-free days (12.3 vs 7.5) and lower 60-day mortality (21% vs 36%); the **2024 ATS guideline conditionally recommends corticosteroids**, most useful when started <14 days, in severe community-acquired pneumonia or COVID-19. Low-dose **hydrocortisone (200 mg/24 h)** is recommended in septic shock with refractory hypotension and in severe CAP — conditions that frequently coexist with ARDS.
- **Disappointing/ineffective therapies:** exogenous surfactant, β_2 -agonists (salbutamol — harmful), statins, ketoconazole, NSAIDs/ibuprofen, N-acetylcysteine, and partial liquid ventilation.

Therapy	Harrison evidence grade
Low tidal volume ventilation	A (strong RCT evidence)
Minimised left-atrial filling pressure	B
High-PEEP / open-lung	B
Prone positioning (severe ARDS)	B
ECMO (select severe ARDS)	B
Recruitment manoeuvres	C
Routine early neuromuscular blockade	C
High-frequency ventilation	D (against)
Glucocorticoids (routine)	D (against)
Inhaled vasodilators	C
Surfactant / other anti-inflammatory	D (against)

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- **Time-course of ARDS (phase diagram):** an x-axis “Days 0 → 2 → 7 → 14 → 21” with three labelled boxes — *Exudative phase* (alveolar Oedema, Hyaline membranes, neutrophilic/interstitial inflammation, diffuse alveolar damage), *Proliferative phase* (interstitial inflammation, **type-II pneumocyte proliferation**, early fibrosis) and *Fibrotic phase* (Fibrosis, bullae, pulmonary hypertension).

Therapy	Harrison evidence grade
▶ Lung-protective ventilation management algorithm: boxes labelled “Initiate volume/pressure-limited ventilation → Tidal volume ≤ 6 mL/kg PBW, Plateau ≤ 30 cmH₂O, RR ≤ 35” → “Oxygenate: FiO₂ ≤ 0.6, SpO₂ 88–95%” → “Minimise acidosis: pH ≥ 7.30” → “Conservative fluid/diuresis: MAP ≥ 65, avoid hypoperfusion” → severe/refractory branch: “Prone (P/F <150) → NMB → ECMO”.	

Clinical / Diagnostic significance

- ▶ **Differential diagnosis** to exclude: cardiogenic pulmonary oedema (echocardiography; BNP is unreliable for separating the two), diffuse alveolar haemorrhage, bilateral pneumonia, acute interstitial pneumonia and acute eosinophilic pneumonia.
- ▶ **Prognosis:** in-hospital mortality ~30–40% (LUNG SAFE: **34.9% mild, 40.3% moderate, 46.1% severe**); **>80% of deaths are from non-pulmonary causes** (sepsis, multi-organ failure), not refractory hypoxaemia — explaining why supportive ICU care drives survival.
- ▶ Adverse prognostic markers: advanced age, chronic liver disease/alcohol abuse, immunosuppression, direct (vs indirect) lung injury, and a **hyperinflammatory (high IL-6) sub-phenotype**.
- ▶ **Survivor sequelae:** most regain near-normal spirometry by 6–12 months, but **ICU-acquired weakness, reduced 6-minute-walk distance, neurocognitive impairment, depression and PTSD** are common and warrant follow-up.
- ▶ Watch for **ventilation complications:** barotrauma (pneumothorax/pneumomediastinum), **ventilator-associated pneumonia**, post-extubation stridor (do a cuff-leak test), stress ulceration, VTE and delirium.

High-yield exam pointers

- ▶ **Low tidal volume (6 mL/kg PBW) + plateau ≤ 30 cmH₂O is the ONLY ventilator strategy proven to reduce mortality (ARDSNet/ARMA).**
- ▶ Berlin severity = PaO₂/FiO₂ on PEEP ≥ 5 : mild ≤ 300 , moderate ≤ 200 , severe ≤ 100 mmHg.
- ▶ **PROSEVA** — prone positioning >16 h/day in severe ARDS (P/F <150) improves survival.
- ▶ **Cisatracurium $\times 48$ h (ACURASYS)** — selective, not routine (ROSE negative).
- ▶ **Conservative fluid strategy (FACTT)** → more ventilator-free days; **balanced crystalloids**; no routine PA catheter.
- ▶ **ECMO = salvage** (VV for lungs, VA for lungs + circulation, ECCO₂R for CO₂); EOLIA/CESAR.
- ▶ **Dexamethasone/low-dose steroids** beneficial in **early (<14 day) ARDS**; 2024 ATS conditional recommendation.

- ▶ Liberate early via **daily spontaneous breathing trials**, not slow “weaning”; permissive hypercapnia ($\text{pH} \geq 7.30$), SpO_2 88–95%, $\text{FiO}_2 < 0.6$.
- ▶ **No mortality benefit**: surfactant, inhaled NO, β_2 -agonists, HFOV, statins, recruitment manoeuvres.
- ▶ Most ARDS deaths are due to **sepsis / multi-organ failure**, not hypoxaemia.

SOURCE & COVERAGE

- ▶ **Harrison’s Principles of Internal Medicine, 22e** — “Acute Respiratory Distress Syndrome” and “Mechanical Ventilatory Support” (Berlin criteria, ARDSNet low-VT trial, evidence-grade recommendations table, management algorithm, ECMO classification, liberation/SBT).
- ▶ **Murray & Nadel’s Textbook of Respiratory Medicine, 7e** — “Acute Respiratory Distress Syndrome” (Berlin definition table, predicted-body-weight formulas, ARDSNet protocol, FACTT conservative fluid, DEXA-ARDS/ACURASYS/ROSE/PROSEVA/CESAR/EOLIA trials, driving pressure, permissive hypercapnia, long-term outcomes).
- ▶ **CMDT 2026** — “Pulmonary Disorders: Acute Respiratory Distress Syndrome” (current diagnostic essentials, conservative fluid targets, $\text{Hb} \geq 7$ g/dL, 2024 ATS corticosteroid guidance, ECMO salvage, prognosis).

Non resolving Pneumonia

Asked in: Paper III Jun 2024 — RGUHS MD General Medicine

Definition / Introduction — *Non-resolving (non-responding) pneumonia* describes a clinical scenario in which a patient treated empirically for pneumonia fails to show the **expected clinical and/or radiographic improvement** within the anticipated time-frame. Two overlapping patterns are recognised: **non-responding pneumonia** (clinical improvement is not achieved — persistent fever and symptoms despite therapy) and **progressive pneumonia** (clinical deterioration to respiratory failure or septic shock). Radiographically, the term also covers *slowly resolving pneumonia*, where infiltrates persist beyond the expected resolution period despite adequate antibiotics. It is best regarded not as a single disease but as a **clinical syndrome** mandating a systematic search for resistant organisms, sequestered infection, an unexpected pathogen, or a non-infectious mimic.

Defining the problem — timelines and patterns

- ▶ **Expected normal response (CAP)**: with appropriate antibiotics a clinical response is usually evident within **24–48 h** (*pneumococcus*, *Legionella*); fever and leukocytosis settle in **2–4 days** in otherwise healthy patients; physical signs persist longer.

- ▶ **Radiographic clearance is the slowest variable** — 4–12 weeks, and is slower in the elderly, in underlying lung disease, and with certain pathogens (e.g. *Legionella* infiltrates may progress despite clinical improvement and take months to clear).
- ▶ A widely used working definition of *non-resolving pneumonia* is **failure of the infiltrate to clear by $\geq 50\%$ at 2 weeks or to clear completely by 4 weeks** despite ≥ 10 days of antibiotics (standard internal medicine; the corpus supports the 4–12-week clearance window).
- ▶ **Timing of reassessment:** evaluate the slow responder at **~ 72 h (day 3)** — or sooner if deteriorating. Earlier escalation is reserved for severe clinical deterioration or dramatic radiologic progression.

Pattern	Defining feature	Typical timing
Early treatment failure	Progressive deterioration / no response	< 72 h of therapy
Non-responding pneumonia	Persistent fever and symptoms, no improvement	Assessed at ≥ 72 h
Progressive pneumonia	Clinical deterioration $\rightarrow$ respiratory failure / septic shock	Any time
Slowly resolving pneumonia	Clinical improvement but infiltrate persists	Beyond 4–12 weeks

Causes / differential diagnosis (the core of the answer)

Causes are classified as **infectious, non-infectious, and of unknown origin**. In hospitalised CAP a specific infection is found in $\sim 40\%$ of non-responders, a non-infectious cause in $\sim 22\%$, and **no cause is identified in $\sim 30\%$** despite adequate treatment.

Category	Mechanism	Examples
Resistant / wrong-spectrum organism	Pathogen not covered or resistant to empirical drug	Drug-resistant <i>S. pneumoniae</i> ; MRSA / CA-MRSA; <i>P. aeruginosa</i> ($\sim 10\%$ of non-responding CAP, not covered unless a fluoroquinolone used); <i>Acinetobacter</i> ; carbapenemase-producing <i>Klebsiella</i>
Unexpected / unusual pathogen	Outside the CAP empirical spectrum	<i>M. tuberculosis</i> , <i>Nocardia</i> , endemic fungi, <i>Pneumocystis jirovecii</i> , anaerobes, protozoa, viruses
Sequestered / complicated focus	Antibiotic cannot reach organism	Empyema / complicated parapneumonic effusion, lung abscess, necrotizing pneumonia

Category	Mechanism	Examples
Metastatic / extrapulmonary infection	Seeding (commoner if bacteraemic)	Endocarditis, brain abscess, septic arthritis, pericarditis, meningitis; nosocomial superinfection
Inadequate therapy	Right diagnosis, wrong execution	Wrong drug, wrong dose/frequency, poor absorption/compliance
Host factors	Impaired response	Immunodeficiency (HIV), age, comorbidity, exaggerated or blunted inflammatory response
Non-infectious mimics	Disease that simulates pneumonia	Pulmonary embolism/infarction, pulmonary oedema, malignancy (esp. lepidic/"alveolar-cell" adenocarcinoma), bronchial obstruction, organizing pneumonia (COP/BOOP), eosinophilic pneumonia, hypersensitivity pneumonitis, drug-induced lung disease, pulmonary haemorrhage/vasculitis (e.g. granulomatosis with polyangiitis), sarcoidosis, radiation pneumonitis, connective-tissue disease, ARDS

The most frequent organisms in proven infectious non-response are ***S. pneumoniae*, *Legionella*, *P. aeruginosa* and *S. aureus*.**

Stepwise approach to evaluation

- ▶ **Re-take history and examine again** — epidemiologic clues (travel, occupational/animal exposure, TB contact, aspiration risk, immunosuppression, drug history) and reconsider the *original* diagnosis.
- ▶ **Biomarkers:** failure of **procalcitonin (PCT)** to fall after 3–4 days suggests inadequate response; high baseline PCT/CRP (and IL-6) independently predict poor response.
- ▶ **Repeat & extend microbiology:** new blood and sputum cultures; urinary antigens (*pneumococcus*, *Legionella*); respiratory-virus and SARS-CoV-2 testing; sputum AFB/molecular TB testing early in endemic settings or HIV.
- ▶ **Cross-sectional imaging** — **chest CT** is pivotal: detects empyema, abscess, cavitation, endobronchial obstruction, lymphadenopathy, and patterns suggesting a specific aetiology —
 - *halo sign* (nodule + ground-glass rim) → **invasive aspergillosis / mucormycosis**;
 - diffuse ground-glass → **PJP**;

- nodules/masses $\pm$ cavitation $\rightarrow$ **Nocardia**, TB, Q fever;
- consider CT-pulmonary angiography to exclude pulmonary embolism and endobronchial lesions.
- ▶ **Bronchoscopy** with BAL + **protected specimen brush** (sensitivity $\sim$ 40% in non-responding CAP) for culture, DFA and nucleic-acid testing; allows direct airway inspection for **obstruction** (tumour, foreign body) and **transbronchial / endobronchial biopsy** when a non-infectious cause (malignancy, COP, vasculitis) is suspected.
- ▶ **Thoracentesis** for any significant pleural effusion — drainage is indicated if fluid pH < 7.2 , glucose < 2.2 mmol/L, LDH > 1000 U/L, or organisms are seen/cultured (complicated effusion / empyema).
- ▶ **Escalate antibiotics** only after re-sampling — broaden to cover resistant pneumococcus, *P. aeruginosa*, MRSA and anaerobes as dictated by risk; add antifungal/anti-TB cover when the clinical scenario supports it; transfer to higher-level care if deteriorating.

Key complicating entities to exclude

- ▶ **Lung abscess** — necrosis/cavitation (dominant cavity > 2 cm). **Primary** ($\sim$ 80%) from aspiration of anaerobes/microaerophilic streptococci, favouring **dependent segments (posterior segments of upper lobes, superior segments of lower lobes), right $>$ left**; *putrid* (foul) sputum $\approx$ anaerobic. **Secondary** abscess implies post-obstructive (tumour, foreign body) or immunocompromise. Treat with **clindamycin** (600 mg IV tds $\rightarrow$ 300 mg PO qds) or a β -lactam/ β -lactamase inhibitor for 3–4 up to $\sim$ 14 weeks; *metronidazole alone is inadequate*. Cavities > 6 –8 cm, or non-response, may need drainage/surgery.
- ▶ **Pulmonary tuberculosis** — a classic “great mimic” of non-resolving consolidation; obtain sputum AFB, NAAT (e.g. cartridge-based) and culture early, especially with weight loss, upper-lobe disease, cavitation or HIV.
- ▶ **Bronchogenic carcinoma / post-obstructive pneumonia** — suspect strongly with **recurrence in the same segment**, in smokers, or non-clearing infiltrate; bronchoscopy $\pm$ CT mandatory.
- ▶ **Lemierre’s syndrome** — *Fusobacterium necrophorum* oropharyngeal infection with septic jugular thrombophlebitis and cavitating septic emboli.

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- ▶ **Algorithm** — “Approach to the non-resolving pneumonia” (vertical flowchart). Labels: *Empirical Rx for pneumonia $\rightarrow$ Reassess at 72 h (day 3) $\rightarrow$ branch into Non-responding vs Progressive $\rightarrow$ Re-history & examine + reconsider diagnosis $\rightarrow$ Repeat cultures, PCT/CRP, urinary antigens, TB/viral tests $\rightarrow$ Chest CT $\rightarrow$ Bronchoscopy (BAL + PSB $\pm$ biopsy) / Thoracentesis $\rightarrow$ outcome boxes: Resistant/unexpected organism, Empyema/abscess (drain), Non-infectious mimic (PE, malignancy, COP, vasculitis), Inadequate therapy.*

- ▶ **Labelled chest CT of a lung abscess:** thick-walled cavity, **air–fluid level**, surrounding consolidation, located in a dependent (posterior upper / superior lower lobe) segment — with a small inset contrasting **abscess vs empyema** (lenticular pleural collection, split-pleura sign).

Clinical / Diagnostic significance

- ▶ Re-labelling a “treatment failure” correctly prevents both **antibiotic over-escalation** and **missed malignancy/TB/PE** — the commonest avoidable errors.
- ▶ **Empyema and abscess** are the most frequent infectious complications requiring a *procedure*, not just a drug change — always image the pleura and tap significant effusions.
- ▶ A **follow-up chest radiograph** at ~4–6 weeks is recommended after hospitalised CAP; **relapse or recurrence in the same bronchopulmonary segment** demands exclusion of an underlying **neoplasm or focal bronchiectasis**.
- ▶ Older patients and those with COPD, diabetes, alcoholism, multilobar disease or bacteraemia resolve more slowly — a *slowly resolving* course in this group may still be benign and need only observation with serial imaging rather than invasive work-up.

High-yield exam pointers

- ▶ **Reassess the non-responder at 72 h (day 3);** wait that long unless rapidly deteriorating.
- ▶ Causes = **infectious (40%) / non-infectious (22%) / unknown (≈30%)**.
- ▶ Commonest infectious culprits: **pneumococcus*, *Legionella*, *P. aeruginosa*, *S. aureus***; *P. aeruginosa* ≈ 10%* of non-responders.
- ▶ Must-exclude non-infectious mimics: **PE, malignancy, organizing pneumonia, eosinophilic pneumonia, vasculitis, pulmonary oedema**.
- ▶ **CT chest + bronchoscopy (BAL/PSB)** are the key escalation investigations; BAL sensitivity ~40%.
- ▶ Drain a parapneumonic effusion if **pH < 7.2, glucose < 2.2 mmol/L, LDH > 1000 U/L** or organisms present.
- ▶ **Lung abscess:** anaerobic, dependent segments, right > left; **clindamycin** first-line, **metronidazole alone fails**; cavity >6–8 cm → consider drainage/surgery.
- ▶ **Recurrence in the same segment** → think **carcinoma / focal bronchiectasis**. TB and HIV must be actively excluded.

SOURCE & COVERAGE

- ▶ **Harrison’s Principles of Internal Medicine, 22e** — “Pneumonia” (Failure to Improve, Complications, Follow-up) and “Lung Abscess.”

- **Murray & Nadel's Textbook of Respiratory Medicine, 7e** — “Community-Acquired Pneumonia” (Nonresponding Pneumonia / Treatment Failure; infectious vs non-infectious causes; diagnostic evaluation, biomarkers, imaging and bronchoscopy).
- **CMDT 2026** — “Pulmonary Disorders” (Pneumonia; Anaerobic Pneumonia & Lung Abscess — drainage and surgical indications).

Coverage note: The corpus richly covers the syndrome, its causes, evaluation and the abscess/empyema complications. The quantitative radiographic criterion (“<50% clearance at 2 weeks / clearance by 4 weeks”) is stated as standard internal medicine; the corpus directly supports the 4–12-week clearance window and the ≥72-h reassessment point rather than that exact percentage cut-off.

Obesity and Obstructive Sleep Apnoea

Asked in: Paper I Nov 2022 — RGUHS MD General Medicine

Definition / Introduction — **Obesity** is a chronic, heterogeneous disorder of excess body fat conventionally graded by **body mass index** ($\text{BMI} = \text{weight kg} / \text{height m}^2$), leading to multiple metabolic, mechanical and cardiovascular complications. **Obstructive sleep apnoea (OSA)** is a sleep-related breathing disorder defined by recurrent episodes of pharyngeal collapse during sleep causing apnoeas/hypopnoeas, intermittent hypoxaemia and arousals, with daytime sleepiness and impaired function. The two are tightly linked: obesity is the single most important modifiable risk factor for OSA, and OSA in turn amplifies obesity's cardio-metabolic harm — hence they are best understood and answered together.

Classification of obesity (WHO / BMI) and abdominal adiposity

- BMI correlates with body fat and disease risk and is the standard screening/population tool; its limitation is that it measures **size, not composition or fat distribution**. Lower thresholds apply to the Asia-Pacific (South Asian) population, who are metabolically at risk at lower weights.

Classification	BMI (kg/m ²)	Obesity class	Disease risk
Underweight	<18.5	—	—
Healthy weight	18.5–24.9	—	—
Overweight	25.0–29.9	—	Increased
Obesity	30.0–34.9	I	High
Obesity	35.0–39.9	II	Very high
Extreme obesity	≥40	III	Extremely high

- ▶ **Waist circumference** (surrogate for visceral fat, measured horizontally above the iliac crest in those with BMI ≤ 35) independently predicts metabolic syndrome, diabetes and CVD. Ethnic cut-points: **Europeans** men >94 cm / women >80 cm; **South Asians & Chinese** men >90 cm / women >80 cm.
- ▶ **Functional/clinical staging**: the **AACE/ACE** system stages by BMI *plus* adiposity-related complications — Stage 0 (no complication), Stage 1 (mild–moderate complication, e.g. *OSA with AHI 5–30 and mild symptoms*), Stage 2 (severe complication, e.g. *OSA with symptoms or AHI >30*). The **Edmonton Obesity Staging System (EOSS)** grades 0–4 across medical, functional and psychological domains independent of BMI.

Obesity → OSA: pathophysiological link

- ▶ During inspiration intraluminal pharyngeal pressure becomes negative (a “suction” force); because the pharynx has **no bony/cartilaginous support**, patency depends on **pharyngeal dilator muscle** tone, which falls at sleep onset — producing transient collapse (**apnoea**) or near-collapse (**hypopnoea**).
- ▶ **Obesity narrows and collapses the airway by several mechanisms**: (1) deposition of upper-airway/parapharyngeal **fat** narrowing the pharyngeal lumen; (2) reduced **chest-wall compliance** and lower **lung volumes**, causing loss of caudal tracheal traction on the pharynx (worst when supine and obese); (3) **android (central) obesity** depositing abdominal and upper-airway fat.
- ▶ Quantitatively: **≈ 40 – 60% of OSA is attributable to excess weight**; obese individuals carry a **fourfold or greater risk** of OSA; a **10% weight gain raises the AHI by $>30\%$** , and weight loss (notably after bariatric surgery) can markedly reduce severity.
- ▶ Collapse sites: **soft palate (most common)**, tongue base, lateral pharyngeal walls and/or epiglottis. Contributory factors include high **nasal resistance**, **retrognathia/micrognathia**, an unstable ventilatory control loop (high CO_2 sensitivity), and a low or high **arousal threshold**.
- ▶ Other (non-obesity) risk factors: **male sex** (twofold higher prevalence), **older age**, post-menopause, family history, adenotonsillar hypertrophy (children), and endocrine disease (**acromegaly, hypothyroidism**).

Definition, severity grading and clinical features of OSA

- ▶ **Diagnosis** requires either (1) symptoms of nocturnal breathing disturbance (snoring, snorting, gasping, witnessed pauses) impairing quality of life, OR unexplained daytime sleepiness/fatigue — **plus ≥ 5 obstructive events/hour** on a sleep study; OR (2) an **AHI $\geq 15/\text{h}$ even without symptoms**.
- ▶ Each event is a ≥ 10 s reduction in breathing: **Apnea** = cessation of airflow ≥ 10 s; **Hypopnoea** = $\geq 30\%$ airflow reduction ≥ 10 s with a $\geq 3\%$ desaturation or arousal; **RERA** = increased respiratory effort terminated by arousal without meeting hypopnoea criteria.

Severity (AHI = apnoeas + hypopnoeas per hour of sleep)	Grade
5–14 events/h	Mild OSAHS
15–29 events/h	Moderate OSAHS
≥30 events/h	Severe OSAHS

- ▶ **Symptoms:** loud habitual **snoring** (commonest; its absence does not exclude OSA), gasping/choking arousals, **excessive daytime sleepiness** (men) or **fatigue** (women preferentially), unrefreshing sleep, nocturia, morning headache, dry mouth, poor concentration, irritability and mood disturbance.
- ▶ **Signs:** central (visceral) obesity with large **neck and waist circumference**, hypertension, crowded oropharynx (enlarged tongue, low bulky soft palate/uvula, large tonsils, high-arched palate), retro-/micrognathia, nasal obstruction. *Cor pulmonale suggests a coexisting cardiopulmonary disorder — OSA alone does not cause right-heart failure.*

Diagnosis and investigations

- ▶ **In-laboratory polysomnography (PSG)** is the **gold standard**; a negative in-lab PSG usually rules out OSA. **Home sleep apnoea testing** (respiratory + cardiac channels) is a cost-effective alternative, but a negative home study with high pretest probability should be followed by PSG.
- ▶ Screening questionnaires (e.g. **STOP-Bang**) evaluating snoring, observed apnoeas and sleepiness aid case-finding, enhanced by considering male sex, obesity and hypertension.
- ▶ Supportive findings: “**non-dipping**” overnight blood-pressure pattern; secondary erythrocytosis (elevated haemoglobin) with severe nocturnal hypoxaemia; waking hypoxaemia/hypercarbia points to coexisting cardiopulmonary disease or **hypoventilation syndrome**. A **multiple sleep latency test / maintenance of wakefulness test** quantifies sleepiness and helps separate OSA from narcolepsy.
- ▶ In obesity, baseline work-up: **fasting lipid profile, fasting glucose/HbA1c, chemistry panel, blood pressure**, and screening for secondary causes (hypothyroidism, Cushing’s, PCOS, hypothalamic disease) and obesogenic drugs.

Health consequences and comorbidities (overlapping burden)

- ▶ **Cardiovascular/metabolic (OSA):** resistant and nocturnal **hypertension** (sympathetic + RAAS activation, non-dipping), coronary artery disease, **heart failure** (HFrEF and HFpEF), **atrial and ventricular arrhythmias / AF**, stroke, type 2 diabetes/insulin resistance, premature death and increased cancer risk. CPAP lowers 24-h ambulatory BP modestly (~2–4 mmHg, greater if high AHI, sleepy or resistant hypertension).
- ▶ **Obesity complications** (shared): type 2 diabetes, dyslipidaemia, metabolic syndrome, hypertension, HFpEF/diastolic dysfunction, AF, **MASLD/NASH→cirrhosis**, GERD, gallstones,

PCOS and male central **hypogonadism**, osteoarthritis and gout, obesity-related glomerulopathy, **obstructive sleep apnoea and obesity-hypoventilation (Pickwickian) syndrome**, idiopathic intracranial hypertension, and several cancers (a 5 kg/m² rise in BMI raises cancer mortality ~10%).

- **Functional:** OSA causes a two-fold rise in occupational accidents and a two- to three-fold rise in motor-vehicle crashes — counsel against **drowsy driving**.

Management

- **Weight loss is the unifying first-line intervention** — even modest loss reduces AHI and metabolic risk; OSA may improve substantially after bariatric surgery.
- **Obesity — lifestyle:** caloric deficit **500–750 kcal/d** ($\approx$ 1200–1500 kcal/d women, 1500–1800 kcal/d men) for ~1–2 lb/week; realistic target **8–10% loss over 6 months**; **$\geq$ 150 min/week moderate (or 75 min vigorous) aerobic activity** (>300 min to sustain loss); plus behavioural therapy (self-monitoring, stimulus control, cognitive restructuring).
- **Obesity — pharmacotherapy** (BMI $\geq$ 30, or $\geq$ 27 with comorbidity). Placebo-subtracted 1-year weight loss:

Drug	Mechanism	Weight loss (placebo-subtracted)
Orlistat 120 mg tid	GI lipase inhibitor (blocks ~30% dietary fat absorption)	~4.4%
Phentermine/topiramate	Sympathomimetic + GABA modulation	~8.0%
Naltrexone SR/bupropion SR	Opioid antagonist + DA/NE reuptake inhibitor (POMC activation)	~5.1%
Liraglutide 3.0 mg SC daily	GLP-1 receptor agonist	~5.4%
Semaglutide 2.4 mg SC weekly	GLP-1 receptor agonist (2nd-generation)	~12.5%
Tirzepatide up to 15 mg SC weekly	Dual GLP-1/GIP receptor agonist	~17.8%

- *GLP-1/dual agonists are contraindicated with personal/family history of medullary thyroid cancer or MEN-2; semaglutide also reduced major adverse cardiovascular events by 20% (SELECT) and improved HFpEF symptoms (STEP-HFpEF).*
- **Bariatric surgery:** for BMI $\geq$ 40, or $\geq$ 35 with **comorbidities**. Procedures — restrictive (adjustable gastric banding, **sleeve gastrectomy**) and restrictive-malabsorptive (**Roux-en-Y gastric bypass**, biliopancreatic diversion $\pm$ duodenal switch); bypass yields ~28–33% total body-weight loss and reduces overall mortality (OR 0.55) and cardiovascular death (OR 0.58), with marked improvement in OSA and type 2 diabetes.

► OSA-specific therapy:

- **General/behavioural:** weight loss, optimise sleep (7–9 h) and schedule, avoid the **supine position**, treat nasal allergy, eliminate **alcohol within 3 h of bedtime**, minimise **opioids/sedatives**.
- **CPAP** — *the standard therapy with the highest level of evidence*; a pneumatic splint maintaining airway patency; auto-titrating (APAP) devices avoid titration studies; adherence ~50–80% and is the key determinant of benefit (improves sleepiness, mood, quality of life, BP, insulin sensitivity). Side-effects (nasal congestion, claustrophobia, aerophagia) are managed by humidification, mask change and pressure adjustment.
- **Oral appliances (mandibular advancement devices)** — reduce AHI by $\geq 50\%$ in two-thirds; best for mild–moderate OSA or CPAP intolerance (caution: TMJ pain, tooth movement).
- **Surgery** — **uvulopalatopharyngoplasty (UPPP)** (commonest, limited as a standalone procedure, often “multilevel”), and **bariatric surgery** for obese patients; less efficacious than CPAP.
- **Upper-airway (hypoglossal nerve) neurostimulation** — for CPAP failure; inclusion AHI 15–65 and BMI < 35 .
- **Positional therapy**, and **GLP-1 agonists/weight-loss drugs** under active investigation (liraglutide shows small AHI effect; tirzepatide in trials). **No FDA-approved drug for OSA currently.**

DIAGRAMS TO DRAW — IMAGE SUGGESTIONS

- **Sagittal upper-airway diagram (OSA collapse sites):** label Soft palate (most common site), Uvula, Tongue base, Lateral pharyngeal walls, Epiglottis, Pharyngeal dilator muscle, Nasal passage (resistance) — show collapse during sleep.
- **Polysomnography apnoea tracing:** label channels Nasal/thermistor airflow (flat = apnoea), Chest and Abdomen effort showing paradoxical (out-of-phase) movement, SaO₂ desaturation, EEG arousal, with a bracket marking ≥ 10 s event.

Clinical / Diagnostic significance

- Suspect and screen OSA in every obese patient with snoring, daytime sleepiness, hypertension (especially resistant/non-dipping), type 2 diabetes, AF or stroke — a large fraction of OSA remains undiagnosed.
- AHI defines and grades disease; PSG is confirmatory; STOP-Bang stratifies pretest probability.
- Weight loss is disease-modifying for both conditions; CPAP plus weight reduction is the cornerstone of moderate–severe OSA.
- Pre-operative recognition matters: obese OSA patients are at higher peri-operative and sedation-related risk.

High-yield exam pointers

- ▶ AHI = apnoeas + hypopnoeas per hour; Mild 5–14, Moderate 15–29, Severe ≥ 30 .
- ▶ Diagnose OSA at AHI ≥ 5 with symptoms or AHI ≥ 15 without symptoms.
- ▶ 40–60% of OSA is due to excess weight; obese persons have $\geq 4\times$ risk; 10% weight gain $\rightarrow >30\%$ rise in AHI.
- ▶ Soft palate is the commonest collapse site; PSG is the gold-standard test.
- ▶ CPAP = highest-evidence therapy; lowers ambulatory BP by $\sim 2\text{--}4$ mmHg; adherence $\sim 50\text{--}80\%$.
- ▶ Obesity classes: I 30–34.9, II 35–39.9, III (extreme) ≥ 40 ; South Asian waist cut-offs men >90 / women >80 cm.
- ▶ Bariatric surgery: BMI ≥ 40 , or ≥ 35 with comorbidity; reduces all-cause mortality (OR 0.70).
- ▶ Weight-loss drug efficacy ranking: tirzepatide ($\approx 18\%$) $>$ semaglutide ($\approx 12.5\%$) $>$ Phen/TPM ($\approx 8\%$) $>$ liraglutide/Nal-Bup $\approx$ orlistat.
- ▶ OSA independently increases hypertension, AF, HF, stroke, diabetes and motor-vehicle crash risk.

SOURCE & COVERAGE

Harrison's Principles of Internal Medicine, 22e — Ch 308 "Sleep Apnea" (Wellman, Gottlieb, Redline) and Ch 414 "Evaluation and Management of Obesity" (Kushner). Coverage note: STOP-Bang and the Epworth Sleepiness Scale, and the obesity-hypoventilation/Pickwickian and "non-dipping BP" terms, are standard textbook internal medicine — STOP-Bang and non-dipping pattern are referenced in Ch 308; the Epworth scale itself is not named in the provided text but is universally accepted. Drug doses/efficacy and bariatric data are taken verbatim from Ch 414 Table 414-5 and text.

Obesity Hypoventilation Syndrome

Asked in: Paper III May 2019 — RGUHS MD General Medicine

Definition / Introduction — Obesity hypoventilation syndrome (OHS), historically the *Pickwickian syndrome*, is defined by the triad of (1) **obesity** (body mass index, BMI ≥ 30 kg/m²), (2) **chronic daytime alveolar hypoventilation** — awake arterial PaCO₂ ≥ 45 mmHg at sea level — and (3) **sleep-disordered breathing**, after exclusion of other causes of hypercapnia (severe COPD, restrictive chest-wall/neuromuscular disease, hypothyroidism, drug-induced hypoventilation). It is therefore a **diagnosis of exclusion** in an obese hypercapnic patient. In the normal lung PaCO₂ is held between 37–43 mmHg; OHS represents a failure of alveolar ventilation to keep pace with CO₂ production despite an *intrinsically normal lung*.

Epidemiology and risk factors

- ▶ No population-based prevalence study exists, but estimates suggest OHS affects up to **~0.4% of US adults** (≈ 1 in 263), and the burden is rising in parallel with the global obesity epidemic.
- ▶ **Obstructive sleep apnoea (OSA) coexists in ~90% of OHS patients**, and close to 70% have **severe OSA** (apnoea–hypopnoea index, AHI $>30/h$). A minority (~10%) hypoventilate *without* significant OSA (pure “sleep hypoventilation” phenotype).
- ▶ Recognised risk factors: **severe obesity** (BMI $>40 \text{ kg/m}^2$) and **severe OSA** (AHI $>30/h$); greater waist/neck circumference; the syndrome is frequently *under-recognised* and often first diagnosed during an episode of acute-on-chronic hypercapnic respiratory failure.

Pathophysiology — a multifactorial “load–drive” imbalance

OHS arises when the **mechanical load** on the respiratory pump outstrips both **respiratory muscle capacity** and a **blunted central drive**. Three interacting mechanisms operate:

Domain	Derangement in OHS
Excess mechanical load	Mass loading of chest wall and abdomen $\downarrow$ respiratory-system compliance; FRC reset to a lower, stiffer part of the volume–pressure curve ; $\uparrow$ airway resistance and expiratory flow limitation (worse supine). Work of breathing up to ~250% of normal (vs ~60% in simple obesity); oxygen cost of breathing rises ~10-fold (vs 5-fold in simple obesity).
Blunted central drive	Unlike <i>eucapnic</i> obesity (where drive is normal/increased to overcome the load), in OHS the ventilatory and occlusion-pressure (P0.1) responses to hypoxia and hypercapnia are reduced . Drive is <i>not</i> genetically low (responses are normal in first-degree relatives) — chemoreceptors appear “reset” by chronic hypercapnia/hypoxaemia and by leptin resistance .
